- JDBCConnectionSpec interface - this interface extends the *com.ibm.websphere.rsadapter.WSConnectionSpec* class, which extends the *javax.resources.cci.ConnectionSpec* class. The standard ConnectionSpec interface provides only the interface marker without any get() and set() methods. The WSConnectionSpec and the JDBCConnectionSpec interfaces define a set of get() and set() methods used by the WebSphere Application Server run time. This interface enables the application to specify all the essential connection properties in order to get an appropriate connection. You can create this class from the WebSphere WSRRAFactory class. For more information see the **JDBCConnection** API documentation topic (as listed in the API documentation index).
- WSRRAFactory class - this is a factory class for the WebSphere Relational Resource Adapter, which allows the user to create a JDBCConnectionSpec object or other resource adapter related object. For more information see the **WSRRAFactory** API documentation topic (as listed in the API documentation index).
- WSConnection interface - this is an interface that allows users to call WebSphere proprietary methods on SQL connections; those methods are:
  - setClientInformation(Properties props) - See the Example: setClientInformation(Properties) API topic for more information and examples of setting client information.
  - Properties getClientInformation() - This method returns the properties object that is set using *setClientInformation(Properties)*. Note that the properties object returned is not affected by implicit settings of client information.
  - WSSystemMonitor getSystemMonitor() - This method returns the SystemMonitor object from the backend database connection if the database supports System Monitors. The backend database will provide some connection statistics in the SystemMonitor object. The SystemMonitor object returned is wrapped in a WebSphere object (*com.ibm.websphere.rsadapter.WSSystemMonitor*) to shield applications from dependency on any database vendor code. See *com.ibm.websphere.rsadapter.WSSystemMonitor* Java documentation for more information. The following code is an example of using the *WSSystemMonitor* class:

```
import com.ibm.websphere.rsadapter.WSConnection;
...
try{
 InitialContext ctx=new InitialContext();
 // Perform a naming service lookup to get the DataSource object.
 DataSource ds=(javax.sql.DataSource]ctx.lookup("java:comp/jdbc/myDS");
} catch (Exception e) {;}

WSConnection conn=(WSConnection)ds.getConnection();
WSSystemMonitor sysMon=conn.getSystemMonitor();
if (sysMon!=null) // indicates that system monitoring is supported on the current backend database
 {
  sysMon.enable(true);
  sysMon.start(WSSystemMonitor.RESET_TIMES);
```

```
     // interact with the database
     sysMon.stop();
     // collect data from the sysMon object
    }
   conn.close();
```

Example: Accessing data using IBM extended APIs for connections: If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can access an extended API in your JDBC application. Instead of using the DataSource interface, you use the WSDataSource interface. The following code segment illustrates how to get the connection.

```
import com.ibm.websphere.rsadapter.*;

...

// Create a JDBCConnectionSpec and set connection properties. If this connection is shared with
the CMP bean, make sure that the isolation level is the same as the isolation level that is mapped by
 the Access Intent defined on the CMP bean.

JDBCConnectionSpec connSpec = WSRRAFactory.createJDBCConnectionSpec();

connSpec.setTransactionIsolation(CONNECTION.TRANSACTION_REPEATABLE_READ);

connSpec.setCatalog("DEPT407");

//Use WSDataSource to get the connection

Connection conn = ((WSDataSource)datasource).getConnection(connSpec);
```

Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans: If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can access an extended API in your JDBC application. Instead of using the DataSource interface, you use the WSDataSource interface.

To ensure that both CMP and bean-managed persistence (BMP) beans are sharing the same physical connection, you can define the same access intent profile on both the CMP and BMP beans. Inside your BMP method, you can get the right isolation level from the relational resource adapter helper class.

```
package fvt.example;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;

import javax.ejb.CreateException;
import javax.ejb.DuplicateKeyException;
import javax.ejb.EJBException;
import javax.ejb.ObjectNotFoundException;
import javax.sql.DataSource;

// following imports are used by the IBM extended API
import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.appprofile.accessintent.AccessIntentService;
import com.ibm.websphere.rsadapter.JDBCConnectionSpec;
import com.ibm.websphere.rsadapter.WSCallHelper;
```

```
import com.ibm.websphere.rsadapter.WSDataSource;
import com.ibm.websphere.rsadapter.WSRRAFactory;

 }
```

Recreating database tables from the exported table data definition language

When the WebSphere Application Server deployment tooling deploys an EJB jar file containing container-managed persistence (CMP) enterprise beans, it selects the target database and creates a corresponding Table.ddl file. This file contains the SQL statement necessary to generate the database table for your CMP beans. You must run the ddl file on your database server to create the tables.

The following steps demonstrate the process for creating tables in DB2.
* Extract the Table.ddl file from your CMP enterprise bean JAR file to a working directory, such as *C:\temp*, on your DB2 machine.
* Run the command **C:\temp>db2cmd**, replacing *C:\temp* with your chosen directory. A DB2 command window is displayed, in which you enter the following commands (replacing *C:\temp* with your chosen directory):
   1. `C:\temp>db2 connect to` *your_db_name*
   2. `C:\temp>db2 -tf Table.ddl` //This command runs and creates tables for your CMP enterprise bean.
   3. `C:\temp>db2 disconnect all`

   Note: If you run DB2 on Unix, use these same commands. Simply run them from a user with permissions for DB2, rather than from a DB2 command window.
   Your tables are created.

Container-managed persistence features
The container-managed persistence (CMP) features include those defined by the EJB 2.1 Specification, as well as capabilities that are beyond the specification.

EJB Specification compliant capabilities

Container-Managed Relationships (CMR) is one of the most significant new features in recent versions of the EJB Specification. Like *Inheritance*, relationships are a key component of object-oriented software development and non-trivial object models can form complex networks with these relationships.

The container automatically manages the state of CMP entity beans. This management includes synchronizing the state of the bean with the underlying database when necessary and also managing any relationships (CMRs) with other entity beans. The bean developer is relieved of writing any database specific code and, instead, can focus on business logic.

Local interfaces are another feature introduced in recent versions of the EJB Specification. Local component interfaces allow co-located beans to interact without the overhead associated with remote access.

Value-add features

WebSphere Application Server provides enhancements to the function of CMP entity beans that supersede those capabilities defined by the specification. These include:

Entity bean inheritance
> Inheritance is a key aspect of object-oriented software development and is a capability currently missing from the EJB Specification.
>
> The use of inheritance enables a developer to define fields, relationships, and business logic in a superclass entity bean that are inherited by all subclasses. See the section *EJB inheritance* of the Rational Application Developer (RAD) documentation for details on using inheritance with WebSphere Application Server and entity beans.

Access Intent Policies
> Access intent policies provide J2EE application developers the mechanism by which they can indicate the intent of an application's interaction with the essential state for entity beans in order that the persistence mechanisms can make appropriate optimizations. For example, if it is known that an entity is not updated during the course of a transaction, then the persistence management is able to ease up on the concurrency control and still maintain data integrity by disallowing update operations on that bean for the duration of the transaction.

Caching data across transactions
> Data caching across transactions is a configurable option set by the bean deployer that can greatly improve performance. Essentially, this is for data that changes infrequently. The option is known as *LifetimeInCache*. The data for an entity configured for lifetime in cache is stored in a cache until its specified lifetime expires. Requests on the entity during that configured lifetime use the cached data, and do not result in the execution of queries against the underlying data store. Lifetime can be expressed as time elapsed since the data was retrieved from the data store or until a specific time of day or week. The *LifetimeInCache* value can be one of the following:
>
> **Off** The LifetimeInCache setting is ignored. Beans of this type are only cached in a transaction scoped cache. The cached data for this instance is not valid when the transaction is completed.
>
> **ElapsedTime**
> > The value in the LifetimeInCache setting is added to the current time when the transaction (in which the bean instance is retrieved) is completed. The cached data for this instance is not valid after this time. The value of the LifetimeInCache setting can add up to minutes, hours, days, and so on.
>
> **ClockTime**
> > The value of LifetimeInCache represents a particular time of day. The value is added to the immediately preceding or following midnight to calculate a future time value, which is then treated as for Elapsed Time. Using this setting enables you to specify that all instances of this bean type have their cached data invalidated at a specific time no matter when the data were retrieved.

The use of preceding or following midnight to calculate a future time value depends on the value of LifetimeInCache. If LifetimeInCache plus preceding midnight is earlier than the current time, then the following midnight is used.

When you use the ClockTime setting, the value of LifetimeInCache must not represent more than 24 hours. If it does, the cache manager subtracts increments of 24 hours from it until a value less than or equal to 24 hours is achieved. To invalidate data at 12 midnight, you set LifetimeInCache to zero (0).

WeekTime

This setting is similar to ClockTime, except the value of LifetimeInCache is added to the preceding or following Sunday midnight (actually, 11:59 PM on Saturday plus 1 minute). In this case, the LifetimeInCache value can represent more than 24 hours, but not more than 7 days.

See the *LifetimeInCache* help sections of the assembly tool for more details.

Note:

Because the data used by an entity bean can be loaded by previous transactions, if you configure the bean as LifeTimeInCache, the isolation level and update lock (access intent policies) for the bean are lost for the current transaction. This can cause data integrity problems if your application has logic to calculate information from read-only data, and then save the result in another bean. This makes it important to perform read-read consistency checking to ensure the data get locked properly if loading the data from in-memory cache; otherwise, data is updated to the database without knowing the underlining data is changed, causing previous changes to be lost. For more information, see "Configuring read-read consistency checking with the assembly tools" on page 188.

Read-only entity beans

Declaring entity beans as read-only potentially increases the performance enhancement offered by caching. Both features operate on the same principle: to minimize the overhead incurred by frequent reloading of entity beans from data in persistent storage. When you designate entity beans as read-only, you can specify the reload requirements and frequency, according to the needs of your application.

To use this function, you declare the bean type as read-only by selecting a particular set of bean caching options, through a selection list within the application assembly tooling (either Rational Application Developer or the Application Server Toolkit). See "Developing read-only entity beans" on page 155 for details.

Container-managed persistence restrictions and exceptions: The container-managed persistence (CMP) features have certain restrictions when used in specific ways.

Enterprise bean deployment and Sybase IMAGE type restriction

When deploying enterprise beans with container managed persistence (CMP) types that are non-primitive and do not have a natural JDBC mapping, the deployment tool maps the CMP type to a binary type in the database, where it is stored as a serialized instance. For Sybase, the tool uses the JDBC type *LONG VARBINARY*. The Sybase driver maps *LONG VARBINARY* to the native type *IMAGE*.

Although the type *VARBINARY* has fewer restrictions than *IMAGE* in Sybase, you cannot use it because it is limited to a size of 255 bytes, which is too small for typical serialized Java objects.

The specific restrictions on the IMAGE type are:

- You cannot use the *IMAGE* type in the *WHERE* clause of an SQL query. You can encounter this restriction whenever an enterprise bean contains an EJB-QL query that has a CMP type in the *WHERE* clause, which maps to the *IMAGE* type in the Sybase relational database (RDB).

- You cannot use *IMAGE* type in select queries marked *DISTINCT*. This situation arises in these user scenarios:
  - When the *DISTINCT* key word is specified in an EJB-QL select query having a Java type mapping to IMAGE.
  - When Enterprise beans have finder and ejbSelect() methods returning java.util. Set and have CMP types mapping to *IMAGE*.

To work around this restriction, edit the EJB mappings in the Rational Application Developer toolset and do either of the following:

- If you are **sure** that the serialized instance of the CMP type is **never** larger than 255 bytes, you can change the CMP type mapping from *IMAGE* or *LONG VARBINARY* to *VARBINARY*.
- Map the CMP type to multiple RDB fields through a composer. For example, if the CMP type is a Java object X with an int field and a string field, then map X to two RDB fields *INTEGER* and *VARCHAR*, using a composer. Refer to the Rational Application Developer documentation for more information about using composers.

A ClassCastException exception occurs when running container-managed persistence 1.1 beans

If you created your Enterprise JavaBeans (EJB) application using Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x , and the application contains container managed persistence (CMP) 1.1 beans with associations (relationships), you might receive a *java.lang.ClassCastException* exception when you run your application on WebSphere Application Server.

The cast operation generated by Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x does not use the *javax.rmi.PortableRemoteObject.narrow(...)* object to convert the remote object to the remote interface of CMP beans in the *XToYLink.java* (or *YToXLink.java*) class where X and Y are CMP 1.1 beans.

Recommended response

1. Locate the following methods in all link classes, for example, XToYLink.java and YToXLink.java where X and Y are CMP 1.1 beans:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB)
public void secondaryRemoveElementCounterLinkOf(javax.ejb.EJBObject anEJB)
public void secondarySetCounterLinkOf(javax.ejb.EJBObject anEJB)
```

2. Add the javax.rmi.PortableRemoteObject.narrow(...) object to convert the remote object to the remote interface of CMP beans.

For example, change the following original method:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
                ((X) anEJB).secondaryAddY((Y) getEntityContext().getEJBObject());
```

to:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
            ((X) anEJB).secondaryAddY((Y)
javax.rmi.PortableRemoteObject.narrow(getEntityContext().getEJBObject(), Y.class));
```

Application performance and entity bean behavior:

WebSphere Application Server allows you to override two behaviors that are required by the EJB specification, because your application might benefit from handling these aspects of bean data management in a slightly different manner.

Application-managed persistent store synchronization for findBy methods

Sections 10.5.3 and 12.1.4.2 of the EJB 2.0 and 2.1 specifications require that prior to running a query as part of any findBy method (except for findByPrimaryKey), the EJB container writes out to persistent storage the state of any entity beans of the type that are enlisted in the current transaction. Stated another way, the container performs the following actions:

1. Creates a list of beans that are both enlisted in the current transaction and are of the same type that the findby method is returning

2. Stores the state of these enterprise beans to persistent storage before running the query

If the state of an EJB instance is not altered in the current transaction, the store operation is skipped for that instance. This practice ensures that the query is performed on the most current state of all the persistent data, reducing the chance of data integrity issues.

However, there are scenarios where it is inefficient and wasteful for the EJB container to automatically perform this action on every findBy method. Examples of this would be where the application itself ensures that the most current data is used on findBy queries, or where the application can tolerate some non-current data as part of the query results.

WebSphere Application Server allows you to initiate the synchronization process under application control, and to disable the container-managed synchronization for specific EJB types within your application. Careful use of these functions can improve the performance of your application without sacrificing data integrity. Details are covered in "Manipulating the synchronization of entity beans and datastores."

Avoiding ejbStore invocations on non-modified entity bean instances

The EJB specification requires that the EJB container invoke the user-provided ejbStore method on all entity beans within a transaction when that transaction is committed. For container-managed persistence (CMP) beans (as opposed to bean-managed persistence beans) this operation is usually unnecessary, because this method on CMP beans is often empty. Even in cases where the method is not empty, the application might only require the method to be called if the bean's persistent state is modified during the current transaction.

WebSphere Application Server provides a mechanism for you to indicate if you want this behavior for specific EJB types within the application. Details are covered in "Avoiding ejbStore invocations on non-modified EntityBean instances" on page 701.

Manipulating the synchronization of entity beans and datastores

There are two options available for indicating that a particular EJB type should not synchronize its state to persistent storage prior to each findBy invocation: You can set an EJB environment variable within the bean's deployment descriptor, or have the bean implementation class implement a marker interface. The second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you can have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

1. **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java 2, Enterprise Edition (J2EE) development tool. Use the following steps as a guide. (For information on your tool options, consult the "Assembly tools" on page 23 article.)

    a. Start the tool.

    b. Select the EJB deployment descriptor of the bean you want to work with.

    c. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/ DisableFlushBeforeFind**.

    d. Set the type of this variable to **java.lang.Boolean**.

    e. Set the value to True to prevent the pre-find synchronization, or False to enable the default behavior.

f. Save your changes.

2. **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.DisableFlushBeforeFind** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

Ensuring data integrity for queries performed during a transaction

If you choose to disable the automatic pre-find synchronization for certain bean types, it is very important that your application use other means to ensure that queries performed during the transaction are not performed on data that may no longer be valid. You can use the flushCache method on the com.ibm.websphere.ejbcontainer.EJBContextExtension class (an extension of javax.ejb.EJBContext) to perform a manual synchronization to persistent storage at application-defined times. For more information on EJBContextExtension and its related classes SessionContextExtension, EntityContextExtension and MessageDrivenContextExtension, see the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

Avoiding ejbStore invocations on non-modified EntityBean instances

There are two options available for indicating that a particular EJB type should only have its ejbStore method invoked if the bean has been modified during the current transaction: You can set an EJB environment variable within the bean's deployment descriptor, or have the bean implementation class implement a marker interface. The second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you may have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

1. **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java 2, Enterprise Edition (J2EE) development tool. Use the following steps as a guide. (For information on your tool options, consult the "Assembly tools" on page 23 article.)

    a. Start the tool.

    b. Select the EJB deployment descriptor of the bean you want to work with.

    c. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/ disableEJBStoreForNonDirtyBeans**.

    d. Set the type of this variable to **java.lang.Boolean.**

    e. Set the value to True to avoid the ejbStore invocation, or False to enable the default behavior.

    f. Save your changes.

2. **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.DisableEJBStoreForNonDirtyBeans** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

The benefits of using resource references

Using a resource reference to access your data source or connection factory is required when running WebSphere Application Server. Reasons for this requirement include the following:

*   If application code looks up a data source directly in the JNDI naming space, every connection that is maintained by that data source inherits the properties that are defined in the application. Consequently, you create the potential for numerous exceptions if you configure the data source to maintain shared connections among multiple applications. For example, an application that requires a different connection configuration might attempt to access that particular data source, resulting in application failure.

*   It relieves the programmer from having to know the name of the actual data source at the target application server.

*   You can set the default isolation level for the data source through resource references. With no resource reference you get the default for the JDBC driver you use.

Use a resource reference (resource-ref) for looking up a data source through the standard Java Naming and Directory Interface (JNDI) naming interface. The JNDI name defined in the resource reference is a logical name of the data source. Have your application use this JNDI name to look up a data source instead of using the JNDI name that is defined on the data source.

Later, you can substitute the real name, either by using an assembly tool or during installation of the application EAR file onto the server.

For example, assume that you use a data source *jdbc/Section* as illustrated in the following code:

```
javax.sql.DataSource specificDataSource  =
   (javax.sql.DataSource) (new InitialContext()).lookup("java:comp/env/jdbc/Section");
```

In the assembly tool, specify the name (*jdbc/Section*) as the resource reference. If you know the name of the data source, specify it in the resource references Bindings page.

Requirements for setting isolation level:

This article discusses the criteria and effects of setting isolation levels for data access components that comprise EJB 2.x modules.

Isolation level requirements for different code specifications

In an Enterprise JavaBean (EJB) 1.1 module, you can set the isolation level at the method level or bean level. This capability also applies to container-managed persistence (CMP) 1.1 beans that you assemble into *EJB 2.x modules*. (WebSphere Application Server permits the deployment descriptor of a CMP bean to declare the version level of 1.1, regardless of the overall module version.)

However, the ability to set isolation level at the method or bean level does **not** apply to other enterprise beans within an EJB 2.x module, including *CMP 2.x beans*. WebSphere Application Server Version 5.0 removed this capability from EJB 2.0 modules to deliver an architecture that ultimately provides more efficient connection use.

Consequently, versions 5.x and 6.x of the product enforce the following restrictions on declaring isolation level for CMP 2.x beans—as well as session beans, message-driven beans, and bean managed persistence (BMP) beans that you assemble into EJB 2.x modules:

* You cannot specify isolation level on the EJB method level or bean level.
* If you configure a JDBC application, a bean-managed persistence (BMP) bean, or a servlet to participate in global transactions, any connection that is shared cannot accept a user-specified isolation level. WebSphere Application Server can only set a user-specified isolation level on a connection that is not shared within a global transaction. *Generally, you want to refrain from specifying isolation levels on shareable connections.*

Isolation level on connections used by 2.x CMP beans

In a EJB 2.x module, when a CMP 2.x bean uses a new data source to access a backend database, the isolation level is determined by the WebSphere Application Server run time, based on the type of access intent assigned to the bean or the calling method. Other non-CMP connection users can access this same data source and also use the access intent and application profile support to manage their concurrency control.

Connections used by other 2.x enterprise beans and other non-CMP components

For all other JDBC connection instances (connections other than those used by CMP beans), you can specify an isolation level on the data source resource reference. For shareable connections that run in global transactions, this method is the only way to set the *isolationLevel* for connections. Trying to directly set the isolation level through the *setTransactionIsolation()* method on a shareable connection that runs in

a global transaction is not allowed. To use a different isolation level on connections, you must provide a different resource reference. Set these defaults through your assembly tool.

Each resource reference associates with one isolation level. When your application uses this resource reference Java Naming and Directory Interface (JNDI) name to look up a data source, every connection returned from this data source using this resource reference has the same isolation level.

Components needing to use shareable connections with multiple isolation levels can create multiple resource references, giving them different JNDI names, and have their code look up the appropriate data source for the isolation level they need. In this way, you use separate connections with the different isolation levels enabled on them.

It is possible to map these multiple resource references to the same configured data source. The connections still come from the same underlying pool, however; the connection manager does not allow sharing of connections requested by resource references with different isolation levels. Consider the following scenario:

- A data source is bound to two resource references: *jdbc/RRResRef* and *jdbc/RCResRef*.
- RRResRef has the *RepeatableRead* isolation level defined. RCResRef has the *ReadCommitted* isolation level defined.

If your application wants to update the tables or a BMP bean updates some attributes, it can use the *jdbc/RRResRef* JNDI name to look up the data source instance. All connections returned from the data source instance have a RepeatableRead isolation level. If the application wants to perform a query for read only, then it is better to use the *jdbc/RCResRef* JNDI name to look up the data source.

If you do not specify the isolation level:

The product does not require you to set the isolation level on a data source resource reference for a non-CMP application module. If you do not specify isolation level on the resource reference, or if you specify TRANSACTION_NONE, the WebSphere Application Server run time uses a default isolation level for the data source. Application Server uses a default setting based on the JDBC driver.

For most drivers, WebSphere Application Server uses an isolation level default of TRANSACTION_REPEATABLE_READ. For Oracle drivers, however, Application Server uses an isolation level of TRANSACTION_READ_COMMITTED. Use the following table for quick reference:

Database:	DB2	Oracle	Sybase	Informix	Cloudscape	SQL Server
Default isolation level: *(for connections used by non-CMP entities)*	RR	RC	RR	RR	RR	RR

- **Note:** These same default isolation levels are used in cases of direct JNDI lookups of a data source.
- RR = JDBC Repeatable read (TRANSACTION_REPEATABLE_READ)
- RC = JDBC Read committed (TRANSACTION_READ_COMMITTED)

Data source lookups for enterprise beans and Web modules:

During either application assembly or deployment, you must bind the resource reference to the actual name of the resource in the run time environment. You can take this action in the assembly tool or as one of the steps during installation of the application EAR file.

Bean-managed persistence bean: When developing your bean-managed persistence (BMP) bean you generally lack knowledge about the name of the data source on the target application server. In your code, do not look up the data source directly. Instead, you look up the resource reference from the *java:comp/env namespace* file. Let us assume that you look up the resource reference named *ref/ds* as illustrated in the code below.

```
javax.sql.DataSource dSource = (javax.sql.DataSource)((new InitialContext()).lookup java:/comp/env/ref/ds);
```

In the assembly tool, you specify the name **ref/ds** in the Resource Reference page on the General Tab. If you know the name of the data source you can specify it in this Resource References page on the Bindings Tab. Note that if you do not specify it here , you must provide this Java Naming and Directory Interface (JNDI) name when you install the application EAR file.

Container-managed persistence bean: The data source binding process for the container-managed persistence (CMP) bean is the same process that you perform for bean-managed persistence (BMP) beans. Use the data source JNDI name as a WebSphere binding property for each bean during application assembly.

Servlets and JavaServer Pages Files: In a servlet application, you look up the data source exactly as you look it up in the BMP bean case.

Access intent and isolation level:

The *access intent* service enables developers to precisely tune the management of application persistence.

Access intent enables developers to configure applications so that the EJB container and its agents can make performance optimizations for entity bean access. Entity beans and entity bean methods are configured with access intent policies. A policy is acted upon by either the combination of the WebSphere EJB container and Persistence Manager (for container-managed persistence (CMP) entities) or by bean-managed persistence (BMP) entities directly. Note that access intent policies apply to entity beans only.

Predefined access intent policies

Seven predefined access intent policies are available. The policies are composed of different attributes. The *access type* is of primary interest and controls the isolation level, lock type, and duration of locks obtained when bean data is read from the database.

A pessimistic access type indicates to hold locks for the duration of the transaction under which the data loads. An optimistic type indicates to drop locks immediately after the data is read from the backend. A *read* type indicates that the run time must not allow updates to the data; any attempt to do so on data read under a *read* type results in an exception. *Update* types permit you to change data.

Though a pessimistic update policy is designed to hold update locks on data records, it does not block threads with other policies that try to access the same data records. When two threads that run pessimistic update policies access a given record, they serialize (but not block) other threads that run pessimistic read or optimistic policies and try to access the same record.

The seven access intent policies and their attribute definitions follow:
wsPessimisticUpdate
- Access type = Pessimistic update
- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsOptimisticUpdate

- Access type = Optimistic update
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsOptimisticRead
- Access type = Optimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticRead
- Access type = Pessimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdate-Exclusive
- Access type = Pessimistic update
- Exclusive = true
- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdate-NoCollision
- Access type = Pessimistic update
- No collision = true
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdateWeakestLockAtLoad
- ***default policy**
- Access type = Pessimistic Update
- Promote = true
- Collection scope = transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

Note that to support connection sharing, you must ensure that all data loaded in the same transaction is under the same isolation level. Verify that all participating methods that drive loads are configured with either a pessimistic access type or an optimistic access type.

Access intent -- isolation levels and update locks: WebSphere Application Server access intent policies provide a consistent way of defining the isolation level for CMP bean data across the different relational databases in your environment. Within a deployed application, the combination of an access intent policy *concurrency definition* and *access type* signifies the isolation level value that Application Server sets on a database connection.

Application Server passes to the database through a JDBC prepared statement.

Databases do not provide as many isolation level definitions as WebSphere Application Server. Databases define an isolation level as one of only three types. Furthermore, only one parameter indicates the type of isolation level that the databases set on incoming connections. Each of the three types can be represented

by a *different* parameter value, as determined by each database vendor. For example, one database might define an isolation level as RR (JDBC Repeatable read), whereas a different database might define the same isolation level as RC (JDBC Read committed).

Because of this inconsistency, WebSphere Application Server does not map access intent policies to the parameter values. Instead, Application Server maps access intent policies to the types of isolation level that are common across all database vendors.

The following matrix shows how access intent policies correspond to different database isolation levels and update lock settings:

Access Intent profile	Isolation level						Update lock implementation
	DB2	Oracle*	SyBase	Informix	Cloudscape	SQL Server	
wsPessimisticUpdate-Weakest LockAtLoad (Default policy)	RR	RC	RR	RR	RR	RR	No (*Oracle, Yes)
wsPessimisticUpdate	RR	RC	RR	RR	RR	RR	Yes
wsPessimisticRead	RR	RC	RR	RR	RR	RR	No
wsOptimisticUpdate	RC	RC	RC	RC	RC	RC	No
wsOptimisticRead	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdate No-Collisions	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdate-Exclusive	S	S	S	S	S	S	Yes

- RC = JDBC Read Committed
- RR = JDBC Repeatable Read
- S = JDBC Serializable
- * Oracle does not support JDBC Repeatable Read (RR). Therefore, wsPessimisticUpdate-weakestLockAtLoad and wsPessimisticUpdate behave the same way on Oracle as do wsPessismisticRead and wsOptimisticRead. Because of an Oracle restriction, the OracleXADataSource JDBC class cannot run with an S transaction isolation level. Therefore, you cannot use this class to run an application containing enterprise beans with access intent policies that are configured to cause the bean to load with S isolation.
- Setting access intent policies per EJB method support is deprecated for Version 6.0. It is recommended that you set access intent only for the entire bean.

New for MS SQL Server 2005: MS SQL Server 2005 offers a new option for the Read Committed isolation level and a new option for the Serializable isolation level:

- Read Committed with Snapshots
- Transaction Snapshot (for Serializable)

Both options use optimistic locking. To use Read Committed with Snapshots instead of Read Committed, enable the READ_COMMITTED_SNAPSHOT setting for the database according to the MS SQL Server 2005 documentation. To use Transaction Snapshot instead of Serializable, configure the custom data source property, snapshotSerializable, to ″true″ and enable the ALLOW_SNAPSHOT_ISOLATION setting for the database according to the MS SQL Server 2005 documentation.

Structured Query Language (SQL) keywords and restrictions

The following table shows which SQL keywords are used during update intent locking, as well as any restrictions imposed on the SQL.

Database	SQL syntax used for locking update	join restrictions	order by restrictions	subselect restrictions	aggregation restrictions
DB2	FOR UPDATE OF	not allowed	not allowed	not allowed	not allowed
DB2 UDB for iSeries (V5R3 and earlier)	FOR UPDATE OF	not allowed	allowed with limitations*	allowed with limitations*	not allowed
DB2 UDB for iSeries (V5R4 and later)	WITH RS/RR USE AND KEEP EXCLUSIVE LOCKS	not allowed	allowed with limitations*	allowed with limitations*	not allowed
DB2 on z/OS V8.x	WITH RS/RR USE AND KEEP UPDATE LOCKS	none	none	none	none
DB2 UDB workstation V8.2	WITH RS/RR USE AND KEEP UPDATE LOCKS	none	none	none	none
Oracle	FOR UPDATE	none	none	none	none
Cloudscape	FOR UPDATE OF	not allowed	not allowed	not allowed	not allowed
Informix	FOR UPDATE	not allowed	not allowed	not allowed	not allowed
Sybase	FOR UPDATE	not allowed	not allowed	not allowed	not allowed
Sqlserver	UPDLOCK	not allowed	not allowed	not allowed	not allowed

* Note: For details on the limitations for these permitted SQL restrictions, refer to the DB2 Universal Database for iSeries SQL Reference. You can find this document at the Web address http://publib.boulder.ibm.com/infocenter/iseries/v5r3/ic2924/info/db2/rbafzmst02.htm .

Custom finder SQL dynamic enhancement:

To ensure data integrity for applications using custom finders defined on Enterprise JavaBeans (EJB) version 1.1 home interfaces, WebSphere Application Server Version 6.x uses custom finder Structured Query Language (SQL) dynamic enhancement to maintain correct SQL locking semantics.

WebSphere Application Server uses SQL clauses applied to the custom finder SQL statements for those custom finders defined with the *Update* attribute and certain method-level isolation level settings. These dynamic enhancements are applied only if the backend data store supports these clauses.

This support takes affect at run time when the run time attempts to execute container-managed persistence (CMP) persistence operations associated with the custom finders. To ensure that the SQL dynamic enhancements occur correctly for custom finders defined on an EJB version 1.1 home interface accessing a backend data store that requires the special SQL locking clauses, WebSphere Application Server provides new Java Virtual Machine (JVM) and bean (module) properties. These properties enable you to indicate which custom finders should be enhanced, provided the backend store supports the SQL clauses. For more information about these properties, see Custom finder SQL dynamic enhancement properties.

There are several important items to consider when using this functionality:
* This support **only** applies to EJB version 1.1 CMP Custom Finder methods
* Option A CMP beans and CMP beans involved in an inheritance relationship are not supported

Custom finder SQL dynamic enhancement properties:

Use this page to modify custom finder SQL dynamic enhancement properties settings.

To ensure that the Structured Query Language (SQL) dynamic enhancements occur correctly for custom finders defined on an EJB 1.1 Home interface that uses a backend data store that requires the special SQL locking clauses, the following Java virtual machine (JVM) and bean (module) properties are provided. These properties enable you to indicate which custom finders to enhance, assuming the backend data store supports the SQL clauses.

To view this administrative console page, click **Servers** > **Application Servers** > *server* > **Process Definition** > **Control** (to define the property in the Control) or **Servant** (to define the property in the Servant) > **Java Virtual Machine** > **Custom Properties** .

com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent:

Used to indicate which enterprise beans should have custom finder SQL dynamic enhancement enabled at runtime.

This property takes effect at the server level. Any EJB 1.1 home interface-defined custom finder (prefix named *find*) that has *Update* as an access intent is a candidate for custom finder SQL dynamic enhancement based on its specified isolation level. If the backend data store requires special SQL semantics, they are applied. The particular SQL used varies according to the isolation level you choose for beans in the application, as well the backend data base being used. If set to **all**, custom finder SQL dynamic enhancement is enabled for all custom finders defined in any beans that are installed into the container. If set to **J2EENAME[:J2EENAME]**, where *J2EENAME* is a fully qualified package or bean name, custom finder SQL dynamic enhancement is enabled for only the custom finders defined in the beans that are installed into the container and represented by the bean names denoted.

Data type	String
Range	Valid values are **all** or **J2EENAME[:J2EENAME]**
Default	Enhancement behavior not active

Note: Some of your applications might use custom finders that have been manually coded and already contain the SQL locking clauses, or keywords *ORDER BY* and *DISTINCT* on the *SELECT* operation. In these instances, if the run time attempts SQL dynamic enhancement, the possibility exists of introducing malformed SQL statements to the underlying backend data store. If an application contains these custom finders, then you must be careful when specifying the value for the JVM property *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent*. A value of **all** causes custom finder SQL dynamic enhancement to occur for every custom finder method defined with an access intent of *Update* found in all beans that are installed in the application server, thus introducing malformed SQL for that subset of custom finders.

To prevent this from happening, ***do not*** set the server-wide setting to **all**. Instead, use the bean method level property, *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel* to indicate on a per bean basis only those custom finder methods that should have the custom finder SQL dynamic enhancement executed on them at run time.

com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel:

Used to indicate custom finder SQL dynamic enhancement be enabled at the method level on a particular bean.

When a bean is defined with this property set to a list of one or more custom finder methods, any custom finder (prefix named *find*) defined on the home interface that has a matching method name and parameter

signature has SQL locking semantics applied at run time. This occurs only if the custom finder method has an access intent of *Update* specified and the backend data store supports the SQL clauses. The particular SQL used varies according to the isolation level chosen for the application as well as the backend data store being used.

Data type   String
Range   Valid value is a string of this form:
           method1(parm1,parm2,..parmn):method2(parm1,parm2,..parmn):methodn(...)

Data access from J2EE Connector Architecture applications

To access data from a J2EE Connector Architecture (JCA) compliant application in WebSphere Application Server, you configure and use resource adapters and connection factories.

Example: Connection factory lookup:

```
import javax.resource.cci.*;
import javax.resource.ResourceException;

import javax.naming.*;

import java.util.*;

/**
 * This class is used to look up a connection factory.
 */
public class ConnectionFactoryLookup {

   String jndiName = "java:comp/env/eis/SampleConnection";
   boolean verbose = false;

   /**
    * main method
    */
   public static void main(String[] args) {
      ConnectionFactoryLookup cfl = new ConnectionFactoryLookup();
      cfl.checkParam(args);

      try {
         cfl.lookupConnectionFactory();
      }
      catch(javax.naming.NamingException ne) {
   System.out.println("Caught this " + ne);
   ne.printStackTrace(System.out);
      }
      catch(javax.resource.ResourceException re) {
   System.out.println("Caught this " + re);
   re.printStackTrace(System.out);
      }
   }

 /**
  * This method does a simple Connection Factory lookup.
  *
  * After the Connection Factory is looked up, a connection is got from
 * the Connection Factory.  Then the Connection MetaData is retrieved
  * to verfiy the connection is workable.
  */
 public void lookupConnectionFactory()
  throws javax.naming.NamingException, javax.resource.ResourceException {

  javax.resource.cci.ConnectionFactory factory = null;
  javax.resource.cci.Connection conn = null;
  javax.resource.cci.ConnectionMetaData metaData = null;
```

```java
    try {
      // lookup the connection factory
        if (verbose) System.out.println("Look up the connection factory...");

      InitialContext ic = new InitialContext();
      factory = (ConnectionFactory) ic.lookup(jndiName);

      // Get connection
        if (verbose) System.out.println("Get the connection...");
      conn = factory.getConnection();

      // Get ConnectionMetaData
      metaData = conn.getMetaData();

      // Print out the metadata Informatin.
      if (verbose) System.out.println("  ** EISProductName   :" + metaData.getEISProductName());
      if (verbose) System.out.println("     EISProductVersion:" + metaData.getEISProductName());
      if (verbose) System.out.println("     UserName          :" + metaData.getUserName());

        System.out.println("Connection factory "+jndiName+" is successfully looked up");
    }
    catch (javax.naming.NamingException ne) {
      // Connection factory cannot be looked up.
      throw ne;
    }
    catch (javax.resource.ResourceException re) {
      // Something wrong with connections.
      throw re;
    }
    finally {
      if (conn != null) {
        try {
          conn.close();
        }
        catch (javax.resource.ResourceException re) {
        }
      }
    }
}

  /**
   * Check and gather all the parameters.
   */
  private void checkParam(String args[]) {
  int i = 0, j;
  String arg;
  char flag;
      boolean help = false;

  // parse out the options
  while (i < args.length && args[i].startsWith("-")) {
    arg = args[i++];

    // get the database name
    if (arg.equalsIgnoreCase("-jndiName")) {
      if (i < args.length)
        jndiName = args[i++];
      else {
        System.err.println("-jndiName requires a J2C Connection Factory JNDI name");
        break;
      }
    }
    else { // check for verbose, cmp , bmp
      for (j = 1; j < arg.length(); j++) {
        flag = arg.charAt(j);
        switch (flag) {
          case 'v' :
```

```
    case 'V' :
     verbose = true;
     break;
                case 'h' :
                case 'H' :
                    help = true;
                    break;
    default :
     System.err.println("illegal option " + flag);
     break;
   }
  }
 }
}

 if ((i != args.length) || help) {
  System.err.println("Usage: java ConnectionFactoryLookup [-v] [-h]");
  System.err.println("    [-jndiName the J2C Connection Factory JNDI name]");
  System.err.println("-v=verbose");
  System.err.println("-h=this information");
  System.exit(1);
 }
  }

}
```

J2EE Connector Architecture migration tips:

Versions of WebSphere Application Server previous to Version 5.0 provided an initial implementation of the J2EE Connector Architecture (JCA) specification, Version 1.0. This implementation provided basic run time support based on the final JCA 1.0 Specification, but it was not a complete implementation.

Version 5.0 of the product provides a complete implementation of the JCA 1.0 Specification, which supports:
* Connection sharing (*res-sharing-scope*).
* Get/use/close programming model for connection handles.
* Get/use/cache programming model for connection handles.
* *XA*, *Local*, and *No Transaction* models of resource adapters, including XA recovery.
* Security options A and C per the specification.
* Applications with embedded .rar files

> **Additional feature:** Version 5.0 also provides connection pooling, for increasing the efficiency of connection usage.

As of Version 6.0, the product provides a complete implementation of the JCA 1.5 Specification, which supports:
* All the features of the JCA 1.0 Specification.
* Deferred enlistment transaction optimization.
* Lazy connection association optimization.
* Inbound communication from an enterprise information system (EIS) to a resource adapter.
* Inbound transactions from an EIS to a resource adapter.
* Work management, which enables a resource adapter to put work on separate threads and to pass execution context (such as inbound transactions) to the thread .
* Life cycle management, which enables a resource adapter to be stopped and started.

Moving from an early implementation of JCA

If you move from one of the earlier implementations of the J2EE Connector Architecture to the current implementation, be aware of the following corresponding changes in WebSphere Application Server:

- This version of the product supports the *res-sharing-scope* tag within the resource reference (resource-ref) element. This tag was not available in previous versions and defaulted to *shareable* connections. Beginning with Version 5.0, WebSphere Application Server supports **both** shareable and unshareable connections.
- The current product supports the Web container. Both enterprise bean and Web components can utilize the J2EE Connector Architecture.
- Both connection handle usage patterns (get/use/close and get/use/cache) are supported. The get/use/close pattern indicates that a connection is retrieved, used, and closed all within the same transaction or method boundary. The get/use/cache pattern indicates that you can cache a connection across transaction or method boundaries.
- The current version supports additional authentication mechanisms. The capability to support Options A and C per the JCA specification is provided, as well as support for *res-auth* settings of either *Application* or *Container*. In versions before Version 5.0, the *res-auth* setting was basically ignored, therefore it was treated as if *res-auth* was set to *Application*. If your existing applications have *res-auth* set to *Container*, they might behave differently if you install them into a current environment without any changes.
- As of Version 6.0, resource authentication for *res-auth* settings of *Container* is preferably specified on the resource-reference mapping during application deployment. Specification of container-managed authentication on a data source or connection factory is deprecated.
- As of Version 5.0, you can no longer specify pool and subpool names. The pool name is based on the data source or connection factory Java Naming and Directory Interface (JNDI) name. Subpools were eliminated to provide better performance.
- As of Version 6.0, configuration data formerly in the *j2c.properties* file is now supported through the wsadmin scripting tool and the administration console. A migration utility updates the *resources.xml* file (or files) based on the settings in a *j2c.properties* file. A template *j2c.properties* file is no longer placed in the installed directory tree, but run-time code remains in place to process the file and favor its settings over those from the real configuration.

Migration involving first-time use of connection pooling

If you are upgrading to WebSphere Application Server V6.x from a version prior to V5.0, be aware of the run-time behavior changes that your applications might incur because of the new connection pooling feature in the product.

Although not required by the J2EE architecture, connection pooling support is provided by the connection management component of WebSphere Application Server to help improve the performance of getting and using connections to a backend, such as a database or transaction resource manager (CICS or IMS, for example). The connection pooling support is provided, individually, to every data source and connection factory that you configure. The properties associated with each connection pool have default values that are sufficient for most application server environments. However, in some cases, the default values might not meet the needs of application connection requests, and result in problems such as ConnectionWaitTimeout exceptions.

Therefore you must consider the application requirements of each data source and connection factory that you configure, and set the corresponding connection pool properties appropriately. The Connection pool settings and Tuning parameters for data access resources topics provide good reference for setting the properties.

Migration issue for the combination of Web services and JCA connectors

For applications that use Web services and JCA connectors, be aware that those generated on WebSphere Studio Application Developer -- Integration Edition Version 4.1.1 can run unchanged on WebSphere Application Server Version 6.x only if they are regenerated using WebSphere Studio Application Developer -- Integration Edition Version 5.0 tools, or Rational Application Developer tools. This limitation is because of the *wsd14j.jar* file. As delivered in WebSphere Application Server Enterprise Version 4.1, the file is not fully compliant with JSR 110 (because JSR 110 was not final at the time that Version 4.1 shipped). The *wsd14j.jar* file shipped with WebSphere Application Server Version 6.0 and later,

of course, is compliant. However, because most of the classes have the same package names and interfaces, BUT NOT ALL, the two *wsd14j.jar* files cannot co-exist in the same WebSphere Application Server installation.

JDBC provider templates: important general migration tip

Always handle the jdbc-resource-provider-templates.xml file as read-only . When updating this file, special consideration should be taken. Before installing a PTF, you should save your updated jdbc-resource-provider-templates.xml file. After applying the PTF, you will need to verify that the new jdbc-resource-provider-templates.xml file has your correct entries. If the entries are not valid, you will have to merge your changes into this new jdbc-resource-provider-templates.xml file manually.

Accessing data using J2EE Connector Architecture connectors

As indicated in the J2EE Connector Architecture (JCA) Specification, each enterprise information system (EIS) needs a resource adapter and a connection factory. This connection factory is then accessed through the following programming model. If you use Rational Application Development (RAD) tools, most of the following deployment descriptors and code are generated for you. This example shows the manual method of accessing an EIS resource.

For each EIS resource, do the following:
1. Declare a connection factory resource reference in your application component deployment descriptors, as described in this example:

```
<resource-ref>
    <description>description</description>
    <res-ref-name>eis/myConnection</res-ref-name>
    <res-type>javax.resource.cci.ConnectionFactory</res-type>
    <res-auth>Application</res-auth>
</resource-ref>
```

2. Configure, during deployment, each resource adapter and associated connection factory through the console. See Configuring J2C resource adapters and Configuring J2C connection factories for more information.
3. Locate the corresponding connection factory for the EIS resource adapter using Java Naming and Directory Interface (JNDI) lookup in your application component, during run time.
4. Get the connection to the EIS from the connection factory.
5. Create an interaction from the connection object.
6. Create an *InteractionSpec* object. Set the function to execute in the InteractionSpec object.
7. Create a record instance for the input and output data used by function.
8. Execute the function through the Interaction object.
9. Process the record data from the function.
10. Close the connection.

The following code segment shows how an application component might create an interaction and execute it on the EIS:

```
javax.resource.cci.ConnectionFactory connectionFactory = null;
javax.resource.cci.Connection connection = null;
javax.resource.cci.Interaction interaction = null;
javax.resource.cci.InteractionSpec interactionSpec = null;
javax.resource.cci.Record inRec = null;
javax.resource.cci.Record outRec = null;

try {
// Locate the application component and perform a JNDI lookup
    javax.naming.InitialContext ctx = new javax.naming.InitialContext();
    connectionFactory = (javax.resource.cci.ConnectionFactory)
ctx.lookup("java:comp/env/eis/myConnection");
```

```
// create a connection
   connection = connectionFactory.getConnection();

// Create Interaction and an InteractionSpec
   interaction = connection.createInteraction();
   interactionSpec = new InteractionSpec();
   interactionSpec.setFunctionName("GET");

// Create input record
   inRec = new javax.resource.cci.Record();

// Execute an interaction
   interaction.execute(interactionSpec, inRec, outRec);

// Process the output...

} catch (Exception e) {
   // Exception Handling
}
finally {
    if (interaction != null) {
        try {
            interaction.close();
        }
        catch (Exception e) {/* ignore the exception*/}
   }
   if (connection != null) {
        try {
            connection.close();
        }
        catch (Exception e) {/* ignore the exception */}
   }
}
```

Cursor holdability support for JDBC applications

The cursor holdability feature can reduce the overhead of JDBC interaction with your relational database, thereby helping to increase application performance.

By activating cursor holdability, you keep a result set available across transaction boundaries for use by multiple JDBC calls. The holdability setting triggers a database cursor to keep newly updated rows active beyond the commit of the transaction that generated the new values, or result set. Hence the cursor makes the result set available for use by statements in a subsequent transaction.

Setting cursor holdability

Use one of the following techniques to set cursor holdability. For more details, see the JDBC 3.0 specification, available at the Sun Microsystems, Inc., Web site at http://java.sun.com.

- Specify the ResultSet.HOLD_CURSORS_OVER_COMMIT parameter when creating or preparing a statement using the createStatement, prepareStatement, or prepareCall methods.

- Invoke the setHoldability method on the Connection object. The cursor holdability value that you set with this method becomes the default. If you specify cursor holdability on the Statement object, that value overrides the value that you specified on the connection.

  You cannot specify cursor holdability on a shareable connection after that connection is referenced by a second handle. Invoking the holdability method at this point generates an exception. If you want to set cursor holdability on a shareable connection, invoke the method before the connection is enlisted. Otherwise a shareable connection retains the same holdability value that applied in the previous enlistment.

- Check your database documentation to see if the product supports cursor holdability as a data source property. DB2, for example, responds to the holdability trigger if you set it as a data source custom property.

The impact of connection and transaction behaviors on cursor holdability

Setting cursor holdability in WebSphere Application Server results in the following behavior for different transaction events:

- When a connection is closed, all statements and result sets are closed even if you have set cursor holdability.
- When a transaction is rolled back, all result sets are closed even if you have set cursor holdability.
- When a local transaction is committed, both shareable and unshareable connections can have an open result set across a transaction boundary.
- When a global transaction is committed, unshareable connections can have an open result set across a transaction boundary. For shareable connections, the statements and result sets are closed even if you have set cursor holdability; the holdability value is moot for shareable connections participating in global transactions.
- When a local transaction scope ends, either at the method level or the activity session level, all statements and result sets for shareable connections are closed. Statements and result sets for unshareable connections remain open until the close method is called on the connection.

Note: For a global transaction with an unshareable connection, the backend database has responsibility for supporting cursor holdability.

Data access bean types

Data access beans are essentially a class library that makes it easier to access a database. The library contains a set of beans with methods that access the database through the JDBC API. There are several sets of classes referred to as data access beans. To make things clearer, you can refer to the classes by the name of the JAR file that contains them:

databeans.jar - This JAR file ships with WebSphere Application Server. This file contains classes that enable you to access the database using the JDBC API.

ivjdab.jar - This JAR file ships with Visual Age for Java. This file contains all of the classes in the databeans.jar file and classes that support easy use of the data access beans from the Visual Age for Java Visual Composition Editor.

dbbeans.jar - This JAR file ships with Rational Application Developer. This file contains a set of data access beans to more closely conform to the JDBC 2.0 *RowSet* standard.

For the current product, data access beans remain unchanged from WebSphere Application Server Version 4.0. The *com.ibm.db* package is provided to support existing applications that use data access beans.

IBM strongly suggests that any new applications using data access beans be developed using the *com.ibm.db.beans* package that is provided with Rational Application Developer.

If you want to continue using applications that use the com.ibm.db package, see the WebSphere Application Server Version 4.0 documentation concerning data access beans.

If you want to create new applications that use the com.ibm.db.beans package, see the Rational Application Developer documentation concerning data access beans. An example is shown here: Example: Using data access beans

Example: Using data access beans:

```
package example;
import com.ibm.db.beans.*;
import java.sql.SQLException;
```

```
public class DBSelectExample {

 public static void main(String[] args) {

  DBSelect select = null;

  select = new DBSelect();
  try {

   // Set database connection information
   select.setDriverName("COM.ibm.db2.jdbc.app.DB2Driver");
   select.setUrl("jdbc:db2:SAMPLE");
   select.setUsername("userid");
   select.setPassword("password");

   // Specify the SQL statement to be executed
   select.setCommand("SELECT * FROM DEPARTMENT");

   // Execute the statement and retrieve the result set into the cache
   select.execute();

   // If result set is not empty
   if (select.onRow()) {
    do {
     // display first column of result set
     System.out.println(select.getColumnAsString(1));
     System.out.println(select.getColumnAsString(2));
    } while (select.next());
   }

   // Release the JDBC resources and close the connection
   select.close();

  } catch (SQLException ex) {
   ex.printStackTrace();
  }
 }
}
```

Accessing data from application clients

To access a database directly from a J2EE application client, you retrieve a *javax.sql.DataSource* object from a resource reference configured in the client deployment descriptor. This resource reference is configured as part of the deployment descriptor for the client application, and provides a reference to a preconfigured data source object.

Note that data access from an application client uses the JDBC driver connection functionality directly from the client side. It does not take advantage of the additional pooling support available in the application server run time. For this reason, your client application should utilize an enterprise bean running on the server side to perform data access. This enterprise bean can then take advantage of the connection reuse and additional added functionality provided by the product run time.

1. Import the appropriate JDBC API and naming packages:

   ```
   import java.sql.*;
   import javax.sql.*;
   import javax.naming.*;
   ```

2. Create the initial naming context:

   ```
   InitialContext ctx = new InitialContext();
   ```

3. Use the *InitialContext* object to look up a data source object from a resource reference.

   ```
   javax.sql.DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/myDS");
   //where jdbc/myDS is the name of the resource reference
   ```

4. Get a *java.sql.Connection* from the data source.

- If no user ID and password are required for the connection, or if you are going to use the *defaultUser* and *defaultPassword* that are specified when the data source is created in the Application Client Resource Configuration tool (ACRCT) in a future step, use this approach:

```
java.sql.Connection conn = ds.getConnection();
```

- Otherwise, you should make the connection with a specific user ID and password:

```
java.sql.Connection conn = ds.getConnection("user", "password");
//where user and password are the user id and password for the connection
```

5. Run a database query using the *java.sql.Statement*, *java.sql.PreparedStatement*, or *java.sql.CallableStatement* interfaces as appropriate.

```
Statement stmt = conn.createStatement();
String query   = "Select FirstNme from " + owner.toUpperCase() + ".Employee where LASTNAME = '" + searchName + "'";
ResultSet rs   = stmt.executeQuery(query);
while (rs.next()) {    firstNameList.addElement(rs.getString(1));
}
```

6. Close the database objects used in the previous step, including any *ResultSet*, *Statement*, *PreparedStatement*, or *CallableStatement* objects.

7. Close the connection. Ideally, you should close the connection in a *finally* block of the *try...catch* statement wrapped around the database operation. This action ensures that the connection gets closed, even in the case of an exception.

```
conn.close();
```

Data access with Service DataObjects

The Service DataObjects (SDO) framework is a data-centric, disconnected, XML-integrated, data access mechanism that provides a source-independent result set.

- SDO is data-centric in that it does not support the retrieval of objects, as is the case with Enterprise JavaBeans (EJB) persistence mechanisms. Results are retrieved as a structured graph of data (the DataGraph).
- SDO is disconnected because the retrieved result is independent of any back end data store connections or transactions.
- SDO is XML-integrated in that it provides services to easily convert retrieved data to and from XML format.

Put simply, SDO is a framework for data application development, which includes an architecture and API. SDO does the following:

- Simplifies the Java Platform, Enterprise Edition (J2EE) data programming model.
- Abstracts data in a service oriented architecture (SOA).
- Unifies data application development.
- Supports and integrates XML.
- Incorporates J2EE patterns and best practices.

The Service DataObjects framework provides a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and utilize data. You need to know only one API, the SDO API, which lets you work with data from multiple data sources, including relational databases, entity EJB components, XML pages, Web services, the Java Connector Architecture, JavaServer Pages, and more.

Unlike some of the other data integration models, SDO does not stop at data abstraction. The SDO framework also incorporates a good number of J2EE patterns and best practices, making it easy to incorporate proven architecture and designs into your applications. For example, the majority of Web applications today are not (and cannot) be connected to backend systems 100 percent of the time; so SDO supports a disconnected programming model. Likewise, many applications tend to be remarkably complex, comprising many layers of concern. How will data be stored? Sent? Presented to end users in a GUI framework? The SDO programming model prescribes patterns of usage that allow clean separation of each of these concerns.

SDO components

An architectural overview of SDO describes each of the components that make up the framework and explains how they work together. The first three components listed are ″conceptual″ features of SDO: They do not have a corresponding interface in the API.

SDO clients

SDO clients use the SDO framework to work with data. Instead of using technology-specific APIs and frameworks, they use the SDO programming model and API. SDO clients work on SDO DataGraphs and do not need to know how the data they are working with is persisted or serialized.

Data mediator services

Data mediators services (DMS) are responsible for creating a DataGraph from data sources, and updating data sources based on changes made to a DataGraph.

The DMS provides the mechanism to move data between a client and a data source. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end. When the DMS is requested to produce a DataGraph, it queries its targeted back end and transforms the native result set into the DataGraph format. Once the DataGraph is returned, the DMS no longer has any reference to it, making it stateless with respect to the DataGraph. When the DMS is requested to flush modifications of an existing DataGraph to the back end, it extracts the changes made from the original state of the DataGraph and flushes those changes to the back end. A DMS typically employs some form of optimistic concurrency control strategy to detect update collisions.

WebSphere Application Server provides functionality for two separate Data Mediator Services. If you simply need to retrieve data from a relational data source and return a DataGraph, using the "Java DataBase Connectivity Mediator Service" on page 719 is a good choice. However, if you have business logic, then you probably want an object oriented (OO) rendering of the data into entity beans. One could consider SDOs as an object rendering of data similar to entity beans. But entity beans have better Object-Relational (OR) mapping tools, and the EJB container and persistence manager for entity beans offer more sophisticated caching policies. Your best choice then is the "Enterprise JavaBeans Data Mediator Service" on page 733. The EJB mediator can work with these caches. Also, the entity bean programming model is a single level store model. You can navigate from entity to entity and the container and persistence manager either prefetches or lazily fetches in data as needed. On update, the programmer commits the transaction and the container and persistence manager do the work of tracking updated beans and writing them back to the data store and in memory cache.

Data sources

Data sources are not restricted to backend data sources (for example, persistence databases). A data source contains data in its own format. Only the DMS accesses data sources, SDO applications do not. SDO applications only work with DataObjects in DataGraphs.

Each of the following components corresponds to a Java interface in the SDO programming model.

DataObjects

DataObjects are the fundamental components of SDO. In fact, they are the *service DataObjects* found in the name of the specification itself. DataObjects are the SDO representation of structured data which can hold multiple different attributes of any serializable type (such as string or integer), including other DataObjects. Each DataObject also has a *type* (see "SDO data object types" on page 722 for more information). DataObjects are generic and provide a common view of structured data built by a DMS. While a JDBC DMS, for instance, needs to know about the persistence technology (for example, relational databases) and how to configure and access it, SDO clients need not know anything about it. DataObjects hold their data in *properties* . DataObjects provide convenience creation and deletion methods (createDataObject() with various signatures and delete()), and reflective methods to get their types (instance class, name, properties, and namespaces). DataObjects are linked together and contained in DataGraphs. DataObjects have

different ways to access linked data, the two most common being through XPath expressions and by a property index. DataObjects keep track of the original value of any attribute that is modified.

DataGraphs

A DataGraph is a structured result returned in response to a service request. The DMS transforms the native backend query results into the DataGraph, which is independent of the originating backend data store. This makes the DataGraph easily transferable between different data sources. The DataGraph is composed of interconnected nodes, each of which is an SDO DataObject. It is independent of connections and transactions of the originating data source. The DataGraph keeps track of the changes made to it from its original source. This change history can be used by the DMS to reflect changes back to the original data source. DataGraphs can easily be converted to and from XML documents enabling them to be transferred between layers within a multi-tiered system architecture. A DataGraph can be accessed in either breadth-first or depth-first manner, and it provides a disconnected data cache that can be serialized for Web services

The DataGraph returned by the mediator can contain either dynamic or generated static DataObjects. Use of generated classes gives type safe interfaces for easier programming and better run time performance. The EMF generated classes must be consistent in name and type with the schema that would be created for dynamic DataObjects except that additional attributes and references can be defined. Only those attributes and references specified in the query are filled in with data. Remaining attributes and references are not set.

Change summary

Change summaries are contained by DataGraphs and are used to represent the changes that have been made to a DataGraph returned by the DMS. They are initially empty (when the DataGraph is returned to a client) and populated as the DataGraph is modified. Change summaries are used by the DMS at backend update time to apply the changes back to the data source. They enable the DMS to efficiently and incrementally update data sources by providing lists of the changed properties (along with their old values) and the created and deleted DataObjects in the DataGraph. Information is added to the change summary of a DataGraph only when the change summary's logging is activated. Change summaries provide methods for DMS to turn logging on and off.

Note: The change summary is **not** a client API, it is used only by the DMS.

Properties, types, and sequences

DataObjects hold their contents in a series of properties. Each property has a type, which is either an attribute type such as a primitive (for example, int) or a commonly used data type (for example, Date) or, if a reference, the type of another DataObject. Each DataObject provides read and write access methods (getters and setters) for its properties. Several overloaded versions of these accessors are provided, allowing the properties to be accessed by passing the property name (String), number (int), or property metaobject itself. The String accessor also supports an XPath-like syntax for accessing properties. For example you can call get(″department[number=123]″) on a company DataObject to get its first department whose number is 123. Sequences are more advanced. They allow order to be preserved across heterogeneous lists of property-value pairs.

For more introductory information

For a good introduction to SDO, including a small sample SDO application, refer to Introduction to Service DataObjects.

Note: To fully understand the EJB data mediator service you need a good understanding of the EJB programming model. For more information refer to "Task overview: Using enterprise beans in applications" on page 145, and "Service Data Objects: Resources for learning" on page 24

Java DataBase Connectivity Mediator Service:

The Java Database Connectivity (JDBC) Data Mediator Service (DMS) is the Service Data Objects (SDO) component that connects to any database that supports JDBC connectivity. It provides the mechanism to move data between a DataGraph and a database.

A regular JDBC call returns a result set in a tabular format. This format does not directly correspond to the object-oriented data model of Java, and can complicate navigation and update operations. When a client sends a query for data through the JDBC DMS, the JDBC result set of tabular data is transformed into a DataGraph composed of related DataObjects. This enables clients to navigate through a graph to locate relevant data rather than iterating through rows of a JDBC result set. After altering the DataGraph, all of the changes can be committed together and propagated back to the database by the JDBC DMS. Between the processes of being populated and being committed, the DataGraph is disconnected from the database, and there are no locks held on the data accessed. Being disconnected allows multiple changes to be made to the graph without making additional round trips to the database, improving performance.

The JDBC DMS is created with backend-specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS, as well as the query to be used against the back end.

Metadata for the Data Mediator Service:

A Data Mediator Service (DMS) is the Service Data Object (SDO) component that connects to the back end database. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end.

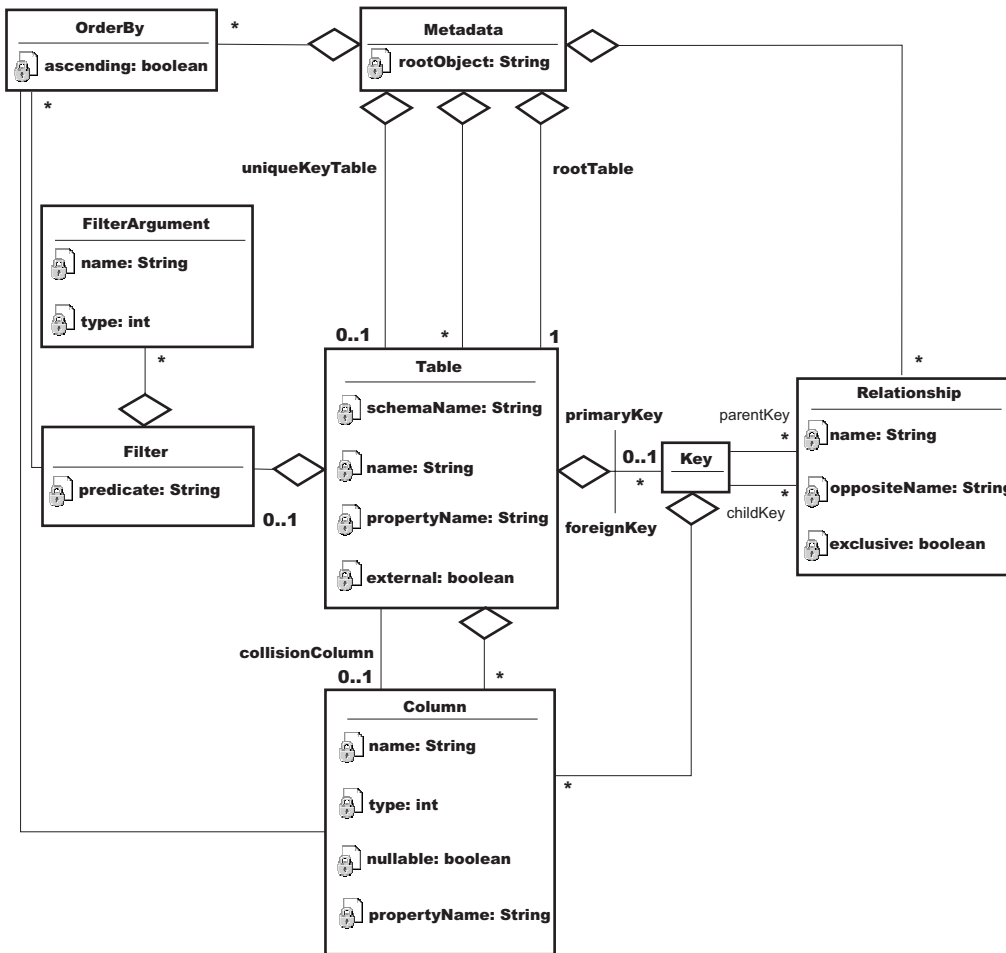
Metadata is composed of the following components:


Table This represents a table within the target database and is composed of the following items:

Name   This is the database table name. A table might also have a property name that can be used to specify the name of the DataObject that corresponds to this table. By default, the property name is the same as the table name.

Columns

The subset of database table columns to return from the database. A column has a type that corresponds to a JDBC type and it can prohibit null entries. A column has a name that corresponds to the name in the database and an optional property name that identifies the column name in the DataObject. By default, the property name is the same as the column name in the database.

Primary Key

The column (or columns) used to uniquely identify a row within the table.

Note: Keys may be composed of multiple columns. The following example illustrates creation of a compound primary key :

```
Key pk = MetadataFactory.eINSTANCE.createKey();
pk.getColumns().add(xColumn);
pk.getColumns().add(yColumn);
coordinateTable.setPrimaryKey(pk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

Foreign Key

The column (or columns) used to relate the table to another table in the metadata. There is an assumed positional mapping between compound primary keys and foreign keys. For example, if a parent table has a primary key such as (x,y) with respective types (integer, string), then it is expected that any pointing foreign key is also (x', y') with respective types (integer, string).

Note: Keys may be composed of multiple columns. The following example illustrates the creation of a compound foreign key :

```
Key fk = MetadataFactory.eINSTANCE.createKey();
fk.getColumns().add(xColumn);
fk.getColumns().add(yColumn);
coordinateTable.getForeignKeys().add(fk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

Filter   A structured query language (SQL) WHERE clause predicate that can be given with or without parameters to fill in later. This is added to the DataGraph SELECT statement WHERE clause. It is not parsed or interpreted in any way; it is used as is. If given with parameters to fill in later, these parameters become arguments passed into the JDBC DMS when getting the DataGraph. Filters are used with generated queries only. If a supplied query is given, the metadata filters are ignored.

Relationship

Relates two tables through the primary key of the parent table and the foreign key of the child table. Relationships are composed of the following items:

Name   This is the name given to the relationship, usually associated with how the two tables are related. If *Customers* is the parent table and *Orders* is the child table, then the default name of the relationship is Customers_Orders.

Opposite Name

This is the name used to navigate from the child DataObject to the parent DataObject.

Parent Key

The primary key of the parent table.

Child Key
> The foreign key of the child table that points to the parent key.

Exclusive
> By default, a Relationship causes the generated query to use an inner join operation on the two tables involved in the relationship. This means that it only returns the parent entries that have children, that is, child entries pointing to them. If the value of the Exclusive attribute is set to false, the query uses a left outer join operation instead and returns all parent entries, even those without children.

Ordering
> Columns used for ordering the tables. Can be either ascending or descending. When specified, this causes generated queries to contain an ORDER BY clause.

SDO data object types: DataObjects in the Service Data Object (SDO) can use either dynamic or static types. With dynamic types, the information that defines the shape of a DataGraph is constructed at runtime. Clients must use a DataGraph dynamic API to access data when using dynamic types. The DataGraph schema is created by the JDBC data mediator service (DMS) from the metadata provided upon creation. The JDBC DMS only requires the metadata and a connection to a data source to produce the DataGraph with dynamic typing. This is the default method for creating the JDBC DMS.

If you know the shape of the DataGraph at development time, you can use tools to generate strongly typed interfaces that simplify DataGraph navigation, provide better compile-time checking for errors, and improve performance.

The tools create classes for each DataObject type in the DataGraph. Each class contains *getter()* and *setter()* methods for each property in the DataObject. This enables a client to call type-safe methods rather than passing in the name of a property. For example, instead of calling the property *DataObject.get("CUSTFIRSTNAME"),* the generated types can contain a DataObject.getCustFirstName() method. If you are accessing a related DataObject, an accessor returns a strongly-typed DataObject rather than a regular DataObject. For example, *DataObject.get("Customers_Orders")* returns a DataObject, but *DataObject.getOrders()* returns an object of type Order.

When using typed DataObjects, the dynamic API is still available. To use static typing with the JDBC DMS, the metadata, a connection to the data source, and the DataGraph schema need to be provided to the JDBCMediatorFactory class *create* methods. In this case, the JDBC DMS metadata does not determine the shape of the DataGraph, but does give the DMS information about the backend data source and the way it maps to a DataGraph.

When using strongly-typed DataObjects, it is important to make sure that the query matches the DataGraph schema. The query is not required to fill all of the data objects and properties in the schema, but a query cannot return data objects or properties that are not defined in the DataGraph schema. For example, a DataGraph schema might define *Customer* and *Order* DataObjects, but a query might only return Customer objects. Also, the Customer object might define properties for *ID*, *Name*, and *Address*, but the query might not return an address. In this case, the value of the address property is null, and the value is not updated in the database when the *applyChanges()* method is called. In this example, the query could not return a *Phone* property because it has not been defined as a property on the Customer object. When a query attempts this, the DMS returns an invalid metadata exception.

JDBC mediator supplied query: Although the JDBC Data Mediator Service (DMS) generates a SELECT statement from the metadata provided at the creation of an instance, the DMS also enables the client to provide a specific SELECT statement to be used instead of the generated one. The provided statement is a standard structured query language (SQL) SELECT string and can contain parameter markers. Using supplied queries gives you more control over the data used to populate a DataGraph. With both supplied queries and generated queries, UPDATE, INSERT, and DELETE statements are automatically generated for each DataObject. They are applied when the mediator commits the changes made to the DataGraph back to the database.

Parameter DataObjects for supplied queries

Clients can use a parameter DataObject to supply arguments to an SQL SELECT query. A parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The ParameterDataObject for supplied queries is created based on the query given to the mediator. Every parameter in the query is given a name like *arg0, arg1, ..., argX*.

Because a parameter DataObject is a DataObject, you can set its properties using either the property name or an index value. The properties can be referenced by their argX name, or by the number associated with that parameter, 0, 1, ... , X. For example, your query is "SELECT CUSTFIRSTNAME WHERE CUSTSTATE = ? AND CUSTZIP = ?". This supplied query contains two parameters. The first parameter corresponds with CUSTSTATE and can be set using the string "arg0" or the index 0. The second parameter corresponds with CUSTZIP and can be set using the string "arg1" or the index 1. Here is sample code of how they are set. This code assumes that you have already set up the metadata and mediator with the metadata and the aforementioned supplied query. Using the index value method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameter.setString(0, "NY");
parameter.setInt(1, 12345);
DataObject graph = mediator.getGraph(parameters);
```

Using the property name method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("arg0", "NY");
parameters.setInt("arg1", 12345);
DataObject graph = mediator.getGraph(parameters);
```

The results are the same for both cases.

Limitations

The JDBC DMS generated SQL SELECT query is not fully supported on Oracle or Informix. This is because the mediator takes advantage of the ResultSetMetaData interface in JDBC 2.0 and requires it to be fully implemented. Oracle, Informix, DB2/390, and older supported versions of Sybase do not implement the ResultSetMetaData interface completely. The supplied select approach can still be used with these databases with one limitation: **column names in the Metadata must be unique across all tables.** An InvalidMetadataException occurs if the select statement returns a column with a name that appears multiple times in the metadata. For instance, if the Customer and the Order tables both contain a column named "ID", this would be invalid and cause problems. The way to fix this is to change the name of at least one of the matching columns in the database to better distinguish the two columns from each other. For the Customer table, the column name could be changed to "CUSTID," as it is in the examples. The Order column name could be changed to "ORDERID". If you change the Customer column name, you do not have to change the Order column name, but for consistency it may be a good idea.

JDBC mediator generated query: If you do not provide a structured query language (SQL) SELECT statement, then the data mediator service (DMS) generates one using the metadata provided at instance creation. The internal query engine uses information in the metadata about tables, columns, relationships, filters, and order bys to construct a query. As with the supplied queries, UPDATE, DELETE, and INSERT statements are automatically generated for each DataObject to be applied when the mediator commits the changes made to the DataGraph back to the database.

Filters

Filters define an SQL WHERE clause that might contain parameter markers. These are added to the DataGraph SELECT statement WHERE clause. Filters are used as is; they are not parsed or interpreted in any way so there is no error checking. If you use the wrong name, predicate, or function, it is not detected and the generated query is not valid. If a Filter WHERE clause contains parameter markers, then the

corresponding parameter name and type are defined using Filter arguments. Parameter DataObjects fill in these parameters before the graph is retrieved. An example of the Filters and Parameter DataObjects for generated queries follows.

Limitation: Because of the tree-like nature of the DataGraph, any table at a branch appears in more than one subquery in the final union with the root table appearing in all paths. This means that it is not possible to filter on a table that appears in more than one path independent of all other paths. All filters defined on a particular table are joined by a boolean AND, and used everywhere that table appears.

Parameter DataObjects for generated queries

Clients use a Parameter DataObject to supply arguments that are applied to the filters provided in the DMS metadata. A Parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The Parameter DataObject for generated queries is created based on the mediator's metadata. Every argument of every filter of every table is put into the Parameter DataObject. Unlike the supplied query Parameter DataObject, the parameters have the name assigned to them by the Filter arguments. The Parameter DataObject uses this name to map to the parameter to be filled in. The following sample code illustrates how a filter is created for a table in the mediator metadata. It also demonstrates the use of a Parameter DataObject to pass filter parameter values to a mediator instance. The sample assumes that the Customer table has already been defined:

```
// The factory is a MetadataFactory object
Filter filter = factory.createFilter();
filter.setPredicate("CUSTSTATE = ? AND CUSTZIP = ?");

FilterArgument arg0 = factory.createFilterArgument();
arg0.setName("customerState");
arg0.setType(Column.String);
queryInfo.getFilterArguments().add(arg0);

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("customerZipCode");
arg1.setType(Column.Integer);
queryInfo.getFilterArguments().add(arg1);

// custTable is the Customer Table object
custTable.setFilter(filter);

..... // setting up mediator

DataObject parameters = mediator.getParameterDataObject();

// Notice the first parameter is the name given to the
// argument by the FilterArgument.
parameter.setString("customerState", "NY");
parameter.setInt("customerZipCode", 12345);
DataObject graph = mediator.getGraph(parameters);
```

Order-by

Ordering of query results is specified using OrderBy objects that identify a column from a table to sort the results. This ordering can be either ascending or descending. The OrderBy objects are part of the metadata and are automatically applied to generated queries. An example of this for a customer table results to be sorted by first names is as follows:

```
// This example assumes that the custTable, a table in
// the metadata, and factory, the MetaDataFactory
// object, have already been created.
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
```

```
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

Limitation: Even though Order-bys are defined on each table in the metadata, the RDBMS model requires them to be applied to the final query. This has many implications. For example, you cannot order a table and then use that in a join to another table and propagate the ordering in the first table. Because a result set is a union of all the tables in the DataGraph, the nature of the single result set requires that it be padded with nulls, which can affect the order-bys, particularly in the non-root tables. This can give unexpected results.

External Tables

An external table is a table defined in the metadata that is not needed in the DataGraph returned by the JDBC DMS. This might be appropriate when you want to filter the result set based on data from a table but that table's data is not needed in the result set. An example of this with the Customers and Orders relationship would be to filter the results to return all customers who ordered items with an order date of the first of the year. In this case, you do not want any order information returned, but you do need to filter on the order information. Making the Orders table external excludes the orders information from the DataGraph and therefore reduces the DataGraph's size, improving efficiency. To designate a table as external, you call the *setExternal(true)* method from a table object in the JDBC DMS metadata. If the client tries to access an external table from the DataGraph, an illegal argument exception occurs.

Limitation: Many RDBMSs require that an orderby column appear in the final result set; the columns from an external table cannot in general be used to order a result set. Order-bys are actually applied to the result set (the word ″set″ is key here), and not to intermediate query results.

General limitations of generated queries

In understanding the limitations of the query generation feature in the JDBC DMS, there are two things to keep in mind. The first is that the DataGraph imposes a model that is a directed, connected graph with no cycles (that is, a model that is a tree) on a relational model that is a non-directed, potentially disconnected graph with cycles. *Directed* means that the developer chooses the orientation of the graph by picking a root table. *Connected* means that all tables that are a member of the DataGraph are reachable from the root. Any tables that are not reachable from the root cannot be included in the DataGraph. In order for a table to be reachable from the root, there must be at least one foreign key relationship defined between each pair of tables in the DataGraph. *No cycles* means that there is only one foreign key relationship between a pair of tables in the DataGraph. The tree nature of the DataGraph determines how the queries are built, and what data is returned from a query.

The second item to keep in mind is the following high level description of how query generation produces read queries for a DataGraph:
1. The JDBC DMS creates a single result set (that is, a DataGraph) whether the DataGraph is composed from a single table or from multiple tables.
2. Each path through the foreign key relationships in DMS Metadata from root to leaves represents a separate path. The data for that path is retrieved by using joins across the foreign keys defined between the tables in the path. The joins are by default inner joins.
3. All the paths in a DataGraph are unioned together in order to create a single result set by the query that is generated by the mediator, and are thus treated independently of one another.
4. Any user-defined filtering is done first on the tables. Then the result is joined to the rest of the path.
5. Relational databases generally require order-bys to be applied to the entire final result set and not on intermediate results.

JDBC mediator performance considerations and limitations:

Miscellaneous database limitations

- Sybase before Version 12.5.1 does not support in-line queries in the "from" clause, and therefore does not support multiple table DataGraphs with filters. To use the Service Data Object in WebSphere Application Server use Sybase Version 12.5.1.
- The Informix Dynamic Server does not support sub-selects, which are needed for multiple table graphs. Use Informix Extended Parallel Server.
- Oracle 8i does not support the ANSI join syntax. The mediator in multiple table cases requires Oracle 9i or 10g.

General performance recommendations

- Evaluate if your target projects are well suited to these technologies. In general, projects that are read-intensive and require disconnected data are good candidates.
- Limit the number of tables in the metadata. One or two is best because relationships, with respect to filters, become ambiguous when graphs have many branches.
- Work with small data sets as often as possible to avoid consuming excessive amounts of memory within your applications. You can limit the amount of data returned to the SDO by specifying filters in the metadata objects or by using paging.
- For Web applications, if the DataGraph is not too large and is to be reused later, store it in the user session.

JDBC mediator transactions:
Mediator managed transactions

A JDBC connection is wrapped in a connection wrapper and passed to the Data Mediator Service (DMS) during the instance creation. The ConnectionWrapper object contains the connection that is used by the JDBC DMS and indicates whether the mediator manages the current transaction. When the JDBC DMS manages the transaction, it performs commit and rollback operations as required. However, the DMS does not perform any transaction management activities if the wrapped connection is currently engaged in another transaction.

The default action is to manage transactions.

Non-mediator managed transactions

When a *passive* connection wrapper is passed to the DMS, the DMS takes no managerial action; a passive wrapper is generally intended for an existing transaction that is under external management. Commit or rollback operations are not performed by the connection wrapper in this case.

Protection against referential integrity (RI) violations

The JDBC Data Mediator Service safeguards data transactions from incurring RI violations and other database logic violations. When the JDBC DMS applies the updates of a data graph to a back end, it automatically orders the change operations so that they do not violate database RI policy. Similarly, the DMS filters counter operations (such as INSERT and DELETE) so that opposing client requests can perform updates in a logical order. The client deletes one object, and then creates an entirely separate object with the same primary key. The DMS transforms these two operations into an update operation that modifies the existing database object.

JDBC mediator exceptions:

```
                        <<signal>>
                     MediatorException
                     _____

                     _____
                     _____

                        <<signal>>
                   JDBCmediatorexception
                   _____

                   _____

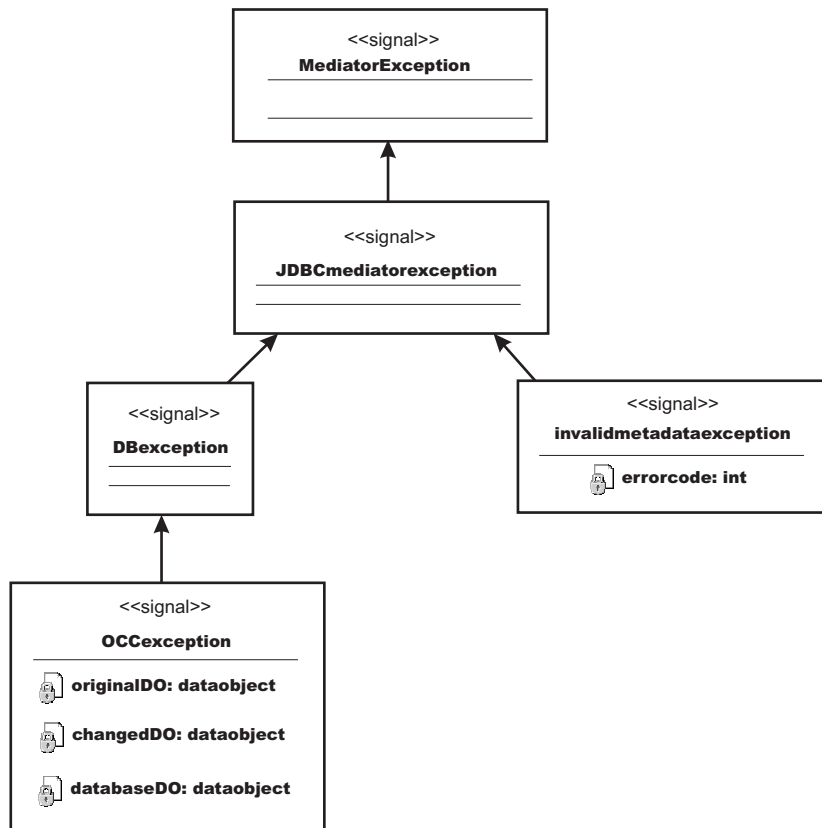
        <<signal>>                          <<signal>>
       DBexception                     invalidmetadataexception
       _____                     _____

       _____                        🔒 errorcode: int

     <<signal>>
    OCCexception
    _____

  🔒 originalDO: dataobject

  🔒 changedDO: dataobject

  🔒 databaseDO: dataobject
```


The `Mediator` exception is the root exception of all the data mediator services, and the `JDBCMediator` exception is the root exception for the JDBC DMS in particular.

The `DB` exception occurs when an error is reported by the database. This can occur several ways:
- when the connection being used has the AutoCommit property set to *true*, but the JDBC DMS is controlling the transaction and needs it to be set to false
- when an unsupported database is trying to be used
- when other backend database errors occur during commit or rollback.

An optimistic concurrency control (OCC) exception occurs when the applyChanges() operation results in an data collision. When this occurs, the exception contains the original row values, current row values, and the attempted row values. These values are used to help recover from the error.

An `InvalidMetadata` exception occurs for invalid metadata supplied to the JDBC DMS upon creation. This can happen when a query requires tables or columns that are not defined in the metadata, or when there are identical column names for different tables for the Oracle, Informix, and older supported versions of Sybase databases.

Example: OCC data collisions and JDBC mediator: The following example forces a collision to demonstrate detection and shows the exception that occurs as a result.

```
// This example assumes that a mediator has already
// been created and the first name in the list is Sam.
// It also assumes that the Customer table has an OCC
// column and the metadata has set this column to be
// the collision column.

DataObject graph1 = mediator.getGraph();
DataObject graph2 = mediator.getGraph();
```

```
DataObject customer1 = (DataObject)graph1.getList("CUSTOMER").get(0);
customer1.set("CUSTFIRSTNAME", "Bubba");

DataObject customer2 = (DataObject)graph2.getList("CUSTOMER").get(0);
customer2.set("BOWLERFIRSTNAME", "Slim");

mediator.applyChanges(graph2);

try
{
 mediator.applyChanges(graph1);
}
catch (OCCException e)
{
// Since graph1 was obtained before graph2 and
// graph2 has already been submitted, trying to
// apply the same changes to graph1 causes
// this OCC Exception.

assertEquals("Sam", e.getOriginalDO(). getString("CUSTFIRSTNAME"));
assertEquals("Bubba", e.getChangedDO(). getString("CUSTFIRSTNAME"));
assertEquals("Slim", e.getDatabaseDO(). getString("CUSTFIRSTNAME"));
}
```

Monitoring optimistic concurrency control collisions:

To diagnose transaction problems that are caused by update collisions, implement an optimistic concurrency control (OCC) strategy for the JDBC DMS.

An *update collision* occurs when client data that populates a data graph is changed in the database before the data graph can submit the modifications of the client. If you configure the JDBC DMS for OCC, the DMS issues an OCC-specific exception when such a data collision happens. The OCC exception contains collision details such as the original row values, current row values, and the attempted row values. The client application uses these values to determine how to recover from the collision. For example, the application can reread the data and restart the transaction.

Be aware, however, that when one exception occurs, there is no way of knowing whether more exceptions exist deeper in the data graph schema and therefore are not displayed.

To activate OCC for the data mediator service, you must incorporate OCC columns into your database tables.

Add an *OCC Integer* column to a given table, and specify that this column is to be used for OCC in the metadata. The defined OCC collision column is reserved for the exclusive use of the mediator. If there is no OCC column defined for a table, the DMS does not monitor and notify you of update collisions. The following generic code segments create this setup.

1. Create the OCC column

   ```
   Column collisionColumn = table.addIntegerColumn("OCC_COUNT");
   ```
2. Ensure that it does not allow null values

   ```
    collisionColumn.setNullable(false);
   ```
3. Designate the column as the table collision column

   ```
    table.setCollisionColumn(collisionColumn);
   ```
   For a full-fledged code example that forces a collision to demonstrate the OCC exception, see the topic "Example: OCC data collisions and JDBC mediator" on page 727.

JDBC mediator integration with presentation layer: The JDBC Data Mediator Service (DMS) can be used in conjunction with Web application presentation layer technologies such as JavaServer Pages Standard Tag Library (JSTL) and JavaServer Faces (JSF). A general understanding of both of these technologies is

assumed for this section. In particular for JSF, the UIData component and the general file structure of a JSF dynamic Web application should be known. For a brief overview of both JSF and JSTL refer to the links at "Service Data Objects: Resources for learning" on page 24.

The JDBC DMS and JSTL work well together because the JSTL access code is equivalent to the code necessary to access attributes and lists inside of a DataObject. For example, in relation to a root Customer DataObject, the JSTL expression:

```
${rootDO.CUSTOMER[index].CUSTNAME}
```

is equivalent to the Java code for a DataObject of:

```
rootDO.getList("CUSTOMER").get(index).get("CUSTNAME")
```

The reason for this is the dot notation in the JSTL expression language correlates to a *getter()* method in Java code, and the bracket notation allows you to access elements inside a list.

The JDBC DMS and JSF fit well together because the DataGraph produced by the JDBC DMS is able to populate a JSF UIData component without having to be transformed. The UIData component uses a *dataTable* tag that takes a list as its input to populate the table. This works out well with the DataGraph because all you need to pass into the dataTable is the root list of the DataGraph. The most common way to lay out the DataGraph in the dataTable is to display each attribute of the DataObject from the list retrieved from the root in its own column, and to embed each additional relationship to the DataObject in a new dataTable contained within the parent DataObject's row. Using this method instead of a traditional ResultSet table eliminates duplicate information and makes it easier to see the separation of the parent object's children. An example of how the Customer and Order scenario is laid out in a dataTable is shown in "Example: JavaServer Faces and JDBC Mediator"

Example: JavaServer Faces and JDBC Mediator: This code would be located inside of a Faces JSP page. It contains the UIData component dataTable tag with all of the customer's information, along with their orders. Each Customer attribute has its own column. The Customer Orders are embedded in another dataTable containing each of the Order attributes in separate columns. This embedded dataTable of Orders is like any other Customer attribute, having its own column inside each Customer row.

```
<h:dataTable id="table1" value=">{pc_Customers.customer}" var=
"varcustomer" styleClass="dataTable">

  <h:column id="column1">
    <f:facet name="header">
      <h:outputText styleClass="outputText" value="Customerid" id=
        "text1"></h:outputText>
    </f:facet>
    <h:outputText id="text2" value=">{varcustomer.CUSTOMERID}"
    styleClass="outputText">
     <f:convertNumber />
    </h:outputText>
    </h:column>

  <h:column id="column2">

```

```
      </h:dataTable>
   </h:column>
</h:dataTable>
```

JDBC mediator paging: Paging can be useful for moving through large data sets because it can limit the amount of data pulled into memory at any given time. If the metadata provided to the data mediator service (DMS) defines customers and the page size is set to ten, then the first page is a DataGraph containing the first ten customer DataObjects. The next page is another DataGraph with the next ten Customers, and so forth.

One thing to note is that the JDBC DMS provides paging at the root of the graph. That is, there is no restriction on the number of related DataObjects returned. For example, if the metadata provided to the DMS defines customers and related orders, it is the customers that are paged. If the page size is set to ten, then the first page is a graph with the first 10 customers and all related orders for each customer.

There are two interfaces provided by the DMS that you can take advantage of, the **Pager** and the **CountingPager**. The Pager interface provides a cursor-like *next()* method capability. The next() function returns a graph representing the next page of data from the entire data set specified by the mediator metadata. There is also a *previous()* function available with the same capabilities, only going backward. The CountingPager interface enables you to retrieve a specific page number. The following example illustrates paging through a large set of customer instances using a CountingPager interface with a maximum of 5 DataObjects from the root table per page.

```
CountingPager pager = PagerFactory.soleInstance.createCountingPager(5);
int count = pager.pageCount(mediator);
for (int i = 1, i <= count, i++) {
DataObject graph = pager.page(i, mediator);
// Iterate through all returned customers in the
// current page.
Iterator iter = graph.getList("CUSTOMER").iterator();
 while (iter.hasNext()) {
  DataObject cust = (DataObject) iter.next();
System.out.println(cust.getString("CUSTFIRS NAME"));
 }
}
```

If you try to move before the first page or after the last available page, a JDBC mediator exception occurs.

JDBC mediator serialization: The DataGraph produced by the JDBC DMS can be serialized and written out to a file, or sent across a network. The following example illustrates serialization and de-serialization of a graph:

```
// This example assumes the creation of the Customer
// metadata and the JDBC DMS.

DataObject object = mediator.getGraph();
DataGraph origGraph = object.getDataGraph();

FileOutputStream out = new FileOutputStream("test.datagraph");
ObjectOutputStream oos = new ObjectOutputStream(out);
oos.writeObject(origGraph);
out.close();

FileInputStream in = new FileInputStream("test.datagraph");
ObjectInputStream oin = new ObjectInputStream(in);
DataGraph graph = (DataGraph) oin.readObject();
DataObject obj = (DataObject) graph.getRootObject();

// Now, the DataObject retrieved from the input stream
// obj is equal to the original variable object put
// through the output stream.
```

Enterprise JavaBeans Data Mediator Service:

The Enterprise JavaBeans (EJB) Data Mediator Service (DMS) is the Service Data Objects (SDO) Java interface that, given a request in the form of EJB queries, returns data as a DataGraph containing DataObjects of various types.

This differs from a normal EJB finder or ejbSelect method, which also takes an EJB query but returns a collection of EJB objects (all of the same type) or a collection of container managed persistence (CMP) values.

The EJB DMS enables you to specify an EJB query that returns a data graph (the DataGraph) of data objects (DataObjects). The query can be expressed as a compound EJB query contained in a string array of EJB query statements. One advantage of using a DataGraph is that much of the code written in an EJB facade session bean that deals with creating, populating, and updating copy helper objects can be replaced with a DataGraph and a DMS.

Important: The EJB Data Mediator Service has support for EJB2.x container managed persistence (CMP) entity beans only.

You can obtain a DataGraph using the getGraph call, either from EJB instances cached in the container or the query request can be compiled into SQL and executed directly against the data source.

Updated DataObjects can be written back to the data store by using the applyChanges method in one of two ways. The updates can be translated into SQL and applied directly to the data store or can be written back through EJB accessor methods. Writing back directly to the data store can improve performance as it avoids EJB activation. However, if business logic or EJB container function is required by the application, then writing back through EJB is the preferred approach. When writing back through EJB, you can specify a user defined MediatorAdapter to allow customized handling of changed DataObjects. This customization can include application specific optimistic concurrency control, invoking business methods on the EJB to perform updates, update of computed values in the DataObject and calling application specific create methods on EJBHome.

Update processing is not dependent on how the DataGraph was originally retrieved. In other words it is possible to retrieve a DataGraph directly from the data source but have the deferred updates applied through EJB or the other way around.

Regardless of which update approach you use, an optimistic concurrency control algorithm is used. Fields designated as consistency fields are read during update to insure that the current value is still equal to the old value of the field in the DataObject.

Runtime processing

An EJB mediator request is a compound EJB query, which consists of an ordered list of more or less regular EJB queries. Each query in the compound query defines an SDO. The SELECT clause of the query specifies the CMP fields or expressions to return in the DataObject. The WHERE clause specifies the filtering conditions. The first query in the list is considered to be the ROOT node in the DataGraph. The FROM clause of a query (other than the first) specifies an EJB relationship which is used to create references between DataObjects. More details about how the DataGraph schema is derived from the query can be found in "DataGraph schema" on page 744.

EJB data mediator service programming considerations:

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in WebSphere Application Server, consider the following items.

EJB programming model

Only a subset of the Enterprise JavaBeans programming model is supported by the EJB data mediator service.

- When using EJB collection parameters to retrieve data from EJB instances, or when using applyChanges to update EJB instances:
  - The EJB DMS uses local interfaces for enterprise beans. *Getter* and *setter* calls for container-managed persistence (CMP) fields must be promoted to the local interface, as well as any EJB methods used in query expressions.
  - For the mediator to create an EJB, there must be a create method using the primary key class as the only argument method defined on the EJB home. If no such method exists, you must supply an adapter that handles the create operation. Also, the EJBLocalHome interface defined for the EJB must include (in addition to the create method) the following method:

    ```
    findByPrimaryKey(<key class>)
    remove (java.lang.Object)
    create (<key class>)
    ```
- When invoking the applyChanges method directly to the database, the following occur:
  - you bypass container update. You should force a refresh as soon as possible by transaction termination and using appropriate container cache options.
  - you bypass EJB container-managed relationship (CMR) maintenance. You must rely on database RI to maintain those relationships not retrieved into the DataGraph.
- CMP fields must be the allowed types. See "EJB mediator query syntax" on page 737 for a list of those types.
- CMP fields of user-defined types that use EJB converters/composer are not supported.

The following table shows limitations in the EJB programming model that are **not** supported by the EJB DMS.

	retrieve direct from db	retrieve from EJB Container	update direct to db	update through EJB
EJB persistence inheritance	No	No	No	No
EJB cmp field with converter	No	Yes	No	Yes

Transactional

- All mediator calls (including create) must be done within a transaction scope – either a user transaction or a container transaction. The various mediator calls (create, getGraph, applyChanges) do not have to be called within the same transaction. In fact, most often the calls are done in separate transactions.

Access Intent

- When the mediator query references an EJB using its abstract schema name (ASN), data is retrieved directly from the database. The access intent and isolation level used on the data source connection is the access intent specified in the application profile for EJB dynamic query access intent. It is recommended that you define an optimistic access intent for your application because a DataGraph is intended to be used in a disconnected programming model.
- When the mediator is retrieving data using an EJB collection, the access intent specified in the application profile is used if the EJB requires activation.
- During applyChanges, optimistic concurrency control is used to verify certain fields in the DataObject before applying changes to the database. Updates are typically processed under a different transaction from the retrieval. Therefore, to avoid lost updates it is necessary to verify that another transaction has not updated the data. When defining the EJB to RDB mapping you can specify one or more EJB fields as optimistic Predicates. The fields are used for verification by comparing the current database value to

the old value from the DataGraph change log. If the verification succeeds, then the current value of the fields is written to the database. If the comparison returns false and the update fails, an exception occurs. All of this is accomplished in a single update statement with extra predicates added, such as in the following example. The optimisticPredicate field is *myColumn1*.

```
update  myTable set  myColumn1 = 'new value1', myColumn2='new value2'
where myKey= 'key value' and myColumn1 ='old value1'
```

- When applyChanges is done through the EJB container, the current values of the enterprise beans are compared with the old values of the optimistic predicates fields. If the values are unequal an exception occurs.

- Provided that you have defined one or more EJB fields as optimisticPredicates, then for the SDO to be updateable, at least one of the optmisticPredicate fields must be retrieved into the data object. Otherwise, applyChanges returns an exception. The field should be updated either by the caller or a database trigger – the mediator does not automatically increment or set the field.

- Not all fields are verified, only those fields marked as optimisticPredicate in the EJB-RDB mapping.

- Note that the EJB mapping tool allows for the possibility of no optimisticPredicate fields. In this case the mediator will perform updates without any verification.

- Creation and deletion operations do not make use of the optimistic predicate fields.

- When applying changes through EJB instances, the EJB might have to be activated first. In this case, the appropriate access intent associated with the EJB methods apply. It is recommended that you run applyChanges in a profile that has pessimistic access intent, otherwise the optimistic concurrency logic is invoked twice – once when copying data object values to the EJB, and a second time when the persistence manager compares the old values of the EJB field values against the database record.

- The access intent used by the mediator when retrieving directly from the database is the default access intent defined for the EJB named in the first query statement.

Best practices

- It is allowable to call getGraph on one mediator instance, update the returned DataGraph, and then call applyChanges on a different mediator instance. However, while they do not need the same mediator instance, they do need the same *query shape*. The query shape is the number and order of query statements, the fields and relationships specified in the SELECT and FROM clauses, and so on.

- Avoid repeated calls to createMediator if possible. Use parameterized queries and use getGraph to pass in different parameter values.

EJB data mediator service data retrieval:

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can obtain a DataGraph using the *getGraph* call.

Directly from the data source

To retrieve data directly from the data source, specify your first EJB query to reference the Abstract Schema Name (ASN) of the EJB.

From the EJB container

To retrieve data through the EJB container, specify your first query to use an input parameter in the FROM clause referring to the EJB collection desired.

You should use this method when there is high likelihood that your EJB instances will be cached in the container. This way you avoid container flush and then read from the database to retrieve data.

For an example, see the section called Collection Input Parameter at "Example: EJB mediator query arguments" on page 738.

EJB data mediator service data update:

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can write an updated DataGraph back to the data source by using the applyChanges method.

The update can be applied directly to the data source or through EJB instances.

When applying changes through EJB instances an optional adapter class can be specified on the applyChanges method. Each changed data object is first passed to the adapter applyChange method. The adapter can process the change itself and return **true**, or have the EJB Mediator process the change by returning **false**.

The adapter can be used to customize the optimistic concurrency (OCC) logic, or process changes to read only DataGraph attributes, or process changes that require business logic.

There are two forms of the applyChanges method. The first, *applyChanges(DataObject)* takes the updated DataGraph and runs structured query language (SQL) insert, update, and delete statements directly against the database, bypassing the EJB container. The second form, *applyChanges(DataObject, MediatorAdapter)* processes updates using EJB instances and accessors. A null value for the MediatorAdapter is supported.

When to use an adapter with applyChanges
- Use when there are create methods other than create(PrimaryKey)
- Use when business methods must be called instead of container-managed persistence (CMP) *setter* methods
- Use when special optimistic caching logic is needed

How the adapter works

Three passes are made over the DataGraph log, passing changed DataObject to the adapter:
1. New DataObjects are passed. The adapter can create the object and set the CMP fields. Container-managed relationships (CMR) that reference enterprise beans not yet created are deferred until pass 2.
2. New and updated DataObjects are passed. CMRs deferred from pass 1 can be set at this time.
3. Deleted DataObjects are passed.

Example: using MediatorAdapter:

In this example, the adapter processes CREATE events for an EMP data object. The name and salary attributes are extracted from the data object and passed to the create method on the EmpLocalHome.

The create method returns an instance of Emp EJB and the primary key value is copied back to the DataObject. The caller can then obtain the generated key value. After processing, the adapter returns a value of **true**. All other changes are ignored by the adapter and processed by the EJB Mediator.

```
package com.example;
import com.ibm.websphere.sdo.mediator.ejb.*;
import javax.naming.InitialContext;
import commonj.sdo.ChangeSummary;
import commonj.sdo.DataObject;
import commonj.sdo.DataGraph;
import commonj.sdo.ChangeSummary;

// example of Adapter class calling a EJB create method.

public class SalaryAdapter implements MediatorAdapter{
```

```
  ChangeSummary log = null;
       EmpLocalHome empHome = null;

 public boolean applyChange(DataObject object,  int phase){

  if (object.getType().getName().equals("Emp")
       && phase == MediatorAdapter.CREATE){
   try{
    String name = object.getString("name");
    double salary = object.getDouble("salary");
    EmpLocal emp = empHome.create(name, salary);
    object.set("empid", emp.getPrimaryKey() ); // set primary key in SDO
    return true;
   } catch(Exception e){ // error handling code goes here
                   }
  }
  return true;
 }

 public void init (ChangeSummary log){
         try {
  this.log = log;
  InitialContext ic = new InitialContext();
  empHome = (EmpLocalHome)ic.lookup( "java:comp/env/ejb/Emp");
         } catch (Exception e) { // error handling code goes here
         }
 }

 public void end(){}
}
```

EJB mediator query syntax:

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in WebSphere Application Server, consider the following items.

- The EJB DMS takes as an input argument a compound EJB query which consists of an array containing EJB query language (QL) statements and an optional XREL command. The XREL command is a list of EJB relationships and must appear last in the array.

- Each EJB QL query returns data in the form of a Service DataObjects (SDO) instance. All of the SDO instances are merged into a DataGraph. The SELECT clause of each query specifies the container-managed persistence (CMP) fields or expressions to return in the SDO. The WHERE clause specifies the filtering conditions and you can define an ORDER BY clause. If two or more SELECTs return the same SDO type, each SELECT must project the same CMP fields and expressions. For updatability, the primary key fields of the EJB must be projected. JOINs, UNIONs, and aggregation are not supported except in subqueries.

- A query in the array can refer to a prior query in the FROM clause by using the identification variable defined in the prior query and a relationship name. This relationship can be single or collection valued.

- Relationships are constructed between data object instances in the graph when a relationship is used in either the FROM clause or in the XREL command.

- Collection valued input arguments are supported in FROM clause If ?1 refers to a collection of Dept EJBs then the following query is valid for the mediator. The cast syntax is required to tell the query compiler the collection element type.

  ```
  select d.deptno from (Dept) ?1 as d
  ```

- The collection input argument is useful when it is desired to build a DataGraph from EJB instances that are cached in the EJB Container or persistence manager data cache.

- The SELECT clause can specify a list of CMP fields to retrieve (the wildcard * notation can be used to retrieve all CMP fields) or valid EJB query language expressions. CMP fields and expressions must be one of the following types:
  - Primitive types: boolean, byte, short, integer, long, float, double, char

- Object wrapper types for the primitive types
- Java.lang.String
- Java.math.BigDecimal
- java.math.BigInteger
- byte [ ]
- Java.sql.Date
- java.sql.Time
- java.sql.Timestamp
- java.util.Date
- java.util.Calendar
- All primary key CMP fields must be retrieved in order for the Service Data Objects (SDO) to be updateable; otherwise, applyChanges returns an exception.
- SDO attributes that come from EJB query language expressions such as *e.salary + e.bonus AS TOTAL_PAY* cannot be updated. If you try to make an update, applyChanges returns a QueryException.
- Aggregate expressions such as *SUM(e.salary)* are not allowed even though they are part of the EJB query language. Aggregate expressions can be used in subselects in the WHERE clause.

Example: EJB mediator query arguments:

The following examples show how you can fine-tune your EJB mediator query arguments.

A simple example

This query returns a DataGraph containing multiple instances of DataObjects of type (Eclass name) *Emp*. The data object attributes are *empid* and *name* and their data types correspond to the container-managed persistence (CMP) field types.

```
select  e.empid, e.name
from Emp as e
where e.salary > 100
```

The returned DataGraph serialized in its XML format looks like this:

```
  <?xml version="1.0" encoding="ASCII"?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Emp empid="1003" name="Eric" />
<Emp empid="1004" name="Dave" />
</root>
</datagraph:DataGraphSchema>
```

Query parameters

This example shows how parameter markers can be used. Recall that the syntax for parameter markers in an EJB query is a question mark followed by a number (?n). When calling the getGraph ( ) method on the EJBMediator, you can optionally pass an array of values. ?n refers to the value of parm[n-1]. The array of values can also be passed on the factory call to create the EJBMediator. Parameters passed on the getGraph( ) override any parameters passed on the create call.

```
select  e.empid, e.name
from Emp as e
where e.salary > ?1
```

Returning expressions and methods

This example illustrates that the data object attributes can be the return values of query expressions. EJB query expressions include arithmetic, date-time, path expressions, and methods. Input arguments and return values from methods are restricted to the list of supported data types (see "EJB mediator query

syntax" on page 737). A data object containing an updated attribute derived from an expression causes an exception to occur during the applyChanges process unless the user has provided a MediatorAdapter to handle the change.

```
select  e.empid as employeeId,
   e.bonus+e.salary as totalPay,
   e.dept.mgr.name as managerNam,
   e.computePension( ) as pension
from Emp as e
where e.salary > 100
```

Data object attribute names are derived from the CMP field names but can be overridden by using the *AS* keyword in the query. When specifying an expression, the *AS* keyword should always be used to give a name to the expression.

The * syntax

The notation *e.* * is a short cut for specifying all the CMP fields (but not container-managed relationships) for an EJB. The following query means the same thing as *e.empid, e.name e.salary, e.bonus*.

```
select e.* from Emp as e
```

No primary key in select clause

This example shows a query that does not return the primary key field. However, unless the data object contains all the primary key fields for an EJB, updates to the DataGraph cannot be processed by the mediator. This is because the primary key is required to translate the changes into structured query language (SQL), or to convert DataObject references to EJB references. An exception when applyChanges tries to run.

```
select e.name, e.salary from Emp as e
```

Order by

DataObjects can be ordered.

```
select d.* from Dept d  order by d.name
 select e.* from in(d.emps) e order by e.empid desc
```

This results in the *Dept* objects being ordered by name and the *Emp* objects within each *Dept* being order by *empid* in descending order.

Navigating a multi-valued relationship

This compound query returns a DataGraph with DataObject classes *Dept* and *Emp*. The shape of the DataGraph reflects the path expressions used in the FROM clauses.

```
select d.deptno, d.name, d.budget from Dept d
   where d.deptno < 10
select e.empid, e.name, e.salary  from in(d.emps) e
   where e.salary > 10
```

In this case *Dept* is the root node in the DataGraph and there is a multivalued reference from *Dept* to *Emp* as shown:

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" budget="500.0"
   emps="//@root/@Emp.1 //@root/@Emp.0" />
<Dept deptno="2" name="WBI_Sales" budget="450.0"
   emps="//@root/@Emp.3 //@root/@Emp.2" />
<Emp empid="1001" name="Rob" salary="100.0" EmpDept="//@root/@Dept.0" />
<Emp empid="1002" name="Jason" salary="100.0" EmpDept="//@root/@Dept.0" />
```

```
<Emp empid="1003" name="Eric" salary="200.0" EmpDept="//@root/@Dept.1" />
<Emp empid="1004" name="Dave" salary="500.0" EmpDept="//@root/@Dept.1" />
</root>
</datagraph:DataGraphSchema>
```

More on query parameters

Search conditions can be specified on any query. Input arguments are global to the query and can be referenced by number anywhere in the compound query. In the example above, the query arguments passed on the create or getGraph call should be in order { deptno value, salary value, deptno value }.

```
select d.* from Dept as d
    where d.deptno between ?1 and ?3
select e.* from in(d.emps) e
    where e.salary < ?2
```

Navigating a path with multiple relationships

The following query navigates the path composed of EJB relationships Dept.projs and Project.tasks and returns DataObjects for Dept, Emp and Project containing selected CMP fields.

```
select d.deptno, d.name from Dept as d
select p.projid  from in(d.projects) p
select t.taskid, t.cost from  in (p.tasks) t
```

The resulting data graph in XML format is shown here.

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0" />
<Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1" />
<Project projid="1" ProjectDept="//@root/@Dept.0
      tasks="//@root/@Task.0   //@root/@Task.2 //@root/@Task.1" />
<Project projid="2" ProjectDept="//@root/@Dept.1"
      tasks="//@root/@Task.3" />
<Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
<Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
<Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
<Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
</root>
</datagraph:DataGraphSchema>
```

Navigating multiple paths

Here is a mediator query returning a DataGraph with DataObjects for Dept with related employees and a second path that retrieves related projects and tasks.

```
select d.deptno, d.name from Dept d
select e.empid, e.name  from in(d.emps) e
select p.projid from in(d.projects) p
select t.taskid, t.cost from in(p.tasks) where t.cost > 10
```

The returned DataGraph looks like this:

```
<?xml version="1.0" encoding="ASCII" ?>
    <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
    <root>
       <Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0"
 emps="//@root/@Emp.1 //@root/@Emp.0" />
       <Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1"
    emps="//@root/@Emp.3 //@root/@Emp.2" />
        <Project projid="1" ProjectDept = "//@root/@Dept.0"
    tasks="//@root/@Task.0 //@root/@Task.2 //@root/@Task.1" />
        <Project projid="2" ProjectDept="//@root/@Dept.1" tasks="//@root/@Task.3" />
     <Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
```

```
            <Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
            <Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
            <Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
            <Emp empid="1001" name="Rob" EmpDept="//@root/@Dept.0" />
            <Emp empid="1002" name="Jason" EmpDept="//@root/@Dept.0" />
             <Emp empid="1003" name="Eric" EmpDept="//@root/@Dept.1" />
             <Emp empid="1004" name="Dave" EmpDept="//@root/@Dept.1" />
      </root>
   </datagraph:DataGraphSchema>
```

Navigating a single valued relationship

The important thing to point out here is that even though Emp is the root data object in the graph, multiple
Emp data objects will be related to the same Dept data object. So unlike the previous examples, the data
graph does not have a tree shape when you look at the data object instances – there are multiple root
Emp objects related to the same Dept object. But then after all it is a data graph, not a data tree. Note that
mediator queries allow single valued path expressions in the FROM clause. This is a change from the
standard EJB query syntax.

```
select e.empid, e.name  from Emp e
select d.deptno, d.name  from in(e.dept) d
```

And the DataGraph in XML format looks like:

```
<?xml version="1.0" encoding="ASCII" ?>
   <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
   <root>
   <Emp empid="1001" name="Rob" dept="//@root/@Dept.0" />
   <Emp empid="1002" name="Jason" dept="//@root/@Dept.0" />
   <Emp empid="1003" name="Eric" dept="//@root/@Dept.1" />
   <Emp empid="1004" name="Dave" dept="//@root/@Dept.1" />
   <Dept deptno="1" name="WAS_Sales"
DeptEmp="//@root/@Emp.1 //@root/@Emp.0" />
   <Dept deptno="2" name="WBI_Sales"
 DeptEmp="//@root/@Emp.3 //@root/@Emp.2" />
 </root>
 </datagraph:DataGraphSchema>
```

Path expressions in the SELECT clause

This query is similar to the preceding one (both queries return employee data along with department
number and name) but note the data graph contains only one data object type in this query (vs. two in the
previous query). The fields deptno and name field are read only because they are result of a path
expression in the SELECT clause and are not CMP fields of the Emp EJB.

```
select  e.empid as EmplId , e.name as EmpName ,
   e.dept.deptno as DeptNo , e.dept.name as DeptName
from Emp as e
```

Navigating a many: many relationship

The Emp to Task relationship is deemed a *many:many* relationship. The following query retrieves
employees, tasks, and projects. There is only a single occurrence of any particular task DataObject in the
DataGraph, even though it can be related to many employees.

```
select e.empid, e.name from Emp as e
select t.taskid, t.description from in(e.tasks) as t
select p.projid, p.cost from in(t.proj) as p
```

Multiple links between data objects

The EJB mediator enables you to retrieve data based on relationships and use the XREL command to
construct one or more additional relationships based on data already retrieved. The mediator also enables
retrieval of data based on ASNname and then construction of one or more relationships based on the data

retrieved using the XREL command. The following query retrieves departments, employees that work in the departments, and the employees that manage the departments.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
select m.empid, m.name from in(d.manager) as m
```

The second and third *select* clauses both return instances of Emp DataObject. It is possible that the same Emp instance is retrieved through the d.emps relationship and the d.manager relationship. The EJB mediator creates one Emp instance, but creates both relationships.

The following query is processed as follows. Dept DataObjects are created from the data in the first query. Emp DataObjects are created from the data in the second query. Relationships in the graph are then constructed for any relationship used in either the FROM clause or an XREL keyword. During relationship construction, no additional data is retrieved. In this example, an employee who works in a department named *Dev* appears in the DataGraph. If this employee manages a department called *Sales*, the *manages* reference is empty. The Dev department was retrieved in the first query, not the Sales department.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
xrel d.manager
```

The emps and manager relationship are constructed based on the DataObject instances created from the queries. An employee whose name is 'Dev' but works in department 'Sales' will have a null dept relationship in the graph.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.name like 'Dev%'
xrel d.emps, d.manager
```

The next example shows the retrieval of data objects for all the employees, projects, and tasks for a given department, and the linkage of employees with tasks.

```
select d.deptno from Dept d where d.deptno = 42
select e.empid from in(d.emps) e
select p.projid from in(d.projs) p
select t.* from in(p.tasks) t
  xrel e.tasks
```

If a task is assigned to an employee in department 42 then that link appears in the data graph. If the task is assigned to an employee not in department 42, then that link does not appear in the data graph because the data object was filtered out by the query. An XREL keyword can be followed by one or more EJB relationships. Bidirectional relationships can refer to either role name. Both source and target of the relationship must be retrieved by one or more queries.

Retrieving unrelated objects

The following query retrieves Dept and Task.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select t.taskid, t.startDate from Task t where t.startDate > '2005'
```

The following query retrieves Dept and Emps. Even though there are relationships between Dept and Emp (namely mgr and emps), neither relationship is used in FROM or XREL and so the resulting graph does not contain the relationship values.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.dept.name like '%Dev%'
```

Retrieving null or empty relationships

This query returns departments that have no employees and employees with no department. Presumably the application wants to assign the employees to one of the departments. The purpose of xrel is to define the e.dept relationship (and the inverse role d.emps) into the graph schema.

```
select d.deptno, d.name from Dept d where d.emps is empty
select e.empid, e.name from Emp e where e.dept is null
xrel e.dept
```

Collection Input Parameter

A collection of enterprise beans can be passed as an input argument to the ejb mediator and referenced in the FROM clause. Using a collection parameter satisfies the requirement to construct a data graph from a user collection of already activated enterprise beans.

```
select d.deptno, d.name from ((Dept) ?1) as d
select e.empid, e.name from in(d.emps) as e where e.salary > 10
```

The above query will iterate through the collection of Dept beans and related Emp beans applying the query predicates and constructing the data graph. Values will be obtained from current values of the beans. An example of a program using an ejb collection parameter.

```
// this method runs in an EJB context and within a transaction scope
public DataGraph myServiceMethod() {
      InitialContext ic = new InitialContext();
      DeptLocalHome deptHome = ic.lookup("java:comp/env/ejb/Dept");
      Integer deptKey = new Integer(10);
      DeptEJB dept = deptHome.findByPrimaryKey( deptKey));
      Iterator i = dept.getEmps().iterator();
      while (i.hasNext()) {
       EmpEJB e = (EmpEJB)i.next();
       e.setSalary( e.getSalary() * 1.10); // give everyone a 10% raise
      }

      // create the query collection parameter
      Collection c = new LinkedList();
      c.add(dept);
      Object[] parms = new Object[] { c};  // put ejb collection in parm array.

      // collection containing the dept EJB is passed to EJB Mediator

      String[] query = new String[]
          { "select d.deptno, d.name from ((Dept)?1 ) as d",
            "select e.empid, e.name, e.salary " +
                " from in (d.employees) as e",
            "select p.projno, p.name from in (d.projects) as p" };

      Mediator m = EJBMediatorFactory.getInstance().createMediator(
 query, parms);
      DataGraph dg = m.getGraph();
      return dg;
      // the DataGraph contains the updated and as yet uncommitted
//  salary information.  Dept and Emp data
      // is fetched through EJB instances active in the EJBContainer.
      //  Project data is retrieved from database using
      //   container managed relationships.
   }
```

XREL keyword: The XREL keyword is used to build relationships independent of how the data was retrieved. XREL is valid only in Enterprise JavaBeans (EJB) Mediator queries. XREL does not retrieve additional data, it only builds relationships from data already retrieved by the select statements. The relationships can be one-to-one, one-to-many, many-to-one, or many-to-many. The relationships can be unidirectional or bidirectional. If you specify a bidirectional relationship in an XREL, the inverse relationship is also established in addition to the specified relationship.

```
xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
           [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

Examples: XREL keyword

This example retrieves all employees and all departments, and establishes the *emps* and *mgr* relationships.

```
select e.name from EmpBean e
  select  d.name from DeptBean d
  xrel  d.emps, d.mgr
```

Notice that the employees are retrieved through d.emps relationship, xrel d.mgr is to establish the *mgr* relationship for those employees who are also a manager.

```
 select  d.name from DeptBean d
   select e.name from in(d.emps) e
   xrel  d.mgr
```

DataGraph schema:

DataGraph schema created by the EJB mediator

The schema created by the mediator for a query consists of an Eclass for each query statement. The name of the Eclass is the Abstract Schema Name (ASN) of the EJB. The Eattributes of the Eclass correspond to the container-managed persistence (CMP) fields or expressions returned by the query statement.

For static DataObjects, the Eclass name can be different provided that the Map argument is used on the createMediator call.

Each EJB relationship specified in the FROM or XREL clause adds an Ereference into the schema. EJB relationships can be unidirectional or bidirectional. However, all Ereferences are defined as bidirectional as this is needed to efficiently navigate the DataGraph on update. An inverse relationship name is generated in the case of a unidirectional EJB relationship. A generated name is of the format <ASName_source><ASName_target>. For example, if the ASNames are EmpBean and DeptBean, and the unidirectional relationship is *dept* going from EmpBean to DeptBean, the generated inverse name is **DeptBeanEmpBean**.

If no ECLass argument is used on createMediator, then the mediator creates a DataGraph schema with the following characteristics:
- the DataObject Eclass names are the corresponding Enterprise JavaBeans (EJB) Abstract Schema Names (ASN)
- the DataObject attributes names and types are the expression names and types in the query SELECT clauses
- the DataObject reference names and types come from the EJB relationships referenced in the FROM clauses.

A "dummy" DataObject with the Eclass name of *DataGraphRoot* is also created and has containment reference to all the DataObjects. The reference is multivalued, using the EJB ASN name.

```
DataObject root =  m.getGraph( parms );
root.getType().getName();   // this would return the string "DataGraphRoot"

List depts = (List) root.get("DeptBean");
// the list of all DeptBean SDOs in the DataGraph

List emps = (List) root.get("EmpBean");
// the list of all EmpBean SDOs in the DataGraph
```

DataGraph containment patterns

References between Service Data Objects (SDO) can be defined as containment references, in which case when an SDO is deleted the delete is cascaded to all of the contained SDO. Also, when the DataGraph is serialized as an XML document, the contained SDO are nested within the parent SDO. Noncontained references are expressed as path expressions in the XML document.

Containment must be defined in the DataGraph schema. When the mediator defines the schema, the root SDO (named *DataGraphRoot*) contains all other SDO. EJB relationships are defined as noncontained SDO references.

When the caller defines the DataGraph schema, there are three patterns.

ROOT_CONTAINS_ALL
> In this pattern there is a dummy SDO that is the root. It is a dummy in the sense that it does not correspond to any EJB. Its purpose is to contain all other SDOs. If the mediator generates the graph schema, the dummy root has a class name of DataGraphRoot and it will have containing references whose names are the EJB ASN names. If the caller uses static schema, the root can have any name. The Eclass of the root is passed on the createMediator call.

ROOT_CONTAINS_SOME
> This pattern is applicable only for static schema. There is still a dummy SDO that is the graph root. Other SDO must either be contained by the Ereference that corresponds to the EJB relationship used in the query statement or the SDO must be contained by the dummy root.

NO_DUMMY ROOT
> This pattern is applicable only for static schema. There is no dummy root. The root SDO corresponds to the first query statement which must return only a single instance. Non-root SDOs must be contained by the Ereference corresponding to the EJB relationship used in the query statement.

Service Data Objects: Resources for learning: Use the following links to find relevant supplemental information about the service data object and various other functions that can be used with it. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Using the Java Database Connectivity data mediator service for data access

The following steps use code samples to describe a simple instance of how to create the Java Database Connectivity (JDBC) data mediator service (DMS) metadata.

1. Create the metadata factory. This can be used for creating metadata, tables, columns, filters, filter arguments, database constraints, keys, order-by objects, and relationships.

   ```
   MetadataFactory factory = MetadataFactory.eINSTANCE;
   Metadata metadata = factory.createMetadata();
   ```

2. Create the table for the metadata. You can do this two ways. Either the metadata factory can create the table and then the table can add itself to the already created metadata, or the metadata can add a new table in which case a new table is created. Because it involves fewer steps, this example uses the second option to create a table called CUSTOMER.

   ```
   Table custTable = metadata.addTable("CUSTOMER");
   ```

3. Set the root table for the metadata. Again, you can do this in two ways. Either the table can declare itself to be the root or the metadata can set its own root table. For the first option, code:

   ```
   custTable.beRoot();
   ```

   If you want to use the second option, you code:

   ```
   metadata.setRootTable(custTable)
   ```

4. Set up the columns in the table. The example table is called CUSTOMER. Each column is created using its type. The column types in the metadata can only be the types supported by the JDBC driver being used. If you have questions on which types the JDBC driver being used supports, consult the JDBC driver documentation.

   ```
   Column custID = custTable.addIntegerColumn("CUSTID");
   custID.setNullable(false);
   ```

   This example creates a column object for this column, but does not for the remainder. The reason is because this column is the primary key, and is used to set the table's primary key after the rest of the columns are added. A primary key cannot be null; therefore custID.setNullable(false) prohibits this from happening. Adding the rest of the columns:

   ```
   custTable.addStringColumn("CUSTFIRSTNAME");
   custTable.addStringColumn("CUSTLASTNAME");
   custTable.addStringColumn("CUSTSTREETADDRESS");
   custTable.addStringColumn("CUSTCITY");
   custTable.addStringColumn("CUSTSTATE");
   custTable.addStringColumn("CUSTZIPCODE");
   custTable.addIntegerColumn("CUSTAREACODE");
   custTable.addStringColumn("CUSTPHONENUMBER");

   custTable.setPrimaryKey(custID);
   ```

5. Create other tables as needed. For this example, create the Orders table. Each order is made by one Customer.

   ```
   Table orderTable = metadata.addTable("ORDER");

   Column orderNumber = orderTable.addIntegerColumn("ORDERNUMBER");
   orderNumber.setNullable(false);
   ```

```
orderTable.addDateColumn("ORDERDATE");
orderTable.addDateColumn("SHIPDATE");
Column custFKColumn = orderTable.addIntegerColumn("CUSTOMERID");

orderTable.setPrimaryKey(orderNumber);
```

6. Create foreign keys for the tables that need relationships. In this example, orders have a foreign key that points to the customer who made the order. In order to create a relationship between the two tables, you must first make a foreign key for the Orders table.

```
Key custFK = factory.createKey();
custFK.getColumns().add(custFKColumn);

orderTable.getForeignKeys().add(custFK);
```

The relationship takes two keys, the parent key and the child key. Because no specific name is given, the default concatenation of CUSTOMER_ORDER is the name used for this relationship.

```
metadata.addRelationship(custTable.getPrimaryKey(), custFK);
```

The default relationship includes all customers who have orders. To get all customers, even if they do not have orders, you need this line as well:

```
metadata.getRelationship("CUSTOMER_ORDER")
                         .setExclusive(false);
```

Now that the two tables are related to one another you can add a filter to the Customer table to find customers with specific characteristics.

7. Specify any filters needed. In this example, set filters to the Customer table to find all the customers in a particular state, with a certain last name, who have made orders.

```
Filter filter = factory.createFilter();
filter.setPredicate("CUSTOMER.CUSTSTATE = ? AND CUSTOMER.CUSTLASTNAME = ?");

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("CUSTSTATE");
arg1.setType(Column.STRING);
filter.getFilterArguments().add(arg1);

FilterArgument arg2 = factory.createFilterArgument();
arg2.setName("CUSTLASTNAME");
arg2.setType(Column.STRING);
filter.getFilterArguments().add(arg2);

custTable.setFilter(filter);
```

8. Add any order by objects needed. In this example, set the order by object to sort by the customer's first name.

```
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

This completes the creation of the metadata for this JDBC DMS.

9. Create a connection to the database. This example does not show the creation of the connection to the database; it assumes that there is a method called *connect()* that does that.

10. Create the JDBC DMS object (DataGraph) using this metadata. For this example,

```
ConnectionWrapperFactory factory = ConnectionWrapperFactory.soleInstance;
connectionWrapper = factory.createConnectionWrapper(connect());
JDBCMediatorFactory mFactory = JDBCMediatorFactory.soleInstance;
JDBCMediator mediator = mFactory.createMediator(metadata, connectionWrapper);
```

```
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("CUSTSTATE", "NY");
parameters.setString('CUSTLASTNAME', 'Smith');
DataObject graph = mediator.getGraph(parameters);
```

Now that you have the DataGraph, you can manipulate the information as you wish. Some simple examples are contained in "Example: manipulating data in a DataGraph."

11. Submit the changed information to the database.

Example: manipulating data in a DataGraph: Using the simple DataGraph that was created during the task "Using the Java Database Connectivity data mediator service for data access" on page 746, some typical data manipulation follows.

First **get the list of customers**, then for each customer **get every order**, then **print out** the customer's first name and order date. (For this example, assume that you already know the last name is Smith).

```
List customersList = graph.getList("CUSTOMER");
Iterator i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
List ordersList = customer.getList("CUSTOMER_ORDER");
Iterator j = ordersList.iterator();
while (j.hasNext())
{
DataObject order = (DataObject)j.next();
System.out.print( customer.get("CUSTFIRSTNAME") + " ");
System.out.println( order.get("ORDERDATE"));
 }
}
```

Now **change** every customer with the name Will to be Matt.

```
i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
 if (customer.get("CUSTFIRSTNAME").equals("Will"))
 {
  customer.set("CUSTFIRSTNAME", "Matt");
 }
}
```

Delete the first Customer entry.

```
((DataObject) customersList.get(0)).delete();
```

Add a new DataObject to the graph

```
DataObject newCust = graph.createDataObject("CUSTOMER");
newCust.setInt("CUSTID", 12345);
newCust.set("CUSTFIRSTNAME", "Will");
newCust.set("CUSTLASTNAME", "Smith");
newCust.set("CUSTSTREETADDRESS", "123 Main St.");
newCust.set("CUSTCITY", "New York");
newCust.set("CUSTSTATE", "NY");
newCust.set("CUSTZIPCODE", "12345");
newCust.setInt("CUSTAREACODE", 555);
newCust.set("CUSTPHONENUMBER", "555-5555");

graph.getList("CUSTOMER").add(newCust);
```

Submit the changes.

```
mediator.applyChanges(graph);
```

Using the Enterprise JavaBeans data mediator service for data access

The following steps use code samples to describe a simple instance of how to create the Enterprise JavaBeans data mediator service (DMS) metadata.

1. A mediator instance is created using one of the create methods on the mediator factory (com.ibm.websphere.sdo.mediator.ejb.MediatorFactory) as in the following example

   ```
   import com.ibm.websphere.sdo.mediator.ejb.Mediator;
   import com.ibm.websphere.sdo.mediator.ejb.MediatorFactory;
   import com.ibm.webpshere.ejbquery.QueryException;
   import commonj.sdo.DataObject;

   try{
    String[] query =  { "select d.deptno,d.name from DeptBean as d" };
    Mediator m = MediatorFactory.getInstance().createMediator( query, null);
    DataObject root = m.getGraph();
   } catch (QueryException e) { ... }
   ```

2. There are 3 different forms of the createMediator method. The arguments are explained below.

   ```
   createMediator( query, parms)
   createMediator( query, parms, schema )
   createMediator( query, parms, schema,  typeMap,  pattern)
   ```

   The arguments to the createMediator method are:

String	query	array of EJB query statements
Object	parms	values for input parameters of the query statements
Eclass*	schema	the EClass of the root DataObject
Map*	typeMap	a java.util.Map that maps EJB Abstract Schema Names from the query statement into Eclass names
int*	pattern	the pattern used for containment
* used only when using caller provided schema		

Establishing custom finder SQL dynamic enhancement server-wide

To establish this support on a server-wide basis (that is, dynamic SQL enhancement of all custom finders defined in all beans is enabled), use the following steps.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Control** or **Servant**. Select **Control** to define the property in the Control, **Servant** to define the property in the Servant.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Select **Custom Properties**.
9. Select **com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent** and enter a value of **all**. If the property is not present in the list, create a new property name, enter the name *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* and the value **all**.

Establishing custom finder SQL dynamic enhancement on a set of beans

To establish this support for all custom finders defined on a set of beans use the following steps.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.

4. Select the server you want to configure.

5. In the Additional Properties area, select **Process Definition**.

6. In the Additional Properties area, select **Control** or **Servant**. Select **Control** to define the property in the Control, **Servant** to define the property in the Servant.

7. In the Additional Properties area, select **Java Virtual Machine**.

8. Select **Custom Properties**.

9. Select **com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent** and enter a value that corresponds to a list of beans that need this support, with each bean's name separated from the others by a colon (:). For example, *beanA:beanB:beanC*.

   If the property is not present in the list, create a new property name, enter the name *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* and enter the list as the value.

Establishing custom finder SQL dynamic enhancement for specific custom finders

To establish this support for specific custom finders use the following steps.

1. Start a J2EE application development environment of your choice.

2. Create or edit the application EAR file needing this support.

3. Check for an environmental variable called *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel* . If the variable does not already exist, add it to the EAR file.

4. Give the variable a value that corresponds to a list of method names (including parameter lists) with each name separated from the others by a colon (:).

5. Deploy and install the application.

Disabling custom finder SQL dynamic enhancement for custom finders on a specific bean

To disable this support for all custom finders defined on a specific bean, assuming that the server-wide support is enabled, follow these steps.

1. Start a J2EE application development environment of your choice.

2. Create or edit the application EAR file needing this support.

3. Check for an environmental variable called *com.ibm.websphere.persistence.bean.managed.custom.finder.access.intent* with a value of **true**. If the variable does not already exist, add it to the EAR file.

4. Ensure that the server-wide setting *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* is in place on the target server.

5. Deploy and install the application.

Embedded Structured Query language in Java (SQLJ) support

Structured Query Language in Java (SQLJ) is a set of programming extensions that enable a programmer, using the Java programming language, to embed statements that provide SQL (Structured Query Language) database requests.

Advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle:
- You improve performance by using static SQL statements.
- You reduce the development cycle because:
  - You write less code with the simpler SQLJ syntax, which reduces the number of lines of code required to execute statements, and to set and retrieve parameters.
  - You detect programming errors earlier in the development phase with the onlinecheck function, which performs data type and schema validation. Activate this function by running it as an option with the **db2sqljcustomize** command. See the DB2 documentation for a complete description of the SQLJ customize command.

You might consider using SQLJ in situations where dynamic SQL is not needed, and where applications use DB2 as the backend database.

Using embedded Structured Query Language in Java (SQLJ) support

WebSphere Application Server Version supports Structured Query Language in Java (SQLJ) with the DB2 universal JDBC driver and the DB2 Legacy CLI-based Type 2 JDBC driver. Perform the following steps to convert existing JDBC applications to SQLJ in WebSphere Application Server.

1. Acquire the required drivers to run SQLJ.
   - DB2 Legacy CLI-based JDBC driver

     You must have the `db2java.zip` and `db2jcc.jar` files in your class path. Define these files in the class path of the WebSphere Application Server DB2 Legacy CLI-based JDBC Driver Provider.
   - DB2 Universal JDBC driver

     You only need the `db2jcc.jar` file.
   - WebSphere Application Server driver
2. Review the appropriate task file for instructions on using SQLJ.
   - Enterprise Java Bean (EJB) Container Managed Persistence (CMP) beans, or with
   - EJB Bean Managed Persistence (BMP) entity beans, session beans, and servlets

Using Structured Query Language in Java (SQLJ) for Enterprise Java Bean (EJB) container-managed persistence (CMP) beans:

Structured Query Language in Java (SQLJ) for EJB Persistence requires DB2 Version 8 FixPak1 or later. You need DB2 UDB Application Development Client Version 8 FixPak1 (or later) on the machine where you generate the deployed code, and DB2 UDB Server (Version 8 FixPak1 or later for Unix and Windows, and Version 6 or Version 7 for DB2 on z/OS and OS/390) on the machine containing the database for running the scenario.

SQLJ support requires Version 2.x CMP Enterprise Java Beans. If you mix EJB 1.1 and 2.x beans in an EJB 2.x module, then only the EJB 2.x beans are deployed to use SQLJ. The EJB 1.1 beans continue using JDBC for data access.

The deployment command for Enterprise Java Beans (EJBDeploy) only provides SQLJ support for the Version 2.0 CMP beans. It is your responsibility to manually translate and customize the profile on the database for the Bean Managed Persistence (BMP) entity beans, session beans, and servlet SQLJ applications. See the Using SQLJ for Enterprise Java Bean (EJB) Bean Managed Persistence (BMP) entity beans, session beans, and Servlets article for more information.

WebSphere Application Server provides tools for using SQLJ as the persistence mechanism for CMP Enterprise Java Beans. You can deploy the CMP beans to use SQLJ either by using the EJB deploy tool in Rational Application Developer (RAD), or by using the command utility **ejbdeploy** with the **-sqlj** option.

You cannot deploy a CMP bean with the **sqlj** option from the administrative console or the assembly tool.

When you install an application comprised of CMP beans, you have the following choices:
- For data access with SQLJ, deploy the CMP beans to use SQLJ before installing the application in WebSphere Application Server. Perform deployment within the RAD environment, or by using the command utility **ejbdeploy** with the **-sqlj** option.

  Do not deploy this bean again in the administrative console when you install the application. If you pre-deploy this bean with the **-sqlj** option and then redeploy it from the administrative console when you install the application, this bean deploys with JDBC access.
- For JDBC access, use the **ejbdeploy** command or the administrative console to deploy the CMP bean.

  If the bean is not deployed, the installation of the application fails.

  1. Deploy the EAR file.

a. Verify that the *was_home*/`bin` directory is in your PATH statement.

b. Verify that the `ws_ant.bat` file is available on your system.

   You need the `ws_ant.bat` file to run the rest of the commands.

   Note: On Windows platforms, the Apache Ant tool is `ws_ant.bat` On Unix systems, the Ant tool is `ws_ant`.

c. Run the **ejbdeploy** command utility with the **-sqlj** option.

2. Perform the following SQLJ profile customization steps if your application is running in a clustered environment.

   You must supply the location of the SQLJ translator `sqlj.zip` file with the **-cp** (class path) option:

   ```
   ejbdeploy d:\MyApplication.ear
             working d:\deployedMyApplication.ear
             -sqlj
             -dbvendor DB2UDB_V81
             -cp "C:\PROGRA~1\IBM\SQLLIB\java\sqlj.zip;C:\PROGRA~1\IBM\SQLLIB\java\sqlj.zip "
   ```

   The **ejbdeploy** command does not access sqlj.zip from your system class path. The **ejbdeploy** command will generate an EAR file with the name you specify as, for example, `deployedMyApplication.ear`, and an Ant script with the name *InputEarName*.`ear.xml`, or in this example, `deployedMyApplication.ear.xml`.

   If you create the EAR file using Rational Application Developer, you can associate SQLJ with a particular database backend in the mapping editor. If you use the mapping editor, you do not have to specify the **-sqlj** option in the **ejbdeploy** command.

   If your application is not running in a clustered environment, go to the Ant tool properties description.

   Perform customization once on a single host.

   a. Run the DB2 SQLJ customizer, **db2sqljcustomize**, against the serialized profiles.

      One serialized profile exists for each EJB `.jar` file. You can find the serialized profile in the EJB `.jar` file. One example of a serialized profile file name is `FS_TopDown1_SJProfile0.ser`.

      When you run the DB2 SQLJ customizer with the "**-automaticbind yes**" default option against the serialized profiles, you create static SQL in the database, which is used at runtime. The customization phase creates four database packages that contain static SQL, one for each isolation level.

   b. Include the customized profiles in the EJB `.jar` files installed on WebSphere Application Server.

      The customization step also updates the generated customized profiles. To make these updated customized profiles available to the generated code at runtime, include the profiles in the EJB `.jar` file, which is installed in WebSphere Application Server.

      If you omit the customization step, the EJB applications run, but do not use the static SQL stored in the database, and you lose all the benefits of SQLJ.

   c. Use the Ant script to make customization easier.

      When you run batch SQLJ `ejbDeploy` against an EAR file, it produces an Ant script. Use this script file to run the DB2 customizer program against every serialized profile in every EJB `.jar` file in the associated EAR file. The script updates each EJB `.jar` file with a serialized profile, and replaces the `.jar` files in the EAR file with the modified versions. The Ant script is specific to the corresponding EAR file.

      This script modifies the existing EAR file.

      The script also uses a set of default names for the packages created in the database. Change the names used by the script file to ensure the names for each customization profile do not conflict with existing package names in the database. Ant scripts generated for different EAR files use the same package names by default, and overwrite existing packages unless you change the names. Overwritten packages cause run-time errors.

   d. Change the values of the database URL, and the database user and password properties in the generated Ant script.

The package names, database URLs, users, and passwords are created in the script using Ant properties.

The Ant script defines the following global properties for the:
- Database URL - `db.url`
- User - `db.user`
- Password - `db.password`

e. Change the values used by the Ant script and the serialized profile by specifying new values in a property file.

The Ant script uses the URL, user, and password properties in the serialized profile to customize the profile. By default, the properties for the serialized profile are created from the global properties.

The script for a particular EAR file reads properties from two files:
- `ejbdeploy.sqlj.properties`

  The `ejbdeploy.sqlj.properties` file is common to all Ant scripts generated by the **EJBDeploy** command. Use the `ejbdeploy.sqlj.properties` file to specify global properties, such as the database user and password.
- *ear-name*`.properties`

  The *ear-name* value is the name of the EAR file. The *ear-name*`.properties` file is specific to the Ant script for the EAR file. If you want your Ant script to use a another file instead of *ear-name*`.properties`, specify the `script.property.file` property when you run the script.

f. Use the DB2 Control Center to identify the packages installed in the database.

The DB2 SQLJ customizer requires a type 4 database URL in the form of:

```
jdbc:db2://host-name:port/database-name
```

It also requires a user and password. The value of the port is 50000, unless you change it when you install DB2.

3. Run the Ant script, specifying the **properties** target:

```
ws_ant -buildfile deployedMyApplication.ear.xml properties
```

This script creates the properties file, `deployedMyApplication.ear.properties`. The `deployedMyApplication.ear.properties` file contains properties specifying default names for the packages corresponding to each serialized profile in the EAR file, as for example:

```
pkg.MyEJB1.jar.DB2UDBNT_V8_1=PKG1_
pkg.MyEJB2.jar.DB2UDBNT_V8_1=PKG2_
```

In this example, the EAR file contains two EJB `.jar` files: `MyEJB1.jar` and `MyEJB2.jar`.

4. Edit the generated properties file to change the package names.

```
url.MyEJB1.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB1
user.MyEJB1.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB1.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB1.jar.DB2UDBNT_V8_1=TEST
url.MyEJB2.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB2
user.MyEJB2.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB2.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB2.jar.DB2UDBNT_V8_1=WORK
```

DB2 uses the first seven characters of the package name. The DB2 customizer uses this name to create four packages in the database. For example, if you specify the name TEST, the customizer will create packages called:

```
TEST1, TEST2, TEST3, TEST4
```

You can also specify other properties in this file, such as the database URL, user, or password.

5. Use the following **db2sqljcustomize** options to temporarily circumvent profile customization problems. These options bypass errors during a profile customization and ensure a successful customization:

```
-onlinecheck NO and -bindoptions "VALIDATE RUN"
```

However, you must understand what the problems are and fix them at the appropriate time.

6. Run the Ant script.

   The DB2 `db2jcc.jar` file must be on the class path. This file should have been added to the class path environment variable when DB2 V8 FixPak1 was installed.

7. Specify a working directory for the Ant script.

   The script will create and delete files and subdirectories in this directory. If the working directory contains existing files and directories with the same name as the files and directories used by the script, the script will erase the files and directories.

   Use the following command to specify a working directory:

   ```
   ws_ant -Dwork.dir=tmp
          -buildfile MyApplication.ear.xml
   ```

   The script creates and uses a directory called `tmp` as its working directory. If you want the script to use a different property file, set the `script.property.file` property when you run the script:

   ```
   ws_ant -Dwork.dir=tmp
          -Dscript.property.file=other.properties
          -buildfile MyApplication.ear.xml
   ```

   The Ant script updates the original EAR file with the modified serialized profiles.

8. If you rerun the **EJBDeploy** command, rerun the Ant script.

   Generate a new properties file if any of the following conditions are true:
   - You change the number of `.jar` files in the EAR file.
   - You change the names of the `.jar` files in the EAR file.
   - You change the database backend ids in any of the `.jar` files

9. Install the updated EAR file in WebSphere Application Server.

10. Create a JDBC provider and data source in WebSphere Application Server.

    Generate a new properties file if any of the following conditions are true:
    - You change the number of `.jar` files in the EAR file.
    - You change the names of the `.jar` files in the EAR file.
    - You change the database backend ids in any of the `.jar` files

    Generate a new properties file if any of the following conditions are true:
    - You change the number of `.jar` files in the EAR file.
    - You change the names of the `.jar` files in the EAR file.
    - You change the database backend IDs in any of the `.jar` files

11. Install your application through the administrative console but do not redeploy the EJB. If you check the **EJBDeploy** box, your application is redeployed to JDBC access.

12. Stop the server.

13. Start the server.

    You are now ready to run your application.

Using Structured Query Language in Java for bean-managed persistence entity beans, session beans, and servlets:

This article describes how JDBC applications, comprised of bean-managed persistence (BMP) entity beans, session beans, or servlets, are converted to SQLJ applications. It also describes how the SQLJ applications are then deployed in WebSphere Application Server.

Follow these steps precisely and in the right order to ensure a correct conversion:

1. Create a backup copy of your `.java` file. For example if your file is called `MyServlet.java`, copy `MyServlet.java` to `MyServlet.java.bkup`.

2. Rename your `.java` file to a file name with a `.sqlj` extension. For example, if your application is a servlet named `MyServlet.java`, rename `MyServlet.java` to `MyServlet.sqlj`.

Now when you run the **sqlj** tool in the next step, the `.java` file that it creates will have the same name as your old `.java` file, providing you with a seamless transition to the SQLJ technology.

3. Edit the `.sqlj` file to convert the JDBC syntax to SQLJ syntax. When using SQLJ in WebSphere Application Server, if you want WebSphere Application Server connection management to function properly, you must specify correct connection contexts.

   For example, convert the following JDBC operation:

   ```
   Connection con = dataSource.getConnection();
   Statement stmt = con.createStatement();
   stmt.execute("INSERT INTO users VALUES (1, 'user1')");
   con.commit();
   ```

   to the following SQLJ:

   ```
   // At the top of the file and just below the import statements, define Connection_Context
   #sql context Connection_context;
    .
    .
   Connection con = dataSource.getConnection();
    .
    .
   Connection_context ctx1 = new Connection_context(con);
    .
    .
   #sql [ctx1] {INSERT INTO users VALUES (1, 'user1')};
    .
    .
   con.commit();
   ctx1.close();
   ```

4. Run the DB2 SQLJ translator. This tool creates a `.java` version of your `.sqlj` file, as well as a `.ser` profile that is used later in the processing. Refer to the DB2 documentation for more information on the SQLJ translator tool.

5. Package your EJB jar and deploy it in the usual manner. After deployment, one serialized profile exists for each EJB `.jar` file. (You can find the profile in the EJB .jar file; one example of a serialized profile file name is MyBMPBeanProfile.ser.)

6. Run the `db2sqljcustomize` tool to customize the `.ser` files that correspond to each EJB `.jar` file. When you run the DB2 SQLJ customizer against the serialized profiles, you create static SQL in the database, which is used at runtime. The customization phase creates four database packages that contain static SQL, one for each isolation level.

   Optionally, you can use the SQLJ customizer tool to enable **context caching** for your application's data source connections, thereby improving application performance.

   - DB2 V8.1 fix pack 6 provides the new caching option, called `db2optimize` , with the `db2sqljcustomize` tool. You can run this option if your application uses the explicit connection context instead of the default context.

   - The following example code demonstrates proper syntax for running the option:

   ```
   sqlj -db2optimize SQLJTransactionTest.sqlj
   db2sqljcustomize -url jdbc:db2://localhost:50000/jtest -user dbuser1 -password dbpwd1
   SQLJTransactionTest_SJProfile0.ser
   ```

   - If you want to enable context caching for an application or BMP bean that caches connections across transaction boundaries, you cannot use shareable connections. You must use the get/use/close pattern of connection usage when you invoke the `db2optimize` option. Otherwise, an object closed exception occurs. The following code gives an example of incorrect connection usage for context caching:

   ```
    utx.begin();
        cons =ds.getConnection(
        request.getParameter("db.user"),
        request.getParameter("db.password"));
            cmctx1 = new CM_context(cons);
            #sql [cmctx1] {DELETE FROM cmtest WHERE id=1};
   ```

```
    utx.commit();
          //The next statement verifies the result:
            #sql [cmctx1] cursor1 = {SELECT id, name FROM cmtest WHERE id=1};
```

In this case, the Select statement elicits an object closed exception. To prevent the exception from occurring, close the connection before committing the transaction. Then get a new connection and a new context before running the Select statement.

7. Configure your database.
8. Update your EJB jar with the .ser file.
9. Package your EJB jar and servlets, along with .ser files, into an .ear file.
10. Install the application in the usual manner.

Exceptions pertaining to data access

All enterprise bean container-managed persistence (CMP) beans under the EJB 2.x specification receive a standard EJB exception when an operation fails.

JDBC applications receive a standard SQL exception if any JDBC operation fails.

The product provides special exceptions for its relational resource adapter (RRA), to indicate that the connection currently held is no longer valid. The ConnectionWaitTimeout exception indicates that the application timed out trying to get a connection. The StaleConnection exception indicates that the connection is no longer valid.

Connection wait timeout:

The ConnectionWaitTimeout exception indicates that the application has waited for the number of seconds specified by the connection timeout setting and has not received a connection. This situation can occur when the pool is at maximum size and all of the connections are in use by other applications for the duration of the wait. In addition, there are no connections currently in use that the application can share because either the connection properties do not match, or the connection is in a different transaction.

For a Version 4.0 data source, the ConnectionWaitTimeout object creates an exception that is instantiated from the com.ibm.ejs.cm.pool.ConnectionWaitTimeoutException class.

For J2C connection factories, the ConnectionWaitTimeout object generates a resource exception of the com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException class.

Later version data sources issue an SQL exception of the com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException subclass.

Example: Handling data access exception - ConnectionWaitTimeoutException (for the JDBC API):   In all cases in which the ConnectionWaitTimeout exception is caught, there is very little to do for recovery.

The following code fragment shows how to use this exception in the JDBC API:
```
 public void test1() {
  java.sql.Connection conn = null;
  java.sql.Statement stmt = null;
  java.sql.ResultSet rs = null;

  try {
   // Look for datasource
   java.util.Properties props = new java.util.Properties();
   props.put(
    javax.naming.Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
   ic = new javax.naming.InitialContext(props);
   javax.sql.DataSource ds1 = (javax.sql.DataSource) ic.lookup(jndiString);
```

```
  // Get Connection.
  conn = ds1.getConnection();
  stmt = conn.createStatement();
  rs = stmt.executeQuery("select * from mytable where this = 54");
 }
 catch (com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException cwte) {
  //notify the user that the system could not provide a
  //connection to the database.  This usually happens when the
  //connection pool is full and there is no connection
  //available for to share.
 }
 catch (java.sql.SQLException sqle) {
  // handle other database problems.
 }
 finally {
  if (rs != null)
   try {
    rs.close();
   }
   catch (java.sql.SQLException sqle1) {
   }
  if (stmt != null)
   try {
    stmt.close();
   }
   catch (java.sql.SQLException sqle1) {
   }
  if (conn != null)
   try {
    conn.close();
   }
   catch (java.sql.SQLException sqle1) {
   }
 }
}
```

Example: Handling data access exception - ConnectionWaitTimeoutException (for J2EE Connector Architecture): In all cases in which the `ConnectionWaitTimeout` exception is caught, there is very little to do for recovery.

The following code fragment shows how to use this exception in J2EE Connector Architecture (JCA):

```
/**
 * This method does a simple Connection test.
 */
public void testConnection()
   throws javax.naming.NamingException, javax.resource.ResourceException,
      com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException {
   javax.resource.cci.ConnectionFactory factory = null;
   javax.resource.cci.Connection conn = null;
   javax.resource.cci.ConnectionMetaData metaData = null;
   try {
      // lookup the connection factory
      if (verbose) System.out.println("Look up the connection factory...");
try {
factory =
  (javax.resource.cci.ConnectionFactory) (new InitialContext()).lookup("java:comp/env/eis/Sample");
   }
   catch (javax.naming.NamingException ne) {
      // Connection factory cannot be looked up.
      throw ne;
   }
   // Get connection
      if (verbose) System.out.println("Get the connection...");
      conn = factory.getConnection();
      // Get ConnectionMetaData
```

```
      metaData = conn.getMetaData();
      // Print out the metadata Informatin.
      System.out.println("EISProductName is " + metaData.getEISProductName());
   }
   catch (com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException cwtoe) {
      // Connection Wait Timeout
      throw cwtoe;
   }
   catch (javax.resource.ResourceException re) {
      // Something wrong with connections.
      throw re;
   }
   finally {
      if (conn != null) {
         try {
            conn.close();
         }
         catch (javax.resource.ResourceException re) {
         }
      }
   }
}
```

Stale connections:

The product provides a special subclass of the *java.sql.SQLException* class for using connection pooling
to access a relational database. This *com.ibm.websphere.ce.cm.StaleConnectionException* subclass exists
in both a WebSphere 4.0 data source and in the most recent version data source that use the relational
resource adapter. It serves to indicate that the connection currently held is no longer valid. This situation
can occur for many reasons, including the following:
* The application tries to get a connection and fails, as when the database is not started.
* A connection is no longer usable because of a database failure. When an application tries to use a
  previously obtained connection, the connection is no longer valid. In this case, all connections currently
  in use by the application can get this error when they try to use the connection.
* The connection is orphaned (because the application had not used it in at most two times the value of
  the *unused timeout* setting) and the application tries to use the orphaned connection. This case applies
  only to Version 4.0 data sources.
* The application tries to use a JDBC resource, such as a statement, obtained on a stale connection.
* A connection is closed by the Version 4.0 data source *auto connection cleanup* feature and is no longer
  usable. Auto connection cleanup is the standard mode in which connection management operates. This
  mode indicates that at the end of a transaction, the transaction manager closes all connections enlisted
  in that transaction. This enables the transaction manager to ensure that connections are not held for
  excessive periods of time and that the pool does not reach its maximum number of connections
  prematurely.

  A negative ramification does ensue, however, when the transaction manager closes the connections and
  returns the connection to the free pool after a transaction ends. An application cannot obtain a
  connection in one transaction and try to use it in another transaction. If the application tries this, a
  `StaleConnection` exception occurs because the connection is already closed.

In the case of trying to use an orphaned connection or a connection that is made unavailable by auto
connection cleanup, a `StaleConnection` exception indicates that the application has attempted to use a
connection already returned to the connection pool. It does not indicate an actual problem with the
connection. However, other cases of a `StaleConnection` exception indicate that the connection to the
database has gone bad, or *stale*. Once a connection has gone stale, you cannot recover it, and you must
completely close the connection rather than returning it to the pool.

Detecting stale connections

When a connection to the database becomes stale, operations on that connection result in an SQL exception from the JDBC driver. Because an SQL exception is a rather generic exception, it contains state and error code values that you can use to determine the meaning of the exception. However, the meanings of these states and error codes vary depending on the database vendor. The connection pooling run time maintains a mapping of which SQL state and error codes indicate a `StaleConnection` exception for each database vendor supported. When the connection pooling run time catches an SQL exception, it checks to see if this SQL exception is considered a `StaleConnection` exception for the database server in use.

Recovering from stale connections

Recovering from stale connections is a joint effort between the application server run time and the application developer. From an application server perspective, the connection pool is purged based on its *PurgePolicy* setting.

Explicitly catching a `StaleConnection` exception is not required in an application. Because applications are already required to catch the `java.sql.SQL` exception, and the `StaleConnection` exception extends an SQL exception, a `StaleConnection` exception can result from any method that is declared to create an SQL exception, and is caught automatically in the general catch-block. However, explicitly catching a `StaleConnection` exception makes it possible for an application to recover from bad connections. When application code catches a `StaleConnection` exception, it should take explicit steps to handle the exception.

Example: Handling data access exception - StaleConnectionException: When an application receives a stale connection exception on a database operation, it indicates that the connection currently held is no longer valid. While it is possible to get a stale connection exception on any database operation, the most common time to see a stale connection exception issued is the first time that a connection is used, just after it is retrieved. Because connections are pooled, a database failure is not detected until the operation immediately following its retrieval from the pool, which is the first time communication to the database is attempted. It is only when a failure is detected that the connection is marked stale. The stale connection exception occurs less often if each method that accesses the database gets a new connection from the pool.

Many stale connection exceptions are caused by intermittent problems with the network of the database server. Obtaining a new connection and retrying the operation can result in successful completion without exceptions to the end user. In some cases it is advantageous to add a small wait time between the retries to give the database server more time to recover. However, applications should not retry operations indefinitely, in case the database is down for an extended period of time.

Before the application can obtain a new connection for a retry of the operation, roll back the transaction in which the original connection was involved and begin a new transaction. You can break down details on this action into two categories:

Objects operating in a bean-managed global transaction context begun in the same method as the database access.

A servlet or session bean with bean-managed transactions (BMT) can start a global transaction explicitly by calling *begin()* on a *javax.transaction.UserTransaction* object, which you can retrieve from naming or from the bean *EJBContext* object. To commit a bean-managed transaction, the application calls *commit()* on the *UserTransaction* object. To roll back the transaction, the application calls *rollback()*. Entity beans and non-BMT session beans cannot explicitly begin global transactions.

If an object that explicitly started a bean-managed transaction receives a stale connection exception on a database operation, close the connection and roll back the transaction. At this point, the application developer can decide to begin a new transaction, get a new connection, and retry the operation.

The following code fragment shows an example of handling stale connection exceptions in this scenario:

```
//get a userTransaction
javax.transaction.UserTransaction tran = getSessionContext().getUserTransaction();
//retry indicates whether to retry or not
//numOfRetries states how many retries have
// been attempted
boolean retry = false;
int numOfRetries = 0;
java.sql.Connection conn = null;
java.sql.Statement stmt = null;
do {
  try {
    //begin a transaction
    tran.begin();
    //Assumes that a datasource has already been obtained
    //from JNDI
    conn = ds.getConnection();
    conn.setAutoCommit(false);
    stmt = conn.createStatement();
    stmt.execute("INSERT INTO EMPLOYEES VALUES
            (0101, 'Bill', 'R', 'Smith')");
    tran.commit();
    retry = false;
  } catch(com.ibm.websphere.ce.cm.StaleConnectionException
          sce)
  {
    //if a StaleConnectionException is caught
    // rollback and retry the action
    try {
      tran.rollback();
    } catch (java.lang.Exception e) {
      //deal with exception
      //in most cases, this can be ignored
    }
    if (numOfRetries < 2) {
      retry = true;
      numOfRetries++;
    } else {
      retry = false;
    }
  } catch (java.sql.SQLException sqle) {
    //deal with other database exception
    retry = false
  } finally {
    //always cleanup JDBC resources
    try {
      if(stmt != null) stmt.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
    try {
      if(conn != null) conn.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
  }
} while (retry) ;
```

Objects operating in a global transaction context and transaction not begun in the same method as the database access.

When the object which receives the stale connection exception does not have direct control over the transaction, such as in a container-managed transaction case, the object must mark the transaction for rollback, and then indicate to its caller to retry the transaction. In most cases, you can do this by creating an application exception that indicates to retry that operation. However this

action is not always allowed, and often a method is defined only to create a particular exception. This is the case with the ejbLoad() and ejbStore() methods on an enterprise bean. The next two examples explain each of these scenarios.

Example 1: Database access method creates an application exception

When the method that accesses the database is free to create whatever exception is required, the best practice is to catch the stale connection exception and create some application exception that you can interpret to retry the method. The following example shows an EJB client calling a method on an entity bean with transaction demarcation *TX_REQUIRED*, which means that the container begins a global transaction when *insertValue()* is called:

```
public class MyEJBClient {
//... other methods here ...
public void myEJBClientMethod()
{
MyEJB myEJB = myEJBHome.findByPrimaryKey("myEJB");
boolean retry = false;
do {
try {
retry = false;
myEJB.insertValue();
}
catch(RetryableConnectionException retryable) {
retry = true;
}
catch(Exception e) { /* handle some other problem */ }
} while (retry);
}
}   //end MyEJBClient

public class MyEJB implements javax.ejb.EntityBean {
//... other methods here ...
public void insertValue() throws RetryableConnectionException,
java.rmi.EJBException {
try
{
conn = ds.getConnection();
stmt = conn.createStatement();
stmt.execute("INSERT INTO my_table VALUES (1)");
}
catch(com.ibm.websphere.ce.cm.StaleConnectionException
sce) {
getSessionContext().setRollbackOnly();
throw new RetryableConnectionException();
}
catch(java.sql.SQLException sqle) {
//handle other database problem
}
finally {
21
//always cleanup JDBC resources
try {
if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
try {
if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
}
}   //end MyEJB
```

MyEJBClient first gets a *MyEJB* bean from the home interface, assumed to have been previously retrieved from the Java Naming and Directory Interface (JNDI). It then calls *insertValue()* on the bean. The method on the bean gets a connection and tries to insert a value into a table. If one of the methods fails with a stale connection exception, it marks the transaction for *rollbackOnly* (which forces the caller to roll back this transaction) and creates a new *retryable connection* exception, cleaning up the resources before the exception is thrown. The retryable connection exception is simply an application-defined exception that tells the caller to retry the method. The caller monitors the retryable connection exception and, if it is caught, retries the method. In this example, because the container is beginning and ending the transaction; no transaction management is needed in the client or the server. Of course, the client could start a bean-managed transaction and the behavior would still be the same, provided that the client also committed or rolled back the transaction.

Example 2: Database access method creates an onlyRemote exception or an EJB exception

Not all methods are allowed to throw exceptions defined by the application. If you use bean-managed persistence (BMP), use the *ejbLoad()* and *ejbStore()* methods to store the bean state. The only exceptions issued from these methods are the java.rmi.Remote exception or the javax.ejb.EJB exception, so you cannot use something similar to the previous example.

If you use container-managed persistence (CMP), the container manages the bean persistence, and it is the container that sees the stale connection exception. If a stale connection is detected, by the time the exception is returned to the client it is simply a remote exception, and so a simple catch-block does not suffice. There is a way to determine if the root cause of a remote exception is a stale connection exception. When a remote exception is created to wrap another exception, the original exception is usually retained. All remote exception instances have a detail property, which is of type *java.lang.Throwable*. With this detail, you can trace back to the original exception and, if it is a stale connection exception, retry the transaction. In reality, when one of these remote exceptions flows from one Java Virtual Machine API to the next, the detail is lost, so it is better to start a transaction in the same server as the database access occurs. For this reason, the following example shows an entity bean accessed by a session bean with bean-managed transaction demarcation.

```
public class MySessionBean extends javax.ejb.SessionBean {
... other methods here ...
public void mySessionBMTMethod() throws
java.rmi.EJBException
{
javax.transaction.UserTransaction tran =
getSessionContext().getUserTransaction();
boolean retry = false;
do {
try {
retry = false;
tran.begin();
// causes ejbLoad() to be invoked
myBMPBean.myMethod();
// causes ejbStore() to be invoked
tran.commit();
}
catch(java.rmi.EJBException re) {
try { tran.rollback();
}
catch(Exception e) {
//can ignore
}
if (causedByStaleConnection(re))
retry = true;
else
throw re;
```

```
}
catch(Exception e) {
// handle some other problem
}
finally {
//always cleanup JDBC resources
try {
if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
try {
if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
}
} while (retry);
}

public boolean causedByStaleConnection(java.rmi.EJBException
EJBException)
{
java.rmi.EJBException re = EJBException;
Throwable t = null;
while (true) {
t = re.getCause();
try { re = (java.rmi.EJBException)t; }
catch(ClassCastException cce) {
return (t instanceof
com.ibm.websphere.ce.cm.StaleConnectionException);
}
}
}
}
public class MyEntityBean extends javax.ejb.EntityBean {
... other methods here ...
public void ejbStore() throws java.rmi.EJBException
{
try {
conn = ds.getConnection();
stmt = conn.createStatement();
stmt.execute("UPDATE my_table SET value=1 WHERE
primaryKey=" + myPrimaryKey);
}
catch(com.ibm.websphere.ce.cm.StaleConnectionException
sce) {
//always cleanup JDBC resources
try {
if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
try {
if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
// rollback the tran when method returns
getEntityContext().setRollbackOnly();
throw new java.rmi.EJBException("Exception occurred in
ejbStore", sce);
}
catch(java.sql.SQLException sqle) {
```

```
// handle some other problem
       }
   }
}
```

In *mySessionBMTMethod()* of the previous example:
- The session bean first retrieves a *UserTransaction* object from the session context and then begins a global transaction.
- Next, it calls a method on the entity bean, which calls the *ejbLoad()* method. If *ejbLoad()* runs successfully, the client then commits the transaction, causing the *ejbStore()* method to be called.
- In *ejbStore()*, the entity bean gets a connection and writes its state to the database; if the connection retrieved is stale, the transaction is marked *rollbackOnly* and a new *EJBException* that wraps the *StaleConnectionException* is thrown. That exception is then caught by the client, which cleans up the JDBC resources, rolls back the transaction, and calls *causedByStaleConnection()*, which determines if a stale connection exception is buried somewhere in the exception.
- If the method returns true, the retry flag is set and the transaction is retried; otherwise, the exception is re-issued to the caller.
- The *causedByStaleConnection()* method looks through the chain of detail attributes to find the original exception. Multiple wrapping of exceptions can occur by the time the exception finally gets back to the client, so the method keeps searching until it encounters a non-Remote exception. If this final exception is a stale connection exception, you find it and *true* is returned; otherwise, there is no stale connection exception in the list (because a stale connection exception can never be cast to a remote exception), and *false* is returned.
- If you are talking to a CMP bean instead of to a BMP bean, the session bean is exactly the same. The CMP bean's *ejbStore()* method would most likely be empty, and the container after calling it would persist the bean with generated code.
- If a stale connection exception occurs during persistence, it is wrapped with a remote exception and returned to the caller. The *causedByStaleConnection()* method would again look through the exception chain and find the root exception, which would be stale connection exception.

Objects operating in a local transaction context.

When a database operation occurs outside of a global transaction context, a local transaction is implicitly begun by the container. This includes servlets or JSPs that do not begin transactions with the *UserTransaction* interface, as well as enterprise beans running in unspecified transaction contexts. As with global transactions, you must roll back the local transaction before the operation is retried. In these cases, the local transaction containment usually ends when the business method ends. The one exception is if you are using activity sessions. In this case the activity session must end before attempting to get a new connection.

When the local transaction occurs in an enterprise bean running in an unspecified transaction context, the enterprise bean client object, outside of the local transaction containment, could use the method described in the previous bullet to retry the transaction. However, when the local transaction containment takes place as part of a servlet or JSP file, there is no client object available to retry the operation. For this reason, it is recommended to avoid database operations in servlets and JSP files unless they are a part of a user transaction.

StaleConnectionException on Linux systems: Linux systems have a semaphore problem causing the DB2 stale connection exception **SQL1224** error. This is related to the extension shared memory attachment.

To work around the problem, set the loopback for your database. For example, if your database is *WAS*, host name is *LHOST*, and database service port number is *50000*, issue the following commands from the DB2 command line window:

```
 db2 catalog TCPIP node RHOST remote LHOST server 50000
 db2 catalog WAS as WASAlias
 db2 uncatalog db WAS
 db2 catalog WASAlias as WAS at node RHOST
```

Verify this by issuing the following commands from the DB2 command line window:

```
db2 connect to WAS user xxx
passwd: xxx
```

Example: Developing servlet with user transaction:

```

```

Example: Handling data access exception - error mapping in DataStoreHelper: Error mapping is necessary because various database vendors can provide differing SQL errors and codes that might mean the same things. For example, the stale connection exception has different codes in different databases.

The **DB2** SQLCODEs of *1015, 1034, 1036* and so on indicate that the connection is no longer available because of a temporary database problem. The **Oracle** SQLCODEs of *28, 3113, 3114* and so on indicate the same situation.

To provide portability for applications, WebSphere Application Server provides a *DataStoreHelper* interface to enable mapping of these codes to the WebSphere Application Server exceptions. The following code segment illustrates how to add two error codes into the error map:

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

Database deadlock and foreign key conflicts:

This article describes troubleshooting issues with database deadlock and foreign key conflicts.

Exceptions resulting from foreign key conflicts due to violations of database referential integrity

A database *referential integrity* (RI) policy prescribes rules for how data is written to and deleted from the database tables to maintain relational consistency. Run-time requirements for managing bean persistence, however, can cause an EJB application to violate RI rules, which can cause database exceptions.

Your EJB application is violating database RI if you see an exception message in your WebSphere Application Server trace or log file that is similar to one of the following messages (which were produced in an environment running DB2):

```
The insert or update value of the FOREIGN KEY table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

or

```
A parent row cannot be deleted because the relationship table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

To prevent these exceptions, you must designate the order in which entity beans update relational database tables by defining sequence groups for the beans.

Exceptions resulting from deadlock caused by optimistic concurrency control schemes

Additionally, sequence grouping can minimize transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. Optimistic concurrency control dictates that database locks be held for minimal amounts of time, so that a maximum number of transactions consistently have access to the data. In such a highly available database, concurrent transactions can attempt to lock the same table row and create deadlock. The resulting exceptions can generate messages similar to the following (which was produced in an environment running DB2):

```
Unsuccessful execution caused by deadlock or timeout.
```

Use the sequence grouping feature to order bean persistence so that database deadlock is less likely to occur.

Assembling data access applications

When you assemble enterprise bean code into files that can be deployed onto an application server, you configure properties that define how the application accesses an enterprise information system (EIS), such as a database.

This topic assumes that you have created an enterprise application containing an EJB module that must transact with a database.

A data access application uses resources, such as data sources or connection factories, to connect with a database. During application assembly you perform activities that enable the application to use these resources. The process typically requires an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer.

1. Identify the logical names that are used by the EJB module to reference application resources. These logical names are called *resource references.* For further explanation, consult the "The benefits of using resource references" on page 701 topic.

2. Start an assembly tool.

3. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **J2EE** capability is enabled.

4. Define mapping and security properties for the resource references. This process includes the following activities:

   a. Bind the resource references to the application resources that provide database connectivity. See the "Data source lookups for enterprise beans and Web modules" on page 703 topic for more information on the concept of binding. At deployment time you can alter your bindings if necessary.

   b. For each resource define an authentication type, which is the security configuration through which database connections are granted. There are two authentication types:

      Component-managed
      The enterprise bean code performs EIS signon for data source or connection factory connections.

      Container-managed
      WebSphere Application Server performs EIS signon.

      Consult the J2EE connector security topic for detailed reference on resource authentication.

5. Configure access intent assembly settings for your enterprise beans.

   a. Right-click your EJB module in a Project Explorer view and click **Open With > Deployment Descriptor Editor**.

   b. In an EJB Deployment Descriptor editor, select the **Access** tab.

   c. Under **Isolation Level**, click **Add**.

   d. Select the isolation level, enterprise beans, and method elements. For information on isolation levels, press **F1**.

   e. Click **Finish**.

6. Map enterprise beans to database tables. For an overview of the mapping options in the Application Server Toolkit, consult Approaches for mapping enterprise beans to database tables.

Files for the updated application are shown in the Project Explorer view.

After testing your application, you are ready to deploy your application to an application server.

Creating or changing a resource reference

A resource reference supports application access to a resource (such as a data source, URL, or mail provider) using a logical name rather than the actual name in the run-time environment. This capability eliminates the necessity to alter application code when you change the resource run-time configurations.

This topic guides you through updating the resource references of an enterprise application that you assembled previously. The topic Chapter 7, "Assembling applications," on page 1345 details the assembly procedure.

Resource references are declared in the deployment descriptor by the application provider. At some point in the application deployment process, you must bind the resource reference to the actual name of the resource in the run time environment.

This topic describes how to update the resource references of an enterprise application using an assembly tool.

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules.
3. Import the enterprise application (EAR file) that you want to change into the EJB project.
4. Display the resource references for the type of module:
   - If an enterprise bean uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **EJB Modules**.
     c. Expand the EJB module wanted.
     d. Expand the section for the appropriate type of enterprise bean (**Session Beans** or **Entity Beans**).
     e. Expand the enterprise bean.
   - If a servlet uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **Web Modules**.
     c. Expand the Web module wanted.
   - If an application client uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **Application Clients**.
     c. Expand the application client module wanted.
5. Right-click the module whose resource references you want to change and click **Open With > Deployment Descriptor Editor**.
6. For servlets and application clients, click **Add**. For EJB modules, select the particular bean and click **Add**.
7. Select the resource reference option and click **Next**.
8. Specify the settings and click **Finish**.
9. **Optional:** Select the **References** tab and, under **WebSphere Extensions**, select an isolation level. If you choose to forego this step, the isolation level defaults to TRANSACTION_NONE.
10. **Optional:** Under **WebSphere Bindings**, specify a JNDI name. If you choose to forego this step you can set (or override) the binding when the application is deployed.
11. Close the deployment descriptor editor and save your changes.

Files for the updated module are shown in the Project Explorer view.

Verify the contents of the updated enterprise application in the Project Explorer view. Then, deploy your enterprise application.

You can generate EJB deployment code and deploy an EJB module to a target server in one step. In the Project Explorer view, right-click on the EJB project and click **Deploy**. See also the article "Deploying EJB modules" on page 201.

Resource adapter archive file

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for WebSphere Application Server.

A RAR file can contain the following:
- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other runnable components, such as dynamic link lists.
- Utility classes.
- Static documents, such as HTML files, images, and sound files.

The standard file extension of a RAR file is *.rar*.

Assembling resource adapter (connector) modules

A resource adapter archive (RAR) file contains code that implements a library for connecting with a backend Enterprise Information System (EIS).

This topic assumes that you have created and unit tested a resource adapter RAR file that you want to assemble in an enterprise application and deploy onto an application server.

In the Application Server Toolkit (AST) and Rational Application Developer assembly tools, RAR files are called *connectors* and assembled resource adapters are called *connector modules*.

A *connector* is a J2EE component that provides access to Enterprise Information Systems (EIS), and must comply with the J2EE Connector Architecture (JCA). An example of an EIS is a transaction manager such as the Customer Information Control System (CICS).

You might see the terms resource adapter *modules*, resource adapter *connectors* and resource adapter *archive files* used interchangeably.

Use an assembly tool to assemble a *connector* in either of the following ways:
- Import an existing RAR file.
- Create a new connector module.

For information on assembling connectors, refer to the online documentation or the information center for your assembly tool. This topic points you to AST documentation. The Application Server Toolkit information center accompanies this WebSphere Application Server information center.
1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **J2EE** and **EJB** capabilities are enabled.
3. Migrate RAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your RAR files to the assembly tool.
4. Create a new connector module.

A connector project is migrated or created. Files for the connector project are shown in the Project Explorer view under **Enterprise Applications** and **Connector Projects**.

After creating a connector project, you can edit the connector deployment descriptor if default properties are not sufficient. In the Connector Deployment Descriptor editor, you can view and edit source code.

For more information, see the online help for the assembly tool. Similar information is in the **Application Server Toolkit** information center available with this information center. Click **Application Server Toolkit > J2EE applications > Working with projects > Creating a connector project**.

After assembling the connector project, deploy the module or its application onto a server. When deploying the RAR file, WebSphere Application Server looks first for the connector module manifest (`manifest.mf`) in the _connectorModule.jar file and loads the manifest from the _connectorModule.jar file. If the class path entry is in the manifest from the _connectorModule.jar file, then the RAR uses that class path. After deployment, to ensure that the connector module finds the classes and resources that it needs, check the **Classpath** setting for the RAR on the console Resource adapter settings page.

Migrating applications to use data sources of the current J2EE Connector Architecture (JCA)

Migrate your applications that use Version 4 data sources, or data sources (WebSphere Application Server V4), to use data sources that support more advanced connection management features, such as connection sharing.

To use the connection management infrastructure in WebSphere Application Server Version 6.x, you must package your application as a J2EE 1.3 (or later) application. This process involves repackaging your Web modules to the 2.3 specification and your EJB modules to the 2.1 specification before installing them onto WebSphere Application Server.

In WebSphere Application Server Version 6.x, data sources are intended for use within J2EE applications and designed to operate within the EJB and Web containers.

Converting a 2.2 Web module to a 2.3 Web module:
Use the following steps to migrate each of your Web modules.

1. Open an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.
2. Create a new Web module by selecting **File > New > Web Module**.
3. Add any required class files to the new module.
   a. Expand the **Files** portion of the tree.
   b. Right-click **Class Files** and select **Add Files**.
   c. In the Add Files window, click **Browse**.
   d. Navigate to your WebSphere Application Server 4.0 EAR file and click **Select**.
   e. In the upper left pane of the Add Files window, navigate to your WAR file and expand the `WEB-INF` and `classes` directories.
   f. Select each of the directories and files in the classes directory and click **Add**.
   g. After you add all of the required class files, click **OK**.
4. Add any required JAR files to the new module.
   a. Expand the **Files** portion of the tree.
   b. Right-click **Jar Files** and select **Add Files**.
   c. Navigate to your WebSphere 4.0 EAR file and click **Select**.
   d. In the upper left pane of the Add Files window, navigate to your WAR file and expand the `WEB-INF` and `lib` directories.
   e. Select each JAR file and click **Add**.
   f. After you add all of the required JAR files, click**OK**.
5. Add any required resource files, such as HTML files, JSP files, GIFs, and so on, to the new module.
   a. Expand the **Files** portion of the tree.
   b. Right-click **Resource Files** and select **Add Files**.
   c. Navigate to your WebSphere Application Server 4.0 EAR file and click **Select**.
   d. In the upper left pane of the Add Files window, navigate to your WAR file.
   e. Select each of the directories and files in the WAR file, excluding `META-INF` and `WEB-INF`, and click **Add**.
   f. After you add all of the required resource files, click**OK**.
6. Import your Web components.
   a. Right-click **Web Components** and select **Import**.
   b. In the Import Components window click **Browse**.
   c. Navigate to your WebSphere Application Server 4.0 EAR file and click **Open**.
   d. In the left top pane of the **Import Components** window, highlight the WAR file that you are migrating.

e. Highlight each of the components that display in the right top pane and click **Add**.

   f. When all of your Web components display in the Selected Components pane of the window, click **OK**.

   g. Verify that your Web components are correctly imported under the Web Components section of your new Web module.

7. Add servlet mappings for each of your Web components.

   a. Right-click **Servlet Mappings** and select **New**.

   b. Identify a URL pattern for the Web component.

   c. Select the web component from the Servlet drop-down box.

   d. Click **OK**.

8. Add any necessary resource references by following the instructions in the Creating a resource reference article in the information center.

9. Add any other Web module properties that are required. Click **Help** for a description of the settings.

10. **Save** the Web module.

Converting a 1.1 EJB module to a 2.1 EJB module (or later):

Use the following steps to migrate each of your EJB modules.

1. Open an assembly tool.

2. Create a new EJB Module by selecting **File > New > EJB Module**.

3. Add any required class files to the new module.

   a. Right-click **Files object** and select **Add Files**.

   b. In the Add Files window click **Browse**.

   c. Navigate to your WebSphere Application Server 4.0 EAR file and click **Select**.

   d. In the upper left pane of the Add Files window, navigate to your enterprise bean JAR file.

   e. Select each of the directories and class files and click **Add**.

   f. After you add all of the required class files, click **OK**.

4. Create your session beans and entity beans. To find help on this subject, see Migrating enterprise bean code to the supported specification, the documentation for Rational Application Developer, or the documentation for WebSphere Studio Application Developer Integration Edition.

5. Add any necessary resource references by following the instructions in the Creating a resource reference article in the information center.

6. Add any other EJB module properties that are required. Click **Help** for a description of the settings.

7. **Save** the EJB module.

8. Generate the deployed code for the EJB module by clicking **File > Generate Code for Deployment**.

9. Fill in the appropriate fields and click **Generate Now**.

Add the EJB modules and Web modules to an EAR file:

1. Open an assembly tool.

2. Create a new Application by selecting **File > New > Application**.

3. Add each of your EJB modules.

   a. Right-click **EJB Modules** and select **Import**.

   b. Navigate to your converted EJB module and click **Open**.

   c. Click **OK**.

4. Add each of your Web modules.

   a. Right-click **Web Modules** and select **Import**.

   b. Navigate to your converted Web module and click **Open**.

   c. Fill in a **Context root** and click **OK**.

5. Identify any other application properties. Click **Help** for a description of the settings.

6. Save the EAR file.

Installing the Application on WebSphere Application Server:

1. Install the application following the instructions in the Installing a new application article in the information center, and bind the resource references to the data source that you created.

2. Perform the necessary administrative task of creating a JDBC provider and a data source object following the instructions in the Creating a JDBC provider and data source article in the information center.

Connection considerations when migrating servlets, JavaServer Pages, or enterprise session beans: Because WebSphere Application Server provides backward compatibility with application modules coded to the J2EE 1.2 specification, you can continue to use Version 4 style data sources when you migrate to Application Server Version 6.x. As long as you configure Version 4 data sources *only* for J2EE 1.2 modules, the behavior of your data access application components does not change.

If you are adopting a later version of the J2EE specification along with your migration to Application Server Version 6.x, however, the behavior of your data access components can change. Specifically, this risk applies to applications that include servlets, JavaServer Page (JSP) files, or enterprise session beans that run inside local transactions over shareable connections. A behavior change in the data access components can adversely affect the use of connections in such applications.

This change affects all applications that contain the following methods:
- `RequestDispatcher.include()`
- `RequestDispatcher.forward()`
- JSP includes (`<jsp:include>`)

Symptoms of the problem include:
- Session hang
- Session timeout
- Running out of connections

Note: You can also experience these symptoms with applications that contain the components and methods described previously if you are upgrading from J2EE 1.2 modules *within* Application Server Version 6.x.

Explanation of the underlying problem

For J2EE 1.2 modules using Version 4 data sources, WebSphere Application Server issues non-sharable connections to JSP files, servlets, and enterprise session beans. All of the other application components are issued shareable connections. However, for J2EE 1.3 and 1.4 modules, Application Server issues shareable connections to *all* logically named resources (resources bound to individual references) unless you specify the connections as unshareable in the individual resource-references. Using shareable connections in this context has the following effects:
- All connections that are received and used outside the scope of a user transaction are *not* returned to the free connection pool until the encapsulating method returns, even when the connection handle issues a `close()` call.
- All connections that are received and used outside the scope of a user transaction are *not* shared with other component instances (that is, other servlets, JSP files, or enterprise beans).

    For example, session bean 1 gets a connection and then calls session bean 2 that also gets a connection. Even if all properties are identical, each session bean receives its own connection.

If you do not anticipate this change in the connection behavior, the way you structure your application code can lead to excessive connection use, particularly in the cases of JSP includes, session beans that run inside local transactions over shareable connections, `RequestDispatcher.include()`routines,

`RequestDispatcher.forward()` routines, or calls from these methods to other components.

Examples of the connection behavior change

Servlet A gets a connection, completes the work, commits the connection, and calls `close()` on the connection. Next, servlet A calls the `RequestDispatcher.include()` to include servlet B, which performs the same steps as servlet A. Because the servlet A connection does not return to the free pool until it returns from the current method, two connections are now busy. In this way, more connections might be in use than you intended in your application. If these connections are not accounted for in the **Max Connections** setting on the connection pool, this behavior might cause a lack of connections in the pool, which results in `ConnectionWaitTimeOut` exceptions. If the **connection wait timeout** is not enabled, or if the **connection wait timeout** is set to a large number, these threads might appear to hang because they are waiting for connections that are never returned to the pool. Threads waiting for new connections do not return the ones they are currently using if new connections are not available.

Alternatives to the connection behavior change

To resolve these problems:
1. Use unshared connections.

   If you use an unshared connection and are not in a user transaction, the connection is returned to the free pool when you issue a `close()` call (assuming you commit or roll back the connection).
2. Increase the maximum number of connections.

   To calculate the number of required connections, multiply the number of configured threads by the deepest level of component call nesting (for those calls that use connections). See the Examples section for a description of call nesting.

Deploying data access applications

Frequently, deploying data access applications involves more than installing your WAR or EAR file onto a server. Deployment can include tasks for configuring your application to use the data access resources of the server and overall run-time environment.

You can only deploy application code that is assembled into the appropriate modules. The topic "Assembling data access applications" on page 790 provides guidelines for this process.

Perform the following steps if your application requires access to a relational database (RDB). If your application requires access to a different type of enterprise information system (EIS), such as an object-oriented database or the Customer Information Control System (CICS), consult the topics "J2EE Connector Architecture resource adapters" on page 662 and "Accessing data using J2EE Connector Architecture connectors" on page 713.

1. If your RDB configuration does not already exist:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      If your application uses CMP entity beans to access the data
      > You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see Recreating database tables from the exported table data definition language.

      If your application uses BMP entity beans, or *does not* **use entity beans**
      > You must use your database server interfaces to create the tables.

      You can also use the EJB to RDB Mapping wizard of an assembly tool to create your database tables for either type of entity bean. Select the top-down mapping option in the wizard. Keep in mind, however, that this option does not give you direct control in naming the RDB elements or choosing column types. Additionally, because the top-down process is automatic, it might not provide mappings to reflect the precise relationships that you intend.

If you use the Application Server Toolkit (AST), consult the that product information center about the mapping wizard. To learn about all of your assembly tool options, consult the "Assembly tools" on page 23 article in this information center.

c. Check Minimum required properties for vendor-specific data sources to see any database vendor requirements for connecting to an application server.

2. If necessary, map your entity beans to the database tables through the meet-in-the-middle mapping option of an assembly tool. This step is necessary only if you did not create your database schema through the top-down mapping option, did not generate your mapping relationships through bottom-up mapping, or did not generate mappings during the application assembly process. For information on the top-down mapping option refer to the **Application Server Toolkit** information center.

3. Install your application onto the application server. Consult "Installing application files" on page 1364. When you install the application, you can alter data access settings that were made during application assembly, or set them for the first time if they were omitted from the assembly process. These settings include resource bindings and resource authentication aliases, which are addressed in the following substeps:

a. Bind application resource references to the data sources, or other resource objects, that provide database connectivity. For details on the concept of binding, see the "Data source lookups for enterprise beans and Web modules" on page 703 topic.

   Tip: After deployment, you can use the WebSphere Application Server administrative console to alter resource bindings. Click **Applications** > **Enterprise Applications** > *application_name*, and select the link to the appropriate mapping page. For example, if you want to alter the binding of an EJB module resource, you might click **1.x CMP bean data sources** or **2.x CMP bean data sources**. For a Web module resource, click **Resource references**.

b. Define authentication alias data for resources that must be authenticated with the backend through *container-managed* authorization. In this security configuration, WebSphere Application Server performs EIS signon for data source or connection factory connections. Consult the J2EE connector security topic for detailed reference on resource authentication.

4. Start the deployed application files using the administrative console , the wsadmin startApplication command, or your own Java program.

5. Save the changes to your administrative configuration.

6. Test the application. For example, point a Web browser at the URL for a deployed application and examine the performance of the application.

If the application does not perform as desired, update the application, then save and test it again.

Available resources

Use this page to select configured resources that you want to bind to the resource references of the enterprise beans or Web modules in your application.

To view this administrative console page:

1. Click **Applications** > **Enterprise Applications** > *Application_name*.

2. Click the link for any of these resource configuration pages:
   - **Resource references**
   - **Map data sources for all 2.x CMP beans**
   - **Provide default data source mapping for modules containing 2.x entity beans**

3. Locate the table row of the EJB or Web module that you want to map to a different resource.

4. Within the row, locate the JNDI name of the resource that is currently bound to the EJB or Web module.

5. Click **Browse**.

   You now see **Available resources**.

Each table row corresponds to a resource that you can bind to your enterprise bean or Web module.

Select:

Select the resource that you want to bind to the resource reference of your module.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the resource that you want to bind to the resource reference of your module.

Data type	String

Scope:

The scope of the resource. Note that this administrative console page displays only resources that are configured for a scope at which your application operates.

Description:

The text description of the resource.

1.x CMP bean data sources

Use this page to designate how the container-managed persistence (CMP) 1.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **1.x CMP bean data sources**.

Guidelines for using this administrative console page:

- The table depicts the 1.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly or installation. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.
  3. Click **Apply**. The console displays the 1.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
  4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To specify data source security settings:
  1. Select one or more rows in the table.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application J2EE Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the "Managing J2EE Connector Architecture authentication data entries" on page 936 information center topic for instruction.
  3. Click **Apply** that immediately follows the user name and password input fields.

- Repeat all of the previous steps as necessary.
- Click **OK** to save your settings.

Table column heading descriptions:

Select:

Select the check boxes of the rows that you want to edit.

EJB:

The name of an enterprise bean in the application.

EJB Module:

The name of the module that contains the enterprise bean.

URI:

Specifies location of the module relative to the root of the application EAR file.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

Data type	String

User name:

The user name and password that comprise the authentication alias for securing the data source.

1.x entity bean data sources

Use this page to set the default data source mapping for EJB modules that contain 1.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 1.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **1.x entity bean data sources**.

Guidelines for using this administrative console page:

- The page displays a table that depicts the EJB modules in your application that contain 1.x CMP beans.
- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
  3. Click **Apply**. The console displays the 1.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.

4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To specify security settings for the default data source:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application J2EE Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the "Managing J2EE Connector Architecture authentication data entries" on page 936 information center topic for instruction.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your work.

Table column heading descriptions:

Select:

Select the check boxes of the rows that you want to edit.

EJB Module:

The name of the module that contains the 1.x enterprise beans.

URI:

Specifies location of the module relative to the root of the application EAR file.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type   String

User name:

The user name and password that comprise the authentication alias for securing the data source.

2.x CMP bean data sources

Use this page to designate how the container-managed persistence (CMP) 2.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **2.x CMP bean data sources**.

Guidelines for using this administrative console page:
- The page displays a table that depicts the 2.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.

2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.

3. Click **Apply**. The console displays the 2.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.

4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.

- To define data source security:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.

  2. Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon. Click **Apply**.

  3. To modify the authorization method of a data source with container-managed authorization, you have three options: None, Default, or Custom login configuration. The reconfiguring process differs slightly for each option:

     – If you select **None**:
       a. Determine which data source configurations to designate with no authentication method.
       b. Select the appropriate table rows.
       c. Select **None** from the list of authentication method options that precede the table.
       d. Click **Apply**.

     – If you select **Default**:
       a. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. You must apply this option to each data source individually if you want to designate different authentication data aliases. See the ″J2EE Connector security″ information center topic for more information on the default mapping configuration.
       b. Select the appropriate table rows.
       c. Select **Use default method** from the list of authentication method options that precede the table.
       d. Select an authentication data entry or alias from the list.
       e. Click **Apply**.

     – If you select **Custom login configuration**:
       a. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the ″J2EE Connector security″ information center topic for more information on custom JAAS login configurations.
       b. Select the appropriate table row.
       c. Select **Use custom login configuration** from the list of authentication method options that precede the table.
       d. Select an application login configuration from the list.
       e. Click **Apply**.
       f. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

- Repeat all of the previous steps as necessary.

- Click **OK** to save your work. You now return to the general configuration page for your enterprise application.

Table column heading descriptions:

Select:

Select the check boxes of the rows that you want to edit.

EJB:

The name of an enterprise bean in the application.

EJB Module:

The name of the module that contains the enterprise bean.

URI:

Specifies location of the module relative to the root of the application EAR file.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

Data type   String

Resource authorization:

The authorization type and the authentication method for securing the data source.

2.x entity bean data sources

Use this page to set the default data source mapping for EJB modules that contain 2.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 2.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **2.x entity bean data sources**.

Guidelines for using this administrative console page:
- The page displays a table that depicts the EJB modules in your application that contain 2.x CMP beans.
- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
  3. Click **Apply**. The console displays the 2.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
  4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To define data source security:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.

2. Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon. Click **Apply**.

3. To modify the authorization method of a data source with container-managed authorization, you have three options: None, Default, or Custom login configuration. The reconfiguring process differs slightly for each option:

   – If you select **None**:

     a. Determine which data source configurations to designate with no authentication method.

     b. Select the appropriate table rows.

     c. Select **None** from the list of authentication method options that precede the table.

     d. Click **Apply**.

   – If you select **Default**:

     a. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. You must apply this option to each data source individually if you want to designate different authentication data aliases. See the ″J2EE Connector security″ information center topic for more information on the default mapping configuration.

     b. Select the appropriate table rows.

     c. Select **Use default method** from the list of authentication method options that precede the table.

     d. Select an authentication data entry or alias from the list.

     e. Click **Apply**.

   – If you select **Custom login configuration**:

     a. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the ″J2EE Connector security″ information center topic for more information on custom JAAS login configurations.

     b. Select the appropriate table row.

     c. Select **Use custom login configuration** from the list of authentication method options that precede the table.

     d. Select an application login configuration from the list.

     e. Click **Apply**.

     f. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

- Repeat all of the previous steps as necessary.

- Click **OK** to save your work. You now return to the general configuration page for your enterprise application.

Table column heading descriptions:

Select:

Select the check boxes of the rows you want to edit.

EJB Module:

The name of the module that contains the 2.x enterprise beans.

URI:

Specifies location of the module relative to the root of the application EAR file.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type   String

Resource authorization:

The authorization type and the authentication method for securing the data source.

Messaging resources

Using asynchronous messaging

These topics describe how enterprise applications can use asynchronous messaging as a method of communication based on the Java Message Service (JMS). With the support provided by WebSphere Application Server, applications can make use of JMS resources and message-driven beans.

WebSphere Application Server support for JMS is provided by one or more *JMS providers*, and associated services and resources, that you configure for use by enterprise applications. You can deploy EJB 2.1 applications that use the JMS 1.1 interfaces and EJB 2.0 applications that use the JMS 1.0.2 interfaces.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure messaging providers and their resources, and can control the activity of messaging services.

For more information about implementing WebSphere enterprise applications that use asynchronous messaging, see the following topics:
* Learning about messaging with WebSphere
* Installing a messaging provider
* Using the default messaging provider
* Maintaining Version 5 default messaging resources
* Using the JMS resources provided by WebSphere MQ
* Using JMS resources of a generic provider
* Administering support for message-driven beans
* "Programming to use asynchronous messaging" on page 823
* Troubleshooting WebSphere messaging

Learning about messaging with WebSphere Application Server

Use this topic to learn about the use of asynchronous messaging for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) and Java Connector Architecture (JCA) programming interfaces. These interfaces provide a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as messages. For additional information about messaging resources, see: Messaging resources.
* JMS providers
* Styles of messaging in applications
* JMS interfaces - explicit polling for messages
* Message-driven beans - automatic message retrieval
* Configuring JMS resources for the WebSphere MQ messaging provider
* Components of message-driven bean support

- WebSphere Application Server cloning and WebSphere MQ clustering
- Security considerations for asynchronous messaging

JMS providers

This topic provides an overview of the support for JMS providers by WebSphere Application Server.

Overview

WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

WebSphere Application Server supports JMS messaging using the following:
- Service integration default messaging provider
- WebSphere MQ JMS provider
- Version 5 default provider
- Generic JMS provider

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Service integration default provider

The service integration technologies of WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere MQ JMS provider

WebSphere Application Server also includes support for the WebSphere MQ JMS provider. This is provided for use with supported versions of WebSphere MQ.

Version 5 default provider

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

The V5 default messaging provider is the version 5 embedded WebSphere MQ provider. It is designed for use with applications that still use version 5 resources to communicate with version 5 nodes in mixed version cells that use embedded messaging.

Generic JMS provider

WebSphere Application Server also includes support for the generic JMS provider. This is provided for use with any third party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For additional information about connecting to WebSphere MQ, see Ways of interoperating with WebSphere MQ

For more information about connecting to WebSphere MQ, see Learning about WebSphere MQ server

Styles of messaging in applications

This topic describes the ways that applications can use point-to-point and publish/subscribe messaging.

Applications can use the following styles of asynchronous messaging:

Point-to-Point

> Point-to-point applications use *queues* to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

Publish/subscribe

> Publish/subscribe systems provide named collection points for messages, called *topics*. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

One-way

> An application sends a message, and does not want a response. This pattern of use is often referred to as a *datagram*.

Request / response

> An application sends a request to another application and expects to receive a response in return.

One-way and forward

> An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:
* An overview of asynchronous messaging with JMS
* An overview of asynchronous messaging with message-driven beans

For more information about these messaging techniques and the Java Message Service (JMS), see Sun's Java Message Service (JMS) specification documentation (http://developer.java.sun.com/developer/ technicalArticles/Networking/messaging/).

For more information about message-driven bean and inbound messaging support, see Sun's Enterprise JavaBeans specification (http://java.sun.com/products/ejb/docs.html).

For information about JCA inbound messaging processing, see Sun's J2EE Connector Architecture specification (http://java.sun.com/j2ee/connector/download.html).

JMS interfaces - explicit polling for messages

This topic provides an overview of applications that use JMS interfaces to explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interfaces. JMS provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

The base support for asynchronous messaging using JMS, shown in the following figure, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics).

Applications can use both point-to-point and publish/subscribe messaging (referred to as "messaging domains" in the JMS specification), while supporting the different semantics of each domain.

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as the "common interfaces" in the JMS specification). With JMS 1.1, the preferred approach for implementing applications is to use the common interfaces. The JMS 1.1 common interfaces provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction.

The common interfaces are also parents of domain-specific interfaces. These domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server version 5) are supported only to provide inter-operation and backward compatibility with applications that have already been implemented to use those interfaces.

A WebSphere application can use the JMS interfaces to explicitly poll a JMS destination to retrieve an incoming message, then pass the message to a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination.
Figure 7. Asynchronous messaging using JMS. This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

WebSphere applications can use standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of functionality for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure; for example, for connection and session pool management. The application server has no role in bean-managed messaging.

WebSphere applications can also use message-driven beans, as described in related topics.

For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

Message-driven beans - automatic message retrieval

WebSphere Application Server supports the use of message-driven beans as asynchronous message consumers.

Messaging with message-driven beans is shown in the figure Messaging with message-driven beans.

A client sends messages to the destination (or endpoint) for which the message-driven bean is deployed as the message listener. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination. The message-driven bean implements some business logic to process incoming messages on the destination.

Message-driven beans can be configured as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter or against a listener port (as in WebSphere Application Server version 5). With a JCA 1.5 resource adapter, message-driven beans can handle generic message types, not just JMS messages. This makes message-driven beans suitable for handling generic requests inbound to WebSphere Application Server from enterprise information systems through the resource adapter. In the JCA 1.5 specification, such message-driven beans are commonly called *message endpoints* or simply *endpoints*.

All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface, javax.jms.MessageListener.

A message driven bean can be registered with the EJB timer service for time-based event notifications if it implements the javax.ejb.TimedObject interface in addition to the message listener interface.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

Messages arriving at a destination being processed by a message-driven bean have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.

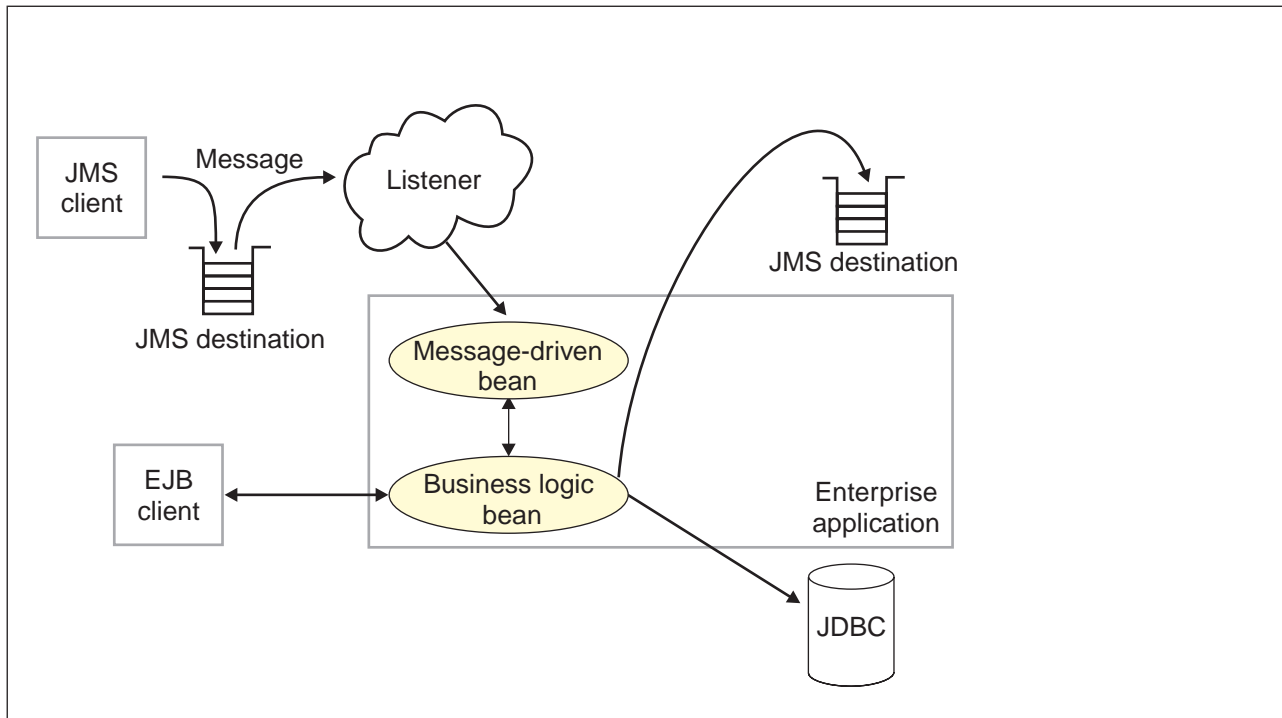
For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA 1.5-compliant resources, to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server version 5).


Figure 8. Messaging with message-driven beans. This figure shows an incoming message being passed automatically to the onMessage() method of a message-driven bean that is deployed as a listener for the destination. The message-driven bean processes the message, in this case passing the message on to a business logic bean for business processing. For more information, see the text that accompanies this figure.

Message-driven beans - JCA components:

This topic provides an overview of the administrative components that you configure for message-driven beans as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter.

Components for a JCA resource adapter

To handle non-JMS requests inbound to WebSphere Application Server from enterprise information systems, message-driven beans use a Java Connector Architecture (JCA) 1.5 *resource adapter* written by a third party for that purpose.

With a Java Connector Architecture (JCA) 1.5 resource adapter, a message-driven bean acts as a listener on a specific endpoint. In the JCA 1.5 specification, such message-driven beans are commonly called *message endpoints* or simply *endpoints*.

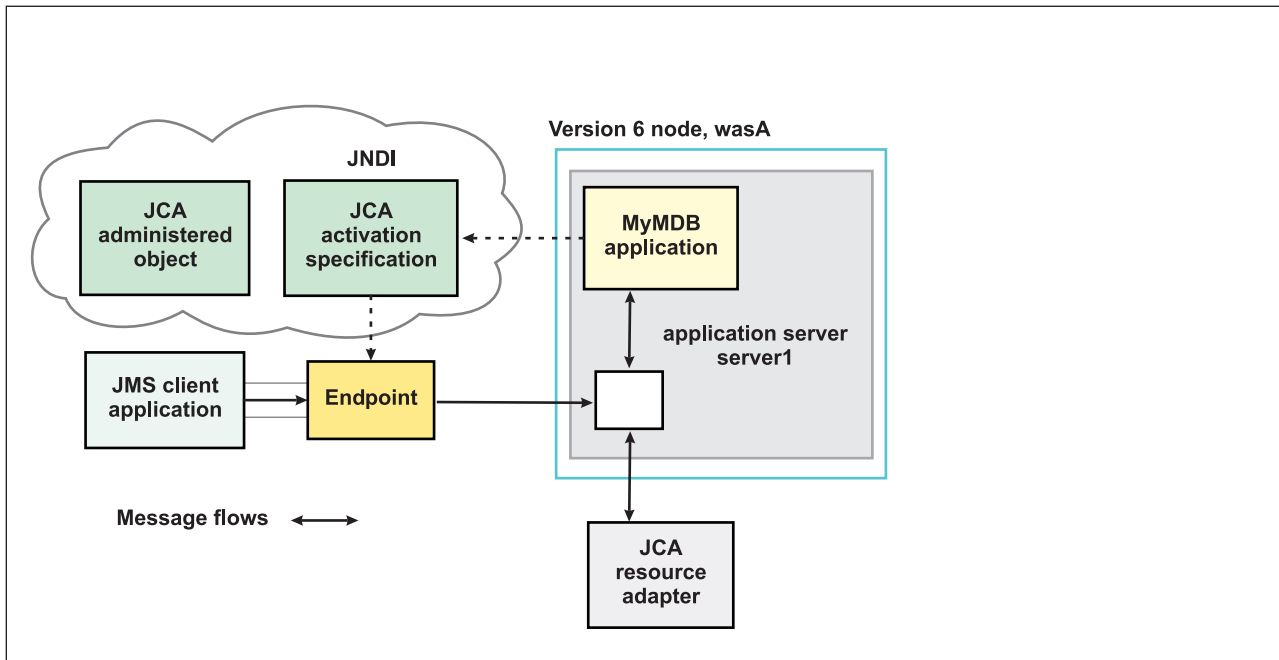
Each application configuring one or more message-driven beans must specify the resource adapter that sends messages to the endpoint. To specify the resource adapter, you configure the message-driven bean to use an activation specification that has been configured by the administrator for the resource adapter.


Figure 9. Message-driven bean components for a JCA resource adapter. This figure shows the main components of WebSphere support for message-driven beans for use with an external JCA resource adapter.

The administrator creates a *J2C activation specification* for the appropriate resource adapter to provide information to the deployer about the configuration properties of an endpoint instance (message-driven bean) related to the processing of the inbound messages. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

When a deployed message-driven bean is installed, it is associated with an activation specification for an endpoint. When a message arrives on the endpoint, the message is passed to a new instance of a message-driven bean for processing.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C *administered objects* with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using programming interfaces specific to a messaging style). Administered objects can also be used to perform transformations on an asynchronously-received message in a way that is specific to a message provider. Administered objects can be accessed by a component by using either a message destination reference (preferred) or a resource environment reference.

JMS components used with a JCA messaging provider

Message-driven beans that implement the javax.jms.MessageListener interface can be used for JMS messaging. For JMS messaging, message-driven beans can use a JCA-based messaging provider such as the SIB JMS Resource Adapter (which is the default messaging provider listed under JMS providers) that is part of WebSphere Application Server and configure message-driven beans to use a JCA activation specification.
Figure 10. Message-driven bean components for the default messaging provider. This figure shows the main components of WebSphere support for message-driven beans for use with the default messaging provider.

With the SIB JMS Resource Adapter, a message-driven bean acts as a listener on a specific *JMS destination*.

The administrator creates a *JMS activation specification* (which, the WebSphere administrative console shows on the panel **Resources** → **JMS providers** → **Default messaging** → **JMS activation specifications**) to provide information to the deployer about the configuration properties of a message-driven bean related to the processing of the inbound messages. WebSphere provides additional support for JCA activation specifications that are JMS-based and shows the JMS-specific panel rather than the generic JCA activation specification panel. For example, a JMS activation specification specifies the name of the service integration bus to connect to, and includes information about the message acknowledgement modes, message selectors, destination types, and whether or not durable subscriptions are shared across connections with members of a server cluster. Properties specified on an activation specification can be overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean.

The administrator also creates other administered objects that configure the JMS destination and the associated resources of a service integration bus that are used to implement messaging with that JMS destination.

For more information about JMS resources and service integration, see:
• Learning about the default messaging provider

J2C activation specification configuration and use:

This topic provides an overview about the configuration and use of J2C activation specifications, used in the deployment of message-driven beans for JCA 1.5 resources.

J2C activation specifications are part of the configuration of inbound messaging support that can be part of a JCA 1.5 resource adapter. Each JCA 1.5 resource adapter that supports inbound messaging defines one or more types of message listener in its deployment descriptor (`messagelistener` in the ra.xml). The message listener is the interface that the resource adapter uses to communicate inbound messages to the message endpoint. A message-driven bean (MDB) is a message endpoint and implements one of the

message listener interfaces provided by the resource adapter. By allowing multiple types of message listener, a resource adapter can support a variety of different protocols. For example, the interface javax.jms.MessageListener, is a type of message listener that supports JMS messaging. For each type of message listener that a resource adapter implements, the resource adapter defines an associated activation specification (`activationspec` in the ra.xml). The activation specification is used to set configuration properties for a particular use of the inbound support for the receiving endpoint.

When an application containing a message-driven bean is deployed, the deployer must select a resource adapter that supports the same type of message listener that the message-driven bean implements. As part of the message-driven bean deployment, the deployer needs to specify the properties to set on the J2C activation specification. Later, during application startup, a J2C activation specification instance is created, and these properties are set and used to activate the endpoint (that is, to configure the resource adapter's inbound support for the specific message-driven bean).

Applications with message-driven beans can also specify all, some, or none of the configuration properties needed by the ActivationSpec class, to override those defined by the resource adapter-scoped definition. These properties, specified as activation-config properties in the application's deployment descriptor, are configured when the application is assembled. To change any of these properties requires redeploying the application. These properties are unique to this applications use and are not shared with other message-driven beans. Any properties defined in the application's deployment descriptor take precedence over those defined by the resource adapter-scoped definition. This allows application developers to choose the best defaults for their applications.

WebSphere activation specification optional binding properties:

Binding properties that you can specify for activation specifications to be deployed on WebSphere Application Server.

J2C authentication alias

If you provide values for user name and password as custom properties on an activation specification, you may not want to have those values exposed in clear text for security reasons. WebSphere security allows you to securely define an authentication alias for such cases. Configuration of activation specifications, both as an administrative object and during application deployment, enable you to use the authentication alias instead of providing the user name and password.

If you set the authentication alias field, then you should not set the user name and password custom properties fields. Also, authentication alias properties set as part of application deployment take precedence over properties set on an activation specification administrative object.

Only the authentication alias is ever written to file in an unencrypted form, even for purposes of transaction recovery logging. The security service is used to protect the real user name and password.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the authentication alias to retrieve the real user name and password from security then set it on the activation specification instance.

Destination JNDI name

For resource adapters that support JMS you need to associate javax.jms.Destinations with an activation specification, such that the resource adapter can service messages from the JMS destination. In this case, the administrator configures a J2C Administered Object which implements the javax.jms.Destination interface and binds it into JNDI.

You can configure a J2C Administered Object to use an ActivationSpec class that implements a setDestination(javax.jms.Destination) method. In this case, you can specify the destination JNDI name (that is, the JNDI name for the J2C Administered object that implements the javax.jms.Destination).

A destination JNDI name set as part of application deployment take precedence over properties set on an activation specification administrative object.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the destination JNDI name to look up the destination administered object then set it on the activation specification instance.

Message-driven beans - transaction support:

Message-driven beans can handle messages on destinations (or endpoints) within the scope of a transaction.

Destination transaction handling

If transaction handling is specified for a destination, the message-driven bean starts a global transaction *before* it reads any incoming message from that destination. When the message-driven bean processing has finished, it commits or rolls back the transaction (using JTA transaction control).

All messages retrieved from a specific destination have the same transactional behavior.

If messages are queued to be sent within a global transaction they are sent when the transaction is committed. If the processing of a message causes the transaction to be rolled back, then the message that caused the bean instance to be invoked is left on the JMS destination.

Inbound resource adapter transaction handling

A message-driven bean can be set up to either have Bean or Container transaction handling. The resource adapter owner must tell the message-driven bean developer how to set up the message-driven bean for transaction handling.

WebSphere Application Server cloning and WebSphere MQ clustering

Here is a summary of information about using WebSphere Application Server horizontal cloning with WebSphere MQ server clustering support. It describes a scenario that shows how the message listener service can be configured to take advantage of WebSphere MQ server clustering and provides some information about how to resolve potential runtime failures in the clustering scenario.

The information in this topic is based on the scenario shown in the figure WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues.

Note: WebSphere MQ server clustering is only available with the full WebSphere MQ product installed as a JMS provider.

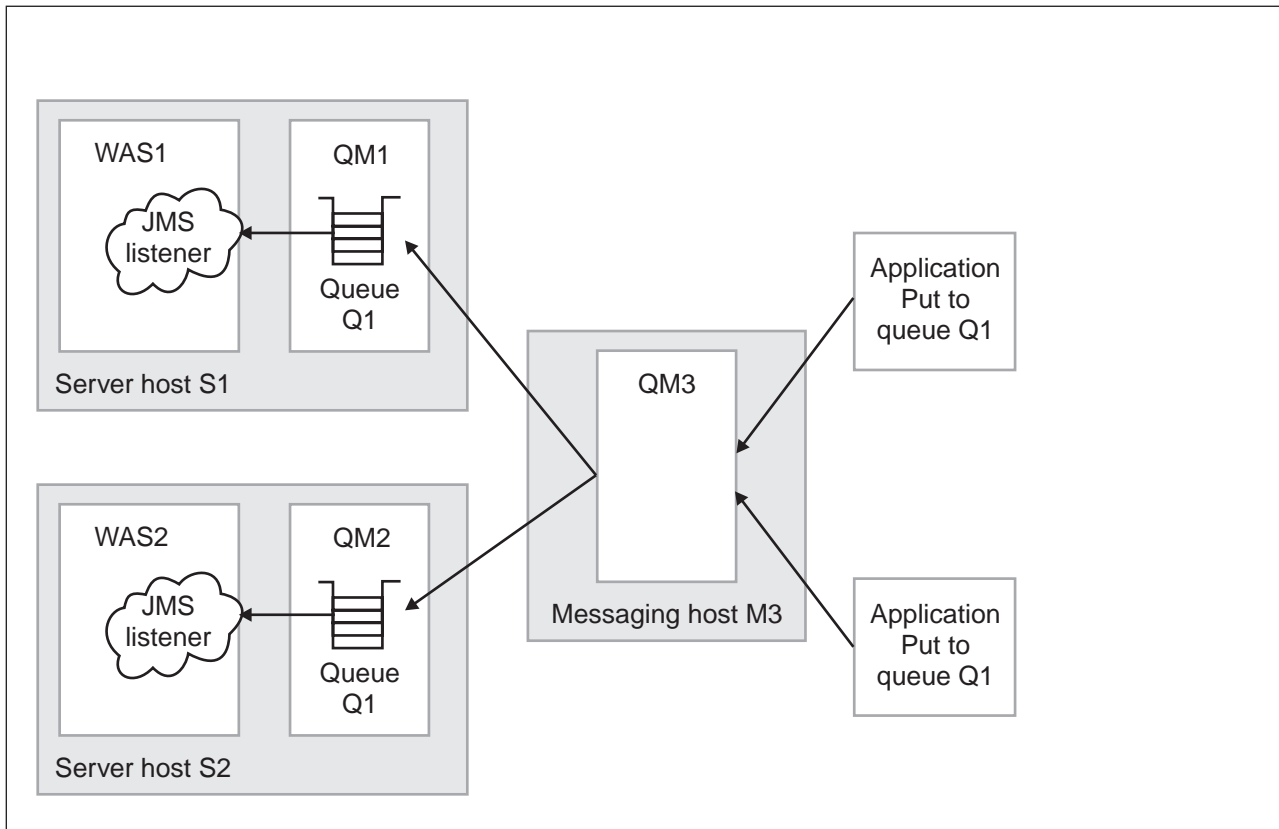
Each JMS listener is used to retrieve messages from a destination defined to the server. In the following information the listener configurations are the same for each WebSphere application server. Each application server host contains a WebSphere application server and an WebSphere MQ server. If a host is only used to distribute messages, it only contains an WebSphere MQ server. There can be many servers defined in the configuration, although for simplicity the information in this topic is based on a scenario containing only three servers as shown in "WebSphere Application Server cloning and WebSphere MQ clustering."


Figure 11. WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues. This figure shows two WebSphere Application Server hosts, with horizontal clustering, and a messaging host used to distribute messages for WebSphere MQ server clustering. For more information, see the text that accompanies this figure.

The scenario shown in "WebSphere Application Server cloning and WebSphere MQ clustering" on page 813 comprises the following three hosts:

- Server host S1 contains the following servers:

  WebSphere MQ server.

  > The server is defined to have a queue manager, QM1, and a local queue, Q1. The queue manager belongs to a cluster. The queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the WebSphere MQ cluster.

  WebSphere Application Server

  > This contains a cloned application server, WAS1, which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Server host S2 contains the following servers:

  WebSphere MQ server.

  > The server is defined to have a queue manager, QM2, and a local queue, Q1. The queue manager belongs to the same cluster as QM1 on host S1. As with QM1, the queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the MQ cluster.

  WebSphere Application Server

  > This contains a cloned application server, WAS2 (identical to WAS1 on host S1), which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Messaging host M3 contains the following servers:

  WebSphere MQ server.

  > The server is defined to have a queue manager, QM3, which also belongs to the same cluster as QM1 and QM2. Applications add messages to the queue manager and queue Q1. The

cluster to which this queue manager belongs causes messages to be distributed to all other queue managers in the cluster which have queue Q1 defined.

Note: Queue Q1 is not defined as a local queue on this host. If the queue was defined locally, then messages would remain on the server for local processing; messages would not be distributed by the queue manager cluster control to the other queue managers in the cluster that do have the queue defined.

This host does not have a WebSphere application server defined. All message retrieval processing is performed by the other two application servers on hosts S1 and S2.

Recovery scenarios

There are several failure scenarios that could occur with the clustering configuration; for example:
- WAS server failures.

  In this scenario the failure of any single WebSphere application server results in the messages for the specified destination remaining on the queue, until the server is restarted.
- WebSphere MQ Queue Manager failures.

  There are two different failures to consider:
  1. Failure of a queue manager on the same host as a WebSphere application server (for example, failure of QM2 on host S2). In this case messages are delivered to the other available application servers, until the WebSphere MQ server is back online, when messages are processed as expected.
  2. Failure of the messaging host M3 and its queue manager, QM3. In this case, the result of an outage is more significant because no messages are delivered to the other queue managers in the cluster. In a fully-deployed and scaled production system, host M3 would not be designed to be a single point of failure, and additional messaging servers would be added to the cluster configuration.

Asynchronous messaging - security considerations

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server.

Security for messaging is enabled only when WebSphere Application Server security is enabled.

The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

When WebSphere Application Server security is enabled, JMS connections made to the JMS provider are authenticated, and access to JMS resources owned by the JMS provider are controlled by access authorizations. Also, all requests to create new connections to the JMS provider must provide a user ID and password for authentication. The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. If your resource authentication (res-auth) is set to Application, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

Restriction:

1. User IDs longer than 12 characters cannot be used for authentication with the version 5 default messaging provider or WebSphere MQ. For example, the default Windows NT user ID, **Administrator**, is not valid for use, because it contains 13 characters.

Therefore, an authentication alias for a WebSphere JMS provider or WebSphere MQ connection factory must specify a user ID no longer than 12 characters.

2. If you want to use Bindings transport mode for JMS connections to WebSphere MQ, you set the property **Transport type**=BINDINGS on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:

- To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws the error `MQJMS2013 invalid security authentication supplied for MQQueueManager` error.

- Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Authorization to access messages stored by the default messaging provider is controlled by authorization to access the service integration bus destinations on which the messages are stored. For information about authorizing permissions for individual bus destinations, see Administering destination permissions.

Messaging: Resources for learning

Use the following links to find relevant supplementary information about messaging. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

Installing and configuring a JMS provider

This topic describes the different ways that you can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
> Provided for use with supported versions of WebSphere MQ.

Generic
> Provided for use with any 3rd party messaging system. If you want to use message-driven beans, the messaging system must support ASF.

For more information about the support for JMS providers, see "JMS providers" on page 805.

For more information about installing and using JMS providers, see the following topics:
- Installing the default messaging provider
- Using WebSphere MQ as a JMS provider. Installing WebSphere MQ as a JMS provider.

  Note:
  - You can install WebSphere MQ in addition to the default messaging provider. The preferred solution for publish/subscribe messaging with WebSphere MQ as a JMS provider is a full message broker such as WebSphere MQ Event Broker.
  - If you install WebSphere MQ as a JMS provider, you can use the WebSphere administrative console to administer the JMS resources provided by WebSphere MQ, such as queue connection factories. However, you cannot administer MQ security, which is administered through WebSphere MQ.

  For more information about scenarios and considerations for using WebSphere MQ with IBM WebSphere Application Server, see the White Papers and Red books provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at http://www-3.ibm.com/software/ts/mqseries/library/
- Installing another JMS provider, which must conform to the JMS specification and, to use message-driven beans, support the ASF function. If you want to use a JMS provider other than the default messaging provider or WebSphere MQ, you should complete the following steps:
  1. Installing and configuring the JMS provider and its resources by using the tools and information provided with the product.
  2. Defining the JMS provider to WebSphere Application Server as a generic messaging provider.

  Note: You can use the WebSphere administrative console to administer JMS connection factories and destinations (within WebSphere Application Server) for a generic provider, but cannot administer the JMS provider or its resources outside of WebSphere Application Server.

Installing the default messaging provider

Use this task to install the default messaging provider of IBM WebSphere Application Server.

The default messaging provider is installed as a fully-integrated component of WebSphere Application Server, and needs no separate installation steps. However, ensure that there is enough space in the file systems where you want to store messaging data.

You can use the WebSphere administrative console to for the default messaging provider.

For more information about the default messaging provider, see Using the default messaging provider.

JMS providers collection

A JMS provider enables messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for JMS destinations.

In the administrative console page, to view this page click **Resources** → **JMS** → **JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define your own JMS provider, other than the default messaging provider or WebSphere MQ, select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

General properties

Name The name of the JMS provider.

Description

     A description of the JMS provider.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Select JMS resource provider

Select the provider with which to create the {0}. The following providers support the selected resource type and are available at the selected scope. The variable, *{0}*, indicates the type of JMS resource that you are creating.

You select the scope setting on an earlier page. The choice of JMS providers depends on the scope that you selected. You might see a choice like the following list:

- Default messaging provider.

  Select this option if you want to the type of JMS resource to be provided by a service integration bus, as part of WebSphere Application Server.

- My JMSprovider

  Select this option if you want the type of JMS resource to be provided by your own JMS provider; not the default messaging provider or WebSphere MQ. You assign the name, in this example "My

JMSprovider", when you define the JMS provider to WebSphere Application Server. You must have installed and configured your own JMS provider before applications can use the JMS resources.

- WebSphere MQ messaging provider

  Select this option if you want the type of JMS resource to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use the JMS resources.

Activation specification collection

A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

In the administrative console page, to view this page click **Resources** › **JMS** › **Activation specification**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS activation specifications that are available to WebSphere applications at the scope indicated by the **Scope** field.

Use a JMS activation specification if you want to use a message-driven bean as a Java Connector Architecture (JCA) 1.5 resource, to act as a listener on the default messaging provider.

General properties

Name   The name of the activation specification.

Provider
> This JMS resource is for the *Default messaging provider*, provided by service integration technologies as part of WebSphere Application Server.

Description
> A description of the activation specification.

Scope   The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Connection factory collection

Use this page to create connections to the associated JMS provider for JMS destinations.

In the administrative console page, to view this page click **Resources** › **JMS** › **Connection factory**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the JMS provider named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the "common interfaces" in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

General properties

Name   The name of the connection factory.

Provider
> Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Description
> A description of the connection factory.

Scope   The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console page, to view this page click **Resources** → **JMS** → **Queue connection factory**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

General properties

Name The name of the queue connection factory.

Provider
> The type of JMS provider that provides the JMS resource. For example, for *Default messaging provider* resources are provided by service integration technologies as part of WebSphere Application Server; for *WebSphere MQ messaging provider* resources are provided by a separate WebSphere MQ installation.

Description
> A description of the queue connection factory.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Queue collection

A JMS queue is used as a destination for point-to-point messaging.

In the administrative console page, to view this page click **Resources** → **JMS** → **Queue**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere applications at the scope indicated by the **Scope** field.

Use topic destination administrative objects to manage JMS queues for the JMS provider that is named in the Provider column of the list. Connections to the queue are created by a connection factory (or queue connection factory) for that JMS provider.

General properties

Name The name of the queue.

Provider
> Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Description
>   A description of the queue.

Scope   The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Topic connection factory collection

A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console page, to view this page click **Resources** → **JMS** → **Topic connection factory**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

General properties

Name   The name of the topic connection factory.

Provider
>   The type of JMS provider that provides the JMS resource. For example, for *Default messaging provider* resources are provided by service integration technologies as part of WebSphere Application Server; for *WebSphere MQ messaging provider* resources are provided by a separate WebSphere MQ installation.

Description
>   A description of the topic connection factory.

Scope   The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.
Delete	Click this button to delete the selected items.

Topic collection

A JMS topic is used as a destination for publish/subscribe messaging.

In the administrative console page, to view this page click **Resources** → **JMS** → **Topic**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere applications at the scope indicated by the **Scope** field.

Use topic destination administrative objects to manage JMS topics for the JMS provider that is named in the Provider column of the list. Connections to the topic are created by a connection factory (or topic connection factory) for that JMS provider.

General properties

Name   The name of the topic.

Provider

> The type of JMS provider that provides the JMS resource. For example, for *Default messaging provider* resources are provided by service integration technologies as part of WebSphere Application Server; for *WebSphere MQ messaging provider* resources are provided by a separate WebSphere MQ installation.

Description

> A description of the topic.

Scope   The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Click this button to create a new JMS resource of this type.

Programming to use asynchronous messaging

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

You can build enterprise beans that use the JMS API directly to provide messaging services along with methods that implement business logic. An enterprise application can explicitly poll for messages on a JMS destination then retrieve messages for processing by business logic beans (enterprise beans).

You can also use message-driven beans (a type of enterprise bean defined in the EJB specification) as asynchronous message consumers. A message-driven bean is invoked by the EJB container when a message arrives at the destination that it is configured to use, without an application having to explicitly poll the destination.

- "Programming to use JMS and messaging directly" This topic provides information about using the Java Message Service (JMS) programming interfaces directly to exchange messages asynchronously.
- "Programming to use message-driven beans" on page 837 This topic provides information about using message-driven beans as asynchronous message consumers.

Programming to use JMS and messaging directly

Use these tasks to implement WebSphere J2EE applications that use JMS programming interfaces directly.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere enterprise applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

Using the base support for JMS, you can build enterprise beans that use the JMS API directly to provide messaging services along with methods that implement business logic.

You can use the WebSphere administrative console to administer the JMS support of WebSphere Application Server. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server.

For more information about JMS, see the JMS documentation at http://java.sun.com/products/jms/docs.html.

Designing an enterprise application to use JMS:

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.
- For messaging operations, you should write application programs that use only references to the interfaces defined in Sun's javax.jms package. JMS defines a generic view of a messaging that maps onto the underlying transport. An enterprise application that uses JMS, makes use of the following interfaces that are defined in Sun's javax.jms package:

Connection
    Provides access to the underlying transport, and is used to create Sessions.
Session
    Provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers.
MessageProducer
    Used to send messages.
MessageConsumer
    Used to receive messages.

The generic JMS interfaces are subclassed into the following more specific versions for Point-to-Point and Publish/Subscribe behavior:

JMS Common Interfaces	Point-to-Point	Publish/Subscribe
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection
Destination	Queue	Topic

JMS Common Interfaces	Point-to-Point	Publish/Subscribe
Session	QueueSession,	TopicSession,
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about using these JMS interfaces, see the Java Message Service Documentation and the WebSphere MQ *Using Java* book, SC34-5456.

The section "Java Message Service (JMS) Requirements" of the J2EE specification gives a list of methods that must not be called in Web and EJB containers:

```
javax.jms.Session method setMessageListener
javax.jms.Session method getMessageListener
javax.jms.Session method run
javax.jms.QueueConnection method createConnectionConsumer
javax.jms.TopicConnection method createConnectionConsumer
javax.jms.TopicConnection method createDurableConnectionConsumer
javax.jms.MessageConsumer method getMessageListener
javax.jms.MessageConsumer method setMessageListener
javax.jms.Connection setExceptionListener
javax.jms.Connection stop
javax.jms.Connection setClientID
```

This method restriction is enforced in IBM WebSphere Application Server by throwing a javax.jms.IllegalStateException.

- Applications refer to JMS resources that are predefined, as administered objects, to WebSphere Application Server.

  Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support. An enterprise application can retrieve these objects from the JNDI namespace and use them without needing to know anything about their implementation. This enables the underlying messaging architecture defined by the JMS resources to be changed without requiring changes to the enterprise application. When designing an enterprise application, you need to identify the details of the following types of JMS resources:

Point-to-Point	Publish/Subscribe
ConnectionFactory (or QueueConnectionFactory) Queue	ConnectionFactory (or TopicConnectionFactory) Topic

  A connection factory is used to create connections from the JMS provider to the messaging system, and encapsulates the configuration parameters needed to create connections.

  For more information about the properties of these JMS resources, see Configuring JMS provider resources.

- The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

- Applications can cache JMS connections, sessions, and producers or consumers. Due to the pooling mentioned above this may not give as much of a performance improvement as you might expect.

  You *must not* cache session handles in stateless session beans that operate in transactions started by a client of the bean. Caching handles in this way causes the bean to be returned to the pool while the session is still involved in the transaction. Also, you should not cache non-durable subscribers due to the restriction mentioned above.

- A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

- Using durable subscriptions with the default messaging provider. A durable subscription on a JMS topic enables a subscriber to receive a copy of all messages published to that topic, even after periods of time when the subscriber is not connected to the server. Therefore, subscriber applications can operate disconnected from the server for long periods of time, and then reconnect to the server and process messages that were published during their absence. If an application creates a durable subscription, it is added to the runtime list that administrators can display and act on through the administrative console.

Each durable subscription is given a unique identifier, *clientID##subName* where:

clientID
> The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you need to relate durable subscriptions to the associated applications for runtime administration.

subName
> The subscription name used to uniquely identify a durable subscription within a given client identifier.

For durable subscriptions created by message-driven beans, these values are set on the JMS activationSpec. For other durable subscriptions, the client identifier is set on the JMS connection factory, and the subscription name is set by the application on the createDurableSubscriber operation.

To create a durable subscription to a topic, an application uses the createDurableSubscriber operation defined in the JMS API:

```
public TopicSubscriber createDurableSubscriber(Topic topic,
                          java.lang.String subName,
                          java.lang.String messageSelector,
                          boolean noLocal)
                          throws JMSException
```

topic   The name of the JMS topic to subscribe to. This is the name of an object supporting the javax.jms.Topic interfaces, such as found by looking up a suitable JNDI entry.

subName
> The name used to identify this subscription.

messageSelector
> Only messages with properties matching the message selector expression are delivered to consumers. A value of null or an empty string indicates that all messages should be delivered.

noLocal
> If set to true, this prevents the delivery of messages published on the same connection as the durable subscriber.

Applications can use a two argument form of createDurableSubscriber that takes only topic and subName parameters. This alternative call directly invokes the four argument version shown above, but sets messageSelector to null (so all messages are delivered) and sets noLocal to false (so messages published on the connection are delivered). For example, to create a durable subscription to the topic called myTopic, with the subscription name of mySubscription:

```
session.createDurableSubscriber(myTopic,"mySubscription");
```

If the createDurableSubscription operation fails, it throws a JMS exception that provides a message and linked exception to give more detail about the cause of the problem.

To delete a durable subscription, an application uses the unsubscribe operation defined in the JMS API

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, the subscriber application can be running in a cloned application server, for failover and load balancing purposes. In this case the "one active subscriber" restriction is lifted to provide a shared durable subscription that can have multiple simultaneous consumers.

For more information about application use of durable subscriptions, see the section "Using Durable Subscriptions" in the JMS specification.

- Decide what message selectors are needed. You can use the JMS message selector mechanism to select a subset of the messages on a queue so that this subset is returned by a receive call. The selector can refer to fields in the JMS message header and fields in the message properties.

- Acting on messages received. When a message is received, you can act on it as needed by the business logic of the application. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

  In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

  ```
      if ( inMessage instanceof TextMessage )
  ```

  ```
  ...
          String replyString = ((TextMessage) inMessage).getText();
  ```

- JMS applications using the default messaging provider can access, without any restrictions, the content of messages that have been received from WebSphere Application Server Version 5 embedded messaging or WebSphere MQ.

- JMS applications can access the full set of JMS_IBM* properties. These properties are of value to JMS applications that use resources provided by the default messaging provider, the V5 default messaging provider, or the WebSphere MQ provider.

  For messages handled by WebSphere MQ, the JMS_IBM* properties are mapped to equivalent WebSphere MQ Message Descriptor (MQMD) fields. For more information about the JMS_IBM* properties and MQMD fields, see the *WebSphere MQ: Using Java* book, SC34-6066.

- JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages. JMS applications can request a full range of report options using JMS_IBM_Report_Xxxx message properties. For more information about using JMS report messages, see "JMS report messages" on page 829.

- JMS applications can use the JMS_IBM_Report_Discard_Msg property to control how a request message is disposed of if it cannot be delivered to the destination queue.

MQRO_Dead_Letter_Queue
> This is the default. The request message should be written to the dead letter queue.

MQRO_Discard
> The request message should be discarded. This is usually used in conjunction with MQRO_Exception_With_Full_Data to return an undeliverable request message to its sender.

- Using a listener to receive messages asynchronously. In a client, not in a servlet or enterprise bean, an alternative to making calls to QueueReceiver.receive() is to register a method that is called automatically when a suitable message is available; for example:

```
...
MyClass listener =new MyClass();
queueReceiver.setMessageListener(listener);
//application continues with other application-specific behavior.
...
```

When a message is available, it is retrieved by the onMessage() method on the listener object.

```
import javax.jms.*;
public class MyClass implements MessageListener
{
public void onMessage(Message message)
{
System.out.println("message is "+message);
//application specific processing here
```

```
   ...

   }
}
```

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to receive() methods. To cope with this situation, you can register an ExceptionListener, which is an instance of a class that implements the onException()method. When an error occurs, this method is called with the JMSException passed as its only parameter.

For more details about using listeners to receive messages asynchronously, see the Java Message Service Documentation.

Note: An alternative to developing your own JMS listener class, you can use a message-driven bean, as described in Programming with message-driven beans.

- If you want to use authentication with WebSphere MQ or the Version 5 Embedded Messaging support, you cannot have user IDs longer than 12 characters. For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere internal messaging, because it contains 13 characters.
- The following points, as defined in the EJB specification, apply to the use of flags on create*xxx*Session calls:
  – The transacted flag passed on create*xxx*Session is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
  – Clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.
- If you want your application to use WebSphere MQ as an external JMS provider, then send messages within a container-managed transaction.

  When you use WebSphere MQ as an external JMS provider, messages sent within a user-managed transaction can arrive before the transaction commits. This occurs only when you use WebSphere MQ as an external JMS provider, and you send messages to a WebSphere MQ queue within a user-managed transaction. The message arrives on the destination queue before the transaction commits.

  The cause of this problem is that the WebSphere MQ resource manager has not been enlisted in the user-managed transaction.

  The solution is to use a container-managed transaction.

The effect of transaction context on non-durable subscribers:

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. A non-durable subscriber is invalidated whenever a sharing boundary (in general, a local or global transaction boundary) is crossed, resulting in a javax.jms.IllegalStateException with message text `Non-durable subscriber invalidated on transaction boundary`.

For example, in the following scenario the non-durable subscriber is invalidated at the begin user transaction. This is because the local transaction context in which the subscriber was created ends when the user transaction begins:

```
...
create subscriber
...
```

```
begin user transaction -
...
complete user transaction -
...
use subscriber
...
```

If you want to cache a subscriber (to wait to receive messages that arrived since it was created), then use a durable subscriber (for which this restriction does not apply). Do not cache non-durable subscribers.

JMS report messages:

JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages.

JMS applications can request the following types of report message by setting appropriate JMS_IBM_Report_Xxxx message properties and options. The options have the same general syntax and meaning:

MQRO_*report-type*
> A report message of the indicated type is generated that contains the MQMD of the original message. It does not contain any message body data.

MQRO_*report-type*_**WITH_DATA**
> A report message of the indicated type is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

MQRO_*report-type*_**WITH_FULL_DATA**
> A report message of the indicated type is generated that contains all data from the original message.

For example, to request a COD report message with full data, the JMS application must set JMS_IBM_Report_COD to the value MQRO_COD_WITH_FULL_DATA.

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Exception	Send a report message if the request message cannot be put to the target queue. The exception report messages are generated when a message has been rerouted to an exception destination.	JMS_IBM_Report_Exception • MQRO_EXCEPTION • MQRO_EXCEPTION_WITH_DATA • MQRO_EXCEPTION_WITH_FULL_DATA
Expiration	Send a report message if the request message passes its expiry time.	JMS_IBM_Report_Expiration • MQRO_EXPIRATION • MQRO_EXPIRATION_WITH_DATA • MQRO_EXPIRATION_WITH_FULL_DATA

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Confirm on arrival (COA)	Send a report message when the request message has been put to the target queue. For publish/subscribe messaging, the COA report message is generated only on the producers messaging engine. Therefore, such reports are relevant only to local subscriptions. For point-to-point messaging, COA messages are generated when the message arrives at the final destination. For partitioned queues, the report message is generated only when the put operation has committed and a final destination has therefore been selected. Any With_Data or With_Full_Data report options specified are ignored; the COA report message deals only with message headers. If a forward-routing path is used, the COA message are generated when the message arrives at the final destination in the path.	JMS_IBM_Report_COA • MQRO_COA • MQRO_COA_WITH_DATA • MQRO_COA_WITH_FULL_DATA
Confirm on delivery (COD)	Send a report message when the request message has been removed from the queue or topic space by a message consumer. For publish/subscribe messaging, the COD message is generated when all subscribers have received the request message. Therefore, there is one COD message generated for every COA. When a message is consumed by a subscriber, the reference count of the message on the topic space is reduced. When the reference count reaches zero, the message is removed from the topic space then a COD report message is generated. For point-to-point messaging, the COD message is generated after the message has been successfully received by a consuming application. Any With_Data or With_Full_Data report options specified are ignored; the COD report message deals only with message headers.	JMS_IBM_Report_COD • MQRO_COD • MQRO_COD_WITH_DATA • MQRO_COD_WITH_FULL_DATA
Positive action notification (PAN)	Ask the consumer application to send a report message when it has successfully processed the request message.	JMS_IBM_Report_PAN • MQRO_PAN
Negative action notification (NAN)	Ask the consumer application to send a report message if it has not successfully processed the request message.	JMS_IBM_Report_NAN • MQRO_NAN

The requesting application can control other aspects of the report message as follows:

• How the message Id is generated for the report message and any reply message:

MQRO_New_Msg_Id
    This the default. A new message Id is generated for the report message.

MQRO_Pass_Msg_Id

The message Id of the report message is set to the message Id of the request message.

- How the correlation Id of the report or reply message is to be set.

MQRO_Copy_Msg_Id_To_Correl_Id

This the default. the correlation Id of the report message is set to the message Id of the request message.

MQRO_Pass_Correl_Id

The correlation Id of the report message is set to the correlation Id of the request message.

For more information about report messages and the associated properties and options, see the *WebSphere MQ: Using Java* book, SC34-6066.

Developing a J2EE application to use JMS:

Use this task to develop a J2EE application to use the JMS API directly for asynchronous messaging.

This topic gives an overview of the steps needed to develop a J2EE application (servlet or enterprise bean) to use the JMS API directly for asynchronous messaging.

This topic only describes the JMS-related considerations; it does not describe general J2EE application programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing a J2EE application to use JMS, see the Java Message Service Documentation

Details of JMS resources that are used by J2EE applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support.

To use JMS, any method of a J2EE application completes the following general steps:

1. Import JMS packages. A J2EE application that uses JMS starts with a number of import statements for JMS, which should include at least the following:

```
import javax.jms.*;        //JMS interfaces
import javax.naming.*;     //Used for JNDI lookup of administered objects
```

2. Get an initial context.

```
    try    {
        ctx = new InitialContext(env);
...
```

3. Retrieve administered objects from the JNDI namespace. The InitialContext.lookup() method is used to retrieve administered objects (a JMS connection factory and JMS destinations); for example, to receive a message from a queue

```
        qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
        inQueue = (Queue)ctx.lookup( qnameIn );
...
```

An alternative, but less manageable, approach to obtaining administratively-defined JMS destination objects by JNDI lookup is to use the Session.createQueue(String) method or Session.createTopic(String) method. For example,

```
Queue q = mySession.createQueue("Q1");
```

creates a JMS Queue instance that can be used to reference the existing destination Q1.

In its simplest form, the parameter to these create methods is the name of an existing destination. For more complex situations, applications can use a URI-based format, which allows an arbitrary number of name value pairs to be supplied to set various properties of the JMS destination object.

4. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The createQueueConnection() method on the factory object is used to create the connection.

```
            connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, MessageConsumers that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
            connection.start();
```

5. Create a session, for sending or receiving messages. The session provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers. The createQueueSession method is used on the connection to obtain a session. The method takes two parameters:

   • A boolean that determines whether or not the session is transacted.
   • A parameter that determines the acknowledge mode.

```
            boolean transacted = false;
            session = connection.createQueueSession( transacted,
                                                Session.AUTO_ACKNOWLEDGE);
```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the application terminates unexpectedly.

The following points, as defined in the EJB specification, apply to these flags:

   • The transacted flag passed on createQueueSession is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
   • Clients cannot use Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

6. Send a message.

   a. Create MessageProducers to create messages. For point-to-point messaging the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

```
            QueueSender queueSender = session.createSender(inQueue);
```

   b. Create the message. Use the session to create an empty message and add the data passed.

      JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

      In this example, a text message is created from the outString property:

```
            TextMessage outMessage = session.createTextMessage(outString);
```

   c. Send the message.

      To send the message, the message is passed to the send method on the QueueSender:

```
            queueSender.send(outMessage);
```

7. Receive replies.

   a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

```
            messageID = outMessage.getJMSMessageID();
```

      The correlation ID is then used in a message selector, to select only messages that have that ID:

```
            String selector = "JMSCorrelationID = '"+messageID+"'";
```

b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait()method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, it is necessary to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
if ( inMessage instanceof TextMessage )

...
        String replyString = ((TextMessage) inMessage).getText();
```

8. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.

```
        queueReceiver.close();
...
        queueSender.close();
...
        session.close();
        session = null;
...
        connection.close();
        connection = null;
```

9. Publishing and subscribing to messages. To use JMS Publish/Subscribe support instead of point-to-point messaging, the general actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```
// Creating a TopicPublisher
        TopicPublisher pub = session.createPublisher(topic);
...
        pub.publish(outMessage);
...
        // Closing TopicPublisher
        pub.close();
```

10. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a JMSException can contain another exception embedded in it. The implementation of JMSException does not include the embedded exception in the output of its toString()method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSException je)
{
    System.out.println("JMS failed with "+je);
    Exception le = je.getLinkedException();
    if (le != null)
    {
        System.out.println("linked exception "+le);
    }
}
```

After you have packaged your application, you can next deploy the application into WebSphere Application Server, as described in Deploying a J2EE application to use JMS.

Developing a JMS client:

Use this task to develop a JMS client application to use messages to communicate with enterprise applications.

This topic gives an overview of the steps needed to develop a JMS client application. This topic only describes the JMS-related considerations; it does not describe general client programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing JMS clients, see the Java Message Service Documentation and the WebSphere MQ *Using Java* book, SC34-5456.

A JMS client assumes that the JMS resources (such as a queue connection factory and queue destination) already exist. A client application can use JMS resources administered by the application server or administered by the client container regardless of whether the client application is running on the same machine as the server or remotely.

For more information about developing client applications and configuring JMS resources for them, see Developing J2EE application client code and related tasks.

To use JMS, a typical JMS client program completes the following general steps:

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS; for example:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import javax.jms.*;
```

2. Get an initial context.

```
    try    {
        ctx = new InitialContext(env);
...
```

3. Define the parameters that the client wants to use; for example, to identify the queue connection factory and to assemble a message to be sent.

```
public class JMSppSampleClient
{
  public static void main(String[] args)
  throws JMSException, Exception

  {
    String  messageID              = null;
    String  outString              = null;
    String  qcfName                = "java:comp/env/jms/ConnectionFactory";
```

```
String  qnameIn                 = "java:comp/env/jms/Q1";
String  qnameOut                = "java:comp/env/jms/Q2";
boolean verbose                 = false;

QueueSession            session    = null;
QueueConnection         connection = null;
Context                 ctx        = null;

QueueConnectionFactory qcf        = null;
Queue                   inQueue    = null;
Queue                   outQueue   = null;
```

...

4. Retrieve administered objects from the JNDI namespace. The InitialContext.lookup() method is used to retrieve administered objects (a queue connection factory and the queue destinations):

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
```

...

```
inQueue = (Queue)ctx.lookup( qnameIn );
outQueue = (Queue)ctx.lookup( qnameOut );
```

...

5. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The createQueueConnection() method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, MessageConsumers that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

6. Create a session, for sending and receiving messages. The session provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers. The createQueueSession method is used on the connection to obtain a session. The method takes two parameters:
   • A boolean that determines whether or not the session is transacted.
   • A parameter that determines the acknowledge mode.

```
boolean transacted = false;
session = connection.createQueueSession( transacted,
                                   Session.AUTO_ACKNOWLEDGE);
```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the client application terminates unexpectedly.

7. Send the message.
   a. Create MessageProducers to create messages. For point-to-point the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

   ```
   QueueSender queueSender = session.createSender(inQueue);
   ```

   b. Create the message. Use the session to create an empty message and add the data passed.

   JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

   In this example, a text message is created from the outString property, which could be provided as an input parameter on invocation of the client program or constructed in some other way:

   ```
   TextMessage outMessage = session.createTextMessage(outString);
   ```

   c. Send the message.

   To send the message, the message is passed to the send method on the QueueSender:

```
        queueSender.send(outMessage);
```
8. Receive replies.
    a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.
```
        messageID = outMessage.getJMSMessageID();
```
    The correlation ID is then used in a message selector, to select only messages that have that ID:
```
        String selector = "JMSCorrelationID = '"+messageID+"'";
```
    b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.
```
        QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```
    c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:
```
        Message inMessage = queueReceiver.receive(2000);
```
    The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait()method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

    d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

    In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.
```
        if ( inMessage instanceof TextMessage )

    ...
            String replyString = ((TextMessage) inMessage).getText();
```
9. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.
```
        queueReceiver.close();
...
        queueSender.close();
...
        session.close();
        session = null;
...
        connection.close();
        connection = null;
```
10. Publishing and subscribing messages. To use publish/subscribe support instead of point-to-point messaging, the general client actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:
```
// Creating a TopicPublisher
        TopicPublisher pub = session.createPublisher(topic);
    ...
```

```
        pub.publish(outMessage);
...
        // Closing TopicPublisher
        pub.close();
```

11. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

    Unlike normal Java exceptions, a JMSException can contain another exception embedded in it. The implementation of JMSException does not include the embedded exception in the output of its toString()method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

    ```
    catch (JMSException je)
    {
      System.out.println("JMS failed with "+je);
      Exception le = je.getLinkedException();
      if (le != null)
      {
          System.out.println("linked exception "+le);
      }
    }
    ```

For information about running a client against a specific remote server: "Running application clients" on page 332.

Deploying a J2EE application to use JMS:

This topic describes how to deploy a J2EE application to use JMS.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for JMS, that can be deployed in WebSphere Application Server.

To deploy a J2EE application to use JMS, complete the following steps:

1. Configure the deployment attributes for the application, as described in Assembling applications.

2. Use the WebSphere administrative console to install the application.

   This stage is a standard WebSphere Application Server task, as described in Installing applications.

Programming to use message-driven beans

Applications can use message-driven beans (a type of enterprise bean defined in the EJB specification) as asynchronous message consumers.

A client sends messages to the destination (or *endpoint*) for which the message-driven bean is deployed as the message listener. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination. The message-driven bean implements some business logic to process incoming messages on the destination.

EJB 2.0 message-driven beans support only Java Message Service (JMS) messaging. EJB 2.1 message-driven beans can handle other messaging types in addition to JMS. The message-driven bean class must implement the message listener interface for the messaging type that the message-driven bean handles. For example, an EJB 2.1 message-driven bean class used for JMS messaging must implement the javax.jms.MessageListener interface.

You can use Rational Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, like the administrative console, to deploy and administer applications that use message-driven beans.

If you are developing message-driven bean applications for use with WebSphere MQ as an external JMS provider, you must write them so that they consume each message before the maximum retry limit is

reached. If you do not do this, the listener port stops when the maximum retry limit is reached for any given message. It then becomes necessary to manually remove the message from the WebSphere MQ queue.

For more information about implementing WebSphere enterprise applications that use message-drive beans, see the following topics:
- Designing an enterprise application to use a message-driven bean
- Developing an enterprise application to use a message-driven bean
- Deploying an enterprise application to use a message-driven bean

Designing an enterprise application to use message-driven beans:

This topic describes things to consider when designing an enterprise application to use message-driven beans.

The considerations in this topic are based on a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination and passes the messages on to another enterprise bean that implements the business logic.

To design an enterprise application to use message-driven beans, complete the following steps:

1. Identify the message listener interface for the message type that the message-driven beans is to handle. The message-driven bean class must implement this message listener interface. For example, an EJB 2.1 message-driven bean class used for JMS messaging must implement the javax.jms.MessageListener interface.

2. **Optional:** If you want to handle messages at a scheduled date and time, or after a specified interval has elapsed, identify the schedule values and the business logic that you want to react to time-based messages. A message-driven bean can be registered with the EJB timer service for time-based event notifications. When a message arrives on the destination, a message-driven bean timer is initiated. When the timer expires, a message-driven bean is selected to process the ejbTimeout() method, which implements the business logic that is to process the message.

3. Identify the resources that the application is to use. This helps to identify the properties of resources that need to be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

JMS resource type	Properties (for example)
JMS connection factory	**Name:** SamplePtoPQueueConnectionFactory **JNDI Name:** Sample/JMS/QCF
JMS destination	**Name:** Q1 **JNDI Name:** Sample/JMS/Q1
J2C activation specification properties	**Name:** MyMDBsActivationSpec **JNDI Name:** eis/MyMDBsActivationSpec **Destination JNDI Name:** MyQueue **Destination type:** javax.jms.Queue
Message-driven bean (deployment properties)	**Name:** JMSppSampleMDBBean **Transaction type:** Container **Message selector:** JMSType='car' **Acknowledge mode:** Dups OK Acknowledge **Destination type:** javax.jms.Queue **ActivationSpec JNDI name:** MyMDBsActivationSpec
Business logic bean	**Name:** MyLogicBean

Ensure that you use consistent values where needed; for example, the JNDI name for the J2C activation specification must be the same in both the activation specification and the Message-driven bean's deployment properties.

4. Separation of business logic. You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

5. Security considerations. Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.

6. Topic durability considerations. A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

7. Discarding of best-effort non-persistent messages with the default messaging provider. If you configure a JMS destination (queue or topic) to use the default messaging provider, you can configure the maximum reliability of messages on the bus destination to which the JMS destination is assigned.For non-transactional JMS message-driven beans and MessageListeners that use a JMS destination configured on the default messaging provider, best-effort nonpersistent messages are not recoverable. In this case, if a message is unlocked because the message-driven bean or MessageListener threw an exception, then the message is not redelivered or sent to the exception destination because it was deleted from the message store when it was passed to the listener. If you want better message reliability for non-transactional JMS message-driven beans and MessageListeners, you should configure a different option for the Maximum reliability property of the bus destination.

Developing an enterprise application to use message-driven beans:

Use this task to develop an enterprise application to use a message-driven bean. The message-driven bean is invoked by a J2C activation specification or a JMS listener when a message arrives on the input destination that the listener is monitoring.

You are recommended to develop the message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or handled in the message-driven bean.

You develop an enterprise application to use a message-driven bean like any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

For more information about writing the message-driven bean class, see *Creating a message-driven bean* in the Rational Application Developer help bookshelf.

To develop an enterprise application to use a message-driven bean, complete the following steps:
1. Create the Enterprise Application project.
2. Create the message-driven bean class.

   You can use the New Enterprise Bean wizard of Rational Application Developer to create an enterprise bean with a bean type of Message-driven bean. The wizard creates appropriate methods for the type of bean.

   By convention, the message bean class is named *name*Bean, where *name* is the name you assign to the message bean; for example:

   ```
   public class MyJMSppMDBBean implements MessageDrivenBean, javax.jms.MessageListener
   ```

All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface, javax.jms.MessageListener. Other JCA-compliant Resource Adapters may provide their own message listener interface that needs to be implemented.

A message-driven bean can be registered with the EJB timer service for time-based event notifications if it also implements the javax.ejb.TimedObject interface and the timer callback method void ejbTimeout(Timer). At the scheduled time, the container invokes the message-driven bean's ejbTimeout method.

The message-driven bean class must define and implement the following methods:
- onMessage(message), which must meet the following requirements:
    - The method must have a single argument of type `javax.jms.Message`.
    - The throws clause must *not* define any application exceptions.
    - If the message-driven bean is configured to use bean-managed transactions, it must call the javax.transaction.UserTransaction interface to scope the transactions. Because these calls occur inside the onMessage() method, the transaction scope does not include the initial message receipt. This means the application server is given one attempt to process the message.

    To handle the message within the onMessage() method (for example, to pass the message on to another enterprise bean), you use standard JMS. (This is known as bean-managed messaging.)

    If you are using a JCA-compliant Resource Adapter with a different message listener interface, another method besides onMessage() may be needed. For information about the message listener interface needed, see the documentation that was provided with your JCA Resource Adapter.
- ejbCreate()

    You must define and implement an ejbCreate method for each way in which you want a new instance of an enterprise bean to be created.
- ejbRemove()

    This method is invoked by the container when a client invokes the remove method inherited by the enterprise bean's home interface from the javax.ejb.EJBHome interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).
- ejbTimeout(Timer)

    This method is needed only to support notifications from the timer service, and contains the business logic that handles time events received.

For example, the following code extract shows how to access the text and the JMS MessageID, from a JMS message of type TextMessage:

```
public void onMessage(javax.jms.Message msg)
{
        String text     = null;
        String messageID = null;

        try
        {
                text = ((TextMessage)msg).getText();

                System.out.println("senderBean.onMessage(), msg text2: "+text);

                //
                // store the message id to use as the Correlator value
                //
                messageID = msg.getJMSMessageID();

                // Call a private method to put the message onto another queue
                putMessage(messageID, text);
        }
        catch  (Exception err)
        {
                err.printStackTrace();
        }
        return;
}
```

Figure 12. Code example: The onMessage() method of a message bean. This figure shows a code extract for a basic onMessage() method of a sample message-driven bean. The method unpacks the incoming text message to extract the text and message identifier and calls a private putMessage method (defined within the same message bean class) to put the message onto another queue.

The result of this step is a message-driven bean that can be assembled into an EAR file for deployment.

3. **Optional:** Use the EJB deployment descriptor editor to review and, if needed, change the deployment properties. You can use the EJB deployment descriptor editor to review deployment properties that you specified on the EJB Creation Wizard (like Transaction type and Message selector) and other default deployment properties.

   If needed, you can override the values of these properties later, after the enterprise application has been exported into an EAR file for deployment.

   a. In the property pane, select the Beans tab.

   b. Specify general deployment properties.
      Transaction type
         Whether the message bean manages its own transactions or the container manages transactions on behalf of the bean. All messages retrieved from a specific destination have the same transactional behavior. To enable the transactional behavior that you want, you must configure the JMS destination with the same transactional behavior as you configure for the message bean.
         Bean   The message bean manages its own transactions
         Container
            The container manages transactions on behalf of the bean

   c. Specify advanced deployment properties.

      Under Activation Configuration, review the following properties:
      Acknowledge mode
         How the session acknowledges any messages it receives.

         This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to Bean).

Auto Acknowledge

The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

As defined in the EJB specification, clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

Destination type

Whether the message bean uses a queue or topic destination.

Queue

The message bean uses a queue destination.

Topic The message bean uses a topic destination.

Durability

Whether a JMS topic subscription is durable or non-durable.

Durable

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

Nondurable

Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

Message selector

The JMS message selector to be used to determine which messages the message bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

For more details about these properties, see "Message-driven bean deployment descriptor properties" on page 843.

d. Specify bindings deployment properties.

Under WebSphere Bindings, select the JCA Adapter option then specify the bindings deployment properties:

ActivationSpec JNDI name

Type the JNDI name of the J2C activation specification that is to be used to deploy this message-driven bean. This name must match the name of a J2C activation specification that you define to WebSphere Application Server.

ActivationSpec Authorization Alias

The name of a J2C authentication alias used for authentication of connections to the JCA resource adapter. A J2C authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

Destination JNDI name

Type the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI name space.

4. Assemble and package the application for deployment.

The result of this task is an EAR file, containing the message-driven bean, for the enterprise application that can be deployed in WebSphere Application Server.

After you have developed an enterprise application to use message-driven beans, configure and deploy the application; for example, define J2C activation specifications for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information about configuring and deploying an application that uses message-driven beans, see Deploying an enterprise application to use message-driven beans

Message-driven bean deployment descriptor properties:

Here are the deployment descriptor properties that are used for message-driven beans.

Transaction type

Whether the message-driven bean manages its own transactions or the container manages transactions on behalf of the bean. All messages retrieved from a specific destination have the same transactional behavior. To enable the transactional behavior that you want, you must configure the JMS destination with the same transactional behavior as you configure for the message-driven bean.

Bean The message-driven bean manages its own transactions

Container

The container manages transactions on behalf of the bean

Message selector

The JMS message selector to be used to determine which messages the message-driven bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

Acknowledge mode

How the session acknowledges any messages it receives.

This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to Bean).

Auto Acknowledge

The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

Dups OK Acknowledge

The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

As defined in the EJB specification, clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

Destination type

Whether the message-driven bean uses a queue or topic destination.

Queue

The message-driven bean uses a queue destination.

Topic The message-driven bean uses a topic destination.

Subscription durability

> Whether a JMS topic subscription is durable or nondurable.
>
> **Durable**
>
> > A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.
>
> **Nondurable**
>
> > Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.
> >
> > A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

ActivationSpec name

> Type the JNDI name of the J2C activation specification that is to be used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

Deploying an enterprise application to use message-driven beans against JCA 1.5-compliant resources:

Use this task to deploy an enterprise application to use EJB 2.1 or EJB 2.0 message-driven beans for use with a JCA 1.5-compliant resource adapter.

Message-driven beans can be configured as listeners on a Java Connector Architecture (JCA) 1.5 resource adapter, such as the default messaging provider in WebSphere Application Server.

You deploy EJB 2.1 message-driven beans against JCA 1.5-compliant resources, and configure the resources as deployment descriptor properties. Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server version 5), you are recommended to deploy such beans against JCA 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for message-driven beans, that can be deployed to use the default messaging provider in WebSphere Application Server.

To deploy an enterprise application to use message-driven beans against JCA 1.5-compliant resources, complete the following steps:

1. For each message-driven bean in the application, configure a J2C activation specification.

   For example, for a message-driven bean to listen on a JMS destination of the default messaging provider, see Configuring a JMS activation specification.

2. For each message-driven bean in the application, configure the J2C deployment attributes, as described in Configuring deployment attributes.

3. Use the WebSphere administrative console to install the application.

   This stage is a standard WebSphere Application Server task, as described in Installing a new application.

Configuring deployment properties for a JCA 1.5-compliant message-driven bean:

Use this task to configure the message-driven bean deployment properties for a JCA 1.5-compliant enterprise bean, to override the deployment properties defined within the application EAR file.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.

This topic describes the use of the Application Server Toolkit (AST) to configure the deployment attributes of an application that is to use message-driven beans against JCA 1.5-compliant resources. If you want to configure the deployment attributes for a message-driven bean against a listener port, see "Configuring deployment attributes for an EJB 2.0 message-driven bean against a listener port" on page 849.

This task description assumes that you have an EAR file, which contains an application enterprise bean developed as a message-driven bean, that can be deployed in WebSphere Application Server. For more details about assembling applications, see assembling applications.

1. Start an assembly tool. See "Starting WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.

2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the assembly tool. To start the import wizard:

   a. Click **File-> Import-> EAR file**

   b. Click **Next**, then select the EAR file.

   c. Click **Finish**

3. In the J2EE Hierarchy view, right-click the EJB module for the message-driven bean , then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.

4. Use the EJB deployment descriptor editor to review and, if needed, change the deployment properties.

   a. In the property pane, select the Beans tab.

   b. Under Activation Configuration, review the following properties:
   Acknowledge mode
   > How the session acknowledges any messages it receives.
   >
   > This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to Bean).
   > **Auto Acknowledge**
   > > The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.
   >
   > **Dups OK Acknowledge**
   > > The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.
   >
   > As defined in the EJB specification, clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

   Destination type
   > Whether the message bean uses a queue or topic destination.
   > **Queue**
   > > The message bean uses a queue destination.
   > **Topic** The message bean uses a topic destination.

   Durability
   > Whether a JMS topic subscription is durable or non-durable.
   > **Durable**
   > > A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the

subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

Nondurable

Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

Message selector

The JMS message selector to be used to determine which messages the message bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

For more details about these properties, see "Message-driven bean deployment descriptor properties" on page 843.

c. Under WebSphere Bindings, select the JCA Adapter option then specify the bindings deployment properties:

ActivationSpec JNDI name

Type the JNDI name of the J2C activation specification that is to be used to deploy this message-driven bean. This name must match the name of a J2C activation specification that you define to WebSphere Application Server.

ActivationSpec Authorization Alias

The name of a J2C authentication alias used for authentication of connections to the JCA resource adapter. A J2C authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

Destination JNDI name

Type the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI name space.

5. Save your changes to the deployment descriptor.

   a. Close the deployment descriptor editor.

   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

6. Verify the archive files with an assembly tool.

7. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

8. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Web Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

Important: Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Web Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

Configuring security for EJB 2.1 message-driven beans:

Use this task to configure resource security and security permissions for Enterprise JavaBeans (EJB) Version 2.1 message-driven beans.

The association between connection factories, destinations, and message-driven beans is provided by listener ports. A listener port allows a deployed message-driven bean associated with the port to retrieve messages from the associated destination. You create listener ports by specifying their administrative name, the connection factory JNDI name, and the destination name (other optional properties are also configurable). Listener ports provide simplified administration of the associations between connection factories, destinations and message-driven beans, and are managed by a listener manager. The listener manager is provided by the message listener service to control and monitor the JMS listeners that are monitoring JMS destinations on behalf of deployed message-driven beans. For more information about listener ports, see Message-driven beans - listener port components

Messages handled by message-driven beans have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see EJB component security. For more information about configuring security for your application, see Assembling secured applications.

Connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define an authentication alias on the J2C activation specification that the message-driven bean is configured with. If defined, the message-driven bean uses the authentication alias for its JMSConnection security credentials instead of any application-managed alias.

To set the authentication alias, you can use the administrative console to complete the following steps. This task description assumes that you have already created an activation specification. If you want to create a new activation specification, see the related tasks.

- For a message-driven bean listening on a JMS destination of the default messaging provider, set the authentication alias on a JMS activation specification.
  1. To display the JMS activation specification settings, click **Resources** → **JMS Providers** → **Default messaging** → **[Activation Specifications] JMS activation specification**
  2. If you have already created a JMS activation specification, click its name in the list displayed. Otherwise, click **New** to create a new JMS activation specification.
  3. Set the **Authentication alias** property.
  4. Click **OK**
  5. Save your changes to the master configuration.
- For a message-driven bean listening on a destination (or endpoint) of another JCA provider, set the authentication alias on a J2C activation specification.
  1. To display the J2C activation specification settings, click **Resources** → **Resource Adapters** → **adapter_name** → **J2C Activation specifications** → **activation specification_name**
  2. Set the **Authentication alias** property.
  3. Click **OK**

4. Save your changes to the master configuration.

Throttling of inbound message flow for JCA 1.5 message-driven beans:

This topic describes how to throttle message delivery for message-driven beans (MDB) which are deployed as message endpoints for J2EE Connector Architecture (JCA) Version 1.5 inbound resource adapters.

For installations that use resource adapters that implement the J2EE Connector Architecture (JCA) Version 1.5 message delivery support, the WebSphere Application Server provides message throttling support to control the delivery of messages to endpoint message-driven beans (MDB). You can use this support to avoid overloading the server with a flood of inbound messages, except in the following two cases:

- The default messaging provider (the SIB JMS Resource Adapter) uses a special type of message throttling. You should not use the JCA 1.5 throttling of messages, described in this topic, for message-driven beans that you have deployed as JCA 1.5 resources on the default messaging provider. You can leave the message-driven bean pools to the default size of 500. For more information about the message throttling support of the default messaging provider (the SIB JMS Resource Adapter), see the related tasks.
- If you want to throttle message delivery for a message-driven bean deployed on a JMS provider that does not have a JCA 1.5 resource adapter (such as the V5 Default Messaging and WebSphere MQ) you can configure message throttling support as described in the related tasks.

Message delivery is throttled on an message-driven bean basis by limiting the maximum number of endpoint instances that can be created by the adapter that the MDB is bound to. When the adapter attempts to create an endpoint instance, a proxy for the MDB instance is created and returned as allowed by the JCA 1.5 architecture. There is a one-to-one correspondence between proxies and MDB instances, and like the MDB instances, the proxies are pooled based on the minimum and maximum pool size values associated with the message-driven bean. Throttling is performed through the management of the proxy pool.

At the time the adapter attempts to create an endpoint, if the number of endpoint proxies currently created is equal to the maximum size of the pool, adapter *createEndPoint* processing returns an Unavailable Exception. When this happens, the adapter is not allowed to issue any more *createEndPoint()* requests until it has released at least one endpoint back to the server for reuse. Installations can thus control the throttling of message delivery to a JCA 1.5 MDB based on the setting of the maximum size of the pool associated with each JCA 1.5 message-driven bean.

You can specify the poolsize by using the *com.ibm.websphere.ejbcontainer.poolsize jvm* System property to define the minimum and maximum poolsize of stateless, message-driven, and entity beans. In the case of an message-driven bean that supports JCA 1.5, the maximum poolsize value specified limits how many message endpoint instances can be created for that message-driven bean. For example, if the installation sets the maximum size of a JCA 1.5 MDB pool to 5, then at most 5 messages can be concurrently delivered to 5 instances of the message-driven bean. This property can be specified using command-line scripting (see EJB container system properties) or by specifying it under the Administrative Console as an environmental variable.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. Under Server Infrastructure, expand **Java and Process Management**.
6. Select **Process Definition**.
7. Select**Servant**.
8. Under Additional Properties, select **Java Virtual Machine**.

9. Under Additional Properties, select **Custom Properties**.

10. Select **New**. A panel with three General Properties fields appears. This is where you set the property.

11. In the Name field, enter **com.ibm.websphere.ejbcontainer.poolsize**.

12. To fill in the Value field, refer to EJB container system properties for possible values.

13. After defining the value of the property, select **OK**. You are now prompted to save the changes you have just made.

14. Select **Save**.

Deploying an enterprise application to use EJB 2.0 message-driven beans with listener ports:

Use this task to deploy an enterprise application to use EJB 2.0 message-driven beans with listener ports.

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server version 5), you are recommended to deploy such beans as JCA 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for EJB 2.0 message-driven beans, that can be deployed in WebSphere Application Server.

To deploy an enterprise application to use EJB 2.0 message-driven beans with listener ports, complete the following steps:

1. Use the WebSphere administrative console to define the listener ports for the application, as described in Adding a new listener port.

2. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions, as described in Configuring deployment attributes.

3. Use the WebSphere administrative console to install the application.

   This stage is a standard WebSphere Application Server task, as described in Installing a new application.

   When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

Configuring deployment attributes for an EJB 2.0 message-driven bean against a listener port:

Use this task to configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer.

This topic describes the use of the Application Server Toolkit (AST) to configure the deployment attributes of an application. This task description assumes that you have an EAR file, which contains an application enterprise bean developed as a message-driven bean, that can be deployed in WebSphere Application Server. For more details about assembling applications, see Assembling applications.

To configure the message-driven beans deployment attributes for an enterprise bean, use the assembly tool to configure the deployment attributes of the application to match the listener port definitions:

1. Start an assembly tool.

2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the assembly tool. To start the import wizard:

   a. Click **File-> Import-> EAR file**

   b. Click **Next**, then select the EAR file.

   c. Click **Finish**

3. In the J2EE Hierarchy view, right-click the EJB module for the message-driven bean , then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.

4. Specify general deployment properties.

   a. In the property pane, select the Beans tab.

   b. Specify the following properties:

      Transaction type

      Whether the message bean manages its own transactions or the container manages transactions on behalf of the bean. All messages retrieved from a specific destination have the same transactional behavior. To enable the transactional behavior that you want, you must configure the JMS destination with the same transactional behavior as you configure for the message bean.

      Bean The message bean manages its own transactions

      Container

      The container manages transactions on behalf of the bean

5. Specify advanced deployment properties.

   a. Under Activation Configuration, review the following properties:

      Acknowledge mode

      How the session acknowledges any messages it receives.

      This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to `Bean`).

      Auto Acknowledge

      The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

      Dups OK Acknowledge

      The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

      As defined in the EJB specification, clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

      Destination type

      Whether the message bean uses a queue or topic destination.

      Queue

      The message bean uses a queue destination.

      Topic The message bean uses a topic destination.

      Durability

      Whether a JMS topic subscription is durable or non-durable.

      Durable

      A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

      Nondurable

      Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

      A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed

when the subscriber was created. For more information about this context restriction, see The effect of transaction context on non-durable subscribers.

Message selector

The JMS message selector to be used to determine which messages the message bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

For more details about these properties, see "Message-driven bean deployment descriptor properties" on page 843.

6. Specify bindings deployment properties.

    a. Under WebSphere Bindings, specify the following property:

    Listener port name

    Type the name of the listener port for this message-driven bean.

7. Save your changes to the deployment descriptor.

    a. Close the deployment descriptor editor.

    b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

8. Verify the archive files. See the Application Server Toolkit documentation for more information.

9. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

10. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Application Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

    Important: Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Application Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Deploying and managing applications.

JMS interfaces

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces and domain-specific interfaces as provided for JMS 1.0.2 in WebSphere Application Server.

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as the "common interfaces" in the JMS specification). With JMS 1.1, the preferred approach for implementing applications is to use the common interfaces. The JMS 1.1 common interfaces provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction.

The common interfaces are also parents of domain-specific interfaces. These domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server version 5) are supported only to provide backward compatibility for applications that have already been implemented to use those interfaces.

Common interfaces	point-point interfaces	publish/subscribe interfaces
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection

Common interfaces	point-point interfaces	publish/subscribe interfaces
Destination	Queue	Topic
Session	QueueSession	TopicSession
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about JMS interfaces, see the JMS documentation at http://java.sun.com/products/jms/docs.html.

JMS and WebSphere MQ message structures

You need to consider how the JMS message structure is mapped onto a WebSphere MQ message if you want to transmit messages between JMS applications and traditional WebSphere MQ applications. This includes scenarios where you want to use WebSphere MQ to manipulate messages transmitted between two JMS applications; for example, using WebSphere MQ as a message broker.

By default, JMS messages held on WebSphere MQ queues use an MQRFH2 header to hold some of the JMS message header information. Many traditional WebSphere MQ applications cannot process messages with these headers, and require their own characteristic headers, for example the MQCIH for CICS Bridge, or MQWIH for WebSphere MQ Workflow applications. For more information about how the JMS message structure is mapped onto an WebSphere MQ message, see the section ″Mapping JMS to a native WebSphere MQ application″ in the chapter ″JMS Messages″ of the WebSphere MQ Using Java book.

Mail, URLs, and other J2EE resources

Using mail

Using the JavaMail API, a code segment can be embedded in any Java 2 Enterprise Edition (J2EE) application component, such as an EJB or a servlet, allowing the application to send a message and save a copy of the mail to the Sent folder.

The following is a code sample that you would embed in a J2EE application:

```
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

    javax.mail.Session mail_session = (javax.mail.Session) ctx.lookup("java:comp/env/mail/MailSession3");
    MimeMessage msg = new MimeMessage(mail_session);

    msg.setRecipients(Message.RecipientType.TO, InternetAddress.parse("bob@coldmail.net"));

    msg.setFrom(new InternetAddress("alice@mail.eedge.com"));

    msg.setSubject("Important message from eEdge.com");

    msg.setText(msg_text);

    Transport.send(msg);

    Store store = mail_session.getStore();

    store.connect();

    Folder f = store.getFolder("Sent");
```

```
    if (!f.exists()) f.create(Folder.HOLDS_MESSAGES);

    f.appendMessages(new Message[] {msg});
```

J2EE applications can use JavaMail APIs by looking up references to logically named mail connection factories through the `java:comp/env/mail` subcontext that is declared in the application deployment descriptor and mapped to installation specific mail session resources. As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources.

1. Locate a resource through Java Naming and Directory Interface (JNDI). The J2EE specification considers a mail session instance as a resource, or a factory from which mail transport and store connections can be obtained. Do not hard code mail sessions (namely, fill up a Properties object, then use it to create a javax.mail.Session object). Instead, you must follow the J2EE programming model of configuring resources through the system facilities and then locating them through JNDI lookups.

   In the previous sample code, the line `javax.mail.Session mail_session = (javax.mail.Session)` `ctx.lookup("java:comp/env/mail/MailSession3");` is an example of not hard coding a mail session and using a resource name located through JNDI. You can consider the lookup name, `mail/MailSession3`, as a *soft link* to the real resource.

2. Define resource references while assembling your application. You must define a resource reference for the mail resource in the deployment descriptor of the component, because a mail session is referenced in the JNDI lookup. Typically, you can use an assembly tool shipped with WebSphere Application Server.

   When you create this reference, be sure that the name of the reference matches the name used in the code. For example, the previous code uses `java:comp/env/mail/MailSession3` in its lookup. Therefore the name of this reference must be `mail/Session3`, and the type of the resource must be `javax.mail.Session`. After configuration, the deployment descriptor contains the following entry for the mail resource reference:

   ```
   <resource-reference>
   <description>description</description>
   <res-ref-name>mail/MailSession3</res-ref-name>
   <res-type>javax.mail.Session</res-type>
   <res-auth>Container</res-auth>
   ```

3. Configure mail providers and sessions. The sample code references a mail resource, the deployment descriptor declares the reference, but the resource itself does not exist yet. Now you need to configure the mail resource that is referenced by your application component. Notice that the mail session you configure must have both its transport and mail access portions defined; the former required because the code is sending a message, the latter because it also saves a copy to the local mail store. When you configure the mail session, you need to specify a JNDI name. This is an important name for installing your application and linking up the resource references in your application with the real resources that you configure.

4. Install your application. You can install your application using either the administrative console or the scripting tool. During installation, WebSphere Application Server inspects all resource references and requires you to supply a JNDI name for each of them. This is not an arbitrary JNDI name, but the JNDI name given to a particular, configured resource that is the target of the reference.

5. Manage existing mail providers and sessions. You can update and remove mail providers and sessions.

   To update mail providers and sessions:

   a. Open the administrative console.

   b. Click **Resources** > **Mail** in the console navigation tree.

   c. Select the appropriate Java Mail resource to modify by clicking either **Mail Providers** or **Mail Sessions**.

   d. Select the specific resource to modify. To remove a mail provider or mail session, select the check box next to the appropriate resource and click **Delete**.

e. Click **Apply** or **OK**.

f. Save the configuration.

6. Enable debugger for a mail session.

If your application has a client, you can update mail providers and mail sessions using the Application Client Resource Configuration Tool (ACRCT).

JavaMail API

The JavaMail APIs provide a platform and protocol-independent framework for building Java-based mail client applications.

WebSphere Application Server supports the JavaMail API, Version 1.3, and the JavaBeans Activation Framework (JAF) Version 1.0. In WebSphere Application Server, the JavaMail API is supported in all Web application components, namely:

*   Servlets
*   JavaServer Pages (JSP) files
*   Enterprise beans
*   Application clients

The JavaMail APIs are generic for sending and reading mail. They require service providers, known in WebSphere Application Server as protocol providers, to interact with mail servers that run on pertaining protocols.

For example, Simple Mail Transfer Protocol (SMTP) is a popular transport protocol for sending mail. JavaMail applications can connect to an SMTP server and send mail through it by using this SMTP protocol provider.

In addition to service providers, the JavaMail API requires the Java Application Framework (JAF) to handle mail content that is not plain text, including Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

The JavaMail APIs, the JAF, the service providers, and the protocols are shipped as part of WebSphere Application Server. The API and related specifications are repackaged from Sun-licensed materials into the following file groupings:

*   `j2ee.jar` - Contains the JavaMail API and the JAF
*   `mail-impl.jar` - Contains the implementation of the JavaMail API
*   `activation-impl.jar` - Contains the implementation of the JAF

Mail providers and mail sessions

A JavaMail service provider is a driver that supports JavaMail interaction with mail servers using a particular mail protocol. WebSphere Application Server includes service providers, also known as *protocol providers*, for mail protocols including Simple Mail Transfer Protocol (SMTP), Internet Message Access Protocol (IMAP), and Post Office Protocol 3 (POP3).

A mail provider encapsulates a collection of protocol providers. For example, WebSphere Application Server has a built-in mail provider that encompasses the three protocol providers: SMTP, IMAP and POP3. These protocol providers are installed as the default and suffice for most applications.

If you have a particular application that requires custom protocol providers, you must first follow the steps outlined in the ″JavaMail API Design Specification, V1.2, Chapter 5 - The Mail Session″ to install your own protocol providers. This document outlines the process for the JavaMail 1.3 API as well as JavaMail 1.2. See the article, *Mail: Resources for learning*, for a link to the specification.

Mail sessions are represented by the `javax.mail.Session` class. A mail `Session` object authenticates users, and controls users' access to messaging systems.

To create platform-independent applications, use a resource factory reference to create a JavaMail session. A resource factory is an object that provides access to resources in the deployed environment of a program using the naming conventions defined by the Java Naming and Directory Interface (JNDI).

Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your new mail session.

JavaMail security permissions best practices

In many of its activities, the JavaMail API needs to access certain configuration files. The JavaMail and JavaBeans Activation Framework binary packages themselves already contain the necessary configuration files. However, the JavaMail API allows the user to define user-specific and installation-specific configuration files to meet special requirements.

The two locations where such configuration files can exist are `<user.home>` and `<java.home>/lib`. For example, if the JavaMail API needs to access a file named `mailcap` when sending a message, it first tries to access `<user.home>/.mailcap`. If that attempt fails, either due to lack of security permission or a nonexistent file, the API continues to try`<java.home> /lib/mailcap`. If that attempts also fails, it tries META-INF/mailcap in the class path, which actually leads to the configuration files contained in the `mail-impl.jar` and `activation-impl.jar` files. WebSphere Application Server uses the general-purpose JavaMail configuration files contained in the `mail-impl.jar` and `activation-impl.jar` files and does not put any mail configuration files in `<user.home>`and `<java.home>/lib`. File read permission for both the `mail-impl.jar` and `activation-impl.jar` files is granted to all applications to ensure proper functioning of the JavaMail API, as shown in the following segment of the `app.policy` file:

```
grant codeBase "file:${application}" {
  // The following are required by Java mail
  permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
};
```

JavaMail code attempts to access configuration files at `<user.home>`and `<java.home>/lib` causing `AccessControlExceptions` to be thrown, since there is no file read permission granted for those two locations by default. This activity does not affect the proper functioning of the JavaMail API, but you might see a large amount of JavaMail-related security exceptions reported in the system log, which might swamp harmful errors that you are looking for. If this situation is a problem, consider adding two more permission lines to the permission block above. This should eliminate most, if not all, JavaMail-related harmless security exceptions from the log file. The application permission block in the `app.policy` file now looks like:

```
grant codeBase "file:${application}" {
  // The following are required by Java mail
  permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
java.io.FilePermission "${java.home}${/}lib${/}.mailcap", "read";
  permission java.io.FilePermission "${user.home}${/}lib${/}.mailcap", "read";
};
```

Mail: Resources for learning

Use the following links to find relevant supplemental information about the JavaMail API. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Programming model and decisions
- JavaMail documentation

Programming specifications

• JavaMail 1.3 API documentation (Sun Java specifications)

JavaMail support for IPv6

WebSphere Application Server and its JavaMail component support Internet Protocol Version 6.0 (IPv6), meaning that:

• Both can run on a pure IPv4 network, a pure IPv6 network, *or* a mixed IPv4 and IPv6 network.

• On either the pure IPv6 network or the mixed network, the JavaMail component works with mail servers (such as the SMTP mail transfer agent, and the IMAP and POP3 mail stores) that are also IPv6 compatible. Additionally, a JavaMail component that is run on the mixed IPv4 and IPv6 network can communicate with mail servers using IPv4.

Use of brackets with IPv6 addresses

When you configure a mail session, you can specify the mail server hosts (also known as mail transport and mail store hosts) with domain-qualified host names or numerical IP addresses. Using host names is generally the preferred method. If you use IP addresses, however, consider enclosing IPv6 addresses in square brackets to prevent parsing inaccuracies. See the following example:

`[fe80::202:57ff:fec4:2334]`

The JavaMail API requires a combination of many host names or IP addresses with a port number, using the `host:port number` syntax . This extra colon can cause the port number to be read as part of an IPv6 address. Using brackets prevents your JavaMail implementation from processing the extra characters erroneously.

Enabling debugger for a mail session

When you need to debug a JavaMail application, you can use the JavaMail debugging feature. Enabling the debugger triggers the JavaMail component of WebSphere Application Server to print the following data to the `stdout` output stream:

• interactions with the mail servers

• properties of the mail session

This output stream is redirected to the `SystemOut.log` file for the specific application server.

The mail debugger functions on a per session basis. To enable the JavaMail debugging feature:

1. Open the administrative console.

2. Click **Resources**>**Mail Providers**>*mail_session*>**Mail Session**>*mail session*.

3. Click **Debug**. Debug is enabled for just that session.

4. Click **Apply** or **OK**.

The following example shows sample JavaMail debugging output:

```
DEBUG: not loading system providers in <java.home>/lib
DEBUG  not loading optional custom providers file: /META-INF/javamail.providers
DEBUG: successfully loaded default providers

```

This output illustrates a connection failure to a Simple Mail Transfer Protocol (SMTP) server because a fictitious name, smtp.coldmail.com, is specified as the server name.

The following list provides tips on reading the previous sample of debugger output:
- The lines headed by *DEBUG* are printed by the JavaMail run-time, while the two lines headed by *** are printed by the WebSphere environment run-time.
- The first two lines say that some configuration files are skipped. At run-time the JavaMail component attempts to load a number of configuration files from different locations. All those files are not required. If a required file cannot be accessed, however, the JavaMail component creates an exception. In this sample, there is no exception and the third line announces that default providers are loaded.
- The next few lines, headed by either *Providers listed by Class Name* or *Providers Listed by Protocols*, show the protocol providers that are loaded. The three providers that are listed are the default protocol providers that come under the WebSphere built-in mail provider. They are the protocols SMTP, IMAP, and POP3, respectively. If you install special protocol providers (or, in JavaMail terminology, service providers) and these providers are used in the current mail session, you see them listed here with the default providers.
- The two lines headed by *** and the few lines below them are printed by WebSphere Application Server to show the configuration properties of the current mail session. Although these properties are listed by their internal name rather than the name you establish in the administrative console, you can easily recognize the relationships between them. For example, the property *mail.store.protocol* corresponds to the Protocol Name property in the Store Access section of the mail session configuration page.

  Note: Review the listed properties and values to verify that they correspond.
- The few lines above the exception stack show the JavaMail activities when sending a message. First, the JavaMail API recognizes that the transport protocol is set to SMTP and that the provider `com.sun.mail.smtp.SMTPTransport` exists. Next, the parameters used by SMTP, `useEhlo` and `useAuth`, are shown. Finally, the log shows the SMTP provider trying to connect to the mail server `smtp.coldmail.com`.

- Next is the exception stack. This data indicates that the specified mail server either does not exist or is not functioning.

Using URL resources within an application

Java 2 Enterprise Edition (J2EE) applications can use Uniform Resource Locators (URLs) by looking up references to logically named URL connection factories through the `java:comp/env/url` subcontext, which is declared in the application deployment descriptor and mapped to installation specific URL resources.

As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources. The process is the same used with other J2EE resources, such as JDBC objects and JavaMail sessions.

1. Develop an application that relies on naming features.
2. Define resource references while assembling your application. A URL resource that uses a built-in protocol, such as HTTP, FTP, or file, can use the default URL provider. URL resources that use other protocols need to use a custom URL provider.
3. Configure your URL resources within an application.
   a. Open the administrative console.
   b. Click **Resources**>**URL** in the console navigation tree.
   c. Click either **URL Providers** or **URLs** to modify the appropriate resource.
4. **Optional:** Configure URL providers and URLs within an application client using the Application Client Resource Configuration Tool (ACRCT).
5. Manage URL providers and URL resources used by the deployed application. To update or remove existing URL configurations:
   a. Open the administrative console.
   b. Click **Resources** > **URL** in the console navigation tree.
   c. Click either **URL Providers** or **URLs** to modify the appropriate resource.
   d. Select the URL to modify.
   e. Modify the URL properties.
   f. Click **Apply** or **OK**.

   To remove URL providers and URLs, after step 2, click *URL_provider* > **URLs**. Select the URL you want to remove and click **Delete**. Then, click **Apply** or **OK**.

URLs

A Uniform Resource Locator (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as HTTP, FTP, file, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The *scheme_information* for HTTP, FTP and file generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www-4.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL provider collection

Use this page to view existing URL providers, which supply the implementation classes that are necessary for WebSphere Application Server to access a URL through a specific protocol. The default URL provider provides connectivity through protocols that are supported by the IBM Developer Kit for the Java™ Platform, compatible with the Java 2 Standard Edition Platform 1.3.1. These protocols include HyperText Transfer Protocol (HTTP) and File Transfer Protocol (FTP), which work for must URLs.

To view this administrative console page, click **Resources** > **URL** > **URL Providers**.

Name:

Specifies the administrative name for the URL provider.

Scope:

Specifies the scope of this URL provider, which can support multiple URL configurations. All of the URL configurations that are supported by this provider inherit this scope.

Description:

Describes the URL provider for your administrative records.

URL provider settings

Use this page to configure URL providers, which support WebSphere Application Server connections to a URL over a specific protocol.

To view this administrative console page, click **Resources** > **URL** > **URL Providers** > *URL_provider*.

Scope:

Specifies the scope of this URL provider, which can support multiple URL configurations. All of the URL configurations that are supported by this provider inherit this scope.

Name:

Specifies the administrative name for the URL provider.

Description:

Describes the URL provider, for your administrative records.

Class path:

Specifies paths or JAR file names which together form the location for the resource provider classes.

Stream handler class name:

Specifies fully qualified name of a user-defined Java class that extends the `java.net.URLStreamHandler` class for a particular URL protocol, such as FTP.

Protocol:

Specifies the protocol supported by this stream handler. For example, NNTP, SMTP, FTP.

URL collection

Use this page to view existing Uniform Resource Locator (URL) configurations, which are sets of properties that define WebSphere Application Server connections to URLs. URLs are location names that represent electronically accessible resources, such as a directory file on a machine in a network or a document stored in a database.

You can access this administrative console page in one of two ways:

* **Resources** > **URL Providers** > *URL_provider* > **URLs**
* **Resources** > **URL** > **URLs**

Name:

Specifies the display name for the resource.

JNDI Name:

Specifies the JNDI name.

Scope:

Specifies the scope of the URL provider that supports this URL configuration. Only applications that are installed within this scope can use this URL configuration to access URL resources.

Provider:

Specifies the URL provider that supplies the implementation classes for using a specific protocol to access this URL.

Description:

Specifies the description of the resource.

Category:

Specifies the category string, which you can use to classify or group the resource.

URL configuration settings

Use this page to define connections to Uniform Resource Locators (URLs), which are location names that represent electronically accessible resources. A collection of URL connection properties is often called a URL configuration in the WebSphere Application Server environment. The targeted resources are remote to your Application Server installation.

You can access this administrative console page in one of two ways:

* **Resources** > **URL** > **URLs** > *URL*
* **Resources** > **URL** > **URL Providers** > *URL_provider* > **URLs** > *URL*

Scope:

Specifies the scope of the URL provider that supports this URL configuration. Only applications that are installed within this scope can use this URL configuration to access URL resources.

Provider:

Specifies the URL provider that WebSphere Application Server uses for this URL configuration.

To create a new URL configuration: If you previously defined one or more URL providers at the relevant scope, you see a list from which you can select an existing URL provider for your new URL configuration.

Create New Provider:

Provides the option of configuring a new URL provider for the new URL configuration.

Create New Provider is displayed only when you create a new URL from the **Resources** > **URL** > **URLs** path. In this flow, you can create a new URL provider if needed. The URL provider can not be changed during an edit.

Clicking **Create New Provider** triggers the console to display the URL provider configuration page, where you create a new provider. After you click **OK** to save your settings, you see the URL collection page. Click **New** to define a new URL configuration for use with the new provider; the console now displays a configuration page that lists the new provider as the URL configuration Provider.

Name:

Specifies the display name for the resource.

JNDI Name:

Specifies the JNDI name.

Description:

Specifies the description of the resource.

Category:

Specifies the category string, which you can use to classify or group the resource.

Specification:

Specifies the string from which to form a URL.

URLs: Resources for learning

Use the following links to find relevant supplemental information about URLs. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. Resource environment entries

This topic provides instructions on configuring *new* resource environment entries, which define environment resources that are the binding targets for resource-environment-references in an application's deployment descriptor.

1. Configure a resource environment provider, which is a library that provides the implementation for an environment resource factory. In the administration console, begin by clicking **Resources > Resource Environment > Resource Environment Providers > New**. (See the New Resource Environment Provider topic for more information.)

2. After saving your resource environment provider, go to the Additional Properties heading and click **Resource environment entries**. Click **New** to define a new resource environment entry. Refer to the "Resource environment entry settings" on page 864 topic for descriptions of the required fields.

3. You also might need to create a referenceable, which specifies the factory class name that converts information in the name space into a class instance for your resource. To view the appropriate administrative console page for referenceables, click **Resources > Resource Environment > Resource Environment Providers >** *your_resource_environment_provider* **> Referenceables**. Click **New** to begin the configuration process. See the "Referenceables settings" on page 866 topic for descriptions of the required fields.

Resource environment providers and resource environment entries

A resource environment reference maps a logical name used by the client application to the physical name of an object.

Not all objects bound into the server JNDI namespace are intended for use by an application client. For example, the WebSphere Application Server client run time does not support the use of Java 2 Connector (J2C) objects on the client. The object needs to be remotable, and the client-side implementations must be made available on the application client run-time classpath.

Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local J2EE resource. The J2EE specification does not specify a particular implementation of a resource.

Resource environment provider collection

Use this page to view resource environment providers, which encapsulate the referenceables that convert resource environment entry data into resource objects.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers**.

Name:

Specifies a text identifier for the resource environment provider.

Data type	String

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Description:

Specifies a text string describing the resource environment provider.

Data type	String

Resource environment provider settings:

Use this page to create settings for a resource environment provider.

To view this administrative console page, click **Resources** > **Resource environment** > **Resource environment providers** > *resource environment provider*.

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Name:

Specifies the name of the resource provider.

Data type	String

Description:

Specifies a text description for the resource provider.

Data type	String

New Resource environment provider:

Use this page to define the configuration for a library that provides the implementation for a environment resource factory.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers > New**.

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Name:

Specifies a text identifier for the resource environment provider.

Data type	String

Description:

Specifies a text string describing the resource environment provider.

Data type	String

Resource environment entries collection

Use this page to view configured resource environment entries. Within an application server name space, the data contained in a resource environment entry is converted into an object that represents a physical resource. This resource is frequently called an *environment resource*.

An environment resource can be of any arbitrary type. See the latest EJB specification for more information about resource environment references and environment resources.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Environment** > **Resource environment entries**
- **Resources** >**Resource Environment** > **Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries**

Name:

Specifies a text identifier that helps distinguish this resource environment entry from others.

For example, you can use *My Resource* for the name.

Data type	String

JNDI Name:

Specifies the string to be used when looking up this environment resource using JNDI.

This is the string to which you bind resource environment reference deployment descriptors.

Data type	String

Scope:

Specifies the resource environment entry scope, which is inherited from the resource environment provider.

Provider:

Specifies the resource environment provider for this entry. The provider encapsulates the classes that, when implemented, convert resource environment entry data into resource objects.

Description:

Specifies text for information to help further identify and distinguish this resource

Data type	String

Category:

Specifies a category you can use to group environment resources according to some common feature.

It is strictly an organizational property and has no effect on the function of the environment resource.

Data type	String

Resource environment entry settings:

Use this page to configure resource environment entries. Within an application server name space, the data contained in a resource environment entry is converted into an object that represents a physical resource. Rather than represent a connection factory, which provides connections to a resource, this object *directly* represents a resource. This design can make the resource available to application modules that do not run entirely on the application server. Examples include some application clients and Web modules.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Environment** > **Resource environment entries** > *resource_environment_entry*
- **Resources** >**Resource Environment** > **Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries** > *resource_environment_entry*

Scope:

Specifies the scope of the resource environment provider, which is a library that supplies the implementation class for a resource environment factory. Within a JNDI name space, WebSphere Application Server uses the factory to transform your resource environment entry into an object that directly represents a physical resource.

Provider:

Specifies the resource environment provider.

Provider shows all of the existing resource environment providers that are defined at the relevant scope. Select one from the list if you want to use an existing resource environment provider as Provider.

Name:

Specifies a display name for the resource.

Data type	String

JNDI name:

Specifies the JNDI name for the resource, including any naming subcontexts.

This name is used as the linkage between the platform's binding information for resources defined by a module's deployment descriptor and actual resources bound into JNDI by the platform.

Data type	String

Description:

Specifies a text description for the resource.

Data type	String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type	String

Referenceables:

Specifies the referenceable, which encapsulates the class name of the factory that converts resource environment entry data into a class instance for a physical resource.

Data type	Drop-down menu

Referenceables collection

Use this page to view configured referenceables, which encapsulate the class name of the factory that converts information in the name space into a class instance for a physical resource.

To view this administrative console page, click **Resources** > **Resource environment** > **Resource Environment Providers** > *resource_environment_provider* > **Referenceables**.

Factory Class name:

Specifies a javax.naming.spi.ObjectFactory implementation name

Data type	String

Class name:

Specifies the package name of the referenceable, for example: `javax.naming.Referenceable`

Data type	String

Referenceables settings:

Use this page to set the class name of the factory that converts information in the name space into a class instance of a physical resource.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers >** *resource_environment_provider* **> Referenceables >** *referenceable*.

Factory class name:

Specifies a javax.naming.ObjectFactory implementation class name

Data type	String

Class name:

Specifies the Java type to which a Referenceable provides access, for binding validation and to create the reference.

Data type	String

Resource environment references

Use this page to designate how the resource environment references of application modules map to remote resources, which are represented in the product as resource environment entries.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **Resource environment references**.

Guidelines for using this administrative console page:

Each row of the table depicts a resource environment reference within a specific module of your application. If you bound any references to resource environment entries during application assembly, you see the JNDI names of those resource environment entries in the applicable rows.

To set the mapping relationships between your resource environment references and resource environment entries:

1. Select a row. Be aware that if you check multiple rows on this page, the resource mapping target that you select in step 2 applies to all of those references.
2. Click **Browse** to select a resource environment entry from the new page that is displayed, the Available Resources page. The Available Resources page shows all resource environment entries that are available mapping targets for your application references.
3. Click **Apply**. The console displays the Resource environment references page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
4. Repeat the previous steps as necessary.
5. Click **OK**. You now return to the general configuration page for your enterprise application.

Table column heading descriptions:

Select:

Select the check boxes of the rows that you want to edit.

Module:

The name of a module in the application.

EJB:

The name of an enterprise bean that is accessed by the module.

URI:

Specifies location of the module relative to the root of the application EAR file.

Reference binding:

The name of a resource environment reference that is declared in the deployment descriptor of the application module. The reference corresponds to a resource that is bound as a resource environment entry into the JNDI name space of the application server.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the resource environment entry that is the mapping target of the resource environment reference.

Data type   String

Security

Task overview: Securing resources

WebSphere Application Server supports the Java 2 Platform, Enterprise Edition (J2EE) model for creating, assembling, securing, and deploying applications. Applications are often created, assembled, and deployed in different phases and by different teams.

You can secure resources in a J2EE environment by following the required high-level steps. Consult the J2EE specifications for complete details.

- Set up and enable security. You must address several issues prior to authenticating users, authorizing access to resources, securing applications, and securing communications. These security issues include migration, interoperability, and installation. After installing WebSphere Application Server, you must determine the proper level of security that is needed for your environment. For more information, see Setting up and enabling security.
- Authenticate users. The process of authenticating users involves a user registry and an authentication mechanism. Optionally, you can define trust between WebSphere Application Server and a proxy server, configure single sign-on capability, and specify how to propagate security attributes between application servers. For more information, see Authenticating users.
- Authorize access to resources. WebSphere Application Server provides many different methods for authorizing accessing resources. For example, you can assign roles to users and configure a built-in or external authorization provider. For more information, see Authorizing access to resources.
- Secure communications. WebSphere Application Server provides several methods to secure communication between a server and a client. For more information, see Securing communications.
- Develop extensions to the WebSphere security infrastructure. WebSphere Application Server provides various plug points so that you can extend the security infrastructure. For more information, see "Developing extensions to the WebSphere security infrastructure."
- Secure various types of WebSphere applications. See **Securing WebSphere applications** for tasks involving developing, deploying, and administering secure applications, including Web applications, Web services, and many other types. This section highlights the security concerns and tasks that are specific to each type of application.
- Tune, harden, and maintain security configurations. After you have installed WebSphere Application Server, there are several considerations for tuning, strengthening, and maintaining your security configuration. For more information, see Tuning, hardening, and maintaining.
- Troubleshoot security configurations. For more information, see Troubleshooting security configurations.

Your applications and production environment are secured.

See Security: Resources for learning for more information on the WebSphere Application Server security architecture.

Developing extensions to the WebSphere security infrastructure

WebSphere Application Server provides various plug points so that you can extend the security infrastructure.

The following topics are covered in this section:
- Developing custom user registries
- Developing applications that use programmatic security
- Customizing Web application login forms
- Customizing application login forms with Java Authentication and Authorization Service (JAAS)
- Securing transports with Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces
- Implementing tokens for security attribute propagation

Developing standalone custom registries

This development provides considerable flexibility in adapting WebSphere Application Server security to various environments where some notion of a user registry, other than LDAP or Local OS, already exists in the operational environment.

WebSphere Application Server security supports the use of standalone custom registries in addition to the local operating system registry, standalone Lightweight Directory Access Protocol (LDAP) registries, and federated repositories for authentication and authorization purposes. A standalone custom-implemented

registry uses the UserRegistry Java interface as provided by WebSphere Application Server. A standalone custom-implemented registry can support virtually any type or notion of an accounts repository from a relational database, flat file, and so on.

Implementing a standalone custom registry is a software development effort. Use the methods that are defined in the UserRegistry interface to make calls to the appropriate registry to obtain user and group information. The interface defines a general set of methods for encapsulating a wide variety of registries. You can configure a standalone custom registry as the selected repository when configuring WebSphere Application Server security on the Secure administration, applications, and infrastructure panel.

In WebSphere Application Server Version 6.1, make sure that your implementation of the standalone custom registry does not depend on any WebSphere Application Server components such as data sources, Enterprise JavaBeans (EJB) and Java Naming and Directory Interface (JNDI). You can not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components, make a change that eliminates the dependency. For example, if your previous implementation used data sources to connect to a database, use DriverManager to connect to the database.

Refer to the Migrating custom user registries for more information on migrating. If your previous implementation uses data sources to connect to a database, change the implementation to use Java database connectivity (JDBC) connections. However, it is recommended that you use the new interface to implement your custom registry.

1. Implement all the methods in the interface except for the CreateCredential method, which is implemented by WebSphere Application Server. FileRegistrySample.java file is provided for reference.

   Attention: The sample provided is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

2. Build your implementation.

   To compile your code, you need the *app_server_install_rootBase*/plugins/ com.ibm.ws.runtime_6.1.0.jar and the *app_server_install_rootBase*/plugins/ com.ibm.ws.security.crypto_6.1.0/cryptosf.jar files in your class path. For example:

   ```
   %install_root%/java/bin/javac -classpath
   %install_root%app_server_install_rootBase/plugins/com.ibm.ws.runtime_6.1.0.jar;
   %install_root%app_server_install_rootBase/plugins/com.ibm.ws.security.crypto_6.1.0
                   /cryptosf.jar your_implementation_file.java
   ```

3. Copy the class files that are generated in the previous step to the product class path.

   The preferred location is the `%install_root%`/lib/ext directory. Copy these class files to all of the product process class paths.

4. Follow the steps in Configuring standalone custom registries to configure your implementation using the administrative console. This step is required to implement custom user registries.

If you enable security, make sure that you complete the remaining steps:

1. Save and synchronize the configuration and restart all of the servers.

2. Try accessing some J2EE resources to verify that the custom registry implementation is correct.

Example: Standalone custom registries:

Use these links to view registry examples.

A *standalone custom registry* is a customer-implemented registry that implements the UserRegistry Java interface, as provided by WebSphere Application Server. A custom-implemented registry can support virtually any type or form of an accounts repository from a relational database, flat file, and so on. The custom registry provides considerable flexibility in adapting WebSphere Application Server security to

various environments where some form of a registry, other than a federated repository, Lightweight Directory Access Protocol (LDAP) registry, or local operating system registry, already exist in the operational environment.

To view a sample standalone custom registry, refer to the following files:
- FileRegistrySample.java file
- users.props file
- groups.props file

Result.java file:

This module is used by user registries in WebSphere Application Server when calling the getUsers and getGroups methods. The user registries use this method to set the list of users and groups and to indicate if more users and groups in the user registry exist than requested.

           CustomRegistryException,
           RemoteException;
}
```

Implementing custom password encryption

WebSphere Application Server supports the use of custom password encryption.

An installation can implement any password encryption algorithm it chooses.

Complete the following steps to implement custom password encryption:

1. Build your custom password encryption class. An example of a custom password encryption class follows.

```
// CustomPasswordEncryption
// Encryption and decryption functions
public interface CustomPasswordEncryption {
    public EncryptedInfo encrypt(byte[] clearText) throws PasswordEncryptException;
    public byte[] decrypt(EncryptedInfo cipherTextInfo) throws PasswordEncryptException;
    public void initialize(HashMap initParameters);
};
// Encapsulation of cipher text and label
public class EncryptedInfo {
```

```
        public EncryptedInfo(byte[] bytes, String keyAlias);
        public byte[] getEncryptedBytes();
        public String getKeyAlias();
};
```

2. Enable custom password encryption.

   a. Set the custom property **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** to the name of the class that is to be given control.

   b. Enable the function. Set the custom property, **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** to `true`.

Custom password encryption at the installation is complete.

Developing applications that use programmatic security

For some applications, declarative security is not sufficient to express the security model of the application. Use this topic to develop applications that use programmatic security.

IBM WebSphere Application Server provides security components that provide or collaborate with other services to provide authentication, authorization, delegation, and data protection. WebSphere Application Server also supports the security features that are described in the Java 2 Platform, Enterprise Edition (J2EE) specification. An application goes through three stages before it is ready to run:
* Development
* Assembly
* Deployment

Most of the security for an application is configured during the assembly stage. The security that is configured during the assembly stage is called *declarative security* because the security is *declared* or *defined* in the deployment descriptors. The declarative security is enforced by the security runtime. For some applications, declarative security is not sufficient to express the security model of the application. For these applications, you can use *programmatic security*.

1. Develop secure Web applications. For more information, see "Developing with programmatic security APIs for Web applications" on page 901.

2. Develop servlet filters for form login processing. For more information, see "Developing servlet filters for form login processing" on page 912.

3. Develop form login pages. For more information, see "Customizing Web application login" on page 909.

4. Develop enterprise bean component applications. For more information, see "Developing with programmatic APIs for EJB applications" on page 905.

5. Develop with Java Authentication and Authorization Service to log in programmatically. For more information, see "Developing programmatic logins with the Java Authentication and Authorization Service" on page 917.

6. Develop your own Java 2 security mapping module. For more information, see "Configuring programmatic logins for Java Authentication and Authorization Service" on page 921.

7. Develop custom user registries. For more information, see "Developing standalone custom registries" on page 868.

8. Develop a custom interceptor for trust associations.

Protecting system resources and APIs (Java 2 security):

Java 2 security is a programming model that is very pervasive and has a huge impact on application development.

Java 2 security is orthogonal to Java 2 Platform, Enterprise Edition (J2EE) role-based security; you can disable or enable it independently of administrative security.

However, it does provide an extra level of access control protection on top of the J2EE role-based authorization. It particularly addresses the protection of system resources and application programming interfaces (API). Administrators need to consider the benefits against the risks of disabling Java 2 security.

The following recommendations are provided to help enable Java 2 security in a test or production environment:

1. Make sure the application is developed with the Java 2 security programming model. Developers have to know whether or not the APIs that are used in the applications are protected by Java 2 security. It is very important that the required permissions for the APIs used are declared in the policy file (`was.policy`), or the application fails to run when Java 2 security is enabled. Developers can reference the Web site for Development Kit APIs that are protected by Java 2 security. See the Programming model and decisions section of the Security: Resources for learning topic to visit this Web site.

2. Make sure that migrated applications from previous releases are given the required permissions. Because Java 2 security is not supported or partially supported in previous WebSphere Application Server releases, applications developed prior to Version 5 most likely are not using the Java 2 security programming model. No easy way to find out all the required permissions for the application is available. The following are activities you can perform to determine the extra permissions that are required by an application:

   - Code review and code inspection
   - Application documentation review
   - Sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Enable tracing in WebSphere Java 2 security manager to help determine the missing permissions in the application policy file. The trace specification is:
     `com.ibm.ws.security.core.SecurityManager=all=enabled`.
   - Use the com.ibm.websphere.java2secman.norethrow system property to aid debugging. Do not use this property in a production environment..

     Refer to Java 2 security

The default permission set for applications is the recommended permission set that is defined in the J2EE 1.3 Specification. The default is declared in the *app_server_root*/profiles/*profile_name*/config/cells/*cell_name*/nodes/*node_name*/app.policy policy file with permissions defined in the Development Kit (*JAVA_HOME*/jre/lib/security/java.policy) policy file that grant permissions to everyone. However, applications are denied permissions that are declared in the profiles/*profile_name*/config/cells/*cell_name*/filter.policy file. Permissions that are declared in the *filter.policy* file are filtered for applications during the permission check.

Define the required permissions for an application in a `was.policy` file and embed the `was.policy` file in the application enterprise archive (EAR) file as *YOURAPP.ear/META-INF/was.policy*, see "Configuring Java 2 security policy files" on page 881 for details.

The following steps describe how to enforce Java 2 security on the cell level for WebSphere Application Server Network Deployment and the server level for WebSphere Application Server and WebSphere Application Server Express:

1. Click **Security > Secure administration, applications, and infrastructure**. The Secure administration, applications, and infrastructure panel is displayed.

2. Select the **Use Java 2 security to restrict application access to local resources** option.

3. Click **OK** or **Apply**.

4. Click **Save** to save the changes.

5. Restart the server for the changes to take effect.

Java 2 security is enabled and enforced for the servers. Java 2 security permission is selected when a Java 2 security protected API is called.

When to use Java 2 security

1. Enable protection on system resources, for example when opening or listening to a socket connection, reading or writing to operating system file systems, reading or writing Java virtual machine system properties, and so on.
2. Prevent application code from calling destructive APIs, for example, calling the System.exit method brings down the application server.
3. Prevent application code from obtaining privileged information (passwords) or gaining extra privileges (obtaining server credentials).

You can enforce Java 2 security on the server level for WebSphere Application Server Network Deployment by completing the following steps.

Note: Changes to Java 2 security settings on the server level override the settings on the cell level.

1. Click **Servers > Application servers >** *server_name*.
2. Under Security, click **Server security**.
3. Select the **Security settings for this server override cell settings** option.
4. Select the **Use Java 2 security to restrict application access to local resources** option.
5. Click **OK** or **Apply**.
6. Click **Save** to save the changes.
7. Restart the server for the changes to take effect.

The Java 2 security manager is enhanced to dump the Java 2 security permissions that are granted to all classes on the call stack when an application is denied access to a resource. The java.security.AccessControlException exception is created. However, this tracing capability is disabled by default. You can enable this capability by specifying the server trace service with the `com.ibm.ws.security.core.SecurityManager=all=enabled` trace specification. When the exception is created, the trace dump provides hints to determine whether the application is missing permissions or the product runtime code or the third-party libraries that are used are not properly marked as `privileged` when accessing Java 2 security-protected resources. See the Security Problem Determination Guide for details.

Using PolicyTool to edit policy files:

Use the **PolicyTool** utility to update policy files.

Java 2 security uses several policy files to determine the granted permission for each Java program. The Java Development Kit provides the **PolicyTool** tool to edit these policy files. This tool is recommended for editing any policy file to verify the syntax of its contents. Syntax errors in the policy file cause an AccessControlException exception when the application runs, including the server start. Identifying the cause of this exception is not easy because the user might not be familiar with the resource that has an access violation. Be careful when you edit these policy files.

See Java 2 security policy files for the list of available policy files.

1. Start the **PolicyTool**.

   ▶ Windows ◀ For example, you can enter the following command at a Windows command prompt:

   `%{was.install.root}/java/jre/bin/policytool`

   The **PolicyTool** window opens. The tool looks for the `java.policy` file in your home directory. If it does not exist, an error message displays.

   Click **OK**.
2. Click **File** > **Open**.
3. Navigate the directory tree in the **Open** window to pick up the policy file that you need to update. After selecting the policy file, click **Open**. The code base entries are listed in the window.
4. Create or modify the code base entry.

a. Modify the existing code base entry by double-clicking the code base, or click the code base and click **Edit Policy Entry**. The Policy Entry window opens with the permission list defined for the selected code base.

b. Create a new code base entry by clicking **Add Policy Entry**.

The Policy Entry window opens. At the code base column, enter the code base information as a URL format.

For example, you can enter:

`app_server_root/InstalledApps/testcase.ear`

where the *app_server_root* variable represents your installation location.

5. Modify or add the permission specification.

a. Modify the permission specification by double-clicking the entry that you want to modify, or by selecting the permission and clicking **Edit Permission**. The Permissions window opens with the selected permission information.

b. Add a new permission by clicking **Add Permission**. The Permissions window opens. In the Permissions window are four rows for Permission, Target Name, Actions, and Signed By.

6. Select the permission from the Permission list. The selected permission displays. After a permission is selected, the Target Name, Actions, and Signed By fields automatically show the valid choices or they enable text input in the right text input area.

a. Select **Target Name** from the list, or enter the target name in the right text input area.

b. Select **Actions** from the list.

c. Input **Signed By** if it is needed.

Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `#java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the java.security.auth.policy Java virtual machine (JVM) system property.

7. Click **OK** to close the Permissions window. Modified permission entries of the specified code base display.

8. Click **Done** to close the window. Modified code base entries are listed. Repeat the previous steps until you complete editing.

9. Click **File** > **Save** after you finish editing the file.

A policy file is updated. If any policy files need editing, use the **PolicyTool** utility. Do not edit the policy file manually. Syntax errors in the policy files can potentially cause application servers or enterprise applications to not start or function incorrectly. For the changes in the updated policy file to take effect, restart the Java processes.

Configuring Java 2 security policy files:

Use can configure Java 2 security policy files so that the required permission is granted for the specified WebSphere Application Server enterprise application.

Java 2 security uses several policy files to determine the permissions for each Java programs.

See the Java 2 security policy files topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions. Six dynamic policy files are provided:

Policy file name	Description
app.policy	Contains default permissions for all of the enterprise applications in the cell.
was.policy	Contains application-specific permissions for an WebSphere Application Server enterprise application. This file is packaged in an enterprise archive (EAR) file.
ra.xml	Contains connector application specific permissions for a WebSphere Application Server enterprise application. This file is packaged in a resource adapter archive (RAR) file.
spi.policy	Contains permissions for Service Provider Interface (SPI) or third-party resources that are embedded in WebSphere Application Server. The default contents grant everything. Update this file carefully when the cell requires more protection against SPI in the cell. This file is applied to all of the SPIs that are defined in the resources.xml file.
library.policy	Contains permissions for the shared library of enterprise applications.
filter.policy	Contains the list of permissions that require filtering from the was.policy file and the app.policy file in the cell. This filtering mechanism only applies to the was.policy and app.policy files.

In WebSphere Application Server, applications must have the appropriate thread permissions specified in the was.policy or app.policy file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. The app.policy file applies to a specified node. If you change the permissions in one app.policy file, you must incorporate the new thread policy in the same file on the remaining nodes. Also, if you add the thread permissions to the app.policy file, you must restart WebSphere Application Server to enforce the new permissions. However, if you add the permissions to the was.policy file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a was.policy or app.policy file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
permission java.lang.RuntimePermission "stopThread";
permission java.lang.RuntimePermission "modifyThread";
permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By keyword is not supported in the following policy files: app.policy, spi.policy, library.policy, was.policy, and filter.policy files. However, the Signed By keyword is supported in the following policy files:java.policy, server.policy, and client.policy files. The Java Authentication and Authorization Service (JAAS) is not supported in the app.policy, spi.policy, library.policy, was.policy, and filter.policy files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the java.security.auth.policy Java virtual machine (JVM) system property. You can statically set the authorization policy files in java.security.auth.policy with auth.policy.url.n=*URL*, where *URL* is the location of the authorization policy.

1. Identify the policy file to update.

   • If the permission is required by an application, update the static policy file. Refer to "Configuring static policy files" on page 895.

   • If the permission is required by all of the WebSphere Application Server enterprise applications in the node, refer to "spi.policy file permissions" on page 890.

   • If the permission is required only by specific WebSphere Application Server enterprise applications and the permission is required only by connector, update the ra.xml file. Refer to "Assembling resource adapter (connector) modules" on page 792. Otherwise, update the was.policy file. Refer to "Configuring the was.policy file" on page 888 and "Adding the was.policy file to applications" on page 893.

- If the permission is required by shared libraries, refer to "library.policy file permissions" on page 891.
- If the permission is required by SPI libraries, refer to "spi.policy file permissions" on page 890.

Tip: Pick up the policy file with the smallest scope. You can avoid giving an extra permission to the Java programs and protect the resources. You can update the `ra.xml` file or the `was.policy` file rather than the `app.policy` file. Use specific component symbols ($(ejbcomponent), ${webComponent},${connectorComponent} and ${jars}) than ${application} symbols. Update dynamic policy files, rather than static policy files.

Add any permission that you never want granted to the WebSphere Application Server enterprise application in the cell to the `filter.policy` file. Refer to "filter.policy file permissions" on page 886.

2. Restart the WebSphere Application Server enterprise application.

The required permission is granted for the specified WebSphere Application Server enterprise application.

If an WebSphere Application Server enterprise application in a cell requires permissions, some of the dynamic policy files need updating. The symptom of the missing permission is the java.security.AccessControlException exception. The missing permission is listed in the exception data.

```
java.security.AccessControlException: access denied
(java.io.FilePermission C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)
```

The previous two lines were split onto two lines because of the width of the page. Enter the permission on one line.

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate dynamic policy file.

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read";
};
```

The previous permission information lines were split onto more than one line because of their length. Enter the permission on one line.

To decide whether to add a permission, refer to the Access control exception topic.

app.policy file permissions:

Java 2 security uses several policy files to determine the granted permissions for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see the Java 2 security policy files article The `app.policy` file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the policy.url.* properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the Network Deployment cell.

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. If an administrator adds thread permissions to the `app.policy` file, the permission change requires a restart of the WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
permission java.lang.RuntimePermission "stopThread";
permission java.lang.RuntimePermission "modifyThread";
permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `app.policy` file. However, the Signed By keyword is supported in the following files: `java.policy`, `server.policy`, and the `client.policy` files. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the java.security.auth.policy Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` property with `auth.policy.url.n=`*URL* `where` *URL* is the location of the authorization policy.

If the default permissions for enterprise applications (the union of the permissions that is defined in the `java.policy` file, the `server.policy` file and the `app.policy` file) are enough; no action is required. The default `app.policy` file is used automatically. If a specific change is required to all of the enterprise applications in the cell, update the `app.policy` file. Syntax errors in the policy files cause start failures in the application servers. Edit these policy files carefully.

To extract the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

wsadmin> set obj [$AdminConfig extract profiles/*profile_name*/cells/*cell_name*/node/ *node_name*/app.policy c:/temp/test/app.policy]

Edit the extracted `app.policy` file with the Policy Tool. For more information, see "Using PolicyTool to edit policy files" on page 880. Changes to the `app.policy` file are local for the node.

To check in the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

wsadmin> $AdminConfig checkin profiles/*profile_name*/cells/*cell_name*/nodes/ *node_name*/app.policy c:/temp/test/was.policy $obj

Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:${application}	Permissions apply to all resources within the application
file:${jars}	Permissions apply to all utility Java archive (JAR) files within the application
file:${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:${webComponent}	Permissions apply to Web resources within the application
file:${connectorComponent}	Permissions apply to connector resources both within the application and within standalone connector resources.

Five embedded symbols are provided to specify the path and name for the java.io.FilePermission permission. These symbols enable flexible permission specifications. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
${app.installed.path}	Path where the application is installed
${was.module.path}	Path where the module is installed
${current.cell.name}	Current cell name
${current.node.name}	Current node name
${current.server.name}	Current server name

Tip: You cannot use the `${was.module.path}` in the `${application}` entry.

The `app.policy` file that is supplied by WebSphere Application Server resides at *app_server_root*/`profiles`/*profile_name*/`config/cells`/*cell_name*/`nodes`/*node_name*/`app.policy`, which contains the following default permissions:

Attention: In the following code sample, the first two lines that are related to java.io.FilePermission permission are split into two lines for illustrative purposes only.

```
grant codeBase "file:${application}" {
  // The following are required by Java mail
  permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
};

grant codeBase "file:${jars}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${connectorComponent}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${webComponent}" {
  permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
  permission java.lang.RuntimePermission "loadLibrary.*";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${ejbComponent}" {
 permission java.lang.RuntimePermission "queuePrintJob";
 permission java.net.SocketPermission "*", "connect";
 permission java.util.PropertyPermission "*", "read";
};
```

If all of the WebSphere Application Server enterprise applications in a cell require permissions that are not defined as defaults in the `java.policy` file, the `server.policy` file and the `app.policy` file, then update the `app.policy` file. The symptom of a missing permission is the java.security.AccessControlException exception. The missing permission is listed in the exception data, for example, `java.security.AccessControlException: access denied (java.io.FilePermission C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)`.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file, for example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:/WebSphere/AppServer/java/jre/lib/ext/mail.jar", "read"; };
```

To decide whether to add a permission, refer to the AccessControlException topic.

Restart all WebSphere Application Server enterprise applications to ensure that the updated `app.policy` file takes effect.

filter.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program. Java 2 security policy filtering is only in effect when Java 2 security is enabled.

Before modifying the `filter.policy` file, you must start the wsadmin tool. See the Starting the wsadmin scripting client article for more information.

Refer to "Protecting system resources and APIs (Java 2 security)" on page 878. The filtering policy defined in the `filter.policy` file is cell wide. The `filter.policy` file is the only policy file that is used when restricting the permission instead of granting permission. The permissions that are listed in the filter policy file are filtered out from the `app.policy` file and the `was.policy` file. Permissions that are defined in the other policy files are not affected by the `filter.policy` file.

When a permission is filtered out, an audit message is logged. However, if the permissions that are defined in the `app.policy` file and the `was.policy` file are compound permissions like the java.security.AllPermission permission, for example, the permission is not removed. A warning message is logged. If the Issue Permission Warning flag is enabled (default) and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Java API permission, the permission package name begins with characters other than `java` or `javax`), a warning message is logged and the permission is not removed. You can change the value of the **Warn if applications are granted custom permissions** option on the Secure administration, applications, and infrastructure panel. It is not recommended that you use the `AllPermission` permission for the enterprise application.

Some default permissions that are defined in the `filter.policy` file. These permissions are the minimal ones that are recommended by the product. If more permissions are added to the `filter.policy` file, certain operations can fail for enterprise applications. Add permissions to the `filter.policy` file carefully.

You cannot use the Policy Tool to edit the `filter.policy` file. Editing must be completed in a text editor. Be careful and verify that no syntax errors exist in the `filter.policy` file. If any syntax errors exist in the `filter.policy` file, the file is not loaded by the product security runtime, which implies that filtering is disabled.

To extract the `filter.policy` file, enter the following command using information from your environment:

set obj [$AdminConfig extract cells/*cell_name*/filter.policy c:/temp/test/filter.policy]

To check in the policy file, enter the following command using information from your environment:

$AdminConfig checkin cells/*cell_name*/filter.policy c:/temp/test/filter.policy $obj

An updated `filter.policy` file is applied to all of the WebSphere Application Server enterprise applications after the servers are restarted. The `filter.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `filter.policy` file that is supplied by WebSphere Application Server resides at: *app_server_root*/ profiles/*profile_name*/config/cells/*cell_name*/filter.policy.

This fill contains these permissions as defaults:

```
filterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
runtimeFilterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
```

The permissions that are defined in `filterMask` filter are for static policy filtering. The security runtime tries to remove the permissions from applications during application startup. Compound permissions are not removed, but are issued with a warning, and application deployment is stopped if applications contain permissions that are defined in the `filterMask` filter, and if scripting is used. The runtimeFilterMask filter defines permissions that are used by the security runtime to deny access to those permissions to application thread. Do not add more permissions to the runtimeFilterMask filter. Application start failure or incorrect functioning might result. Be careful when adding more permissions to the runtimeFilterMask filter. Usually, you only need to add permissions to the `filterMask` stanza.

WebSphere Application Server relies on the filter policy file to restrict or disallow certain permissions that can compromise the integrity of the system. For instance, WebSphere Application Server considers the exitVM and setSecurityManager permissions as those permissions that most applications never have. If these permissions are granted, the following scenarios are possible:

exitVM

A servlet, JavaServer Pages (JSP) file, enterprise bean, or other library that is used by the aforementioned might call the System.exit API and cause the entire WebSphere Application Server process to terminate.

setSecurityManager

An application might install its own security manager and either grant more permissions or bypass the default policy that the WebSphere Application Server security manager enforces.

Important: In application code, do not use the setSecurityManager permission to set a security manager. When an application uses the setSecurityManager permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must enable the **Enforce Java 2 Security** option on the Global security settings page within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the System.getSecurityManager application programming interface (API).

Important: In application code, do not use the setSecurityManager permission to set a security manager. When an application uses the setSecurityManager permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must enable the **Use Java 2 security to restrict application access to local resources** option on the Secure administration, applications, and infrastructure panel within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the System.getSecurityManager application programming interface (API).

For the updated `filter.policy` file to take effect, restart related Java processes.

Configuring the was.policy file:

You should update the `was.policy` file if the application has specific resources to access.

Java 2 security uses several policy files to determine the granted permission for each Java program. The `was.policy` file is an application-specific policy file for WebSphere Application Server enterprise applications. This file is embedded in the `META-INF/was.policy` enterprise archive (.EAR) file. The `was.policy` file is located in:

profile_root/config/cells/*cell_name*/applications/
ear_file_name/deployments/*application_name*/META-INF/was.policy

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server Version 6.1.

The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the policy.url.* properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the cell.

Several product-reserved symbols are defined to associate the permission lists to a specific type of resources.

Symbol	Definition
file:${application}	file:${application}
file:${jars}	Permissions apply to all utility Java archive (JAR) files within the application
file:${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:${webComponent}	Permissions apply to Web resources within the application
file:${connectorComponent}	Permissions apply to connector resources within the application

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. If you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
permission java.lang.RuntimePermission "stopThread";
permission java.lang.RuntimePermission "modifyThread";
permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

An administrator can add the thread permissions to the `app.policy` file, but the permission change requires a restart of WebSphere Application Server.

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `was.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy file. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` file with the `auth.policy.url.n=URL`, where *URL* is the location of the authorization policy.

Other than these blocks, you can specify the module name for granular settings. For example,

```
"file:DefaultWebApplication.war" {
     permission java.security.SecurityPermission "printIdentity";
 };

grant codeBase "file:IncCMP11.jar" {
     permission java.io.FilePermission
     "${user.install.root}${/}bin${/}DefaultDB${/}-",
     "read,write,delete";
};
```

Five embedded symbols are provided to specify the path and name for the java.io.FilePermission permission. These symbols enable flexible permission specification. The absolute file path is fixed after the application is installed.

Symbol	Definition
${app.installed.path}	Path where the application is installed
${was.module.path}	Path where the module is installed
${current.cell.name}	Current cell name
${current.node.name}	Current node name
${current.server.name}	Current server name

If the default permissions for the enterprise application are enough, an action is not required. The default permissions are a union of the permissions that are defined in the `java.policy` file, the `server.policy` file, and the `app.policy` file. If an application has specific resources to access, update the `was.policy` file. The first two steps assume that you are creating a new policy file.

Tip: Syntax errors in the policy files cause the application server to fail. Use care when editing these policy files.

1. Create or edit a new `was.policy` file by using the PolicyTool. For more information, see "Using PolicyTool to edit policy files" on page 880.

2. Package the `was.policy` file into the enterprise archive (EAR) file.

   For more information, see "Adding the was.policy file to applications" on page 893.The following instructions describe how to import a `was.policy` file.

   a. Import the EAR file into an assembly tool.

   b. Open the Project Navigator view.

   c. Expand the EAR file and click **META-INF**. You might find a `was.policy` file in the META-INF directory. If you want to delete the file, right-click the file name and select **Delete**.

   d. At the bottom of the Project Navigator view, click **J2EE Hierarchy**.

   e. Import the `was.policy` file by right-clicking the **Modules** directory within the deployment descriptor and by clicking **Import > Import > File system**.

   f. Click **Next**.

g. Enter the path name to the `was.policy` file in the **From directory** field or click **Browse** to locate the file.

h. Verify that the path directory that is listed in the **Into directory** field lists the correct `META-INF` directory.

i. Click **Finish**.

j. To validate the EAR file, right-click the EAR file, which contains the Modules directory, and click **Run Validation**.

k. To save the new EAR file, right-click the EAR file, and click **Export > Export EAR file**. If you do not save the revised EAR file, the EAR file will contain the new `was.policy` file. However, if the workspace becomes corrupted, you might lose the revised EAR file.

l. To generate deployment code, right-click the EAR file and click **Generate Deployment Code**.

3. Update an existing installed application, if one already exists.

a. Modify the `was.policy` file with the Policy Tool. For more information, see "Using PolicyTool to edit policy files" on page 880.

The updated `was.policy` file is applied to the application after the application restarts.

If an application must access a specific resource that is not defined as a default in the `java.policy` file, the `server.policy` file, and the `app.policy`, delete the `was.policy` file for that application. The symptom of the missing permission is the java.security.AccessControlException exception. The missing permission is listed in the exception data:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)
```

The previous example was split onto several lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add the following permission to the `was.policy` file:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission "app_server_root/lib/mail-impl.jar", "read"; };
```

The previous example was split onto several lines for illustrative purposes only.

To determine whether to add a permission, see Access control exception.

Restart all applications for the updated `app.policy` file to take effect.

spi.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server Version 6.0.x, see Java 2 security policy files.

Because the default permission for the Service Provider Interface (SPI) is the AllPermission permission, the only reason to update the `spi.policy` file is a restricted SPI permission. When a change in the `spi.policy` is required, complete the following steps.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the codebase keyword or any other keyword after the filterMask and runtimeFilterMask keywords. The Signed By and the Java Authentication and Authorization Service (JAAS) Principal keywords are not supported in the `spi.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy files. The

JAAS Principal keyword is supported in a JAAS policy file that is specified by the java.security.auth.policy Java virtual machine (JVM) system property. You can statically set the authorization policy files in `java.security.auth.policy` with `auth.policy.url.n=`*URL*`,` where *URL* is the location of the authorization policy.

To extract the `filter.policy` file, enter the following command using information from your environment:

set obj [$AdminConfig extract profiles/*profile_name*/cells/*cell_name*/nodes/*node_name*/spi.policy c:/temp/test/spi.policy]

Edit the file using the Policy Tool. For more information, see "Using PolicyTool to edit policy files" on page 880.

To check in the policy file, enter the following command using information from your environment:

$AdminConfig checkin profiles/*profile_name*/cells/*cell_name*/nodes/*node_name*/spi.policy c:/temp/test/spi.policy $obj

The updated `spi.policy` is applied to the Service Provider Interface (SPI) libraries after the Java process is restarted.

Examples

The `spi.policy` file is the template for SPIs or third-party resources embedded in the product. Examples of SPIs are Java Message Services (JMS) (MQSeries) and Java database connectivity (JDBC) drivers. They are specified in the `resources.xml` file. The dynamic policy grants the permissions that are defined in the `spi.policy` file to the class paths defined in the `resources.xml` file. The union of the permission that is contained in the `java.policy` file and the `spi.policy` file are applied to the SPI libraries. The `spi.policy` files are managed by configuration and file replication services.

Changes made in these files are replicated to other nodes in the cell.

You can find the `spi.policy` file that is supplied by WebSphere Application Server in the following location: *app_server_root*/`profiles/`*profile_name*/`config/cells/`*cell_name*/`nodes/`*node_name*/`spi.policy`. This file contains the following default permission:

```
grant {
  permission java.security.AllPermission;
};
```

Restart the related Java processes for the changes in the `spi.policy` file to become effective.

library.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

The `library.policy` file is the template for shared libraries (Java library classes). Multiple enterprise applications can define and use shared libraries. Refer to Managing shared libraries for information on how to define and manage the shared libraries.

If the default permissions for a shared library (union of the permissions defined in the `java.policy` file, the `app.policy` file and the `library.policy` file) are enough, no action is required. The default library policy is picked up automatically. If a specific change is required to share a library in the cell, update the `library.policy` file.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the codebase keyword or any other keyword after the grant keyword. The Signed By keyword and the Java Authentication and Authorization Service (JAAS) Principal keyword are not supported in the `library.policy` file. The Signed By keyword is supported in the `java.policy`, the `server.policy`, and the `client.policy` policy files. The JAAS Principal keyword is supported in a JAAS policy file when it is specified by the Java virtual machine (JVM) system property, java.security.auth.policy. You can statically set the authorization policy files in the `java.security.auth.policy` file with `auth.policy.url.n=`*URL* where *URL* is the location of the authorization policy.

To extract the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:

wsadmin> set obj [$AdminConfig extract cells/*cell_name*/nodes/
node_name/library.policy c:/temp/test/library.policy]

The previous two lines were split onto two lines for illustrative purposes only.

Edit the extracted `library.policy` file with the Policy Tool. For more information, see "Using PolicyTool to edit policy files" on page 880.

To check in the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:

wsadmin> $AdminConfig checkin cells/*cell_name*/nodes/*node_name*/library.policy
c:/temp/test/library.policy $obj

An updated `library.policy` is applied to shared libraries after the servers restart.

Example

The union of the permission that is contained in the `java.policy` file, the `app.policy` file, and the `library.policy` file are applied to the shared libraries. The `library.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `library.policy` file are supplied by WebSphere Application Server resides at: *app_server_root*/
`config/cells/`*cell_name*`/nodes/`*node_name*`/` directory. The file contains an empty permission entry as a default. For example:

```
grant {
  };
```

If the shared library in a cell requires permissions that are not defined as defaults in the `java.policy` file, the `app.policy` file and the `library.policy` file, update the `library.policy` file. The missing permission causes the java.security.AccessControlException exception. The missing permission is listed in the exception data.

Windows For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)
```

The previous lines are split into two lines for illustrative purposes only. The *app_server_root* variable represents your installation directory.

When a Java program receives this exception and adding this permission is justified, add a permission to the `library.policy` file.

▶ Windows   For example:

```
grant { permission java.io.FilePermission "app_server_root/lib/mail-impl.jar", "read"; };
```

The previous lines are split into two lines for illustrative purposes only. The *app_server_root* variable represents your installation directory.

To decide whether to add a permission, refer to Access control exception.

Restart the related Java processes for the changes in the `library.policy` file to become effective.

Adding the was.policy file to applications:

An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file.

When Java 2 security is enabled for a WebSphere Application Server, all the applications that run on WebSphere Application Server undergo a security check before accessing system resources. An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file. By default, the product security reads an `app.policy` file that is located in each node and grants the permissions in the `app.policy` file to all the applications. Include any additional required permissions in the `was.policy` file. The `was.policy` file is only required if an application requires additional permissions.

The default policy file for all applications is specified in the `app.policy` file. This file is provided by the product security, is common to all applications, and you do not change this file. Add any new permissions that are required for an application in the `was.policy` file.

The `app.policy` file is located in the *profile_root*/config/cells/*cell_name*/nodes/*node_name* directory. The contents of the `app.policy` file are presented in the following example:

Attention: In the following code sample, the two permissions that are required by JavaMail are split onto two lines for illustrative purposes only.

```
// The following permissions apply to all the components under the application.
grant codeBase "file:${application}" {
   // The following are required by JavaMail
   permission java.io.FilePermission "
       ${was.install.root}${/}lib${/}mail-impl.jar","read";
   permission java.io.FilePermission "
       ${was.install.root}${/}lib${/}activation-impl.jar","read"; };
   // The following permissions apply to all utility .jar files  (other
   //  than enterprise beans JAR files) in the application.
grant codeBase "file:${jars}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to connector resources within the application
grant codeBase "file:${connectorComponent}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
```

```
};

// The following permissions apply to all the Web modules (.war files)
// within the application.
grant codeBase "file:${webComponent}" {
  permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
      // where "was.module.path" is the path where the Web module is
      // installed. Refer to Dynamic policy concepts for other symbols.
  permission java.lang.RuntimePermission "loadLibrary.*";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the EJB modules within the application.
grant codeBase "file:${ejbComponent}" {
 permission java.lang.RuntimePermission "queuePrintJob";
 permission java.net.SocketPermission "*", "connect";
 permission java.util.PropertyPermission "*", "read";
};
```

If additional permissions are required for an application or for one or more modules of an application, use the `was.policy` file for that application. For example, use codeBase of ${application} and add required permissions to grant additional permissions to the entire application. Similarly, use codeBase of ${webComponent} and ${ejbComponent} to grant additional permissions to all the Web modules and all the enterprise bean modules in the application. You can assign additional permissions to each module (`.war` file or `.jar` file), as shown in the following example.

The following example illustrates adding extra permissions for an application in the `was.policy` file:

Attention: In the following code sample, the permission for the EJB module was split onto two lines for illustrative purposes only.

```
// grant additional permissions to a Web module
grant codeBase " file:aWebModule.war" {
 permission java.security.SecurityPermission "printIdentity";
};

// grant additional permission to an EJB module
grant codeBase "file:aEJBModule.jar"  {
    permission java.io.FilePermission "
      ${user.install.root}${/}bin${/}DefaultDB${/}-" ."read.write,delete";
    // where, ${user.install.root} is the system property whose value is
    // located in the app_server_root directory.
 };
```

To use a `was.policy` file for your application, perform the following steps:

1. Create a `was.policy` file using the policy tool. For more information on using the policy tool, see "Using PolicyTool to edit policy files" on page 880.

2. Add the required permissions in the `was.policy` file using the policy tool.

3. Place the `was.policy` file in the application enterprise archive (EAR) file under the META-INF directory. Update the application EAR file with the newly created `was.policy` file by using the **jar** command.

4. Verify that the `was.policy` file is inserted and start an assembly tool.

5. Verify that the `was.policy` file in the application is syntactically correct. In an assembly tool, right-click the enterprise application module and click **Run Validation**.

An application EAR file is now ready to run when Java 2 security is enabled.

This step is required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not access system resources.

The symptom of the missing permissions is the java.security.AccessControlException exception. The missing permission is listed in the exception data, for example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
app_server_root/lib/mail-impl.jar read)
```

The previous two lines are one continuous line for illustration purposes only.

When an application program receives this exception and adding this permission is justified, include the permission in the was.policy file, for example,

```
grant codeBase "file:${application}" {
  permission java.io.FilePermission
 "app_server_root/lib/mail-impl.jar", "read";
  };
```

Lines are split in this example for illustration purposes only.

Install the application.

Configuring static policy files:

By configuring the static policy files, the required permission will be granted for all of the Java programs.

Java 2 security uses several policy files to determine the granted permission for each Java program.

See the Java 2 security policy files topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions.

Policy file name	Description
java.policy	Contains default permissions for all of the Java programs on the node. This file seldom changes.
server.policy	Contains default permissions for all of the WebSphere Application Server programs on the node. This file is rarely updated.
client.policy	Contains default permissions for all of the applets and client containers on the node.

The static policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine.

1. Identify the policy file to update.
   - If the permission is required only by an application, update the dynamic policy file. Refer to "Configuring Java 2 security policy files" on page 881.
   - If the permission is required only by applets and client containers, update the client.policy file. Refer to "client.policy file permissions" on page 899.
   - If the permission is required only by WebSphere Application Server (servers, agents, managers and application servers), update the server.policy file. Refer to "server.policy file permissions" on page 897.
   - If the permission is required by all of the Java programs running on the Java virtual machine (JVM), update the java.policy file. Refer to "java.policy file permissions" on page 896.

2. Stop and restart WebSphere Application Server.

The required permission is granted for all of the Java programs that run with the restarted JVM.

If Java programs on a node require permissions, the policy file needs updating. If the Java program that required the permission is not part of an enterprise application, update the static policy file. The missing permission results in the creation of the java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:/WAS_HOME/lib/mail-impl.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate policy file.

For example:

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
  "C:/WAS_HOME/lib/mail-impl.jar",
  "read";
};
```

To decide whether to add a permission, refer to Access control exception.

java.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `java.policy` file is a global default policy file that is shared by all of the Java programs that run in the Java virtual machine (JVM) on the node. Modifying this file is not recommended.

If a specific change is required to some of the Java programs on a node and the `java.policy` file requires updating, modify the `java.policy` file with the policy tool. For more information, see "Using PolicyTool to edit policy files" on page 880. A change to the `java.policy` file is local for the node. The default Java policy is picked up automatically. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `java.policy` file is applied to all the Java programs that run in all the JVMs on the local node. Restart the programs for the updates to take effect.

The `java.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine. The `java.policy` file that is supplied by WebSphere Application Server is located at *install_root*/java/jre/lib/security/ `java.policy`. This file contains these default permissions.

```
// Standard extensions get all permissions by default
grant codeBase "file:${java.home}/lib/ext/*" {
        permission java.security.AllPermission;
};
// default permissions granted to all domains
grant {
        // Allows any thread to stop itself using the java.lang.Thread.stop()
        // method that takes no argument.
        // Note that this permission is granted by default only to remain
        // backwards compatible.
        // It is strongly recommended that you either remove this permission
        // from this policy file or further restrict it to code sources
        // that you specify, because Thread.stop() is potentially unsafe.
        // See "http://java.sun.com/notes" for more information.
        // permission java.lang.RuntimePermission "stopThread";

        // allows anyone to listen on un-privileged ports
```

```
        permission java.net.SocketPermission "localhost:1024-", "listen";

        // "standard" properties that can be read by anyone

        permission java.util.PropertyPermission "java.version", "read";
        permission java.util.PropertyPermission "java.vendor", "read";
        permission java.util.PropertyPermission "java.vendor.url", "read";
        permission java.util.PropertyPermission "java.class.version", "read";
        permission java.util.PropertyPermission "os.name", "read";
        permission java.util.PropertyPermission "os.version", "read";
        permission java.util.PropertyPermission "os.arch", "read";
        permission java.util.PropertyPermission "file.separator", "read";
        permission java.util.PropertyPermission "path.separator", "read";
        permission java.util.PropertyPermission "line.separator", "read";

        permission java.util.PropertyPermission "java.specification.version", "read";
        permission java.util.PropertyPermission "java.specification.vendor", "read";
        permission java.util.PropertyPermission "java.specification.name", "read";

        permission java.util.PropertyPermission "java.vm.specification.version","read";
        permission java.util.PropertyPermission "java.vm.specification.vendor","read";
        permission java.util.PropertyPermission "java.vm.specification.name", "read";
        permission java.util.PropertyPermission "java.vm.version", "read";
        permission java.util.PropertyPermission "java.vm.vendor", "read";
        permission java.util.PropertyPermission "java.vm.name", "read";
    };
```

If some Java programs on a node require permissions that are not defined as defaults in the `java.policy` file, consider updating the `java.policy` file. Most of the time, other policy files are updated instead of the `java.policy` file. The missing permission causes the creation of the , java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)
```

The previous two lines are one continuous line.

When a Java program receives this exception and adding this permission is justified, add a permission to the `java.policy` file.

For example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception.

Restart all of the Java processes for the updated `java.policy` file to take effect.

server.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `server.policy` file is a default policy file that is shared by all of the WebSphere Application Servers on a node. The `server.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.

If the default permissions for a server (the union of the permissions that is defined in the `java.policy` file and the `server.policy` file) are enough, no action is required. The default server policy is picked up automatically. If a specific change is required to some of the server programs on a node, update the `server.policy` file with the Policy Tool. Refer to the "Using PolicyTool to edit policy files" on page 880 topic to edit policy files. Changes to the `server.policy` file are local for the node. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `server.policy` file is applied to all the server programs on the local node. Restart the servers for the updates to take effect.

If you want to add permissions to an application, use the `app.policy` file and the `was.policy` file.

When you do need to modify the `server.policy` file, locate this file at: *install_root*/properties/ `server.policy`. This file contains these default permissions:

```
// Allow to use ibm jdk extensions
grant codeBase "file:${was.install.root}/java/ext/-" {
  permission java.security.AllPermission;
};

// Allow to use ibm tools
grant codeBase "file:${was.install.root}/java/tools/ibmtools.jar" {
  permission java.security.AllPermission;
};

// Allow to use sun tools
grant codeBase "file:/QIBM/ProdData/Java400/jdk14/lib/tools.jar" {
  permission java.security.AllPermission;
};

// Allow to use sun tools (V5R2M0 codebase)
grant codeBase "file:/QIBM/ProdData/OS400/Java400/jdk/lib/tools.jar" {
  permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/plugins/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/lib/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
  permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/deploytool/-" {
  permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/optionalLibraries/-" {
  permission java.security.AllPermission;
};

// Allow Channel Framework classes all permission
grant codeBase "file:${was.install.root}/installedChannels/-" {
  permission java.security.AllPermission;
};

grant codeBase "file:${user.install.root}/lib/-" {
  permission java.security.AllPermission;
};
```

```
grant codeBase "file:${user.install.root}/classes/-" {
  permission java.security.AllPermission;
};
```

If some server programs on a node require permissions that are not defined as defaults in the server.policy file and the server.policy file, update the server.policy file. The missing permission creates the java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail-impl.jar read)
```

The previous two lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the server.policy file.

For example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception.

Restart all of the Java processes for the updated server.policy file to take effect.

client.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.
- The client.policy file is a default policy file that is shared by all of the WebSphere Application Server client containers and applets on a node.
- The union of the permissions that is contained in the java.policy file and the client.policy file are given to all of the client containers for WebSphere Application Server and applets running on the node.
- The client.policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.
- The client.policy file supplied by WebSphere Application Server is located in the *profile_root*/properties/client.policy.
- If the default permissions for a client (union of the permissions defined in the java.policy file and the client.policy file) are enough, no action is required. The default client policy is picked up automatically.
- If a specific change is required to some of the client containers and applets on a node, modify the client.policy file with the Policy Tool. Refer to "Using PolicyTool to edit policy files" on page 880, to edit policy files. Changes to the client.policy file are local for the node.

This file contains these default permissions:

```
grant codeBase "file:${was.install.root}/java/ext/*" {
  permission java.security.AllPermission;
};

// JDK classes
grant codeBase "file:${was.install.root}/java/ext/-" {
```

```
    permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/java/tools/ibmtools.jar" {
  permission java.security.AllPermission;
};
grant codeBase "file:/QIBM/ProdData/Java400/jdk14/lib/tools.jar" {
  permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/lib/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/plugins/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/installedConnectors/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${user.install.root}/installedConnectors/-" {
  permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/installedChannels/-" {
  permission java.security.AllPermission;
};

// J2EE 1.4 permissions for client container WebSphere Application Server applications
// in $WAS_HOME/installedApps
grant codeBase "file:${user.install.root}/installedApps/-" {
  //Application client permissions
  permission java.awt.AWTPermission "accessClipboard";
  permission java.awt.AWTPermission "accessEventQueue";
  permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "loadLibrary";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.net.SocketPermission "localhost:1024-", "accept,listen";
  permission java.io.FilePermission "*", "read,write";
  permission java.util.PropertyPermission "*", "read";

};

// J2EE 1.4 permissions for client container - expanded ear file code base
grant codeBase "file:${com.ibm.websphere.client.applicationclient.archivedir}/-" {
  permission java.awt.AWTPermission "accessClipboard";
  permission java.awt.AWTPermission "accessEventQueue";
  permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "loadLibrary";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.net.SocketPermission "localhost:1024-", "accept,listen";
  permission java.io.FilePermission "*", "read,write";
  permission java.util.PropertyPermission "*", "read";
};
```

All of the client containers and applets on the local node are granted the updated permissions when they
start. If some client containers or applets on a node require permissions that are not defined as defaults in
the java.policy file and the default client.policy file, update the client.policy file. The missing
permission creates the java.security.AccessControlException exception. The missing permission is listed in
the exception data, for example,

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)
```

The previous two lines of sample code are one continuous line, but presented as such for illustrative purposes only.

When a client program receives this exception and adding this permission is justified, add a permission to the `client.policy` file, for example, grant codebase ″file:*user_client_installed_location*″ { permission java.io.FilePermission ″C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar″, ″read″; };.

To decide whether to add a permission, refer to Access control exception.

If you update the policy file, you must restart the browser and any client applications.

Developing with programmatic security APIs for Web applications:

Use this information to programmatically secure APIs for Web applications.

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. Programmatic security consists of the following methods of the HttpServletRequest interface:

getRemoteUser
> Returns the user name that the client used for authentication. Returns `null` if no user is authenticated.

isUserInRole
> (String role name): Returns `true` if the remote user is granted the specified security role. If the remote user is not granted the specified role, or if no user is authenticated, it returns `false`.

getUserPrincipal
> Returns the java.security.Principal object that contains the remote user name. If no user is authenticated, it returns `null`.

You can configure several options for Web authentication that determine how the Web client interacts with protected and unprotected Uniform Resource Identifiers (URI). Also, you can specify whether WebSphere Application Server challenges the Web client for basic authentication information if the certificate authentication for the HTTPS client fails. For more information, see Authentication mechanisms.

When the isUserInRole method is used, declare a security-role-ref element in the deployment descriptor with a role-name subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the security-role-ref element to link that role to the actual role. During assembly, the assembler creates a role-link subelement to link the role name to the actual role. Creation of a security-role-ref element is possible if an assembly tool such as Rational Application Developer (RAD) is used. You also can create the security-role-ref element during assembly stage using an assembly tool.

1. Add the required security methods in the servlet code.
2. Create a security-role-ref element with the **role-name** field. If a security-role-ref element is not created during development, make sure it is created during the assembly stage.

A programmatically secured servlet application.

This step is required to secure an application programmatically. This action is particularly useful when a Web application needs to access external resources and wants to control the access to external resources using its own authorization table (external-resource to remote-user mapping). In this case, use the getUserPrincipal or the getRemoteUser methods to get the remote user and then it can consult its own authorization table to perform authorization. The remote user information also can help retrieve the

corresponding user information from an external source such as a database or from an enterprise bean. You can use the isUserInRole method in a similar way.

After development, a security-role-ref element can be created:

```
<security-role-ref>
    <description>Provide hints to assembler for linking this role
                name to an actual role here<\description>
    <role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a role-link element:

```
<security-role-ref>
    <description>Hints provided by developer to map the role
                name to the role-link</description>
    <role-name>Mgr</role-name>
    <role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic servlet security methods inside any servlet doGet, doPost, doPut, and doDelete service methods. The following example depicts using a programmatic security API:

```
public void doGet(HttpServletRequest request,
HttpServletResponse response) {

    ....

    // to get remote user using getUserPrincipal()
    java.security.Principal principal = request.getUserPrincipal();
    String remoteUser = principal.getName();

    // to get remote user using getRemoteUser()
    remoteUser = request.getRemoteUser();

    // to check if remote user is granted Mgr role
    boolean isMgr = request.isUserInRole("Mgr");

    // use the above information in any way as needed by
    // the application
    ....

}
```

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. For more information, see "Securing Web applications using an assembly tool" on page 82.

getRemoteUser and getAuthType methods:

The getRemoteUser and getAuthType methods are methods of the javax.servlet.http.HttpServletRequest interface. If the user has been authenticated, the getRemoteUser method returns the login of the user that makes the request. If the user is not authenticated, the getRemoteUser method returns null. The getAuthType method returns the name of the authentication scheme that is used to protect the servlet (for example, BASIC or SSL). If the servlet is not protected, the getAuthType method returns null.

For both methods, the data that is returned depends upon whether security is enabled in the application server where the servlet is deployed. The following possibilities exist:

- If security is not enabled, a servlet is requested and it is configured with Web server protection. The getRemoteUser method returns the login and getAuthType method returns the authentication scheme.
- If security is enabled and a servlet is requested, both methods return null when WebSphere Application Server protection is not configured for the servlet.

- If security is enabled, a servlet is requested, and the servlet is configured with WebSphere Application Server protection, then the getRemoteUser method returns the login and the getAuthType method returns the configured authentication scheme.

Attention: You can disable security at the application server level by overriding the administrative security setting. For more information, see Securing specific application servers.

Example: Web application code:

The following example depicts a Web application or servlet using the programmatic security model.

This example illustrates one use and not necessarily the only use of the programmatic security model. The application can use the information that is returned by the getUserPrincipal, isUserInRole, and the getRemoteUser methods in any other way that is meaningful to that application. Using the declarative security model whenever possible is strongly recommended.

File : HelloServlet.java

```
public class HelloServlet extends javax.servlet.http.HttpServlet {

 public void doPost(
  javax.servlet.http.HttpServletRequest request,
  javax.servlet.http.HttpServletResponse response)
  throws javax.servlet.ServletException, java.io.IOException {
 }
public void doGet(
  javax.servlet.http.HttpServletRequest request,
  javax.servlet.http.HttpServletResponse response)
  throws javax.servlet.ServletException, java.io.IOException {

        String s = "Hello";

        // get remote user using getUserPrincipal()
        java.security.Principal principal = request.getUserPrincipal();
        String remoteUserName = "";
        if( principal != null )
          remoteUserName = principal.getName();
// get remote user using getRemoteUser()
        String remoteUser = request.getRemoteUser();

        // check if remote user is granted Mgr role
        boolean isMgr = request.isUserInRole("Mgr");

        // display Hello username for managers and bob.
        if ( isMgr || remoteUserName.equals("bob") )
            s = "Hello " + remoteUserName;

   String message =  "<html> \n" +
             "<head><title>Hello Servlet</title></head>\n" +
        "<body> /n +"
   "<h1> "  +s+ </h1>/n " +
  byte[] bytes = message.getBytes();

  // displays "Hello" for ordinary users
        // and displays "Hello username" for managers and "bob".
        response.getOutputStream().write(bytes);
 }

}
```

After developing the servlet, you can create a security role reference for the HelloServlet servlet as shown in the following example:

```
<security-role-ref>
    <description> </description>
    <role-name>Mgr</role-name>
</security-role-ref>
```

Web authentication settings:

Use this page to specify the Web authentication settings that are associated with a Web client.

To view this administrative console page, complete the following steps:
1. Click **Security > Secure administration and applications**.
2. Under Authentication, expand **Web security** and click **General settings**.

You can override the global Web authentication setting that you select on this panel by specifying a system property on the server level. To specify the system property, complete the following steps:
1. Click **Servers > Application servers >** *server_name*.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom properties > New**

You can specify the following system properties on the server level for Web authentication.

Table 28. Web authentication system property values

Property name	Value	Explanation
com.ibm.wsspi.security.web.webAuthReq	`lazy`	This value is equivalent to the **Authenticate only when the URI is protected** option.
com.ibm.wsspi.security.web.webAuthReq	`persisting`	This value is equivalent to the **Use available authentication data when an unprotected URI is accessed** option.
com.ibm.wsspi.security.web.webAuthReq	`always`	This value is equivalent to the **Authenticate when any URI is accessed** option.
com.ibm.wsspi.security.web.failOverToBasicAuth	`true`	This value is equivalent to the **Default to basic authentication when certificate authentication for the HTTPS client fails** option.

Authenticate only when the URI is protected:

The application server challenges the Web client to provide authentication data when the Web client accesses a Uniform Resource Identifier (URI) that is protected by a Java 2 Platform, Enterprise Edition (J2EE) role. The authenticated identity is available only when the Web client accesses a protected URI.

This option is the default J2EE Web authentication behavior that is also available in previous releases of WebSphere Application Server.

Default: Enabled

Use available authentication data when an unprotected URI is accessed:

The Web client can access validated authenticated data that it previously could not access. This option enables the Web client to call the getRemoteUser, isUserInRole, and getUserPrincipal methods to retrieve an authenticated identity from an unprotected URI.

When you select this option with the **Authenticate only when the URI is protected** option, the Web client can use authenticated data when the URI is protected or not protected.

Important: This option does not challenge the Web client to provide authenticated data if the Web client accesses an unprotected URI without authenticated data.

Default: Disabled

Authenticate when any URI is accessed:

The Web client must provide authentication data regardless of whether the URI is protected.

Default: Disabled

Default to basic authentication when certificate authentication for the HTTPS client fails:

When the required HTTPS client certificate authentication fails, the application server uses the basic authentication method to challenge the Web client to provide a user ID and password.

The HTTP client certification authentication that is performed by the application server security is different from the client authentication that is performed by the Web server plug-in. If you configure the Web server plug-in for mutual authentication and client authentication fails, the following situations will occur:

- The Web server produces a error and the Web request is not processed by application server security.
- The application server cannot fail over to basic authentication.

Default: Disabled

Developing with programmatic APIs for EJB applications:

Use this topic to programmatically secure your Enterprise JavaBeans (EJB) applications.

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. The javax.ejb.EJBContext application programming interface (API) provides two methods whereby the bean provider can access security information about the enterprise bean caller.

- **IsCallerInRole**(String rolename): Returns `true` if the bean caller is granted the security role that is specified by role name. If the caller is not granted the specified role, or if the caller is not authenticated, it returns `false`. If the specified role is granted Everyone access, it always returns `true`.
- **getCallerPrincipal**: Returns the java.security. Principal object that contains the bean caller name. If the caller is not authenticated, it returns a principal that contains an unauthorized name.

You can enable a login module to indicate which principal class is returned by these calls.

When the isCallerInRole method is used, declare a security-role-ref element in the deployment descriptor with a role-name that is subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the security-role-ref element to link that role to an actual role. During assembly, the assembler creates a role-link subelement to link the role-name to the actual role. Creation of a security-role-ref element is possible if an assembly tool such as Rational Application Developer (RAD) is used. You also can create the security-role-ref element during the assembly stage using an assembly tool.

1. Add the required security methods in the EJB module code.

2. Create a security-role-ref element with a role-name field for all the role names used in the isCallerInRole method. If a security-role-ref element is not created during development, make sure it is created during the assembly stage.

Performing the previous steps result in a programmatically secured EJB application.

Hard coding security policies in applications is strongly discouraged. The Java 2 Platform, Enterprise Edition (J2EE) security model capabilities of declaratively specifying security policies is encouraged wherever possible. Use these APIs to develop security-aware EJB applications.

Using J2EE security model capabilities to specify security policies declaratively is useful when an EJB application wants to access external resources and wants to control the access to these external resources using its own authorization table (external-resource to user mapping). In this case, use the getCallerPrincipal method to get the caller identity and then the application can consult its own authorization table to perform authorization. The caller identification also can help retrieve the corresponding user information from an external source, such as database or from another enterprise bean. You can use the isCallerInRole method in a similar way.

After development, you can create a security-role-ref element:

```
<security-role-ref>
<description>Provide hints to assembler for linking this role-name to
actual role here<\description>
<role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a role-link element:

```
<security-role-ref>
<description>Hints provided by developer to map role-name to role-link</description>
<role-name>Mgr</role-name>
<role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic EJB component security methods for example isCallerInRole and getCallerPrincipal, inside any business methods of an enterprise bean. The following example of programmatic security APIs includes a session bean:

```
public class aSessionBean implements SessionBean {

    .....

    // SessionContext extends EJBContext. If it is entity bean use EntityContext
    javax.ejb.SessionContext context;

    // The following method will be called by the EJB container
    // automatically
    public void setSessionContext(javax.ejb.SessionContext ctx) {
        context = ctx; // save the session bean's context
    }

    ....

    private  void aBusinessMethod()  {
    ....

    // to get  bean's caller using getCallerPrincipal()
    java.security.Principal principal = context.getCallerPrincipal();
    String  callerId= principal.getName();

    // to check if  bean's caller is granted Mgr role
    boolean isMgr = context.isCallerInRole("Mgr");
```

```
        // use the above information in any way as needed by the
        //application

        ....
        }

        ....
}
```

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. For more information, see Securing enterprise bean applications.

Example: Enterprise bean application code:

The following Enterprise JavaBeans (EJB) component example illustrates the use of the isCallerInRole and the getCallerPrincipal methods in an EJB module.

Using that declarative security is recommended. The following example is one way of using the isCallerInRole and the getCallerPrincipal methods. The application can use this result in any way that is suitable.

A remote interface

```
File : Hello.java

package tests;
import java.rmi.RemoteException;
/**
 * Remote interface for Enterprise Bean: Hello
 */
public interface Hello extends javax.ejb.EJBObject {
      public abstract String getMessage()throws RemoteException;
     public abstract void setMessage(String s)throws RemoteException;
}
```

A home interface

```
File : HelloHome.java
package tests;
/**
 * Home interface for Enterprise Bean: Hello
 */
public interface HelloHome extends javax.ejb.EJBHome {
 /**
  * Creates a default instance of Session Bean: Hello
  */
 public tests.Hello create() throws javax.ejb.CreateException,
  java.rmi.RemoteException;
}
```

A bean implementation

```
File : HelloBean.java

package tests;
/**
 * Bean implementation class for Enterprise Bean: Hello
 */
public class HelloBean implements javax.ejb.SessionBean {
 private javax.ejb.SessionContext mySessionCtx;
```

```java
/**
 * getSessionContext
 */
public javax.ejb.SessionContext getSessionContext() {
 return mySessionCtx;
}
/**
 * setSessionContext
 */
public void setSessionContext(javax.ejb.SessionContext ctx) {
 mySessionCtx = ctx;
}
/**
 * ejbActivate
 */
public void ejbActivate() {
}
/**
 * ejbCreate
 */
public void ejbCreate() throws javax.ejb.CreateException {
}
/**
 * ejbPassivate
 */
public void ejbPassivate() {
}
/**
 * ejbRemove
 */
public void ejbRemove() {
}

public java.lang.String message;

    //business methods

    // all users can call getMessage()
    public String getMessage() {
        return message;
    }

    // all users can call setMessage() but only few users can set new message.
    public void setMessage(String s) {

      // get  bean's caller using getCallerPrincipal()
      java.security.Principal principal = mySessionCtx.getCallerPrincipal();
      java.lang.String  callerId= principal.getName();

      // check if  bean's caller is granted Mgr role
      boolean isMgr = mySessionCtx.isCallerInRole("Mgr");

      // only set supplied message if caller is "bob" or caller is granted Mgr role
      if ( isMgr || callerId.equals("bob") )
          message = s;
      else
```

```
        message = "Hello";
    }

}
```

After the development of the entity bean, create a security role reference in the deployment descriptor under the session bean, Hello:

```
<security-role-ref>
    <description>Only Managers can call setMessage() on this bean (Hello)</description>
    <role-name>Mgr</role-name>
</security-role-ref>
```

For an explanation of how to create a <security-role-ref> element, see Securing enterprise bean applications. Use the information under Map security-role-ref and role-name to role-link to create the element.

Customizing Web application login

You can create a form login page and an error page to authenticate a user.

A Web client or a browser can authenticate a user to a Web server using one of the following mechanisms:
- **HTTP basic authentication**: A Web server requests the Web client to authenticate and the Web client passes a user ID and a password in the HTTP header.
- **HTTPS client authentication**: This mechanism requires a user (Web client) to possess a public key certificate. The Web client sends the certificate to a Web server that requests the client certificates. This authentication mechanism is strong and uses the Hypertext Transfer Protocol with Secure Sockets Layer (HTTPS) protocol.
- **Form-based Authentication**: A developer controls the look and feel of the login screens using this authentication mechanism.

The Hypertext Transfer Protocol (HTTP) basic authentication transmits a user password from the Web client to the Web server in simple base64 encoding. Form-based authentication transmits a user password from the browser to the Web server in plain text. Therefore, both HTTP basic authentication and form-based authentication are not very secure unless the HTTPS protocol is used.

The Web application deployment descriptor contains information about which authentication mechanism to use. When form-based authentication is used, the deployment descriptor also contains entries for login and error pages. A login page can be either an HTML page or a JavaServer Pages (JSP) file. This login page displays on the Web client side when a secured resource (servlet, JSP file, HTML page) is accessed from the application. On authentication failure, an error page displays. You can write login and error pages to suit the application needs and control the look and feel of these pages. During assembly of the application, an assembler can set the authentication mechanism for the application and set the login and error pages in the deployment descriptor.

Form login uses the servlet sendRedirect method, which has several implications for the user. The sendRedirect method is used twice during form login:
- The sendRedirect method initially displays the form login page in the Web browser. It later redirects the Web browser back to the originally requested protected page. The sendRedirect(String URL) method tells the Web browser to use the HTTP GET request to get the page that is specified in the Web address. If HTTP POST is the first request to a protected servlet or JavaServer Pages (JSP) file, and no previous authentication or login occurred, then HTTP POST is not delivered to the requested page. However, HTTP GET is delivered because form login uses the sendRedirect method, which behaves as an HTTP GET request that tries to display a requested page after a login occurs.
- Using HTTP POST, you might experience a scenario where an unprotected HTML form collects data from users and then posts this data to protected servlets or JSP files for processing, but the users are

not logged in for the resource. To avoid this scenario, structure your Web application or permissions so that users are forced to use a form login page before the application performs any HTTP POST actions to protected servlets or JSP files.

1. Create a form login page with the required look and feel, including the required elements to perform form-based authentication. For an example, see "Example: Form login."
2. Create an error page. You can program error pages to retry authentication or to display an appropriate error message.
3. Place the login page and error page in the Web archive (`.war`) file relative to the top directory. For example, if the login page is configured as `/login.html` in the deployment descriptor, place it in the top directory of the WAR file. An assembler can also perform this step using the assembly tool.
4. Create a form logout page and insert it to the application only when the Web application requires a form-based authentication mechanism.

See the "Example: Form login" article for sample form login pages.

The WebSphere Application Server Samples Gallery provides a form login Sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The Sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see "Accessing the Samples (Samples Gallery)" on page 11.

After developing login and error pages, add them to the Web application. Use the assembly tool to configure an authentication mechanism and insert the developed login page and error page in the deployment descriptor of the application.

Example: Form login:

This article provides several examples pertaining to form login.

For the authentication to proceed appropriately, the action of the login form must always have the j_security_check action. The following example shows how to code the form into the HTML page:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="text" name="j_password">
<\form>
```

Use the **j_username** input field to get the user name, and use the **j_password** input field to get the user password.

On receiving a request from a Web client, the Web server sends the configured form page to the client and preserves the original request. When the Web server receives the completed form page from the Web client, the server extracts the user name and password from the form and authenticates the user. On successful authentication, the Web server redirects the call to the original request. If authentication fails, the Web server redirects the call to the configured error page.

The following example depicts a login page in HTML (`login.html`):

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
<title> Security FVT Login Page </title>
<body>
```

```
<h2>Form Login</h2>
<FORM METHOD=POST ACTION="j_security_check">
<p>
<font size="2"> <strong> Enter user ID and password: </strong></font>
<BR>
<strong> User ID</strong> <input type="text" size="20" name="j_username">
<strong> Password </strong>  <input type="password" size="20" name="j_password">
<BR>
<BR>
<font size="2">  <strong> And then click this button: </strong></font>
<input type="submit" name="login" value="Login">
</p>

</form>
</body>
</html>
```

The following example depicts an error page in a JSP file:

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<head><title>A Form login authentication failure occurred</head></title>
<body>
<H1><B>A Form login authentication failure occurred</H1></B>
<P>Authentication may fail for one of many reasons. Some possibilities include:
<OL>
<LI>The user-id or password may be entered incorrectly; either misspelled or the
wrong case was used.
<LI>The user-id or password does not exist, has expired, or has been disabled.
</OL>
</P>
</body>
</html>
```

After an assembler configures the Web application to use form-based authentication, the deployment descriptor contains the login configuration as shown:

```
<login-config id="LoginConfig_1">
<auth-method>FORM<auth-method>
<realm-name>Example Form-Based Authentication Area</realm-name>
<form-login-config id="FormLoginConfig_1">
<form-login-page>/login.html</form-login-page>
<form-error-page>/error.jsp</form-error-page>
</form-login-config>
</login-config>
```

A sample Web application archive (WAR) file directory structure that shows login and error pages for the previous login configuration follows:

```
META-INF
    META-INF/MANIFEST.MF
    login.html
    error.jsp
    WEB-INF/
    WEB-INF/classes/
    WEB-INF/classes/aServlet.class
```

Form logout

Form logout is a mechanism to log out without having to close all Web-browser sessions. After logging out of the form logout mechanism, access to a protected Web resource requires re-authentication. This feature is not required by J2EE specifications, but it is provided as an additional feature in WebSphere Application Server security.

Suppose that you want to log out after logging into a Web application and perform some actions. A form logout works in the following manner:

1. The logout-form URI is specified in the Web browser and loads the form.
2. The user clicks **Submit** on the form to log out.
3. The WebSphere security code logs the user out.
4. Upon logout, the user is redirected to a logout exit page.

Form logout does not require any attributes in a deployment descriptor. The form-logout page is an HTML or a JavaServer Pages (JSP) file that is included with the Web application. The form-logout page is like most HTML forms except that like the form-login page, the form-logout page has a special post action. This post action is recognized by the Web container, which dispatches the post action to a special internal form-logout servlet. The post action in the form-logout page must be `ibm_security_logout`.

You can specify a logout-exit page in the logout form and the exit page can represent an HTML or a JSP file within the same Web application to which the user is redirected after logging out. Additionally, the logout-exit page permits a fully qualified URL in the form of `http://hostname:port/URL`. The logout-exit page is specified as a parameter in the form-logout page. If no logout-exit page is specified, a default logout HTML message is returned to the user.

Here is a sample form logout HTML form. This form configures the logout-exit page to redirect the user back to the login page after logout.

```
<!DOCTYPE HTML PUBliC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
  <META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
  <title>Logout Page </title>
  <body>
  <h2>Sample Form Logout</h2>
      <FORM METHOD=POST ACTION="ibm_security_logout" NAME="logout">
      <p>
      <BR>
      <BR>
      <font size="2"><strong> Click this button to log out: </strong></font>
      <input type="submit" name="logout" value="Logout">
      <INPUT TYPE="HIDDEN" name="logoutExitPage" VALUE="/login.html">
      </p>
      </form>
  </body>
</html>
```

The WebSphere Application Server Samples Gallery provides a form login Sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The Sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login Sample is part of the Technology Samples package.

Developing servlet filters for form login processing:

You can control the look and feel of the login screen using the form-based login mechanism. In form-based login, you specify a login page that is used to retrieve the user ID and password information. You also can specify an error page that displays when authentication fails.

If additional authentication or additional processing is required before and after authentication, servlet filters are an option. Servlet filters can dynamically intercept requests and responses to transform or to use the information that is contained in the requests or responses. One or more servlet filters can be attached

to a servlet or to a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All of the attached servlet filters are called before the servlet is invoked.

Both form-based login and servlet filters are supported by any servlet Version 2.3 specification-complaint Web container. The form login servlet performs the authentication and servlet filters perform additional authentication, auditing, or logging information.

To perform pre-login and post-login actions using servlet filters, configure these filters for either form login page support or for the /j_security_check URL. The j_security_check is posted by a form login page with the j_username parameter that contains the user name and the j_password parameter that contains the password. A servlet filter can use the user name parameter and password information to perform more authentication or other special needs.

1. A servlet filter implements the javax.servlet.Filter class. Implement three methods in the filter class:
   - **init(javax.servlet.FilterConfig cfg)**. This method is called by the container once, when the servlet filter is placed into service. The FilterConfig passed to this method contains the init-parameters of the servlet filter. Specify the init-parameters for a servlet filter during configuration using the assembly tool.
   - **destroy**. This method is called by the container when the servlet filter is taken out of a service.
   - **doFilter(ServletRequest req, ServletResponse res, FilterChain chain)**. This method is called by the container for every servlet request that maps to this filter before invoking the servlet. The FilterChain chain that is passed to this method can be used to invoke the next filter in the chain of filters. The original requested servlet runs when the last filter in the chain calls the chain.doFilter method. Therefore, all filters call the chain.doFilter method for the original servlet to run after filtering. If an additional authentication check is implemented in the filter code and results in failure, the original servlet does not run. The chain.doFilter method is not called and can be redirected to some other error page.

2. If a servlet maps to many servlet filters, servlet filters are called in the order that is listed in the `web.xml` deployment descriptor of the application. Place the servlet filter class file in the `WEB-INF/classes` directory of the application.

An example of a servlet filter follows: This login filter can map to the /j_security_check URL to perform pre-login and post-login actions.

```
import javax.servlet.*;
    public class LoginFilter implements Filter {
    protected FilterConfig filterConfig;
    // Called once when this filter is instantiated.
    // If mapped to j_security_check, called
    // very first time j_security_check is invoked.
    public void init(FilterConfig filterConfig) throws ServletException {
       this.filterConfig = filterConfig;
       }
    public void destroy() {
       this.filterConfig = null;
       }
     // Called for every request that is mapped to this filter.
    // If mapped to j_security_check,
    // called for every  j_security_check action
    public void doFilter(ServletRequest request,
    ServletResponse response, FilterChain chain)
       throws java.io.IOException, ServletException   {
       // perform pre-login action here
       chain.doFilter(request, response);
       // calls the next filter in chain.
       // j_security_check if this filter is
       // mapped to j_security_check.
      // perform post-login action here.
             }
       }
```

Example of servlet filters:

This example illustrates one way that the servlet filters can perform pre-login and post-login processing during form login.

```
Servlet filter source code: LoginFilter.java
/**
 * A servlet filter example: This example filters j_security_check and
 * performs pre-login action to determine if the user trying to log in
 * is in the revoked list. If the user is on the revoked list, an error is
 * sent back to the browser.
 *
 * This filter reads the revoked list file name from the FilterConfig
 * passed in the init() method. It reads the revoked user list file and
 * creates a revokedUsers list.
 *
 * When the doFilter method is called, the user logging in is checked
 * to make sure that the user is not on the revoked Users list.
 *
 */

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class LoginFilter implements Filter {

    protected FilterConfig filterConfig;

    java.util.List revokeList;

    /**
     * init() : init() method called when the filter is instantiated.
     * This filter is instantiated the first time j_security_check is
     * invoked for the application (When a protected servlet in the
     * application is accessed).
     */
    public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;

        // read revoked user list
        revokeList = new java.util.ArrayList();
        readConfig();
    }

    /**
     * destroy() : destroy() method called when the filter is taken
     * out of service.
     */
    public void destroy() {
        this.filterConfig = null;
        revokeList = null;
    }

    /**
     * doFilter() : doFilter() method called before the servlet to
     * which this filter is mapped is invoked. Since this filter is
     * mapped to j_security_check,this method is called before
     * j_security_check action is posted.
     */
    public void doFilter(ServletRequest request, ServletResponse response,
FilterChain chain) throws java.io.IOException, ServletException {

        HttpServletRequest req = (HttpServletRequest)request;
        HttpServletResponse res = (HttpServletResponse)response;

        // pre login action

        // get username
        String username = req.getParameter("j_username");
```

```
        // if user is in revoked list send error
        if ( revokeList.contains(username) ) {
        res.sendError(javax.servlet.http.HttpServletResponse.SC_UNAUTHORIZED);
        return;
        }

        // call next filter in the chain : let j_security_check authenticate
        // user
        chain.doFilter(request, response);

        // post login action

    }

    /**
     * readConfig() : Reads revoked user list file and creates a revoked
     * user list.
     */
    private void readConfig() {
        if ( filterConfig != null ) {

            // get the revoked user list file and open it.
            BufferedReader in;
            try {
                    String filename = filterConfig.getInitParameter("RevokedUsers");
                    in = new BufferedReader( new FileReader(filename));
            } catch ( FileNotFoundException fnfe) {
                    return;
            }

            // read all the revoked users and add to revokeList.
            String userName;
            try {
                    while ( (userName = in.readLine()) != null )
                        revokeList.add(userName);
            } catch (IOException ioe) {
            }

        }

    }

}
```

Important: In the previous code sample, the line that begins `public void doFilter(ServletRequest request` is broken into two lines for illustrative purposes only. The `public void doFilter(ServletRequest request` line and the line after it are one continuous line.

An example of the `web.xml` file that shows the LoginFilter filter configured and mapped to the j_security_check URL:

```
<filter id="Filter_1">
    <filter-name>LoginFilter</filter-name>
    <filter-class>LoginFilter</filter-class>
        <description>Performs pre-login and post-login operation</description>
    <init-param>
    <param-name>RevokedUsers</param-name>
    <param-value>c:\WebSphere\AppServer\installedApps\
                        <app-name>\revokedUsers.lst</param-value>
    </init-param>
</filter-id>

<filter-mapping>
 <filter-name>LoginFilter</filter-name>
     <url-pattern>/j_security_check</url-pattern>
</filter-mapping>
```

An example of a revoked user list file:

```
user1
cn=user1,o=ibm,c=us
user99
cn=user99,o=ibm,c=us
```

Configuring servlet filters:

IBM Rational Application Developer or an assembly tool can configure the servlet filters. Two steps are involved in configuring a servlet filter.

1. Name the servlet filter and assign the corresponding implementation class to the servlet filter.

   Optionally, assign initialization parameters that get passed to the init method of the servlet filter.After configuring the servlet filter, the `web.xml` application deployment descriptor contains a servlet filter configuration similar to the following example:

```
<filter id="Filter_1">
    <filter-name>LoginFilter</filter-name>
    <filter-class>LoginFilter</filter-class>
    <description>Performs pre-login and post-login
        operation</description>
    <init-param>// optional
      <param-name>ParameterName</param-name>
      <param-value>ParameterValue</param-value>
    </init-param>
</filter>
```

2. Map the servlet filter to a URL or a servlet.

   After mapping the servlet filter to a URL or a servlet, the `web.xml` application deployment descriptor contains servlet mapping similar to the following example:

```
<filter-mapping>
    <filter-name>LoginFilter</filter-name>
    <url-pattern>/j_security_check</url-pattern>
                // can be servlet <servlet>servletName</servlet>
</filter-mapping>
```

You can use servlet filters to replace the CustomLoginServlet servlet, and to perform additional authentication, auditing, and logging.

The WebSphere Application Server Samples Gallery provides a form login sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The sample integrates the following technologies to demonstrate the WebSphere Application Server and Java 2 Platform, Enterprise Edition (J2EE) login functionality:

- J2EE form-based login
- J2EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see "Accessing the Samples (Samples Gallery)" on page 11.

Customizing application login with Java Authentication and Authorization Service

The following topics are covered in this section:

- Developing programmatic logins with the Java Authentication and Authorization Service (JAAS)
- Configuring programmatic logins for JAAS
- Configuring a server-side Java Authentication and Authorization Service authentication and login configuration

Developing programmatic logins with the Java Authentication and Authorization Service:

Use this topic to develop programmatic logins with the Java Authentication and Authorization Service.

Java Authentication and Authorization Service (JAAS) represents the strategic application programming interfaces (API) for authentication.

JAAS replaces the Common Object Request Broker Architecture (CORBA) programmatic login application programming interfaces (APIs).

WebSphere Application Server provides some extension to JAAS:
- Refer to the "Developing applications that use CosNaming (CORBA Naming interface)" on page 1047 article for details on how to set up the environment for thin client applications to access remote resources on a server.
- If the application uses a custom JAAS login configuration, verify that the JAAS login configuration is properly defined. See "Configuring programmatic logins for Java Authentication and Authorization Service" on page 921 for details.
- Some of the JAAS APIs are protected by Java 2 security permissions. If these APIs are used by application code, verify that these permissions are added to the application `was.policy` file.

  For details, see the following articles:
  – "Adding the was.policy file to applications" on page 893
  – "Using PolicyTool to edit policy files" on page 880
  – "Configuring the was.policy file" on page 888

  For more details on which APIs are protected by Java 2 security permissions, check the IBM Developer Kit, Java Technology Edition; JAAS and WebSphere Application Server public APIs documentation in Security: Resources for learning.

  Some of the APIs that are used in the sample code in this documentation and the Java 2 security permissions that are required by these APIs are in the following list:
  – javax.security.auth.login.LoginContext constructors are protected by the javax.security.auth.AuthPermission ″createLoginContext″ object.
  – javax.security.auth.Subject.doAs and com.ibm.websphere.security.auth.WSSubject.doAs methods are protected by the javax.security.auth.AuthPermission ″doAs″ object.
  – javax.security.auth.Subject.doAsPrivileged and com.ibm.websphere.security.auth.WSSubject.doAsPrivileged methods are protected by the javax.security.auth.AuthPermission ″doAsPrivileged″ object.
- **Enhanced model to Java 2 Platform, Enterprise Edition (J2EE) resources for authorization checks**.

  Due to a design oversight in JAAS Version 1.0, the javax.security.auth.Subject.getSubject method does not return the Subject that is associated with the running thread inside a java.security.AccessController.doPrivileged code block. This oversight can present inconsistent behavior, which might have unwanted effects. The com.ibm.websphere.security.auth.WSSubject class provides a workaround to associate a Subject to a running thread. The com.ibm.websphere.security.auth.WSSubject class extends the JAAS model to Java 2 Platform, Enterprise Edition (J2EE) resources for authorization checks. If the Subject associates with the running thread within the com.ibm.websphere.security.auth.WSSubject.doAs method or if the com.ibm.websphere.security.auth.WSSubject.doAsPrivileged code block contains product credentials, the Subject is used for J2EE resource authorization checks.
- **User interface support for defining new JAAS login configuration**.

  You can configure a JAAS login configuration in the administrative console and store the JAAS login configuration in a configuration repository. Applications can define a new JAAS login configuration in the administrative console and the data is persisted in the configuration repository. However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the

configuration repository and the plain text file format, the one in the repository takes precedence. Advantages to defining the login configuration in the configuration repository includes:

– Administrative console support in defining JAAS login configuration
– Central management of the JAAS login configuration
– Distribution of the JAAS login configuration

- **Application support for programmatic authentication**.

  WebSphere Application Server provides JAAS login configurations for applications to perform programmatic authentication to the WebSphere security runtime. These configurations perform authentication to the WebSphere Application Server-configured authentication mechanism (Simple WebSphere Authentication Mechanism (SWAM) or Lightweight Third Party Authentication (LTPA)) and user registry (Local OS, Lightweight Directory Access Protocol (LDAP), custom registries, or federated repositories) based on the authentication data that is supplied. The authenticated Subject from these JAAS login configurations contains the required principal and credentials that the WebSphere security runtime can use to perform authorization checks on J2EE role-based protected resources.

  Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

  Here are the JAAS login configurations that are provided by WebSphere Application Server:

  – **WSLogin JAAS login configuration**. A generic JAAS login configuration can use Java clients, client container applications, servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components to perform authentication based on a user ID and password, or a token to the security runtime for WebSphere Application Server. However, this configuration does not honor the CallbackHandler handler that is specified in the client container deployment descriptor.
  – **ClientContainer JAAS login configuration**. This JAAS login configuration honors the CallbackHandler handler that is specified in the client container deployment descriptor. The login module of this login configuration uses the CallbackHandler handler in the client container deployment descriptor if one is specified, even if the application code specified one callback handler in the login context. This is for a client container application.

    A Subject authenticated with the previously mentioned JAAS login configurations contains a com.ibm.websphere.security.auth.WSPrincipal principal and a com.ibm.websphere.security.cred.WSCredential credential. If the authenticated Subject is passed in the com.ibm.websphere.security.auth.WSSubject.doAs or the other doAs methods, the product security runtime can perform authorization checks on J2EE resources based on the com.ibm.websphere.security.cred.WSCredential Subject.

- **Customer-defined JAAS login configurations**.

  You can define other JAAS login configurations to perform programmatic authentication to your authentication mechanism. See the "Configuring programmatic logins for Java Authentication and Authorization Service" on page 921 for details. For the product security runtime to perform authorization checks, the subjects from these customer-defined JAAS login configurations must contain the required principal and credentials.

- **Naming requirements for programmatic login on a pure Java client**.

  When programmatic login occurs on a pure Java client and the property com.ibm.CORBA.validateBasicAuth equals `true`, it is necessary for the security code to know where the SecurityServer resides. Typically, the default InitialContext is sufficient when a java.naming.provider.url property is set as a system property or when the property is set in the `jndi.properties` file. In other cases it is not desirable to have the same java.naming.provider.url properties set in a system-wide scope. In this case, there is a need to specify security specific bootstrap information in the `sas.client.props` file. The following steps present the order of precedence for determining how to find the SecurityServer in a pure Java client:

1. Use the `sas.client.props` file and look for the following properties:

   ```
   com.ibm.CORBA.securityServerHost=myhost.mydomain
   com.ibm.CORBA.securityServerPort=mybootstrap port
   ```

If you specify these properties, you are guaranteed that security looks here for the SecurityServer. The host and port specified can represent any valid WebSphere host and bootstrap port. The SecurityServer resides on all server processes and therefore it is not important which host or port you choose. If specified, the security infrastructure within the client process look up the SecurityServer based on the information in the `sas.client.props` file.

2. Place the following code in your client application to get a new InitialContext():

```
...
    import java.util.Hashtable;
    import javax.naming.Context;
    import javax.naming.InitialContext;
    ...

// Perform an InitialContext and default lookup prior to logging
// in so that target realm and bootstrap host/port can be
// determined for SecurityServer lookup.

        Hashtable env = new Hashtable();
        env.put(Context.INITIAL_CONTEXT_FACTORY,    "
                com.ibm.websphere.naming.WsnInitialContextFactory");
        env.put(Context.PROVIDER_URL,
                "corbaloc:iiop:myhost.mycompany.com:2809");
        Context initialContext = new InitialContext(env);
        Object obj = initialContext.lookup("");

    // programmatic login code goes here.
```

Complete this step prior to running any programmatic login. It is in this code that you specify a URL provider for your naming context, but it must point to a valid WebSphere Application Server within the cell to which you are authenticating. Pointing to one cell allows thread specific programmatic logins going to different cells to have a single system-wide SecurityServer location.

3. Use the new default InitialContext() method relying on the naming precedence rules. These rules are defined in the article, "Example: Getting the default initial context" on page 1033.

See the "Example: Programmatic logins" article.

Example: Programmatic logins:

This example illustrates how application programs can perform a programmatic login using Java Authentication and Authorization Service (JAAS).

```
LoginContext lc = null;

 try {
      lc = new LoginContext("WSLogin",
                new WSCallbackHandlerImpl("userName", "password"));
} catch (LoginException le) {
        System.out.println("Cannot create LoginContext. " + le.getMessage());
        // Insert the error processing code
} catch(SecurityException se) {
        System.out.println("Cannot create LoginContext." + se.getMessage());
        // Insert the error processing code
 }

 try {
        lc.login();
} catch(LoginException le) {
        System.out.println("Fails to create Subject. " + le.getMessage());
         // Insert the error processing code
```

As shown in the example, the new login context is initialized with the WSLogin login configuration and the WSCallbackHandlerImpl callback handler. Use the WSCallbackHandlerImpl instance on a server-side application where you do not want prompting. A WSCallbackHandlerImpl instance is initialized by the specified user ID, password, and realm information. The present WSLoginModuleImpl class implementation that is specified by the WSLogin login configuration can only retrieve authentication information from the specified callback handler. You can construct a login context with a Subject object, but the Subject is disregarded by the present WSLoginModuleImpl implementation. For product client-container applications, replace WSLogin login configuration by ClientContainer login configuration, which specifies the WSClientLoginModuleImpl implementation that is tailored for client container requirements.

For a pure Java application client, the product provides two other callback handler implementations: WSStdinCallbackHandlerImpl and WSGUICallbackHandlerImpl, which prompt for user ID, password, and realm information on the command line and pop-up panel, respectively. You can choose either of these product callback handler implementations, depending on the particular application environment. You can develop a new callback handler if neither of these implementations fit your particular application requirement.

You also can develop your own login module if the default WSLoginModuleImpl implementation fails to meet all your requirements. This product provides utility functions that the custom login module can use, which are described in the next section.

In cases where no java.naming.provider.url property is set as a system property or in the `jndi.properties` file, a default InitialContext context does not function if the product server is not at the `localhost:2809` location. In this situation, construct a new InitialContext context programmatically ahead of the JAAS login. JAAS needs to know where the security server resides to verify that the entered user ID or password is correct, prior to performing a commit method. By constructing a new InitialContext context in the way specified below, the security code has the information that is needed to find the security server location and the target realm.

Attention: The first line starting with `env.put` was split into two lines for illustration purposes only.

```
import java.util.Hashtable;
   import javax.naming.Context;
   import javax.naming.InitialContext;
   ...

// Perform an InitialContext and default lookup prior to logging in so that target realm
// and bootstrap host/port can be determined for SecurityServer lookup.

   Hashtable env = new Hashtable();
   env.put(Context.INITIAL_CONTEXT_FACTORY,
           "com.ibm.websphere.naming.WsnInitialContextFactory");
   env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
   Context initialContext = new InitialContext(env);
   Object obj = initialContext.lookup("");

    LoginContext lc = null;
    try {
       lc = new LoginContext("WSLogin",
                 new WSCallbackHandlerImpl("userName", "realm", "password"));
    } catch (LoginException le) {
       System.out.println("Cannot create LoginContext. " + le.getMessage());
       // insert error processing code
    } catch(SecurityException se) {
       System.out.printlin("Cannot create LoginContext." + se.getMessage());
       // Insert error processing
    }

    try {
        lc.login();
```

```
    } catch(LoginException le) {
        System.out.println("Fails to create Subject. " + le.getMessage());
        // Insert error processing code
    }
```

Configuring programmatic logins for Java Authentication and Authorization Service:

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers.

Java Authentication and Authorization Service (JAAS) is a feature in WebSphere Application Server. JAAS is a collection of WebSphere Application Server strategic authentication APIs and replaces the Common Object Request Broker Architecture (CORBA) programmatic login APIs.

WebSphere Application Server provides some extensions to JAAS:
* **com.ibm.websphere.security.auth.WSSubject**. The com.ibm.websphere.security.auth.WSSubject API extends the JAAS authorization model to Java 2 Platform, Enterprise Edition (J2EE) resources.
* You can configure the JAAS login in the administrative console and store this login configuration in the Application Server configuration. However, WebSphere Application Server still supports the default JAAS login configuration format (plain text file) that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere Application Server configuration API and the plain text file format, the one in the WebSphere Application Server configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:
  – User interface support in defining JAAS login configuration
  – Central management of the JAAS login configuration
  – Distribution of the JAAS login configuration during installation

  Due to a design oversight in JAAS Version 1.0, the javax.security.auth.Subject.getSubject method does not return the subject that is associated with the running thread inside a java.security.AccessController.doPrivileged code block. This problem presents an inconsistent behavior that might cause unfavorable results. The com.ibm.websphere.security.auth.WSSubject API provides a workaround to associate the subject to a running thread.
* **Proxy LoginModule**. The Proxy LoginModule loads the actual LoginModule module. The default JAAS implementation does not use the thread context class loader to load classes. The LoginModule module cannot load if the LoginModule class file is not in the application class loader or the Java extension class loader class path. Due to this class loader visibility problem, WebSphere Application Server provides a proxy LoginModule module to load the JAAS LoginModule using the thread context class loader. You do not need to place the LoginModule implementation on the application class loader or the class path for the Java extension class loader with this proxy LoginModule module.

  If you do not want to use the Proxy LoginModule module, you can place the LoginModule module in the *app_server_root*/lib/ext/ directory. However, this action is not recommended due to the security risks.

JAAS login configurations are defined in the WebSphere Application Server configuration application programming interface (API) security document. Click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **Application logins**. The following JAAS login configurations are available:

ClientContainer
> Defines a login configuration and a LoginModule implementation that is similar to that of the WSLogin configuration, but enforces the requirements of the WebSphere Application Server client container. For more information, see "Configuration entry settings for Java Authentication and Authorization Service" on page 925.

DefaultPrincipalMapping,
> Defines a special LoginModule module that is typically used by J2EE connectors to map an authenticated WebSphere Application Server user identity to a set of user authentication data

(user ID and password) for the specified back-end enterprise information system (EIS). For more information about J2EE Connector and the DefaultMappingModule module, refer to the J2EE security section.

WSLogin

Defines a login configuration and a LoginModule implementation that applications can use in general.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at run time.

Attention: Do not remove or delete the predefined JAAS login configurations (such as, ClientContainer, WSLogin, and DefaultPrincipalMapping). Deleting or removing them can cause other enterprise applications to fail.

1. Delete a JAAS login configuration.

   a. Click **Security > Secure administration, applications, and infrastructure**.

   b. Under Java Authentication and Authorization Service, click **Application logins**. The Application Login Configuration panel is displayed.

   c. Select the check box for the login configurations to delete and click **Delete**.

2. Create a new JAAS login configuration.

   a. Click **Security > Secure administration, applications, and infrastructure**.

   b. Under Java Authentication and Authorization Service, click **Application logins**.

   c. Click **New**. The Application Login Configuration panel is displayed.

   d. Specify the alias name of the new JAAS login configuration and click **Apply**. This value is the name of the login configuration that you pass in the javax.security.auth.login.LoginContext implementation for creating a new LoginContext context.

      Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the `security.xml` file.

   e. Under Additional properties, click **JAAS Login Modules**.

   f. Click **New**.

   g. Specify the Module class name. Specify the WebSphere Application Server proxy LoginModule module because of the limitation of the class loader visibility.

   h. Specify the LoginModule implementation as the delegate property of the Proxy LoginModule module. The WebSphere Application Server proxy LoginModule class name is com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy.

   i. Select **Authentication strategy** from the list and click **Apply**.

   j. Under Additional properties, click **Custom properties**. The Custom properties panel is displayed for the selected LoginModule.

   k. Create a new property with the name `delegate` and the value of the real LoginModule implementation. You can specify other properties like debug with the `true` value. These properties are passed to the LoginModule class as options to the initialize method of the LoginModule instance.

   l. Click **Save**.

      For a Network Deployment installation, make sure that a file synchronization operation is performed to propagate the changes to other nodes.

Several locations are within the WebSphere Application Server directory structure where you can place a JAAS login module. The following list provides locations for the JAAS login module in order of recommendation:

- Within an enterprise archive (EAR) file for a specific Java 2 Platform, Enterprise Edition (J2EE) application.

  If you place the login module within the EAR file, the login module is accessible by the specific application only.

- In the WebSphere Application Server-shared library.

  If you place the login module in the shared library, you must specify which applications can access the module. For more information on shared libraries, see Managing shared libraries.

- In the Java extensions directory.

  If you place the JAAS login module in the Java extensions directory, the login module is available to all applications.

  Although the Java extensions directory provides the greatest availability for the login module, place the login module in an application EAR file. If other applications need to access the same login module, consider using shared libraries.

3. Change the plain text file.

   WebSphere Application Server supports the default JAAS login configuration format, which is a plain text file, that is provided by the JAAS default implementation. However, a tool is not provided that edits plain text files in this format. You can define the JAAS login configuration in the plain text file, which is located in the *app_server_root*/properties/wsjaas.conf file. Any syntax errors can cause the incorrect parsing of the plain JAAS login configuration text file. This problem can cause other applications to fail.

   Java client programs that use the Java Authentication and Authorization Service (JAAS) for authentication must invoke with the JAAS configuration file specified. This configuration file is set in the *app_server_root*/bin/launchClient.bat file as:

   ```
   set JAAS_LOGIN_CONFIG=-Djava.security.auth.login.config=%install_root%\properties\wsjaas_client.conf
   ```

   If the **launchClient.bat** file is not used to invoke the Java client program, verify that the appropriate JAAS configuration file is passed to the Java virtual machine with the **-Djava.security.auth.login.config** flag.

A new JAAS login configuration is created or an old JAAS login configuration is removed. An enterprise application can use a newly created JAAS login configuration without restarting the application server process.

However, new JAAS login configurations that are defined in the *app_server_root*/properties/wsjaas.conf file, do not refresh automatically. Restart the application servers to validate changes. These JAAS login configurations are specific to a particular node and are not available for other application servers running on other nodes.

Create new JAAS login configurations that are used by enterprise applications to perform custom authentication. Use these newly defined JAAS login configurations to perform programmatic login.

Login configuration for Java Authentication and Authorization Service:

Java Authentication and Authorization Service (JAAS) is a new feature in WebSphere Application Server. JAAS is WebSphere Application Server strategic application programming interface (API) for authentication that replaces the Common Object Request Broker Architecture (CORBA) programmatic login API.

WebSphere Application Server provides some extensions to JAAS:
- **com.ibm.websphere.security.auth.WSSubject**: The com.ibm.websphere.security.auth.WSSubject API extends the JAAS authorization model to Java 2 Platform, Enterprise Edition (J2EE) resources. You can configure JAAS login in the administrative console or by using the scripting functions and store this configuration in the WebSphere Application Server configuration API. However, WebSphere Application Server still supports the default JAAS login configuration format, a plain text file, which is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere

Application Server configuration API and the plain text file format, the one in the WebSphere Application Server configuration API takes precedence. Advantages to defining the login configuration in the WebSphere configuration API include:

- User interface support in defining JAAS login configuration
- Central management of the JAAS login configuration
- Distribution of the JAAS login configuration in a Network Deployment product installation

Due to a design oversight in JAAS 1.0, the javax.security.auth.Subject.getSubject method does not return the Subject that is associated with the running thread inside a java.security.AccessController.doPrivileged code block. This action can present an inconsistent behavior that is problematic. The com.ibm.websphere.security.auth.WSSubject extension provides a workaround to associate the Subject to the running thread. The com.ibm.websphere.security.auth.WSSubject extension expands the JAAS authorization model to J2EE resources.

Why WebSphere Application Server has its own subject class: You can retrieve the subjects in a Subject.doAs block with the Subject.getSubject call. However, this procedure does not work if an AccessController.doPrivileged call is contained within the Subject.doAs block. In the following example, s1 is equal to s, but s2 is null:

```
* AccessController.doPrivileged() not only truncates the Subject propagation,
* but also reduces the permissions. It does not include the JAAS security
* policy defined for the principals in the Subject.
Subject.doAs(s, new PrivilegedAction() {
  public Object run() {
    System.out.println("Within Subject.doAsPrivileged()");
    Subject s1 = Subject.getSubject(AccessController.getContext());
    AccessController.doPrivileged(new PrivilegedAction() {
      public Object run() {
      Subject s2 = Subject.getSubject(AccessController.getContext());
      return null;
    }
  });
  return null;
}
});
```

- JAAS Login Configuration can be configured in either the administrative console or by using the scripting functions and stored in the WebSphere Application Server configuration repository. An application can define a new JAAS login configuration in the administrative console and persist the data in the configuration repository that is stored in the WebSphere Application Server configuration API. However, WebSphere Application Server still supports the default JAAS login configuration format that is provided by the JAAS default implementation. If duplicate login configurations are defined in both the WebSphere Application Server configuration API and the plan text file format, the one in the WebSphere Application Server configuration API takes precedence. The advantages to defining the login configuration in the WebSphere Application Server configuration API include:
  - UI support in defining JAAS login configuration.
  - The JAAS configuration login configuration can be managed centrally.
  - The JAAS configuration login configuration is distributed in a Network Deployment installation.
- **Proxy LoginModule**: The Proxy.LoginModule is a proxy to the configured user or the system-defined module that the context class loader uses to load the module instead of the system class loader. The default JAAS implementation does not use the thread context class loader to load classes. The LoginModule module cannot be loaded if the LoginModule class file is not in the application class loader or the class loader class path for the Java extension. WebSphere Application Server provides a proxy LoginModule module to load the JAAS LoginModule using the thread context class loader. You do not need to place the LoginModule implementation on the application class loader or the class loader class path for the Java extension with this proxy LoginModule module.

Tip: Do not remove or delete the predefined JAAS login configurations (ClientContainer, WSLogin and DefaultPrincipalMapping). Deleting or removing them can cause other enterprise applications to fail.

A system administrator determines the authentication technologies, or login modules, to use for each application and configures them in a login configuration. The source of the configuration information, for example, a file or a database, is up to the current javax.security.auth.login.Configuration implementation.

The WebSphere Application Server implementation permits the definition of the login configuration in both the WebSphere Application Server configuration API security document and in a JAAS configuration file, where the former takes precedence.

JAAS login configurations are defined in the API security document for WebSphere Application Server configuration for applications to use. To access the configurations, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **Application logins**.

The WSLogin module defines a login configuration and the LoginModule implementation that can be used by applications in general.

The ClientContainer module defines a login configuration and the LoginModule implementation that is similar to the WSLogin module, but enforces the requirements of the WebSphere Application Server client container.

The DefaultPrincipalMapping module defines a special LoginModule that is typically used by Java 2 Connector to map an authenticated WebSphere Application Server user identity to a set of user authentication data (user ID and password) for the specified back-end enterprise information system (EIS). For more information about Java 2 Connector and the DefaultMappingModule, see the Java 2 Security section.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers. An application server restart is required for the changes to take effect at runtime and for the client container login configuration to be made available.

WebSphere Application Server also reads JAAS configuration information from the `wsjaas.conf` file under the properties subdirectory of the root directory under which WebSphere Application Server is installed. Changes made to the `wsjaas.conf` file are used only by the local application server and take effect after the application server restarts. The JAAS configuration in the WebSphere Application Server configuration API security document takes precedence over that defined in the `wsjaas.conf` file. A configuration entry in the `wsjaas.conf` is overridden by an entry of the same alias name in the WebSphere Application Server configuration API security document.

The Java Authentication and Authorization Service (JAAS) login configuration entries in the administrative console are propagated to the server runtime when they are created, not when the configuration is saved. However, the deleted JAAS login configuration entries are not removed from the server runtime. To remove the entries, save the new configuration, then stop and restart the server.

The Samples Gallery provides a JAAS login sample that demonstrates how to use JAAS with WebSphere Application Server. The sample uses a server-side login with JAAS to authenticate a user with the security runtime for WebSphere Application Server. The sample demonstrates the following technology:

- Java 2 Platform, Enterprise Edition (J2EE) Java Authentication and Authorization Service (JAAS)
- JAAS for WebSphere Application Server
- WebSphere Application Server security

The form login sample is a component of the technology samples. For more information on how to access the form login sample, see "Accessing the Samples (Samples Gallery)" on page 11.

Configuration entry settings for Java Authentication and Authorization Service:

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) login configurations for the application code to use, including Java 2 Platform, Enterprise Edition (J2EE) components such as enterprise beans, JavaServer Pages (JSP) files, servlets, resource adapters, and message-driven beans (MDBs).

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.

Read the JAAS specifications before you begin defining additional login modules for authenticating to the application server security run time. You can define additional login configurations for your applications. However, if the application server LoginModule com.ibm.ws.security.common.auth.module.WSLoginModuleImpl module is not used or the LoginModule module does not produce a credential that is recognized by the application server. The application server security run time cannot use the authenticated subject from these login configurations for an authorization check for resource access.

You must invoke Java client programs that use Java Authentication and Authorization Service (JAAS) for authentication with a JAAS configuration file that is specified. The application server supplies the wsjaas_client.conf default JAAS configuration file under the *app_server_root*/properties directory. This configuration file is set in the *app_server_root*/bin/launchClient.bat file as:

```
set JAAS_LOGIN_CONFIG=-Djava.security.auth.login.config=%WAS_HOME%\properties\wsjaas_client.conf
```

ClientContainer:

Specifies the login configuration used by the client container application, which uses the CallbackHandler API that is defined in the client container deployment descriptor.

The ClientContainer configuration is the default login configuration for the application server. Do not remove this default, as other applications that use it fail.

Default:	ClientContainer

DefaultPrincipalMapping:

Specifies the login configuration that is used by Java 2 Connectors to map users to principals that are defined in the J2C authentication data entries.

The ClientContainer configuration is the default login configuration for the application server. Do not remove this default, as other applications that use it fail.

Default:	ClientContainer

WSLogin:

Indicates whether all of the applications can use the WSLogin configuration to perform authentication for the application server security run time.

This login configuration does not honor the CallbackHandler handler that is defined in the client container deployment descriptor. To use this functionality, use the ClientContainer login configuration.

The WSLogin configuration is the default login configuration for the application server. Do not remove this default because other administrative applications that use it fail. This login configuration authenticates users for the application server security run time. Use the credentials from the authenticated subject that

are returned from this login configuration as an authorization check for access to application server resources.

Default: ClientContainer

System login configuration entry settings for Java Authentication and Authorization Service:

Use this page to specify a list of Java Authentication and Authorization Service (JAAS) system login configurations.

To view this administrative console page, complete the following steps:
1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > System logins**.

Read the Java Authentication and Authorization Service documentation before you begin defining additional login modules for authenticating to the application server security runtime. Do not remove the following system login modules:
- RMI_INBOUND
- WEB_INBOUND
- DEFAULT
- RMI_OUTBOUND
- SWAM
- wssecurity.IDAssertion
- wssecurity.signature
- wssecurity.PKCS7
- wssecurity.PkiPath
- wssecurity.UsernameToken
- wssecurity.X509BST
- LTPA
- LTPA_WEB

RMI_INBOUND, WEB_INBOUND, DEFAULT:

Processes inbound login requests for Remote Method Invocation (RMI), Web applications, and most of the other login protocols.

RMI_INBOUND
> This login configuration handles logins for inbound RMI requests. Typically, these logins are requests for authenticated access to Enterprise JavaBeans (EJB) files. When using the RMI connector, these logins might be requests for Java Management Extensions (JMX).

WEB_INBOUND
> This login configuration handles logins for Web application requests, which include servlets and JavaServer Pages (JSP) files. This login configuration can interact with the output that is generated from a trust association interceptor (TAI), if configured. The Subject that is passed into the WEB_INBOUND login configuration might contain objects that are generated by the TAI.

DEFAULT
> This login configuration handles the logins for inbound requests that are made by most of the other protocols and internal authentications.

These three login configurations will pass in the following callback information, which is handled by the login modules within these configurations. These callbacks are not passed in at the same time. However, the combination of these callbacks determines how the application server authenticates the user.

Callback

```
callbacks[0] = new javax.security.auth.callback.
NameCallback("Username: ");
```

Responsibility

Collects the user name that is provided during a login. This information can be the user name for the following types of logins:

- User name and password login, which is known as *basic authentication*.
- User name only for identity assertion.

Callback

```
callbacks[1] = new javax.security.auth.callback.
PasswordCallback("Password: ", false);
```

Responsibility

Collects the password that is provided during a login.

Callback

```
callbacks[2] = new com.ibm.websphere.security.auth.callback.
WSCredTokenCallbackImpl("Credential Token: ");
```

Responsibility

Collects the Lightweight Third Party Authentication (LTPA) token or other token type during a login. Typically, this information is present when a user name and a password are not present.

Callback

```
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback("Authz Token List: ");
```

Responsibility

Collects the ArrayList list of the TokenHolder objects that are returned from the call to the WSOpaqueTokenHelper. The callback uses the createTokenHolderListFromOpaqueToken method with the Common Secure Interoperability version 2 (CSIv2) authorization token as input.

Restriction: This callback is present only when the **Security Attribute Propagation** option is enabled and this login is a propagation login. In a propagation login, sufficient security attributes are propagated with the request to prevent having to access the user registry for additional attributes. You must enable security attribute propagation for both the outbound and inbound authentication.

You can enable the **Security attribute propagation** option for CSIv2 outbound authentication by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IIOP security and click **CSIv2 outbound authentication**.
3. Enable the **Security attribute propagation** option.

You can enable the **Security attribute propagation** option for CSIv2 inbound authentication by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IIOP security and click **CSIv2 inbound authentication**.
3. Enable the **Security attribute propagation** option.

In system login configurations, the application server authenticates the user based upon the information that is collected by the callbacks. However, a custom login module does not need to act upon any of these callbacks. The following list explains the typical combinations of these callbacks:

- The `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");` callback only

  This callback occurs for CSIv2 identity assertion; Web and CSIv2 X509 certificate logins; old-style trust association interceptor logins, and so on. In Web and CSIv2 X509 certificate logins, the application server maps the certificate to a user name. This callback is used by any login type that establishes trust with the user name only.

- Both the `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");` callback and the `callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);` callbacks.

  This combination of callbacks is typical for basic authentication logins. Most user authentications occur using these two callbacks.

- The `callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");` only

  This callback is used to validate a Lightweight Third Party Authentication (LTPA) token. This validation typically occurs during a single sign-on (SSO) or downstream login. Any time a request originates from the application server, instead of a pure client, the LTPA token flows to the target server. For single sign-on (SSO), the LTPA token is received in the cookie and the token is used for login. If a custom login module needs the user name from an LTPA token, the module can use the following method to retrieve the unique ID from the token:

  ```
  com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
  validateLTPAToken(byte[])
  ```

  After retrieving the unique ID, use the following method to get the user name:

  ```
  com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
  getUserFromUniqueID(uniqueID)
  ```

  Important: Any time a custom login module is plugged in ahead of the application server login modules and it changes the identity using a credential mapping service, it is important that this login module validates the LTPA token, if present. Calling the following method is sufficient to validate the trust in the LTPA token:

  ```
  com.ibm.wsspi.security.token.WSSecurityPropagationHelper.
  validateLTPAToken(byte[])
  ```

  The receiving server must have the same LTPA keys as the sending server for this validation to be successful. A security exposure is possible if you do not validate this LTPA token, when present.

- A combination of any of the previously mentioned callbacks plus the `callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");` callback.

  This callback indicates that some propagated attributes arrived at the server. The propagated attributes still require one of the following authentication methods:

  - `callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");`
  - `callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);`
  - `callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");`

If the attributes are added to the Subject from a pure client, then the NameCallback and PasswordCallback callbacks authenticate the information and the objects that are serialized in the token holder are added to the authenticated Subject.

If both CSIv2 identity assertion and propagation are enabled, the application server uses the NameCallback callback and the token holder, which contains all of the propagated attributes, to deserialize most of the objects. The application server uses the NameCallback callback because trust is established with the servers that you indicate in the CSIv2 trusted server list. To specify trusted servers, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **CSIv2 inbound authentication**.

A custom login module needs to handle custom serialization. For more information, see ″Security attribute propagation″ in the information center.

In addition to the callbacks that are defined previously, the WEB_INBOUND login configuration can contain the following additional callbacks only:

Callback
```
callbacks[4] = new com.ibm.websphere.security.auth.callback.
WSServletRequestCallback("HttpServletRequest: ");
```

Responsibility
Collects the HTTP servlet request object, if presented. This callback enables login modules to retrieve information from the HTTP request to use during a login.

Callback
```
callbacks[5] = new com.ibm.websphere.security.auth.callback.
WSServletResponseCallback("HttpServletResponse: ");
```

Responsibility
Collects the HTTP servlet response object, if presented. This callback enables login modules to add information into the HTTP response as a result of the login. For example, login modules might add the SingleSignonCookie cookie to the response.

Callback
```
callbacks[6] = new com.ibm.websphere.security.auth.callback.
WSAppContextCallback("ApplicationContextCallback: ");
```

Responsibility
Collects the Web application context used during the login. This callback consists of a hashtable, which if present contains the application name and the redirected Web address.

Callback
callbacks[7] = new WSRealmNameCallbackImpl(″Realm Name: ″, <default_realm>);

Responsibility
Collects the realm name for the login information. The realm information might not always be provided and should be assumed to be the current realm if it is not provided.

Callback
callbacks[8] = new WSX509CertificateChainCallback(″X509Certificate[]: ″);

Responsibility
If the login source is an X509Certificate from SSL client authentication, this callback contains the certificate that was validated by SSL. The ltpaLoginModule calls the same mapping functions as in previous releases. Once it is passed into the login, it provides a custom login module with the opportunity to map the certificate in a custom way. It then perform a hashtable login (see Example: Custom login module for inbound mapping for an example of a hashtable login).

If you want to use security attribute propagation with the WEB_INBOUND login configuration, you can enable **Web inbound security attribute propagation** option on the Single sign-on panel.

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand Web security and click **Single sign-on (SSO)**.
3. Select the **Web inbound security attribute propagation** option.

The following login modules are predefined for the RMI_INBOUND, WEB_INBOUND, and DEFAULT system login configurations. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules:

- com.ibm.ws.security.server.lm.ltpaLoginModule

  Performs the primary login when attribute propagation is either enabled or disabled. A primary login uses normal authentication information such as a user ID and password, an LTPA token, or a trust association interceptor (TAI) and a certificate distinguished name (DN). If any of the following scenarios are true, this login module is not used and the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule module performs the primary login:

  – The java.util.Hashtable object with the required user attributes is contained in the Subject.
  – The java.util.Hashtable object with the required user attributes is present in the sharedState HashMap of the LoginContext.
  – The WSTokenHolderCallback callback is present without a specified password. If a user name and a password are present with a WSTokenHolderCallback callback, which indicates propagated information, the request likely originates from either a pure client or a server from a different realm that mapped the existing identity to a user ID and password.

- com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule

  This login module performs the primary login using the normal authentication information if any of the following conditions are true:

  – A java.util.Hashtable object with required user attributes is contained in the Subject.
  – A java.util.Hashtable object with required user attributes is present in the sharedState HashMap of the LoginContext context.
  – The WSTokenHolderCallback callback is present without a PasswordCallback callback.

  When the java.util.Hashtable object is present, the login module maps the object attributes into a valid Subject. When the WSTokenHolderCallback callback is present, the login module deserializes the byte token objects and regenerates the serialized Subject contents. The java.util.Hashtable hashtable takes precedence over all of the other forms of login. Be careful to avoid duplicating or overriding what the application server might have propagated previously.

  By specifying a java.util.Hashtable hashtable to take precedence over other authentication information, the custom login module must have already verified the LTPA token, if present, to establish sufficient trust. The custom login module can use the com.ibm.wsspi.security.token.WSSecurityPropagationHelper.validationLTPAToken(byte[]) method to validate the LTPA token present in the WSCredTokenCallback callback. Failure to validate the LTPA token presents a security risk.

  For more information on adding a hashtable containing well-known and well-formed attributes used by the application server as sufficient login information, see ″Configuring inbound identity mapping″ in the information center.

RMI_OUTBOUND:

Processes Remote Method Invocation (RMI) requests that are sent outbound to another server when either the com.ibm.CSI.rmiOutboundLoginEnabled or the com.ibm.CSIOutboundPropagationEnabled properties are true.

These properties are set in the CSIv2 authentication panel. To access the panel, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, expand RMI/IIOP security and click **CSIv2 outbound authentication**.

To set the com.ibm.CSI.rmiOutboundLoginEnabled property, select **Custom outbound mapping**. To set the com.ibm.CSIOutboundPropagationEnabled property, select the **Security attribute propagation** option.

This login configuration determines the security capabilities of the target server and its security domain. For example, if the application server Version 5.1.1 or later (or 5.1.0.2 for z/OS) communicates with a Version 5.x Application Server, then the Version 5.1.1 Application Server sends the authentication information only, using an LTPA token, to the Version 5.x Application Server. However, if WebSphere Application Server Version 5.1.1 or later communicates with a Version 5.1.x Application Server, the authentication and authorization information is sent to the receiving application server if propagation is enabled at both the sending and receiving servers. When the application server sends both the authentication and authorization information downstream, the application server removes the need to access the user registry again and look up the security attributes of the user for authorization purposes. Additionally, any custom objects that are added at the sending server are present in the Subject at the downstream server.

The following callback is available in the RMI_OUTBOUND login configuration. You can use the `com.ibm.wsspi.security.csiv2.CSIv2PerformPolicy` object that is returned by this callback to query the security policy for this particular outbound request. This query can help determine if the target realm is different than the current realm and if the application server must map the realm. For more information, see "Configuring outbound mapping to a different target realm" in the information center.

Callback
>   callbacks[0] = new WSProtocolPolicyCallback("Protocol Policy Callback: ");

Responsibility

> Provides protocol-specific policy information for the login modules on this outbound invocation. This information is used to determine the level of security, including the target realm, target security requirements, and coalesced security requirements.

> The following method obtains the CSIv2PerformPolicy policy from this specific login module:

>   csiv2PerformPolicy = (CSIv2PerformPolicy)
>   ((WSProtocolPolicyCallback)callbacks[0]).getProtocolPolicy();

> A different protocol other than RMI might have a different type of policy object.

The following login module is predefined in the RMI_OUTBOUND login configuration. You can add custom login modules before, between, or after any of these login modules, but you cannot remove these predefined login modules.

com.ibm.ws.security.lm.wsMapCSIv2OutboundLoginModule
> Retrieves the following tokens and objects before creating an opaque byte that is sent to another server by using the Common Secure Interoperability Version 2 (CSIv2) authorization token layer:
> - Forwardable com.ibm.wsspi.security.token.Token implementations from the Subject
> - Serializable custom objects from the Subject
> - Propagation tokens from the thread

> You can use a custom login module prior to this login module to perform credential mapping. However, it is recommended that the login module change the contents of the Subject that is passed in during the login phase. If this recommendation is followed, the login modules are processed after this login module acts on the new Subject contents.

For more information, see "Configuring outbound mapping to a different target realm" in the information center.

SWAM:

Processes login requests in a single server environment when Simple WebSphere Authentication Mechanism (SWAM) is used as the authentication method.

SWAM does not support forwardable credentials. When SWAM is the authentication method, the application server cannot send requests from server to server. In this case, you must use LTPA.

Note: The SWAM login configuration is deprecated and will be removed in a future release.

wssecurity.IDAssertion:

Processes login configuration requests for Web services security using identity assertion.

This login configuration is for Version 5.x systems. For more information, see ″Identity assertion authentication method″ in the information center.

wssecurity.PKCS7:

Verifies an X.509 certificate with a certificate revocation list in a Public Key Cryptography Standards #7 (PKCS7) object.

This login configuration is for Version 6.0.x systems.

wssecurity.PkiPath:

Verifies an X.509 certificate with a public key infrastructure (PKI) path.

This login configuration is for Version 6.0.x systems.

wssecurity.signature:

Processes login configuration requests for Web services security using digital signature validation.

This login configuration is for Version 5.x systems.

wssecurity.UsernameToken:

Verifies basic authentication (user name and password).

This login configuration is for Version 6.0.x systems.

wssecurity.X509BST:

Verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path.

This login configuration is for Version 6.0.x systems.

LTPA_WEB:

Processes login requests to components in the Web container such as servlets and JavaServer pages (JSP) files.

The com.ibm.ws.security.web.AuthenLoginModule login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the LTPA_WEB login configuration.

The LTPA_WEB login configuration can process the HttpServletRequest object, the HttpServletResponse object, and the Web application name that are passed in using a callback handler. For more information, see ″Example: Customizing a server-side Java Authentication and Authorization Service authentication and logon configuration″ in the information center.

LTPA:

Processes login requests that are not handled by the LTPA_WEB login configuration.

This login configuration is used by WebSphere Application Server Version 5.1 and previous versions.

The com.ibm.ws.security.server.lm.ltpaLoginModule login module is predefined in the LTPA login configuration. You can add custom login modules before or after this module in the LTPA login configuration. For more information, see ″Example: Customizing a server-side Java Authentication and Authorization Service authentication and logon configuration″ in the information center.

Login module settings for Java Authentication and Authorization Service:

Use this page to define the login module for a Java Authentication and Authorization Service (JAAS) login configuration.

You can define the JAAS login modules for application and system logins. To define these login modules in the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins** or **System logins** > *alias_name*.
3. Under Additional properties, click **JAAS login modules**.

Module class name:

Specifies the class name of the given login module.

Data type:	String

Use login module proxy:

Specifies that the Java Authentication and Authorization Service (JAAS) loads the login module proxy class. JAAS then delegates calls to the login module classes that are defined in the Module class name field.

Use this option when you use both Version 5.x and Version 6 Application Servers in the same environment. If you migrate a Version 5.x Application Server to Version 6, WebSphere Application Server Version 6 automatically enables this option. If you have Version 6 only cells in your environment, you might choose to deselect this option.

Default:	Enabled

Proxy class name:

Specifies the name of the proxy login module class.

The default login modules that are defined by the application server use the com.ibm.ws.security.common.auth.module.WSLoginModuleProxy proxy LoginModule class. This proxy class loads the application server login module with the thread context class loader and delegates all the

operations to the real login module implementation. The real login module implementation is specified as the delegate option in the option configuration. The proxy class is needed because the Developer Kit application class loaders do not have visibility of the application server product class loaders.

Data type: String

Authentication strategy:

Specifies the authentication behavior as authentication proceeds down the list of login modules.

A Java Authentication and Authorization Service (JAAS) authentication provider supplies the authentication strategy. In JAAS, an authentication strategy is implemented through the LoginModule interface.

Data type: String
Default: Required
Range: Required, Requisite, Sufficient and Optional

Required
>   The LoginModule module is required to succeed. Whether authentication succeeds or fails, the process still continues down the LoginModule list for each realm.

Requisite
>   The LoginModule module is required to succeed. If authentication is successful, the process continues down the LoginModule list in the realm entry. If authentication fails, control immediately returns to the application. Authentication does not proceed down the LoginModule list.

Sufficient
>   The LoginModule module is not required to succeed. If authentication succeeds, control immediately returns to the application. Authentication does not proceed down the LoginModule list. If authentication fails, the process continues down the list.

Optional
>   The LoginModule module is not required to succeed. Whether authentication succeeds or fails, the process still continues down the LoginModule list.

Specify additional options by clicking **Custom Properties** under Additional Properties. These name and value pairs are passed to the login modules during initialization. This process is one of the mechanisms that is used to passed information to login modules.

Module order:

Specifies the order in which the Java Authentication and Authorization Service (JAAS) login modules are processed.

Click **Set Order** to change the processing order of the login modules.

Login module order settings for Java Authentication and Authorization Service:

Use this page to specify the order in which the application server processes the login configuration modules.

You can specify the order of the login modules for application and system logins. To define these login modules in the administrative console, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins** or **System logins** > *alias*. You can create a new configuration by clicking **New**.

3. Under Additional properties, click **JAAS login modules**.

4. Click **Set order**.

When you select one of the JAAS login module class names, you can move that class name up and down the list. After you click **OK** and save the changes, the new order is reflected on either the Application login configuration or the System login configuration panel.

Login configuration settings for Java Authentication and Authorization Service:

Use this page to configure application login configurations.

To view this administrative console page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.

2. Under Authentication, click **Java Authentication and Authorization Service > Application logins** or **System logins > *alias_name***.

Click **Apply** to save changes and to add the extra node name that precedes the original alias name. Clicking **OK** does not save the new changes in the `security.xml` file.

Alias:

Specifies the alias name of the application login.

Do not use the forward slash character (/) in the alias name when defining JAAS login configuration entries. The JAAS login configuration parser cannot process the forward slash character.

Data type: String

Managing J2EE Connector Architecture authentication data entries:

This task creates and deletes Java 2 Connector (J2C) authentication data entries.

Java 2 Platform, Enterprise Edition (J2EE) Connector authentication data entries are used by resource adapters and Java DataBase Connectivity (JDBC) data sources. A J2EE Connector authentication data entry contains authentication data, which includes the following information:

Alias   An identifier that identifies the authentication data entry. When configuring resource adapters or data sources, the administrator can specify which authentication data to choose using the corresponding alias.

User ID

A user identity of the intended security domain. For example, if a particular authentication data entry is used to open a new connection to DB2, this entry contains a DB2 user identity.

Password

The password of the user identity is encoded in the configuration repository.

Description

A short text description.

1. Delete a J2C authentication data entry.

   a. Click **Security > Secure administration, applications, and infrastructure**.

   b. Under Java Authentication and Authorization Service, click **J2C authentication data**. The **J2C Authentication Data Entries** panel is displayed.

   c. Select the check boxes for the entries to delete and click **Delete**. Before deleting or removing an authentication data entry, make sure that it is not used or referenced by any resource adapter or data source. If the deleted authentication data entry is used or referenced by a resource, the application that uses the resource adapter or the data source fails to connect to the resources.

2. Create a new J2C authentication data entry.

a. Click **Security > Secure administration, applications, and infrastructure**.

b. Under Java Authentication and Authorization Service, click **J2C authentication data**. The **J2C Authentication Data Entries** panel is displayed.

c. Click **New**.

d. Enter a unique alias, a valid user ID, a valid password, and a short description (optional).

e. Click **OK** or **Apply**. No validation for the user ID and password is required.

f. Click **Save**.

Make sure that a file synchronized operation is performed to propagate the changes to other nodes.

A new J2C authentication data entry is created or an old entry is removed. The newly created entry is visible without restarting the application server process to use in the data source definition. But the entry is only in effect after the server is restarted. Specifically, the authentication data is loaded by an application server when starting an application and is shared among applications in the same application server.

If you create or update a data source that points to a newly created J2C authentication data alias, the test connection fails to connect until you restart the deployment manager. After you restart the deployment manager, the J2C authentication data is reflected in the run-time configuration. Any changes to the J2C authentication data fields require a deployment manager restart for the changes to take effect. The node agent must also be restarted.

This step defines authentication data that you can share among resource adapters and data sources. Use the authentication data entry that is defined in the resource adapters or the data sources.

Java 2 Connector authentication data entry settings:

Use this page as a central place for administrators to define authentication data, which includes user identities and passwords. These values can reference authentication data entries by resource adapters, data sources, and other configurations that require authentication data using an alias.

You can display this page directly from the Java Authentication and Authorization Service (JAAS) configuration page or from other pages for resources that use J2EE Connector (J2C) authentication data entries. To view this administrative page, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.

2. Under Authentication, click **Java Authentication and Authorization Service > J2C authentication data**.

Deleting authentication data entries: Be careful when deleting authentication data entries. If the deleted authentication data is used by other configurations, the initializing resources process fails.

Define a new authentication data entry by clicking **New**.

Alias:

Specifies the name of the authentication data entry.

Data type:	String
Units:	String
Default:	None

User ID:

Specifies the user identity.

| **Data type:** | String |

Password:

Specifies the password that is associated with the user identity.

This field is not available on the collections panel. However, the panel is available when you create a new J2C authentication data entry.

Data type: String

Description:

Specifies an optional description of the authentication data entry. For example, this authentication data entry is used to connect to DB2.

Data type: String

J2C principal mapping modules:

You can develop your own J2EE Connector (J2C) mapping module if your application requires more sophisticated mapping functions. The mapping login module that you might have developed on WebSphere Application Server Version 5.*x* is still supported in WebSphere Application Server Version 6.0.*x* and later.

You can use the Version 5.*x* login modules in the connection factory mapping configuration. These login modules can also be used in the reference mapping configuration for the resource manager connection factory. A version 5.*x* mapping login module is not able to use the custom mapping properties.

If you want to develop a new mapping login module in Version 6.0.*x* and later, use the programming interface that is described in the following sections.

transition: Migrate your Version 5.*x* mapping login module to use the new programming model and the new custom properties as well as the mapping configuration isolation at application scope. Note that mapping login modules that are developed using WebSphere Application Server Version 6.0.*x* cannot be used in the deprecated mapping configuration for the resource connection factory.

Invoking the login module for the resource reference mapping

A com.ibm.wsspi.security.auth.callback.WSMappingCallbackHandler class, which implements the javax.security.auth.callback.CallbackHandler interface, is a new WebSphere Application Service Provider Programming Interface (SPI) in WebSphere Application Server Version 6.0.*x*.

Application code uses the com.ibm.wsspi.security.auth.callback.WSMappingCallbackHandlerFactory helper class to retrieve a CallbackHandler object:

```
package  com.ibm.wsspi.security.auth.callback;

public class WSMappingCallbackHandlerFactory {
 private WSMappingCallbackHandlerFactory;
 public static CallbackHandler getMappingCallbackHandler(
ManagedConnectionFactory mcf,
HashMap mappingProperties);
}
```

The WSMappingCallbackHandler class implements the CallbackHandler interface:

```
package com.ibm.wsspi.security.auth.callback;

public class WSMappingCallbackHandler implements CallbackHandler {
 public WSMappingCallbackHandler(ManagedConnectionFactory mcf,
HashMap mappingProperties);
 public void handle(Callback[] callbacks) throws IOException,
     UnsupportedCallbackException;
}
```

The WSMappingCallbackHandler handler can manage two new callback types that are defined in Version 6.0.x:

```
com.ibm.wsspi.security.auth.callback.WSManagedConnectionFactoryCallback
com.ibm.wsspi.security.auth.callback.WSMappingPropertiesCallback
```

The new login modules use the two callback types that are used at the reference mapping configuration for the resource manager connection factory. The WSManagedConnectionFactoryCallback callback provides a ManagedConnectionFactory instance that you set in the PasswordCredential credential. With this setting, the ManagedConnectionFactory instance can determine whether a PasswordCredential instance is used for signon to the target Enterprise Information Systems (EIS) instance. The WSMappingPropertiesCallback callback provides a hash map that contains custom mapping properties. The com.ibm.mapping.authDataAlias property name is reserved for setting the authentication data alias.

The WebSphere Application Server WSMappingCallbackHandle handle continues to support the two WebSphere Application Server Version 5.*x* callback types that older mapping login modules can use. The two callbacks defined can be used only by login modules that the login configuration uses at the connection factory. For backward compatibility, WebSphere Application Server Version 6.0.x and later passes the authentication data alias, if defined in the list of custom properties under the com.ibm.mapping.authDataAlias property name using the WSAuthDataAliasCallback callback to Version 5.*x* login modules:

```
com.ibm.ws.security.auth.j2c.WSManagedConnectionFactoryCallback
com.ibm.ws.security.auth.j2c.WSAuthDataAliasCallback
```

Invoking the login module for the connection factory mapping

The WSPrincipalMappingCallbackHandler class handles two callback types:

```
com.ibm.wsspi.security.auth.callback.WSManagedConnectionFactoryCallback
com.ibm.wsspi.security.auth.callback.WSMappingPropertiesCallback
```

The WSPrincipalMappingCallbackHandler handler and the two callbacks are deprecated in WebSphere Application Server Version 6.

Passing the mapping properties for the resource reference to the mapping login module

You can pass arbitrary custom properties to your mapping login module. The following example shows how the WebSphere Application Server default mapping login module looks for the authentication data alias property.

```
  try {
      wspm_callbackHandler.handle(callbacks);
            String userID = null;
            String password = null;
            String alias = null;
            wspm_properties = ((WSMappingPropertiesCallback)callbacks[1]).getProperties();

            if (wspm_properties != null) {
                alias = (String) wspm_properties.get(com.ibm.wsspi.security.auth.callback.
                    Constants.MAPPING_ALIAS);
                if (alias != null) {
                    alias = alias.trim();
```

```
                    }
                }
            } catch (UnsupportedCallbackException unsupportedcallbackexception) {
 . . . // error handling
```

The default mapping login module for WebSphere Application Server Version 6.0.*x* requires one mapping property to define the authentication data alias. The mapping property, which is called MAPPING_ALIAS, is defined in the Constants.class file in the com.ibm.wsspi.security.auth.callback package.

MAPPING_ALIAS   =   ″com.ibm.mapping.authDataAlias″

When you click **Use default method** > **Select authentication data entry authentication** on the Map resource references to resources panel, the administrative console automatically creates a MAPPING_ALIAS entry with the selected authentication data alias value in the mapping properties. If you create your own custom login configuration and then use the default mapping login module, you must set this property manually on the mapping properties for the resource factory reference.

In a custom login module, you can use the WSSubject.getRunAsSubject method to retrieve the subject that represents the identity of the current running thread. The identity of the current running thread is known as the *RunAs* identity. The RunAs subject typically contains a WSPrincipal principal in the principal set and a WSCredential credential in the public credential set. The subject instance that is created by your mapping module contains a Principal instance in the principals set and a PasswordCredential credential or an org.ietf.jgss.GSSCredential instance in the set of private credentials.

The GenericCredential interface that is defined in Java Cryptography Architecture (JCA) Specification Version 1.0 is removed in the JCA Version 1.5 specification. The GenericCredential interface is supported by WebSphere Application Server Version 6.0.*x* to support older resource adapters that might be programmed to the GenericCredential interface.

Customizing an application login to perform an identity assertion:

Using the Java Authentication and Authorization Service (JAAS) login framework, you can create a JAAS login configuration that can be used to perform login to an identity assertion.

You can allow an application or system provider to perform an identity assertion with trust validation. To do this, you use the JAAS login framework, where trust validation is accomplished in one login module and credential creation is accomplished in another module. The two custom login modules allow you to create a JAAS login configuration that can be used to perform a login to an identity assertion.

Two custom login modules are required:

User implemented trust association login module (trust validation)
> The user implemented trust association login module performs whatever trust verification the user requires. When trust is verified, the trust verification status and the login identity should be put into a map in the share state of the login module so that the credential creation login module can use the information. This map should be stored in the property:
>
> com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state
> > (which consists of)
>
> com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted
> > (which is set to **true** if trusted and **false** if not trusted)
>
> com.ibm.wsspi.security.common.auth.module.IdenityAssertionLoginModule.principal
> > (which contains the principal of the identity)

com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates
(which contains the certificate of the identity)

Identity assertion login module (credential creation)

The com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule performs the credential creation. This module relies on the trust state information being in the login context's shared state. This login module is protected by the Java 2 security runtime permissions for:

- com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.initialize
- com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.login

The identity assertion login module looks for the trust information in the shared state property, com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state, which contains the trust status and the identity to login and should include:

com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted
(which when *true* indicates trusted and *false* when not trusted)

com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal
(which contains the principal of the identity to login, if using a principal)

com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates
(which contains a array of a certificate chain that contains the identity to login, if using a certificate)

A WSLoginFailedException is returned if the state, trust, or identity information is missing. The login module then performs a login of the identity, and the subject will contain the new identity

1. Delegate trust validation to a user implemented plug point. Trust validation must be accomplished in a custom login module. This custom login module should perform any trust validation required, then set the trust and identity information in the shared state to be passed on to the identity assertion login module. A map is required in the shared state key, com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state. If the state is missing then a WSLoginFailedException is thrown by the IdentityAssertionLoginModule. This map must include:

- A trust key called com.ibm.wsspi.secuirty.common.auth.module.IdentityAssertionLoginModule.trust. If the key is set to *true*, then trust is established. If the key is set to *false*, then no trust is established. If the trust key is not set to true, then the IdentityAssertionLoginModule will throw a WSLoginFailedException.
- • An identity key is set: A java.security.Principal can be set in the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal key.
- Or a java.security.cert.X509Certificate[] can be set in the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certficates key

If both a principal and certificate are supplied, then the principal is used and a warning is issued.

2. Create a new JAAS configuration for application logins The JAAS configuration will contain the user implemented trust validation custom login module and the IdentityAssertionLoginModule. Then to configure an application login configuration, perform the following on the administration console:

   a. Expand **Security > Secure administration, applications, and infrastructure**
   b. Expand **Java authentication and authorization services > Application logins**
   c. Select **New**.
   d. Give the JAAS configuration an alias.
   e. Click **Apply**.
   f. Select **JAAS Login Modules**
   g. Select **New**.
   h. Enter the **Module class name** of the user implemented trust validation custom login module.

    i. Click **Apply**.

    j. Enter the **Module class name** of
com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule

    k. Make sure the **Module class name** classes are in the correct order. The user implemented trust validation login module should be first and the IdentityAssertionLoginModule should be the second class in the list.

    l. Click **Save**.

    This JAAS configuration is then used by the application to perform an Identity Assertion.

3. Perform the programmable identity assertion. A program can now use the JAAS login configuration to perform a programmatic identity assertion. The application program can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity they would assert to. If the login is successful then that identity can be set in the current running process. Here is a example of how such code would operate:

```
MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login();  //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on , the runas identity is "Joe"
```

Using the JAAS login framework and two user implemented login modules, you can create a JAAS login configuration that can be used to perform login to an identity assertion.

Customization of a server-side Java Authentication and Authorization Service authentication and login configuration:

WebSphere Application Server supports plugging in a custom Java Authentication and Authorization Service (JAAS) login module before or after the WebSphere Application Server system login module. However, WebSphere Application Server does not support the replacement of the WebSphere Application Server system login modules, which are used to create the WSCredential credential and WSPrincipal principal in the Subject. By using a custom login module, you can either make additional authentication decisions or add information to the Subject to make additional, potentially finer-grained, authorization decisions inside a Java 2 Platform, Enterprise Edition (J2EE) application.

WebSphere Application Server enables you to propagate information downstream that is added to the Subject by a custom login module. For more information, see Security attribute propagation. To determine which login configuration to use for plugging in your custom login modules, see the descriptions of the login configurations that are located in the "System login configuration entry settings for Java Authentication and Authorization Service" on page 927.

WebSphere Application Server supports the modification of the system login configuration through the administrative console and by using the wsadmin scripting utility. To configure the system login configuration using the administrative console, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**.

Refer to the following code sample to configure a system login configuration using the wsadmin tool. The following sample Jacl script adds a custom login module into the Lightweight Third-party Authentication (LTPA) Web system login configuration:

Attention: Lines 32, 33, and 34 in the following code sample are split into two lines.

```
1. #######################################
2. #
3. # Open security.xml
4. #
5. #######################################
6.
```

```
7.
8. set sec [$AdminConfig getid /Cell:hillside/Security:/]
9.
10.
11. #######################################
12. #
13. # Locate systemLoginConfig
14. #
15. #######################################
16.
17.
18. set slc [$AdminConfig showAttribute $sec systemLoginConfig]
19.
20. set entries [lindex [$AdminConfig showAttribute $slc entries] 0]
21.
22.
23. #######################################
24. #
25. # Append a new LoginModule to LTPA_WEB
26. #
27. #######################################
28.
29. foreach entry $entries {
30. set alias [$AdminConfig showAttribute $entry alias]
31. if {$alias == "LTPA_WEB"} {
32.     set newJAASLoginModuleId [$AdminConfig create JAASLoginModule
         $entry {{moduleClassName
         "com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"}}]
33.     set newPropertyId [$AdminConfig create Property
         $newJAASLoginModuleId {{name delegate}{value
         "com.ABC.security.auth.CustomLoginModule"}}]
34.     $AdminConfig modify $newJAASLoginModuleId
         {{authenticationStrategy REQUIRED}}
35.     break
36.     }
37. }
38.
39.
40. #######################################
41. #
42. # save the change
43. #
44. #######################################
45.
46. $AdminConfig save
47.
```

Attention: The wsadmin scripting utility inserts a new object to the end of the list. To insert the custom login module before the AuthenLoginModule login module, delete the AuthenLoginModule login module and recreate it after inserting the custom login module. Save the sample script into a `sample.jacl` file, and run the sample script using the following command:

```
wsadmin -f sample.jacl
```

You can use the following sample Jacl script to remove the current LTPA_WEB login configuration and all the login modules:

```
48. #######################################
49. #
50. # Open security.xml
51. #
52. #######################################
53.
```

```
54.
55. set sec [$AdminConfig getid /Cell:hillside/Security:/]
56.
57.
58. #######################################
59. #
60. # Locate systemLoginConfig
61. #
62. #######################################
63.
64.
65. set slc [$AdminConfig showAttribute $sec systemLoginConfig]
66.
67. set entries [lindex [$AdminConfig showAttribute $slc entries] 0]
68.
69.
70. #######################################
71. #
72. # Remove the LTPA_WEB login configuration
73. #
74. #######################################
75.
76. foreach entry $entries {
77.     set alias [$AdminConfig showAttribute $entry alias]
78.     if {$alias == "LTPA_WEB"} {
79.         $AdminConfig remove $entry
80.         break
81.     }
82. }
83.
84.
85. #######################################
86. #
87. # save the change
88. #
89. #######################################
90.
91. $AdminConfig save
```

You can use the following sample Jacl script to recover the original LTPA_WEB configuration:

Attention: Lines 122, 124, and 126 in the following code sample are split into two or more lines for illustrative purposes only.

```
92. #######################################
93. #
94. # Open security.xml
95. #
96. #######################################
97.
98.
99. set sec [$AdminConfig getid /Cell:hillside/Security:/]
100.
101.
102. #######################################
103. #
104. # Locate systemLoginConfig
105. #
106. #######################################
107.
108.

     $newJAASConfigurationEntryId
     {{moduleClassName
     "com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"}}]
125.
126. set newPropertyId [$AdminConfig create Property
     $newJAASLoginModuleId {{name delegate}
     {value "com.ibm.ws.security.web.AuthenLoginModule"}}]
127.
128. $AdminConfig modify $newJAASLoginModuleId {{authenticationStrategy REQUIRED}}
129.
130.
131. ########################################
132. #
133. # save the change
134. #
135. ########################################
136.
137. $AdminConfig save
```

The WebSphere Application Server Version ltpaLoginModule and AuthenLoginModule login modules use the shared state to save state information so that custom login modules can modify the information. The ltpaLoginModule login module initializes the callback array in the login method using the following code. The callback array is created by the ltpaLoginModule login module only if an array is not defined in the shared state area. In the following code sample, the error handling code is removed to make the sample concise. If you insert a custom login module before the ltpaLoginModule login module, the custom login module might follow the same style to save the callback into the shared state.

Attention: In the following code sample, several lines of code are split into two lines for illustrative purposes only.

```
138.        Callback callbacks[] = null;
139.        if (!sharedState.containsKey(
              com.ibm.wsspi.security.auth.callback.Constants.
              CALLBACK_KEY)) {
140.          callbacks = new Callback[3];
141.          callbacks[0] = new NameCallback("Username: ");
142.          callbacks[1] = new PasswordCallback("Password: ", false);
143.          callbacks[2] = new com.ibm.websphere.security.auth.callback.
              WSCredTokenCallbackImpl( "Credential Token: ");
144.          try {
145.              callbackHandler.handle(callbacks);
146.          } catch (java.io.IOException e) {
147.              . . .
148.          } catch (UnsupportedCallbackException uce) {
149.              . . .
150.          }
151.          sharedState.put(
```

```
                    com.ibm.wsspi.security.auth.callback.Constants.CALLBACK_KEY,
                    callbacks);
152.            } else {
153.                callbacks = (Callback [])
                    sharedState.get( com.ibm.wsspi.security.auth.callback.
                    Constants.CALLBACK_KEY);
154.            }
```

The ltpaLoginModule and AuthenLoginModule login modules generate both a WSPrincipal object and a
WSCredential object to represent the authenticated user identity and security credentials. The WSPrincipal
and WSCredential objects also are saved in the shared state. A JAAS login uses a two-phase commit
protocol.

First, the login methods in login modules, which are configured in the login configuration, are called. Then,
their commit methods are called. A custom login module, which is inserted after the ltpaLoginModule and
the AuthenLoginModule login modules, can modify the WSPrincipal and WSCredential objects before
these objects are committed. The WSCredential and WSPrincipal objects must exist in the Subject after
the login is completed. Without these objects in the Subject, WebSphere Application Server run-time code
rejects the Subject to make security decisions.

AuthenLoginModule uses the following code to initialize the callback array:

Attention: In the following code sample, several lines of code are split into two lines for illustrative
purposes only.

```
155.            Callback callbacks[] = null;
156.            if (!sharedState.containsKey(
                    com.ibm.wsspi.security.auth.callback.Constants.
                    CALLBACK_KEY)) {
157.                callbacks = new Callback[6];
158.                callbacks[0] = new NameCallback("Username: ");
159.                callbacks[1] = new PasswordCallback("Password: ", false);
160.                callbacks[2] =
                    new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl(
                    "Credential Token: ");
161.                callbacks[3] =
                    new com.ibm.wsspi.security.auth.callback.WSServletRequestCallback(
                    "HttpServletRequest: ");
162.                callbacks[4] =
                    new com.ibm.wsspi.security.auth.callback.WSServletResponseCallback(
                    "HttpServletResponse: ");
163.                callbacks[5] =
                    new com.ibm.wsspi.security.auth.callback.WSAppContextCallback(
                    "ApplicationContextCallback: ");
164.                try {
165.                    callbackHandler.handle(callbacks);
166.                } catch (java.io.IOException e) {
167.                    . . .
168.                } catch (UnsupportedCallbackException uce {
169.                    . . .
170.                }
171.                sharedState.put( com.ibm.wsspi.security.auth.callback.
                    Constants.CALLBACK_KEY, callbacks);
172.            } else {
173.                callbacks = (Callback []) sharedState.get(
                    com.ibm.wsspi.security.auth.callback.
                    Constants.CALLBACK_KEY);
174.            }
```

Three more objects, which contain callback information for the login, are passed from the Web container to
the AuthenLoginModule login module: a java.util.Map, an HttpServletRequest, and an HttpServletResponse

object. These objects represent the Web application context. The WebSphere Application Server Version 5.1 application context, java.util.Map object, contains the application name and the error page web address. You can obtain the application context, java.util.Map object, by calling the getContext method on the WSAppContextCallback object. The java.util.Map object is created with the following deployment descriptor information.

Attention: In the following code sample, several lines of code are split into two lines for illustrative purposes only.

```
175.        HashMap appContext = new HashMap(2);
176.        appContext.put(
            com.ibm.wsspi.security.auth.callback.Constants.WEB_APP_NAME,
            web_application_name);
177.        appContext.put(
            com.ibm.wsspi.security.auth.callback.Constants.REDIRECT_URL,
            errorPage);
```

The application name and the HttpServletRequest object might be read by the custom login module to perform mapping functions. The error page of the form-based login might be modified by a custom login module. In addition to the JAAS framework, WebSphere Application Server supports the trust association interface (TAI).

Other credential types and information can be added to the caller Subject during the authentication process using a custom login module. The third-party credentials in the caller Subject are managed by WebSphere Application Server as part of the security context. The caller Subject is bound to the running thread during the request processing. When a Web or an Enterprise JavaBeans (EJB) module is configured to use the caller identity, the user identity is propagated to the downstream service in an EJB request. The WSCredential credential and any third-party credentials in the caller Subject are not propagated downstream. Instead, some of the information can be regenerated at the target server based on the propagated identity. Add third-party credentials to the caller Subject at the authentication stage. The caller Subject, which is returned from the WSSubject.getCallerSubject method, is read-only and cannot be modified. For more information on the WSSubject subject, see "Example: Getting the caller subject from the thread" on page 961.

Custom login module development for a system login configuration:

For WebSphere Application Server, multiple Java Authentication and Authorization Service (JAAS) plug-in points exist for configuring system logins. WebSphere Application Server uses system login configurations to authenticate incoming requests, outgoing requests, and internal server logins.

Application login configurations are called by Java 2 Platform, Enterprise Edition (J2EE) applications for obtaining a Subject that is based on specific authentication information. This login configuration enables the application to associate the Subject with a specific protected remote action. The Subject is picked up on the outbound request processing. The following list identifies the main system plug-in points. If you write a login module that adds information to the Subject of a system login, these are the main login configurations to plug in:

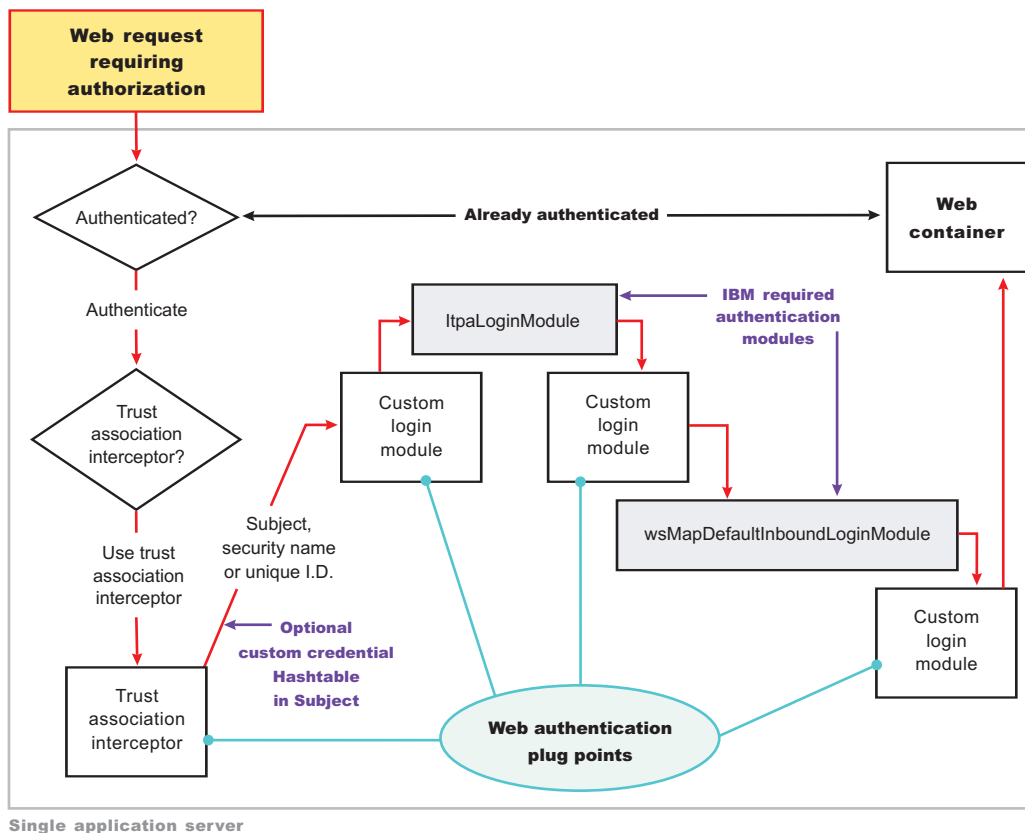
- WEB_INBOUND
- RMI_OUTBOUND
- RMI_INBOUND
- DEFAULT

WEB_INBOUND login configuration

The WEB_INBOUND login configuration authenticates Web requests. Figure 1 shows an example of a configuration using a trust association interceptor (TAI) that creates a Subject with the initial information that is passed into the WEB_INBOUND login configuration. If the trust association interceptor is not

configured, the authentication process goes directly to the WEB_INBOUND system login configuration, which consists of all the login modules combined in Figure 1. Figure 1 shows where you can plug in custom login modules and where the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

Figure 1

Single application server


For more detailed information on the WEB_INBOUND configuration including its associated callbacks, see ″RMI_INBOUND, WEB_INBOUND, DEFAULT″ in "System login configuration entry settings for Java Authentication and Authorization Service" on page 927.

RMI_OUTBOUND login configuration

The RMI_OUTBOUND login configuration is a plug point for handling outbound requests. WebSphere Application Server uses this plug point to create the serialized information that is sent downstream based on the invocation Subject passed in and other security context information such as propagation tokens. A custom login module can use this plug point to change the identity. For more information, see Configuring outbound mapping to a different target realm. Figure 2 shows where you can plug in custom login modules and shows where the wsMapCSIv2OutboundLoginModule login module is required.

Single application server

For more information on the RMI_OUTBOUND login configuration, including its associated callbacks, see ″RMI_OUTBOUND″ in "System login configuration entry settings for Java Authentication and Authorization Service" on page 927.

RMI_INBOUND login configuration

The RMI_INBOUND login configuration is a plug point that handles inbound authentication for enterprise bean requests. WebSphere Application Server uses this plug point for either an initial login or a propagation login. For more information about these two login types, see Security attribute propagation. During a propagation login, this plug point is used to deserialize the information that is received from an upstream server. A custom login module can use this plug point to change the identity, handle custom tokens, add custom objects into the Subject, and so on. For more information on changing the identity using a Hashtable object, which is referenced in figure 3, see Configuring inbound identity mapping. Figure 3 shows where you can plug in custom login modules and shows that the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

Figure 3

Single application server
For more information on the RMI_INBOUND login configuration, including its associated callbacks, see ″RMI_INBOUND, WEB_INBOUND, DEFAULT″ in "System login configuration entry settings for Java Authentication and Authorization Service" on page 927.

DEFAULT login configuration

The DEFAULT login configuration is a plug point that handles all of the other types of authentication requests, including administrative SOAP requests and internal authentication of the server ID. Propagation logins typically do not occur at this plug point.

For more information on the DEFAULT login configuration including its associated callbacks, see ″RMI_INBOUND, WEB_INBOUND, DEFAULT″ in "System login configuration entry settings for Java Authentication and Authorization Service" on page 927.

Writing a login module

When you write a login module that plugs into a WebSphere Application Server application login or system login configuration, read the JAAS programming model, which is located at: http://java.sun.com/products/ jaas. The JAAS programming model provides basic information about JAAS. However, before writing a login module for the WebSphere Application Server environment, read the following sections in this article:
- Useable callbacks
- Shared state variables
- Initial versus propagation logins
- Sample custom login module

Useable callbacks

Each login configuration must document the callbacks that are recognized by the login configuration. However, the callbacks are not always passed data. The login configuration must contain logic to know when specific information is present and how to use the information. For example, if you write a custom login module that can plug into all four of the pre-configured system login configurations mentioned

previously, three sets of callbacks might be presented to authenticate a request. Other callbacks might be present for other reasons, including propagation and making other information available to the login configuration.

Login information can be presented in the following combinations:

User name (NameCallback) and password (PasswordCallback)
> This information is a typical authentication combination.

User name only (NameCallback)
> This information is used for identity assertion, trust association interceptor (TAI) logins, and certificate logins.

Token (WSCredTokenCallbackImpl)
> This information is for Lightweight Third Party Authentication (LTPA) token validation.

Propagation token list (WSTokenHolderCallback)
> This information is used for a propagation login.

The first three combinations are used for typical authentication. However, when the WSTokenHolderCallback callback is present in addition to one of the first three information combinations, the login is called a *propagation login*. A propagation login means that some security attributes are propagated to this server from another server. The servers can reuse these security attributes if the authentication information validates successfully. In some cases, a WSTokenHolderCallback callback might not have sufficient attributes for a full login. Check the requiresLogin method on the WSTokenHolderCallback callback to determine if a new login is required. You can always ignore the information returned by the requiresLogin method, but, as a result, you might duplicate information. The following list contains the callbacks that might be present in the system login configurations. The list includes the callback name and a description of their responsibility.

callbacks[0] = new javax.security.auth.callback.NameCallback(″Username: ″);
> This callback handler collects the user name for the login. The result can be the user name for a basic authentication login (user name and password) or a user name for an identity assertion login.

callbacks[1] = new javax.security.auth.callback.PasswordCallback(″Password: ″, false);
> This callback handler collects the password for the login.

callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl(″Credential Token: ″);
> This callback handler collects the Lightweight Third Party Authentication (LTPA) token or other token type for the login. This callback handler is typically present when a user name and password are not present.

callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback(″Authz Token List: ″);
> This callback handler collects the ArrayList of TokenHolder objects that are returned from a call to the WSOpaqueTokenHelper.createTokenHolderListFromOpaqueToken API using the Common Secure Interoperability Version 2 (CSIv2) authorization token as input.

callbacks[4] = new com.ibm.websphere.security.auth.callback.WSServletRequestCallback(″HttpServletRequest: ″);
> This callback handler collects the HTTP servlet request object, if present. This callback handler enables login modules to get information from the HTTP request for use in the login, and is presented from the WEB_INBOUND login configuration only.

callbacks[5] = new com.ibm.websphere.security.auth.callback.WSServletResponseCallback(″HttpServletResponse: ″);
> This callback handler collects the HTTP servlet response object, if present. This callback handler enables login modules to put information into the HTTP response as a result of the login. An

example of this situation might be adding the SingleSignonCookie cookie to the response.This callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[6] = new com.ibm.websphere.security.auth.callback.WSAppContextCallback(″**ApplicationContextCallback:** ″**);**

> This callback handler collects the Web application context that is used during the login. This callback handler consists of a HashMap object, which contains the application name and the redirect web address, if present. The callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[7] = new WSRealmNameCallbackImpl(″**Realm Name:** ″**,** *default_realm***);**

> This callback handler collects the realm name for the login information. The realm information might not always be provided. If the realm information is not provided, assume that it is the current realm.

callbacks[8] = new WSX509CertificateChainCallback(″**X509Certificate[]:** ″**);**

> This callback handler contains the certificate that was validated by Secure Sockets Layer (SSL) if the login source is an X509Certificate from SSL client authentication. The ltpaLoginModule calls the same mapping functions as WebSphere Application Server releases prior to version 6.1. However, having it passed into the login gives a custom login module the opportunity to map the certificate in a custom way. Then, it performs a Hashtable login. See Configuring inbound identity mapping for more information on a Hashtable login.

Shared state variables

Shared state variables are used to share information between login modules during the login phase. The following list contains recommendations for using the shared state variables:

- When you have a custom login module, use the shared state variables to communicate to a WebSphere Application Server login module using a documented shared state variable, as shown in the following table.
- Try not to update the Subject until the commit phase. If you call the abort method, you must remove any objects added to the Subject.
- Enable the login module that adds information into the shared state Map during login to remove this information during commit in case the same shared state is used for another login.
- If a stop or logout occurs, clean up the information in the login configuration for the shared state and the Subject.

The com.ibm.wsspi.security.token.AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY shared state variable can inform the WebSphere Application Server login configurations about asserted privilege attributes. This variable references the com.ibm.wsspi.security.cred.propertiesObject property. Associate a java.util.Hashtable with this property. This hashtable contains properties that are used by WebSphere Application Server for login purposes and ignores the callback information. This hashtable enables a custom login module, which is carried out first in the login configuration to map user identities or enable WebSphere Application Server to avoid making unnecessary user registry calls if you already have the required information. For more information, see Configuring inbound identity mapping.

If you want to access the objects that WebSphere Application Server creates during a login, refer to the following shared state variables. The variables are set in the following login modules: ltpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule.

Shared state variable

> com.ibm.wsspi.security.auth.callback.Constants.WSPRINCIPAL_KEY

Purpose

> Specifies the com.ibm.websphere.security.auth.WSPrincipal object. See the WebSphere

Application Server API documentation for application programming interface (API) usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

The login module in which variables are set
ltpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule

Shared state variable
com.ibm.wsspi.security.auth.callback.Constants.WSCREDENTIAL_KEY

Purpose
Specifies the com.ibm.websphere.security.cred.WSCredential object. See the WebSphere Application Server API documentation for API usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

Login module in which variables are set
wsMapDefaultInboundLoginModule

Shared state variable
com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY

Purpose
Specifies the default com.ibm.wsspi.security.token.AuthorizationToken object. Login modules can use this object to set custom attributes plugged in after the wsMapDefaultInboundLoginModule login module. The information set here is propagated downstream and is available to the application. See the WebSphere Application Server API documentation for API usage.

Initial versus propagation logins

As mentioned previously, some logins are considered initial logins because of the following reasons:
- It is the first time authentication information is presented to WebSphere Application Server.
- The login information is received from a server that does not propagate security attributes so this information must be gathered from a user registry.

Other logins are considered propagation logins when a WSTokenHolderCallback callback is present and contains sufficient information from a sending server to recreate all the required objects needed by WebSphere Application Server runtime. In cases where there is sufficient information for the WebSphere Application Server runtime, the information you might add to the Subject is likely to exist from the previous login. To verify if your object is present, you can get access to the ArrayList object that is present in the WSTokenHolderCallback callback, and search through this list looking at each TokenHolder getName method. This search is used to determine if WebSphere Application Server is deserializing your custom object during this login. Check the class name returned from the getName method using the String startsWith method because the runtime might add additional information at the end of the name to know which Subject is set to add the custom object after deserialization.

The following code snippet can be used in your login() method to determine when sufficient information is present. For another example, see Configuring inbound identity mapping.

```
// This is a hint provided by WebSphere Application Server that
// sufficient propagation information does not exist and, therefore,
// a login is required to provide the sufficient information. In this
// situation, a Hashtable login might be used.
boolean requiresLogin = ((com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback) callbacks[1]).requiresLogin();

if (requiresLogin)
{
// Check to see if your object exists in the TokenHolder list,
if not, add it.
java.util.ArrayList authzTokenList = ((WSTokenHolderCallback) callbacks[6]).
getTokenHolderList();boolean found = false;
```

```
if (authzTokenList != null)
{
Iterator tokenListIterator = authzTokenList.iterator();

while (tokenListIterator.hasNext())
{
com.ibm.wsspi.security.token.TokenHolder th = (com.ibm.wsspi.security.token.
TokenHolder) tokenListIterator.next();

if (th != null && th.getName().startsWith("com.acme.myCustomClass"))
{
found=true;
break;
}
}
if (!found)
{
// go ahead and add your custom object.
}
}
}
else
{
// This code indicates that sufficient propagation information is present.
// User registry calls are not needed by WebSphere Application Server to
// create a valid Subject. This code might be a no-op in your login module.
}
```

Sample custom login module

You can use the following sample to get ideas on how to use some of the callbacks and shared state variables.

```
{
 // Defines your login module variables
 com.ibm.wsspi.security.token.AuthenticationToken customAuthzToken = null;
 com.ibm.wsspi.security.token.AuthenticationToken defaultAuthzToken = null;
 com.ibm.websphere.security.cred.WSCredential credential = null;
 com.ibm.websphere.security.auth.WSPrincipal principal = null;
 private javax.security.auth.Subject _subject;
 private javax.security.auth.callback.CallbackHandler _callbackHandler;
 private java.util.Map _sharedState;
 private java.util.Map _options;

 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _subject = subject;
  _callbackHandler = callbackHandler;
  _sharedState = sharedState;
  _options = options;
 }

 public boolean login() throws LoginException
 {
  boolean succeeded = true;

  // Gets the CALLBACK information
  javax.security.auth.callback.Callback callbacks[] = new javax.security.
      auth.callback.Callback[7];
  callbacks[0] = new javax.security.auth.callback.NameCallback(
      "Username: ");
  callbacks[1] = new javax.security.auth.callback.PasswordCallback(
      "Password: ", false);
  callbacks[2] = new com.ibm.websphere.security.auth.callback.
      WSCredTokenCallbackImpl ("Credential Token: ");
```

```
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
      WSServletRequestCallback ("HttpServletRequest: ");
callbacks[4] = new com.ibm.wsspi.security.auth.callback.
      WSServletResponseCallback ("HttpServletResponse: ");
callbacks[5] = new com.ibm.wsspi.security.auth.callback.
      WSAppContextCallback ("ApplicationContextCallback: ");
callbacks[6] = new com.ibm.wsspi.security.auth.callback.
       WSTokenHolderCallback ("Authz Token List: ");

try
{
 callbackHandler.handle(callbacks);
}
catch (Exception e)
{
 // Handles exceptions
 throw new WSLoginFailedException (e.getMessage(), e);
}

// Sees which callbacks contain information
uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
javax.servlet.http.HttpServletRequest request = ((WSServletRequestCallback)
      callbacks[3]).getHttpServletRequest();
javax.servlet.http.HttpServletResponse response = ((WSServletResponseCallback)
      callbacks[4]).getHttpServletResponse();
java.util.Map appContext = ((WSAppContextCallback)
      callbacks[5]).getContext();
java.util.List authzTokenList = ((WSTokenHolderCallback)
      callbacks[6]).getTokenHolderList();

// Gets the SHARED STATE information
principal = (WSPrincipal) _sharedState.get(com.ibm.wsspi.security.
      auth.callback.Constants.WSPRINCIPAL_KEY);
credential = (WSCredential) _sharedState.get(com.ibm.wsspi.security.
      auth.callback.Constants.WSCREDENTIAL_KEY);
defaultAuthzToken = (AuthorizationToken) _sharedState.get(com.ibm.
      wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

   // What you tend to do with this information depends upon the scenario
   // that you are trying to accomplish. This example demonstrates how to
   // access various different information:
   // - Determine if a login is initial versus propagation
   // - Deserialize a custom authorization token (For more information, see
   //   Security attribute propagation
   // - Add a new custom authorization token (For more information, see
   //   Security attribute propagation
   // - Look for a WSCredential and read attributes, if found.
   // - Look for a WSPrincipal and read attributes, if found.
   // - Look for a default AuthorizationToken and add attributes, if found.
   // - Read the header attributes from the HttpServletRequest, if found.
   // - Add an attribute to the HttpServletResponse, if found.
   // - Get the Web application name from the appContext, if found.

   // - Determines if a login is initial versus propagation. This is most
   //   useful when login module is first.
boolean requiresLogin = ((WSTokenHolderCallback) callbacks[6]).requiresLogin();

// initial login - asserts privilege attributes based on user identity
if (requiresLogin)
{

 // If you are validating a token from another server, there is an
    // application programming interface  (API) to get the uniqueID from it.
 if (credToken != null && uid == null)
 {
```

```
  try
  {
   String uniqueID = WSSecurityPropagationHelper.
             validateLTPAToken(credToken);
   String realm = WSSecurityPropagationHelper.getRealmFromUniqueID
               (uniqueID);
          // Now set it to the UID so you can use that to either map or
          // login with.
   uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
  }
  catch (Exception e)
  {
   // handle exception
  }
}
    // Adds a Hashtable to shared state.
    // Note: You can perform custom mapping on the NameCallback value returned
    // to change the identity based upon your own mapping rules.
uid = mapUser (uid);

// Gets the default InitialContext for this server.
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

// Gets the local UserRegistry object.
com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.security.
        UserRegistry) ctx.lookup("UserRegistry");

    // Gets the user registry uniqueID based on the uid specified in the
    // NameCallback.
String uniqueid = reg.getUniqueUserId(uid);
 uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

// Gets the display name from the user registry based on the uniqueID.
String securityName = reg.getUserSecurityName(uid);

// Gets the groups associated with this uniqueID.
java.util.List groupList = reg.getUniqueGroupIds(uid);

    // Creates the java.util.Hashtable with the information you gathered from
    // the UserRegistry.
java.util.Hashtable hashtable = new java.util.Hashtable();
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_UNIQUEID, uniqueid);
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_SECURITYNAME, securityName);
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_GROUPS, groupList);

    // Adds a cache key that is used as part of the lookup mechanism for
    // the created Subject. The cache key can be an Object, but should
    // implement the toString() method. Make sure the cacheKey contains
    // enough information to scope it to the user and any additional
    // attributes that you use. If you do not specify this property the
    // Subject is scoped to the WSCREDENTIAL_UNIQUEID returned, by default.
hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_CACHE_KEY,
   "myCustomAttribute" + uniqueid);

  // Adds the hashtable to the sharedState of the Subject.
  _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
          WSCREDENTIAL_PROPERTIES_KEY,hashtable);
}
// propagation login - process propagated tokens
else
{
 // - Deserializes a custom authorization token. For more information, see
     //     Security attribute propagation.
```

```
      //     This can be done at any login module plug in point (first,
      //       middle, or last).
  if (authzTokenList != null)
  {
   // Iterates through the list looking for your custom token
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

}
}

  return succeeded;

 }

}
```

After developing your custom login module for a system login configuration, you can configure the system login using either the administrative console or using the wsadmin utility. To configure the system login using the administrative console, click **Security > Secure administration, applications, and infrastructure**. Under Java Authentication and Authorization Service, click **System logins**. For more information on using the wsadmin utility for system login configuration, see "Customization of a server-side Java Authentication and Authorization Service authentication and login configuration" on page 942. Also refer to the "Customization of a server-side Java Authentication and Authorization Service authentication and login configuration" on page 942 article for information on system login modules and to determine whether to add additional login modules.

Example: Getting the caller subject from the thread:

The Caller subject (or "received subject") contains the user authentication information that is used in the call for this request. This subject is returned after issuing the WSSubject.getCallerSubject application programming interface (API) to prevent replacing existing objects. The subject is marked read-only. This API can be used to get access to the WSCredential credential so that you can put or set data in the hashmap within the credential.

Most data within the subject is not propagated downstream to another server. Only the credential token within the WSCredential credential is propagated downstream and a new caller subject is generated.

```
try
{
 javax.security.auth.Subject caller_subject;
 com.ibm.websphere.security.cred.WSCredential caller_cred;

 caller_subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();

 if (caller_subject != null)
 {
  caller_cred = caller_subject.getPublicCredentials
      (com.ibm.websphere.security.cred.WSCredential.class).iterator().next();
  String CALLERDATA = (String) caller_cred.get ("MYKEY");
  System.out.println("My data from the Caller credential is:  " + CALLERDATA);
 }
}
catch (WSSecurityException e)
{
 // log error
}
```

```
catch (Exception e)
{
 // log error
}
```

Requirement: You need the following Java 2 security permissions to runthis API: `permission`
`javax.security.auth.AuthPermission "wssecurity.getCallerSubject;"`.

Example: Getting the RunAs subject from the thread:

The RunAs subject or invocation subject contains the user authentication information for the RunAs mode
set in the application deployment descriptor for this method.

The RunAs subject (or invocation subject) contains the user authentication information for the RunAs
mode set in the application deployment descriptor for this method. This subject is marked read-only when
returned from the WSSubject.getRunAsSubject application programming interface (API) to prevent
replacing existing objects. You can use this API to get access to the WSCredential credential, which is
documented in the API documentation, so that you can put or set data in the hashmap within the
credential.

Most data within the Subject is not propagated downstream to another server. Only the credential token
within the WSCredential credential is propagated downstream and a new Caller subject is generated.

```
try
{
 javax.security.auth.Subject runas_subject;
 com.ibm.websphere.security.cred.WSCredential runas_cred;

 runas_subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

 if (runas_subject != null)
 {
  runas_cred = runas_subject.getPublicCredentials(
                com.ibm.websphere.security.cred.WSCredential.class).iterator().next();
  String RUNASDATA = (String) runas_cred.get ("MYKEY");
  System.out.println("My data from the RunAs credential is:  " + RUNASDATA );
 }
}
catch (WSSecurityException e)
{
 // log error
}
catch (Exception e)
{
 // log error
}
```

Requirements: You need the Java 2 security permissions to run this API: permission
javax.security.auth.AuthPermission "wssecurity.getRunAsSubject;".

Example: Overriding the RunAs subject on the thread:

To extend the function that is provided by the Java Authentication and Authorization Service (JAAS)
application programming interfaces (APIs), you can set the RunAs subject or invocation subject with a
different valid entry that is used for outbound requests on this running thread.

This extension gives you the flexibility to associate the Subject with all the remote calls on this thread
whether you use a WSSubject.doAs method to associate the subject with the remote action. For example:

```
try
{
javax.security.auth.Subject runas_subject, caller_subject;

 runas_subject = com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();
 caller_subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();

 // set a new RunAs subject for the thread, overriding the one declaratively set
 com.ibm.websphere.security.auth.WSSubject.setRunAsSubject(caller_subject);

 // do some remote calls

 // restore back to the previous runAsSubject
 com.ibm.websphere.security.auth.WSSubject.setRunAsSubject(runas_subject);
}
catch (WSSecurityException e)
{
 // log error
}
catch (Exception e)
{
 // log error
}
```

You need the following Java 2 security permissions to run these APIs:

- permission javax.security.auth.AuthPermission ″wssecurity.getRunAsSubject″;
- permission javax.security.auth.AuthPermission ″wssecurity.getCallerSubject″;
- permission javax.security.auth.AuthPermission ″wssecurity.setRunAsSubject″;

Example: User revocation from a cache:

In WebSphere Application Server, Version 5.0.2 and later, revocation of a user from the security cache using an MBean interface is supported.

This procedure can be called from another JACL script. The following Java Command Language (JACL) revokes a user when given the realm and the user ID, and cycles through all the security administration MBean instances that are returned for the entire cell when run from the deployment manager wsadmin command. The command also purges the user from the cache during each process.

Note: When a user is removed from authentication cache, the user can still login to WebSphere Application Server at any time. Removing the cache only removes the user from the runtime cache. It does not remove the user from registry, nor does it lock out the user.

Attention: In some of the following lines of code, the lines are split into two or more lines for illustrative purposes only.

Enabling identity assertion with trust validation:

By enabling identity assertion with trust validation, an application can use the JAAS login configuration to perform a programmatic identity assertion.

To enable an identity assertion with trust validation, follow these steps:
1. Create a custom login module to perform a trust validation. The login module must set trust and identity information in the shared state, which is then passed on to the IdentityAssertionLoginModule. The trust and identity information is stored in a map in the shared state under the key,

com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state. If this key is missing from the shared state, a WSLoginFailedException error is thrown by the IdentityAssertionLoginModule module. The custom login module should include the following:

- A trust key named com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust. If the trust key is set to `true`, trust is established. If the trust key is set to `false`, the IdentityAssertionLoginModule module creates a WSLoginFailedException error.
- The identity of the java.security.Principal type set in the com.ibm.wsspi.security.common.auth.module.IdenityAssertionLoginModule.principal key.
- The identity in the form of a java,security.cert.X509Certificate[] certificate set in the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates key.

Note: If both a principal and a certificate are supplied, the principal is used, and a warning is issued.

2. Create a new Java Authentication and Authorization Service (JAAS) configuration for application logins. It contains the user-implemented trust validation custom login module and the IdentityAssertionLoginModule module. To configure an application login configuration from the administrative console, complete the following steps:

   a. Click **Security > Secure administration, applications, and infrastructure**.
   b. Under Java Authentication and Authorization Service, click **Application logins > New**.
   c. Supply the JAAS configuration with an alias, and then click **Apply**.
   d. Under Additional properties, click **JAAS Login Modules > New**.
   e. Enter the module class name of the user-implemented trust validation custom login module, and then click **Apply**.
   f. Enter the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule module class name.
   g. Make sure that the module class name classes are in the correct order. The user-implemented trust validation login module must be the first class in the list, and the IdentityAssertionLoginModule module must be the second class.
   h. Click **Save**. The new JAAS configuration is used by the application to perform an identity assertion.

An application can now use the JAAS login configuration to perform a programmatic identity assertion. The application can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity it asserts to. If the login is successful, that identity can be set in the current running process, as in the following example:

```
MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login();  //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on, the runas identity is "Joe"
```

Secure transports with JSSE and JCE programming interfaces

This topic provides detailed information about transport security using Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces. Within this topic, there is a description of the IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS).

Java Secure Socket Extension

Java Secure Socket Extension (JSSE) provides the transport security for WebSphere Application Server. JSSE provides the application programming interface (API) framework and the implementation of the APIs for Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols, including functionality for data encryption, message integrity, and authentication.

JSSE APIs are integrated into the Java 2 SDK, Standard Edition (J2SDK), Version 5. The API package for JSSE APIs is `javax.net.ssl.*`. Documentation for using JSSE APIs can be found in the J2SE 5 API documentation that is located at `http://java.sun.com/j2se/1.5.0/docs/api/index.html`.

Several JSSE providers ship with the J2SDK Version 5 that comes with WebSphere Application Server. The IBMJSSE provider is used in previous WebSphere Application Server releases. Associated with the IBMJSSE provider is the IBMJSSEFIPS provider, which is used when FIPS is enabled on the server. Both of these providers do not work with the Java Message Service (JMS) and HTTP transports in WebSphere Application Server Version 6.1. These transports take advantage of the J2SDK Verison 5 network input/output (NIO) asynchronous channels.

The HTTP and JMS transports use a new IBMJSSE2 provider. All other transports in WebSphere Application Server Version 6.*x* currently use the IBMJSSE2 provider, but can be switched to the old IBMJSSE provider, if necessary (specified in the SSL repertoire configuration).

For more information on the new IBMJSSE2 provider, please review the documentation located in the `http://www.ibm.com/developerworks/java/jdk/security/142/jsse2docs.zip` file. After it is unzipped, the JSSE2 Reference Guide can be found at `jsse2Docs/JSSE2RefGuide.html`, the JSSE2 API documentation can be found at `jsse2Docs/api/index.html` and finally, the JSSE2 samples can be found at `jsse2Docs/samples`.

Customizing Java Secure Socket Extension

You can customize a number of aspects of JSSE by plugging in different implementations of Cryptography Package Provider, X509Certificate and HTTPS protocols, or specifying different default keystore files, key manager factories, and trust manager factories. The following table summarizes which aspects can be customized, what the defaults are, and which mechanisms are used to provide customization. You can customize the following key aspects:

Customizable item	Default	How to customize
X509Certificate	X509Certificate implementation from IBM	The cert.provider.x509v1 security property
HTTPS protocol	Implementation from IBM	The java.protocol.handler.pkgs system property
Cryptography Package Provider	IBMJSSE	A security.provider.n= line in security properties file. See description.
Default keystore	None	The * javax.net.ssl.keyStore system property
Default truststore	jssecacerts, if it exists. Otherwise, cacerts	The * javax.net.ssl.trustStore system property
Default key manager factory	IbmX509	The ssl.KeyManagerFactory.algorithm security property
Default trust manager factory	IbmX509	The ssl.TrustManagerFactory.algorithm security property

For aspects that you can customize by setting a system property, statically set the system property by using the **-D** option of the **Java** command. You can set the system property using the administrative console, or set the system property dynamically by calling the java.lang.System.setProperty method in your code: System.setProperty(propertyName,″propertyValue″).

For aspects that you can customize by setting a Java security property, statically specify a security property value in the `java.security` properties file, which is located in the *app_server_root*/java/jre/lib/ security directory. The security property is propertyName=propertyValue. Dynamically set the Java security property by calling the java.security.Security.setProperty method in your code.

Application Programming Interface

The JSSE provides a standard application programming interface (API) that is available in packages of the `javax.net` file, `javax.net.ssl` file, and the `javax.security.cert` file. The APIs cover:
* Sockets and SSL sockets
* Factories to create the sockets and SSL sockets
* Secure socket context that acts as a factory for secure socket factories
* Key and trust manager interfaces
* Secure HTTP URL connection classes
* Public key certificate API

You can find more information documented for the JSSE APIs if you access the following information:

Version 1.4.2

1. Access the http://www.ibm.com/developerworks/java/jdk/security/ Web site.
2. Click **Java 1.4.2**.
3. Click **Javadoc HTML documentation** in the Java Secure Socket Extension (JSSE) Guide section.

Samples using Java Secure Socket Extension

The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. You can access the samples in the following location:

Version 1.4.2

1. Access the http://www.ibm.com/developerworks/java/jdk/security/ Web site.
2. Click **Java 1.4.2**.
3. Click **jssedocs_samples.zip** in the Java Secure Socket Extension (JSSE) Guide section.

Look for the following files:

Files	Description
ClientJsse.java	Demonstrates a simple client and server interaction using JSSE. All enabled cipher suites are used.
OldServerJsse.java	Back-level samples
ServerPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
ClientPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
UseHttps.java	Demonstrates accessing an SSL or non-SSL Web server using the Java protocol handler of the com.ibm.net.ssl.www.protocol class. The URL is specified with the `http` or `https` prefix. The HTML that is returned from this site is displayed.

See more instructions in the source code. Follow these instructions before you run the samples.

Permissions for Java 2 security

You might need the following permissions to run an application with JSSE: This list is for reference only.
* java.util.PropertyPermission ″java.protocol.handler.pkgs″, ″write″
* java.lang.RuntimePermission ″writeFileDescriptor″
* java.lang.RuntimePermission ″readFileDescriptor″
* java.lang.RuntimePermission ″accessClassInPackage.sun.security.x509″
* java.io.FilePermission ″${user.install.root}${/}etc${/}.keystore″, ″read″

- java.io.FilePermission ″${user.install.root}${/}etc${/}.truststore″, ″read″

For the IBMJSSE provider:
- java.security.SecurityPermission ″putProviderProperty.IBMJSSE″
- java.security.SecurityPermission ″insertProvider.IBMJSSE″

For the SUNJSSE provider:
- java.security.SecurityPermission ″putProviderProperty.SunJSSE″
- java.security.SecurityPermission ″insertProvider.SunJSSE″

Debugging

By configuring through the javax.net.debug system property, JSSE provides the following dynamic debug tracing: `-Djavax.net.debug=true`.

A value of `true` turns on the trace facility, provided that the debug version of JSSE is installed.

Documentation

See the Security: Resources for learning topic for documentation references to JSSE.

JCE

Java Cryptography Extension (JCE) provides cryptographic, key and hash algorithms for WebSphere Application Server. JCE provides a framework and implementations for encryption, key generation, key agreement, and Message Authentication Code (MAC) algorithms. Support for encryption includes symmetric, asymmetric, block and stream ciphers.

IBMJCE

The IBM version of the Java Cryptography Extension (IBMJCE) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCE is similar to SunJCE, except that the IBMJCE offers more algorithms:
- Cipher algorithm (AES, DES, TripleDES, PBEs, Blowfish, and so on)
- Signature algorithm (SHA1withRSA, MD5withRSA, SHA1withDSA)
- Message digest algorithm (MD5, MD2, SHA1, SHA-256, SHA-384, SHA-512)
- Message authentication code (HmacSHA1, HmacMD5)
- Key agreement algorithm (DiffieHellman)
- Random number generation algorithm (IBMSecureRandom, SHA1PRNG)
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])

The IBMJCE belongs to the com.ibm.crypto.provider.* packages.

For further information, see the information on JCE on the following web site: http://www.ibm.com/developerworks/java/jdk/security/142/.

IBMJCEFIPS

The IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCEFIPS service provider implements the following:
- Signature algorithms (SHA1withDSA, SHA1withRSA)
- Cipher algorithms (AES, TripleDES, RSA)
- Key agreement algorithm (DiffieHellman)
- Key (pair) generator (DSA, AES, TripleDES, HmacSHA1, RSA, DiffieHellman)

- Message authentication code (MAC) (HmacSHA1)
- Message digest (MD5, SHA-1, SHA-256, SHA-384, SHA-512)
- Algorithm parameter generator (DiffieHellman, DSA)
- Algorithm parameter (AES, DiffieHellman, DES, TripleDES, DSA)
- Key factory (DiffieHellman, DSA, RSA)
- Secret key factory (AES, TripleDES)
- Certificate (X.509)
- Secure random (IBMSecureRandom)

Application Programming Interface

Java Cryptography Extension (JCE) has a provider-based architecture. Providers can be plugged into the JCE framework by implementing the APIs that are defined by the JCE. The JCE APIs cover:
- Symmetric bulk encryption, such as DES, RC2, and IDEA
- Symmetric stream encryption, such as RC4
- Asymmetric encryption, such as RSA
- Password-based encryption (PBE)
- Key agreement
- Message authentication codes

There is more information documented for the JCE APIs on the `http://www.ibm.com/developerworks/java/jdk/security/` Web site.

Samples using Java Cryptography Extension

There are samples located on the `http://www.ibm.com/developerworks/java/jdk/security/` Web site in the `jceDocs_samples.zip` file. Unzip the file and locate the following samples in the `jceDocs/samples` directory:

File	Description
SampleDSASignature.java	Demonstrates how to generate a pair of DSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withDSA algorithm
SampleMarsCrypto.java	Demonstrates how to generate a Mars secret key, and how to do Mars encryption and decryption
SampleMessageDigests.java	Demonstrates how to use the message digest for MD2 and MD5 algorithms
SampleRSACrypto.java	Demonstrates how to generate an RSA key pair, and how to do RSA encryption and decryption
SampleRSASignatures.java	Demonstrates how to generate a pair of RSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withRSA algorithm
SampleX509Verification.java	Demonstrates how to verify X509 certificates

Documentation

Refer to the Security: Resources for learning for documentation on JCE.

Configuring Federal Information Processing Standard Java Secure Socket Extension files:

Use this topic to configure Federal Information Processing Standard Java Secure Socket Extension files.

In WebSphere Application Server, the Java Secure Socket Extension (JSSE) provider used is the IBMJSSE2 provider. This provider delegates encryption and signature functions to the Java Cryptography Extension (JCE) provider. Consequently, IBMJSSE2 does not need to be Federal Information Processing Standard (FIPS)-approved because it does not perform cryptography. However, the JCE provider requires FIPS-approval.

WebSphere Application Server provides a FIPS-approved IBMJCEFIPS provider that IBMJSSE2 can utilize. The IBMJCEFIPS provider that is shipped in WebSphere Application Server Version 6.1 supports the following SSL ciphers:

- SSL_RSA_WITH_AES_128_CBC_SHA
- SSL_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_RSA_WITH_AES_128_CBC_SHA
- SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_DSS_WITH_AES_128_CBC_SHA
- SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA

Even though the IBMJSSEFIPS provider is still present, the runtime does not use this provider. If IBMJSSEFIPS is specified as a contextProvider, WebSphere Application Server automatically defaults to the IBMJSSE2 provider (with the IBMJCEFIPS provider) for supporting FIPS. When enabling the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel, the runtime always uses IBMJSSE2, despite the contextProvider that you specify for SSL (IBMJSSE, IBMJSSE2 or IBMJSSEFIPS). Also, because FIPS requires the SSL protocol be TLS, the runtime always uses TLS when FIPS is enabled, regardless of the SSL protocol setting in the SSL repertoire. This simplifies the FIPS configuration in Version 6.1Version 6.1 because an administrator needs to enable only the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel to enable all transports using SSL.

1. Click **Security > SSL certificate and key management**.
2. Select the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option and click **Apply**. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.
3. Accommodate Java clients that must access enterprise beans.

   Change the com.ibm.security.useFIPS property value from `false` to `true` in the `profile_root/properties/ssl.client.props` file.
4. Ensure that the java.security includes the provider.

   Edit the `java.security` file to insert the IBMJCEFIPS provider (com.ibm.crypto.fips.provider.IBMJCEFIPS) before the IBMJCE provider, and also renumber the other providers in the provider list. The IBMJCEFIPS provider must be in the `java.security` file provider list.

   The `java.security` file is located in the `WASHOME/java/jre/lib/security` directory.

   The IBM SDK `java.security` file looks like the following example after completing this step:

   ```
   security.provider.1=com.ibm.crypto.fips.provider.IBMJCEFIPS
   security.provider.2=com.ibm.crypto.provider.IBMJCE
   security.provider.3=com.ibm.jsse.IBMJSSEProvider
   security.provider.4=com.ibm.jsse2.IBMJSSEProvider2
   security.provider.5=com.ibm.security.jgss.IBMJGSSProvider
   security.provider.6=com.ibm.security.cert.IBMCertPath
   security.provider.7=com.ibm.crypto.pkcs11.provider.IBMPKCS11
   security.provider.8=com.ibm.security.cmskeystore.CMSProvider
   security.provider.9=com.ibm.security.jgss.mech.spnego.IBMSPNEGO
   ```

   If you are using the Sun JDK, the java.security file looks like the following example after completing this step:

```
security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.security.jgss.IBMJGSSProvider
security.provider.3=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.4=com.ibm.crypto.provider.IBMJCE
security.provider.5=com.ibm.jsse.IBMJSSEProvider
security.provider.6=com.ibm.jsse2.IBMJSSEProvider2
security.provider.7=com.ibm.security.cert.IBMCertPath
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
```

After completing these steps, a FIPS-approved JSSE or JCE provider offers increased encryption capabilities. However, when you use FIPS-approved providers:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the Internet Explorer browser and click **Tools > Internet Options**. On the Advanced tab, select the Use TLS 1.0 option.

  Note: Netscape Version 4.7.*x* and earlier versions might not support TLS.
- IBM Directory Server Version 5.1 (and earlier versions) do not support TLS.
- If you have an administrative client that uses a SOAP connector and you enable FIPS, add the following line to the *profile_root*/properties/soap.client.props file:

  ```
  com.ibm.ssl.contextProvider=IBMJSSEFIPS
  ```
- When you select the **Use the Federal Information Processing Standard (FIPS)** option on the SSL certificate and key management panel, the Lightweight Third-Party Authentication (LTPA) token format is not backwards-compatible with previous releases of WebSphere Application Server. However, you can import the LTPA keys from a previous version of the application server.

Note: When enabling FIPS, you cannot configure cryptographic token devices in the SSL repertoires. IBMJSSE2 must use IBMJCEFIPS when utilizing cryptographic services for FIPS.

The following FIPS 140-2 approved cryptographic providers that are the only devices that are supported with the FIPS option:

- IBMJCEFIPS (certificate 376)
- IBM Cryptography for C (ICC) (certificate 384)

The relevant certificates are listed on the NIST Web site: Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Pre-validation List

To unconfigure the FIPS provider, reverse the changes that you made in the previous steps. After you reverse the changes, verify that you have made the following changes to the sas.client.props, soap.client.props, and java.security files:

- In the ssl.client.props file, you must change the com.ibm.security.useFIPS value to false.
- In the java.security file, you must change the FIPS provider to a non-FIPS provider.

  If you are using the IBM SDK java.security file, you must change the first provider to a non-FIPS provider as shown in the following example:

  ```
  #security.provider.1=com.ibm.crypto.fips.provider.IBMJCEFIPS
  security.provider.1=com.ibm.crypto.provider.IBMJCE
  security.provider.2=com.ibm.jsse.IBMJSSEProvider
  security.provider.3=com.ibm.jsse2.IBMJSSEProvider2
  security.provider.4=com.ibm.security.jgss.IBMJGSSProvider
  security.provider.5=com.ibm.security.cert.IBMCertPath
  #security.provider.6=com.ibm.crypto.pkcs11.provider.IBMPKCS11
  ```

  If you are using the Sun JDK java.security file, you must change the third provider to a non-FIPS provider as shown in the following example:

  ```
  security.provider.1=sun.security.provider.Sun
  security.provider.2=com.ibm.security.jgss.IBMJGSSProvider
  security.provider.3=com.ibm.crypto.fips.provider.IBMJCEFIPS
  security.provider.4=com.ibm.crypto.provider.IBMJCE
  ```

```
security.provider.5=com.ibm.jsse.IBMJSSEProvider
security.provider.6=com.ibm.jsse2.IBMJSSEProvider2
security.provider.7=com.ibm.security.cert.IBMCertPath
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
```

Implementing tokens for security attribute propagation

As part of an extensible architecture, WebSphere Application Server enables you to implement your own tokens in which to propagate security attributes.

The following topics are covered in this section:
- Implementing a custom propagation token
- Implementing a custom authorization token
- Implementing a custom a single sign-on token
- Implementing a custom authentication token
- Propagating a custom Java serializable object

Implementing a custom propagation token:

This topic explains how you might create your own propagation token implementation, which is set on the running thread and propagated downstream.

The default propagation token usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:
- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom propagation token, you must complete the following steps:
1. Write a custom implementation of the PropagationToken interface. Many different methods are available for implementing the PropagationToken interface. However, make sure that the methods that are required by the PropagationToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/`classes` directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so that it has the required permissions for the server code.

   Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the propagation token, might extend the abstract class and then most of the work is complete.

   To see an implementation of the propagation token, see "Example: com.ibm.wsspi.security.token.PropagationToken implementation" on page 972.
2. Add and receive the custom propagation token during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, to deserialize the information, you need to plug in a custom login module, which is discussed in "Propagating a custom Java serializable object" on page 1006. The WSSecurityPropagationHelper class has APIs that are used to set a propagation token on the thread and to retrieve the token from the thread to make updates.

The code sample in "Example: Custom propagation token login module" on page 977 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom propagation token implementation and set it on the thread. If the callback contains propagation data, look for your specific custom propagation token TokenHolder instance, convert the byte array back into your customer PropagationToken object, and set it back on the thread. The code sample shows both instances.

You can add attributes any time your custom propagation token is added to the thread. If you add attributes between requests and the getUniqueId method changes, the Common Secure Interoperability Version 2 (CSIv2) client session is invalidated so that it can send the new information downstream. Adding attributes between requests can affect performance. In many cases, you want the downstream requests to receive the new propagation token information.

To add the custom propagation token to the thread, call the WSSecurityPropagationHelper.addPropagationToken token. This call requires the WebSphereRuntimePerMission "setPropagationToken" Java 2 Security permission.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module for receiving serialized versions of your custom propagation token You can also add this login module to any of the application logins where you might want to generate your custom propagation token on the thread during the login. Alternatively, you can generate the custom PropagationToken implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

For information on how to add your custom login module to the existing login configurations, see "Custom login module development for a system login configuration" on page 947

After completing these steps, you have implemented a custom PropagationToken.

Example: com.ibm.wsspi.security.token.PropagationToken implementation:

Use this file to see an example of a propagation token implementation. The following sample code does not extend an abstract class, but implements the com.ibm.wsspi.security.token.PropagationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom propagation token, see "Implementing a custom propagation token" on page 971.

```
package com.ibm.websphere.security.token;

   deep_clone.addAttribute(key, list[i]);
 }

     return deep_clone;
}
}
```

Example: Custom propagation token login module:

This example shows how to determine if the login is an initial login or a propagation login.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
         Map sharedState, Map options)
 {
  // (For more information on what to do during initialization, see
     // "Custom login module development for a system login configuration" on page 947.)
 }

 public boolean login() throws LoginException
 {
  // (For more information on what to do during login, see
     // "Custom login module development for a system login configuration" on page 947.)

  // Handles the WSTokenHolderCallback to see if this is an initial
     // or propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // handle exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
```

```
 if (authzTokenList != null)
 {
  // Iterates through the list looking for your custom token
  for (int i=0; i<authzTokenList.size(); i++)
  {
   TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

   // Looks for the name and version of your custom PropagationToken implementation
   if (tokenHolder.getName().equals("
            com.ibm.websphere.security.token.CustomPropagationTokenImpl") &&
      tokenHolder.getVersion() == 1)
   {
    // Passes the bytes into your custom PropagationToken constructor
          //  to deserialize
    customPropToken = new
     com.ibm.websphere.security.token.CustomPropagationTokenImpl(tokenHolder.
               getBytes());

   }
  }
 }
 else // This is not a propagation login. Create a new instance of
        // your PropagationToken implementation
 {
  // Adds a new custom propagation token. This is an initial login
  customPropToken = new com.ibm.websphere.security.token.CustomPropagationTokenImpl();

  // Adds any initial attributes
  if (customPropToken != null)
  {
   customPropToken.addAttribute("key1", "value1");
   customPropToken.addAttribute("key1", "value2");
   customPropToken.addAttribute("key2", "value1");
   customPropToken.addAttribute("key3", "something different");
  }
 }

 // Note: You can add the token to the thread during commit in case
    // something happens during the login.
}

public boolean commit() throws LoginException
{
 // For more information on what to do during commit, see
    // "Custom login module development for a system login configuration" on page 947
 if (customPropToken != null)
 {
  // Sets the propagation token on the thread
  try
  {

   System.out.println(tc, "*** ADDED MY CUSTOM PROPAGATION TOKEN TO THE THREAD ***");
   // Prints out the values in the deserialized propagation token
   java.util.Enumeration keys = customPropToken.getAttributeNames();
   while (keys.hasMoreElements())
   {
    String key = (String) keys.nextElement();
    String[] list = (String[]) customPropToken.getAttributes(key);
    for (int k=0; k<list.length; k++)
    System.out.println("Key/Value: " + key + "/" + list[k]);
   }

   // This sets it on the thread using getName() + getVersion() as the key
   com.ibm.wsspi.security.token.WSSecurityPropagationHelper.addPropagationToken(
            customPropToken);
  }
  catch (Exception e)
```

```
    {
     // Handles exception
    }

    // Now you can verify that you have set it properly by trying to get
        // it back from the thread and print the values.
    try
    {
     // This gets the PropagationToken from the thread using getName()
          // and getVersion() parameters.
     com.ibm.wsspi.security.token.PropagationToken tempPropagationToken =
      com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getPropagationToken
       ("com.ibm.websphere.security.token.CustomPropagationTokenImpl", 1);

     if  (tempPropagationToken != null)
     {
      System.out.println(tc, "*** RECEIVED MY CUSTOM PROPAGATION
               TOKEN FROM THE THREAD ***");
      // Prints out the values in the deserialized propagation token
      java.util.Enumeration keys = tempPropagationToken.getAttributeNames();
      while (keys.hasMoreElements())
      {
       String key = (String) keys.nextElement();
       String[] list = (String[]) tempPropagationToken.getAttributes(key);
       for (int k=0; k<list.length; k++)
       System.out.println("Key/Value: " + key + "/" + list[k]);
      }
     }
    }
    catch (Exception e)
    {
     // Handles exception
    }
   }
 }

 // Defines your login module variables
 com.ibm.wsspi.security.token.PropagationToken customPropToken = null;

}
```

Implementing a custom authorization token:

This task explains how you might create your own AuthorizationToken implementation, which is set in the login Subject and propagated downstream.

The default AuthorizationToken usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID() application programming interface (API).

To implement a custom authorization token, you must complete the following steps:

1. Write a custom implementation of the AuthorizationToken interface. There are many different methods for implementing the AuthorizationToken interface. However, make sure that the methods required by the AuthorizationToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions.

You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so that it has the necessary permissions that are needed by the server code.

Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the AuthorizationToken, might extend the abstract class and then most of the work is completed.

To see an implementation of AuthorizationToken, see "Example: com.ibm.wsspi.security.token.AuthorizationToken implementation"

2. Add and receive the custom AuthorizationToken during WebSphere Application Server logins This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in "Propagating a custom Java serializable object" on page 1006. After the object is instantiated in the login module, you can add the object to the Subject during the commit() method.

If you only want to add information to the Subject to get propagated, see "Propagating a custom Java serializable object" on page 1006. If you want to ensure that the information is propagated, want to do you own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own AuthorizationToken implementation.

The code sample in "Example: custom AuthorizationToken login module" on page 985 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback contains propagation data. If the callback does not contain propagation data, initialize a new custom AuthorizationToken implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom AuthorizationToken TokenHolder instance, convert the byte[] back into your custom AuthorizationToken object, and set it back into the Subject. The code sample shows both instances.

You can make your AuthorizationToken read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving serialized versions of your custom authorization token

Because this login module relies on information in the sharedState added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule, add this login module after com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule. For information on how to add your custom login module to the existing login configurations, see "Custom login module development for a system login configuration" on page 947

After completing these steps, you have implemented a custom AuthorizationToken.

Example: com.ibm.wsspi.security.token.AuthorizationToken implementation:

Use this file to see an example of a AuthorizationToken implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthorizationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom AuthorizationToken, see "Implementing a custom authorization token" on page 979.

Example: custom AuthorizationToken login module:

This file shows how to determine if the login is an initial login or a propagation login

For information on what to do during initialization, login and commit, see "Custom login module development for a system login configuration" on page 947.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _sharedState = sharedState;
 }
```

```
public boolean login() throws LoginException
{
// Handles the WSTokenHolderCallback to see if this is an initial or
    // propagation login.
Callback callbacks[] = new Callback[1];
callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

try
{
 callbackHandler.handle(callbacks);
}
catch (Exception e)
{
 // Handles exception
}

// Receives the ArrayList of TokenHolder objects (the serialized tokens)
List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

if (authzTokenList != null)
{
 // Iterates through the list looking for your custom token
 for (int i=0; i
 for (int i=0; i<authzTokenList.size(); i++)
 {
  TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

        // Looks for the name and version of your custom AuthorizationToken
        // implementation
  if (tokenHolder.getName().equals("com.ibm.websphere.security.token.
           CustomAuthorizationTokenImpl") &&
      tokenHolder.getVersion() == 1)
  {
          // Passes the bytes into your custom AuthorizationToken constructor
          // to deserialize
    customAuthzToken = new
     com.ibm.websphere.security.token.CustomAuthorizationTokenImpl(
                tokenHolder.getBytes());

  }
 }
}
else
   // This is not a propagation login. Create a new instance of your
   // AuthorizationToken implementation
{
    // Gets the prinicpal from the default AuthenticationToken. This must match
    // all tokens.
 defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
  sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
 String principal = defaultAuthToken.getPrincipal();

    // Adds a new custom authorization token. This is an initial login. Pass the
    // principal into the constructor
 customAuthzToken = new com.ibm.websphere.security.token.
        CustomAuthorizationTokenImpl(principal);

 // Adds any initial attributes
 if (customAuthzToken != null)
 {
  customAuthzToken.addAttribute("key1", "value1");
  customAuthzToken.addAttribute("key1", "value2");

com.ibm.wsspi.security.token.AuthenticationToken defaultAuthToken = null;
java.util.Map _sharedState = null;
}
```

Implementing a custom single sign-on token:

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

The cookie name is the concatenation of the SingleSignonToken.getName application programming interface (API) and the SingleSignonToken.getVersion API. There is no delimiter. When you add a single sign-on token to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other Web requests. You must deserialize your custom single sign-on token when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following tasks:

• Isolate your attributes within your own implementation.

- Serialize the information using custom serialization. Encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the getUniqueID API

To implement a custom single sign-on token, complete the following steps:

1. Write a custom implementation of the SingleSignonToken interface.

   Many different methods are available for implementing the SingleSignonToken interface. However, make sure the methods that are required by the SingleSignonToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/`classes` directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the `server.policy` file so that it has the required permissions for the server code.

   Tip: All of the token types that are defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the single sign-on token, might extend the abstract class and then most of the work is complete.

   To see an implementation of the single sign-on token, see "Example: A com.ibm.wsspi.security.token.SingleSignonToken implementation" on page 989

2. Add and receive the custom single sign-on token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information, you need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit method.

   The code sample in "Example: A custom single sign-on token login module" on page 994, shows how to determine if the login is an initial login or a propagation login. The difference is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom single sign-on token implementation and set it into the Subject. Also, look for the HTTP cookie from the HTTP request if the HTTP request object is available in the callback. You can get your custom single sign-on token both from a horizontal propagation login and from the HTTP request. However, it is recommended that you make the token available in both places because then the information arrives at any front-end application server, even if that server does not support propagation.

   You can make your single sign-on token read-only in the commit phase of the login module. If you make the token read-only, additional attributes cannot be added within your applications.

   Restriction:
   - HTTP cookies have a size limitation so do not add too much data to this token.
   - The WebSphere Application Server runtime does not handle cookies that it does not generate, so this cookie is not used by the runtime.
   - The SingleSignonToken object, when in the Subject, does affect the cache lookup of the Subject if you return something in the getUniqueID method.

3. Get the HTTP cookie from the HTTP request object during login or from an application. The sample code that is found in "Example: An HTTP cookie retrieval" on page 996 shows how you can retrieve the HTTP cookie from the HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes.

4. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving

serialized versions of your custom propagation token. Because this login module relies on information in the sharedState state that is added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module, add this login module after the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module.

For information on adding your custom login module into the existing login configurations, see "Custom login module development for a system login configuration" on page 947.

After completing these steps, you have implemented a custom single sign-on token.

Example: A com.ibm.wsspi.security.token.SingleSignonToken implementation:

Use this file to see an example of a single sign-on implementation. The following sample code does not extend an abstract class, but implements the com.ibm.wsspi.security.token.SingleSignonToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom single sign-on token, see "Implementing a custom single sign-on token" on page 987.

  }
```

```
        return deep_clone;
  }
}
```

Example: A custom single sign-on token login module:

This file shows how to determine if the login is an initial login or a propagation login.

For information on initialization and on what to do during login and commit, see "Custom login module development for a system login configuration" on page 947.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // Handles the WSTokenHolderCallback to see if this is an initial or
     // propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // handle exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

  if (authzTokenList != null)
  {
   // iterate through the list looking for your custom token
   for (int i=0; i
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

    // Looks for the name and version of your custom SingleSignonToken
         // implementation
    if (tokenHolder.getName().equals("myCookieName")
            && tokenHolder.getVersion() == 1)
    {
     // Passes the bytes into your custom SingleSignonToken constructor
          // to deserialize
     customSSOToken = new
      com.ibm.websphere.security.token.CustomSingleSignonTokenImpl
                (tokenHolder.getBytes());

    }
   }
  }
  else
         // This is not a propagation login. Create a new instance of your
         // SingleSignonToken implementation
  {
      // Gets the principal from the default SingleSignonToken. This principal
```

```
       //  must match all tokens.
   defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
    sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
   String principal = defaultAuthToken.getPrincipal();

   // Adds a new custom single sign-on (SSO) token. This is an initial login.
       //  Pass the principal into the constructor
   customSSOToken = new com.ibm.websphere.security.token.
           CustomSingleSignonTokenImpl(principal);

   // add any initial attributes
   if (customSSOToken != null)
   {
    customSSOToken.addAttribute("key1", "value1");
    customSSOToken.addAttribute("key1", "value2");
    customSSOToken.addAttribute("key2", "value1");
    customSSOToken.addAttribute("key3", "something different");
   }
  }

     // Note: You can add the token to the Subject during commit in case something
     // happens during the login.
}

public boolean commit() throws LoginException
{
 if (customSSOToken != null)
 {
  // Sets the customSSOToken token into the Subject
  try
  {
   public final SingleSignonToken customSSOTokenPriv = customSSOToken;
         // Do this in a doPrivileged code block so that application code does not
         // need to add additional permissions
   java.security.AccessController.doPrivileged(new java.security.PrivilegedAction()
   {
    public Object run()
    {
     try
     {
      // Adds the custom SSO token if it is not null and
              //  not already in the Subject
                            if ((customSSOTokenPriv != null) &&
        (!subject.getPrivateCredentials().
                      contains(customSSOTokenPriv)))
     {
      subject.getPrivateCredentials().
                  add(customSSOTokenPriv);
     }
     }
     catch (Exception e)
     {
      throw new WSLoginFailedException (e.getMessage(), e);
     }

     return null;
    }
   });
  }
  catch (Exception e)
  {
   throw new WSLoginFailedException (e.getMessage(), e);
  }
 }
}

// Defines your login module variables
```

```
 com.ibm.wsspi.security.token.SingleSignonToken customSSOToken = null;
 com.ibm.wsspi.security.token.AuthenticationToken defaultAuthToken = null;
 java.util.Map _sharedState = null;
}
```

Example: An HTTP cookie retrieval:

The following example shows you how to retrieve a cookie from an HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes. This example shows how to complete these steps from a login module. However, you also can complete these steps using a servlet.

For information on what to do during initialization, login and commit, see "Custom login module development for a system login configuration" on page 947.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
      Map sharedState, Map options)
 {
   _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // Handles the WSTokenHolderCallback to see if this is an
     // initial or propagation login.
  Callback callbacks[] = new Callback[2];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");
  callbacks[1] = new WSServletRequestCallback("HttpServletRequest: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // Handles the exception
  }

  // receive the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
  javax.servlet.http.HttpServletRequest request =
        ((WSServletRequestCallback) callbacks[1]).getHttpServletRequest();

  if (request != null)
  {

   // Checks if the cookie is present
   javax.servlet.http.Cookie[] cookies = request.getCookies();
   String[] cookieStrings = getCookieValues (cookies, "myCookeName1");

   if (cookieStrings != null)
   {
    String cookieVal = null;
    for (int n=0;n<cookieStrings.length;n++)
    {
     cookieVal = cookieStrings[n];
     if (cookieVal.length()>0)
     {
              // Removes the cookie encoding from the cookie to get
              // your custom bytes
      byte[] cookieBytes =
       com.ibm.websphere.security.WSSecurityHelper.
                    convertCookieStringToBytes(cookieVal);
      customSSOToken =
```

```
          new com.ibm.websphere.security.token.
                      CustomSingleSignonTokenImpl(cookieBytes);

              // Now that you have your cookie from the request,
              // you can do something with it here, or add it
              // to the Subject in the commit() method for use later.

```

Implementing a custom authentication token:

This topic explains how you might create your own authentication token implementation, which is set in the login Subject and propagated downstream.

With this implementation you can specify an authentication token that can be used by a custom login module or application. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID application programming interface (API).

Important: Custom authentication token implementations are not used by the security runtime in WebSphere Application Server to enforce authentication. WebSphere Application Security runtime uses this token in the following situations only:

- Call the getBytes method for serialization
- Call the getForwardable method to determine whether to serialize the authentication token.
- Call the getUniqueId method for uniqueness
- Call the getName and the getVersion methods for adding serialized bytes to the token holder that is sent downstream

All of the other uses are custom implementations.

To implement a custom authentication token, you must complete the following steps:

1. Write a custom implementation of the AuthenticationToken interface. Many different methods are available for implementing the AuthenticationToken interface. However, make sure the methods that are required by the AuthenticationToken interface and the token interface are fully implemented. After you implement this interface, you can place it in the *install_dir*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so the class has the necessary permissions required by the server code.

Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the authentication token, might extend the abstract class and then most of the work is complete.

To see an implementation of the AuthenticationToken interface, see "Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation."

2. Add and receive the custom authentication token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information you must plug in a custom login module. After the object is instantiated in the login module, you can add the object to the Subject during the commit method.

If you only want to add information to the Subject to get propagated, see "Propagating a custom Java serializable object" on page 1006. If you want to ensure that the information is propagated, do your own custom serialization, or specify the uniqueness for Subject caching purposes, consider writing your own authentication token implementation.

The code sample in "Example: A custom authentication token login module" on page 1004, shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom authentication token implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom authentication token TokenHolder instance, convert the byte array back into your custom AuthenticationToken object, and set it back into the Subject. The code sample shows both instances.

You can make your authentication token read-only in the commit phase of the login module. If you do not make the token read-only, attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the shared state that is added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module, add this login module after the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module. For information on how to add your custom login module to the existing login configurations, see "Custom login module development for a system login configuration" on page 947.

After completing these steps, you have implemented a custom authentication token.

Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation:

The following example illustrates an authentication token implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthenticationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;
import com.ibm.websphere.security.auth.WSLoginFailedException;
import com.ibm.wsspi.security.token.*;
import com.ibm.websphere.security.WebSphereRuntimePermission;
import java.io.ByteArrayOutputStream;
import java.io.ByteArrayInputStream;
import java.io.DataOutputStream;
import java.io.DataInputStream;
import java.io.ObjectOutputStream;
import java.io.ObjectInputStream;
```

```
import java.io.OutputStream;
import java.io.InputStream;
import java.util.ArrayList;

public class CustomAuthenticationTokenImpl implements com.ibm.wsspi.security.

java.util.Map _sharedState = null;
}
```

Propagating a custom Java serializable object:

This document describes how to add an object into the Subject from a login module and describes other
infrastructure considerations to make sure that the Java object gets propagated.

Prior to completing this task, verify that security propagation is enabled in the administrative console.

With security attribute propagation enabled, you can propagate data either horizontally with single sign-on
(SSO) enabled or downstream using Common Secure Interoperability Version 2 (CSIv2). When a login
occurs, either through an application login configuration or a system login configuration, a custom login
module can be plugged in to add Java serialized objects into the Subject during login. This document

describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

1. Add your custom Java object into the Subject from a custom login module. A two-phase process exists for each Java Authentication and Authorization Service (JAAS) login module. WebSphere Application Server completes the following processes for each login module present in the configuration:

login method
> In this step, the login configuration callbacks are analyzed, if necessary, and the new objects or credentials are created.

commit method
> In this step, the objects or credentials that are created during login are added into the Subject.

After a custom Java object is added into the Subject, WebSphere Application Server serializes the object on the sending server, deserializes the object on the receiving server, and adds the object back into the Subject downstream. However, some requirements exist for this process to occur successfully. For more information on the JAAS programming model, see the JAAS information provided in Security: Resources for learning.

Important: Whenever you plug a custom login module into the login infrastructure of WebSphere Application Server, make sure that the code is trusted. When you add the login module into the *install_root*/classes directory, the login module has Java 2 Security AllPermissions permissions . It is recommended that you add your login module and other infrastructure classes into any private directory. However, you must modify the *install_root*/properties/server.policy file to make sure that your private directory, Java archive (JAR) file, or both have the permissions required to run the application programming interfaces (API) that are called from the login module. Because the login module might be run after the application code on the call stack, you might add doPrivileged code so that you do not need to add additional properties to your applications.

The following code sample shows how to add doPrivileged code. For information on what to do during initialization, login and commit, see "Custom login module development for a system login configuration" on page 947.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {

 }

 public boolean login() throws LoginException
 {
     // Construct callback for the WSTokenHolderCallback so that you
     // can determine if
     // your custom object has propagated
     Callback callbacks[] = new Callback[1];
     callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

     try
     {
         _callbackHandler.handle(callbacks);
     }
     catch (Exception e)
     {
     throw new LoginException (e.getLocalizedMessage());
     }

     // Checks to see if any information is propagated into this login
     List authzTokenList = ((WSTokenHolderCallback) callbacks[1]).
             getTokenHolderList();
```

```
    if (authzTokenList != null)
    {
        for (int i = 0; i< authzTokenList.size(); i++)
            {
            TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                // Look for your custom object. Make sure you use
                // "startsWith"because there is some data appended
                // to the end of the name indicating in which Subject
                // Set it belongs. Example from getName():
                // "com.acme.CustomObject (1)". The class name is
                // generated at the sending side by calling the
                // object.getClass().getName() method. If this object
                // is deserialized by WebSphere Application Server,
                // then return it and you do not need to add it here.
                // Otherwise, you can add it below.
                // Note: If your class appears in this list and does
                // not use custom serialization (for example, an
                // implementation of the Token interface described in
                // the Propagation Token Framework), then WebSphere
                // Application  Server automatically deserializes the
                // Java object for you. You might just return here if
                // it is found in the list.

            if (tokenHolder.getName().startsWith("com.acme.CustomObject"))
            return true;
        }
    }
        //  If you get to this point, then your custom object has not propagated
        myCustomObject = new com.acme.CustomObject();
        myCustomObject.put("mykey", "mydata");
}

public boolean commit() throws LoginException
{
 try
 {
    // Assigns a reference to a final variable so it can be used in
    // the doPrivileged block
  final com.acme.CustomObject myCustomObjectFinal = myCustomObject;
  // Prevents your applications from needing a JAAS getPrivateCredential
    // permission.
  java.security.AccessController.doPrivileged(new java.security.
        PrivilegedExceptionAction()
  {
   public Object run() throws java.lang.Exception
   {
        // Try not to add a null object to the Subject or an object
        // that already exists.
    if (myCustomObjectFinal != null && !subject.getPrivateCredentials().
            contains(myCustomObjectFinal))
    {
        // This call requires a special Java 2 Security permission,
        // see the JAAS application programming interface (API)
        // documentation.
     subject.getPrivateCredentials().add(myCustomObjectFinal);
    }
    return null;
   }
  });
 }
 catch (java.security.PrivilegedActionException e)
 {
  // Wraps the exception in a WSLoginFailedException
  java.lang.Throwable myException = e.getException();
  throw new WSLoginFailedException (myException.getMessage(), myException);
 }
```

```
    }

    // Defines your login module variables
    com.acme.CustomObject myCustomObject = null;
    }
```

2. Verify that your custom Java class implements the java.io.Serializable interface. An object that is added to the Subject must be serialized if you want the object to propagate. For example, the object must implement the java.io.Serializable interface. If the object is not serialized, the request does not fail, but the object does not propagate. To make sure an object that is added to the Subject is propagated, implement one of the token interfaces that is defined in Security attribute propagation or add attributes to one of the following existing default token implementations:

   AuthorizationToken
   > Add attributes if they are user-specific. For more information, see Default authorization token.

   PropagationToken
   > Add attributes that are specific to an invocation. For more information, see Default propagation token.

   If you are careful adding custom objects and follow all the steps to make sure that WebSphere Application Server can serialize and deserialize the object at each hop, then it is sufficient to use custom Java objects only.

3. Verify that your custom Java class exists on all of the systems that might receive the request.

   When you add a custom object into the Subject and expect WebSphere Application Server to propagate the object, make sure that the class definition for that custom object exists in the `install_root`/classes directory on all of the nodes where serialization or deserialization might occur. Also, verify that the Java class versions are the same.

4. Verify that your custom login module is configured in all of the login configurations used in your environment where you need to add your custom object during a login. Any login configuration that interacts with WebSphere Application Server generates a Subject that might be propagated outbound for an Enterprise JavaBeans (EJB) request. If you want WebSphere Application Server to propagate a custom object in all cases, make sure that the custom login module is added to every login configuration that is used in your environment. For more information, see "Custom login module development for a system login configuration" on page 947.

5. Verify that security attribute propagation is enabled on all of the downstream servers that receive the propagated information. When an EJB request is sent to a downstream server and security attribute propagation is disabled on that server, only the authentication token is sent for backwards compatibility. Therefore, you must review the configuration to verify that propagation is enabled in all of the cells that might receive requests. You must check several places in the administrative console to make sure propagation is fully enabled. For more information, see Propagating security attributes among application servers.

6. Add any custom objects to the propagation exclude list that you do not want to propagate. You can configure a property to exclude the propagation of objects that match specific class names, package names, or both. For example, you can have a custom object that is related to a specific process. If the object is propagated, it does not contain valid information. You must tell WebSphere Application Server not to propagate this object. Complete the following steps to specify the object in the propagation exclude list, using the administrative console:

   a. Click **Security > Secure administration, applications, and infrastructure > Custom properties > New**.

   b. Add com.ibm.ws.security.propagationExcludeList in the **Name** field.

   c. Add the name of the custom object in the **Value** field. You can add a list of custom objects to the propagation exclude list, separated by a colon (:). For example, you might enter com.acme.CustomLocalObject:com.acme.private.*. You can enter a class name such as com.acme.CustomLocalObject or a package name such as com.acme.private.*. In this example, WebSphere Application Server does not propagate any class that equals com.acme.CustomLocalObject or begins with com.acme.private.

Although you can add custom objects to the propagation exclude list, you must be aware of a side effect. WebSphere Application Server stores the opaque token, or the serialized Subject contents, in a local cache for the life of the single sign-on (SSO) token. The life of the SSO token, which has a default of two hours, is configured in the SSO properties on the administrative console. The information that is added to the opaque token includes only the objects not in the exclude list.

If your authentication cache does not match your SSO token timeout, configure the authentication cache properties. See Configuring the authentication cache. It is recommended that you make your authentication cache timeout value equal to the SSO token timeout.

As a result of this task, custom Java serializable objects are propagated horizontally or downstream. For more information on the differences between horizontal and downstream propagation, see Security attribute propagation.

Developing a custom interceptor for trust associations

You can define the interceptor class method that you want to use. WebSphere Application Server supports two trust association interceptor interfaces: com.ibm.websphere.security.TrustAssociationInterceptor and com.ibm.wsspi.security.tai.TrustAssociationInterceptor.

If you are using a third party reverse proxy server other than Tivoli WebSEAL, you must provide an implementation class for the product interceptor interface for your proxy server. This article describes the com.ibm.websphere.security.TrustAssociationInterceptor.java interface that you must implement.

WebSphere Application Server version 4 and WebSphere Application Server version 5.*x* support the com.ibm.websphere.security.TrustAssociationInterceptor.java interface described in this article. WebSphere Application Server version 6.0 and later support the com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface described in "Developing a custom trust association interceptor" on page 140.

Note: The Trust Association Interceptor (TAI) interface (com.ibm.wsspi.security.tai.TrustAssociationInterceptor) supports several new features and is different from the existing com.ibm.websphere.security.TrustAssociationInterceptor interface.

1. Define the interceptor class method. WebSphere Application Server provides the interceptor Java interface, com.ibm.websphere.security.TrustAssociationInterceptor, which defines the following methods:

   - **`public boolean isTargetInterceptor(HttpServletRequest req)`** creates `WebTrustAssociationException;`.

     The isTargetInterceptor method determines whether the request originated with the proxy server associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server forwarding the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request or not.

   - **`public void validateEstablishedTrust (HttpServletRequest req)`** creates `WebTrustAssociationException;`.

     The validateEstablishedTrust method determines if the proxy server from which the request originated is trusted or not. This method is called after the isTargetInterceptor method. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry used by WebSphere Application Server. If the credentials are invalid, the code creates the WebTrustAssociationException, indicating that the proxy server is not trusted and the request is to be denied.

   - **`public String getAuthenticatedUsername(HttpServletRequest req)`** creates `WebTrustAssociationException;`.

     The getAuthenticatedUsername method is called after trust is established between the proxy server and WebSphere Application Server. The product has accepted the proxy server authentication of the request and must now authorize the request. To authorize the request, the name of the original requestor must be subjected to an authorization policy to determine if the requestor has the

necessary privilege. The implementation code for this method must extract the user name from the HTTP request header and determine if that user is entitled to the requested resource. For example, in the product implementation for the WebSEAL server, the method looks for an `iv-user` attribute in the HTTP request header and extracts the user ID associated with it for authorization.

2. Configuring the interceptor. To make an interceptor configurable, the interceptor must extend com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor. Implement the following methods:

`public int init (java.util.Properties props);`
> The init(Properties) method accepts a `java.util.Properties` object, which contains the set of properties required to initialize the interceptor. All the properties set for an interceptor (by using the **Custom Properties** link for that interceptor or using scripting) is sent to this method. The interceptor then can use these properties to initialize itself. For example, in the product implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to originate from trusted hosts and ports. A return value of **0** implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is ignored.

> **Applicability of the following list**

> If a previous implementation of the trust association interceptor returns a different error status you can either change your implementation to match the expectations or make one of the following changes:
> - Add the com.ibm.websphere.security.trustassociation.initStatus property in the trust association interceptor custom properties. Set the property to the value that indicates that the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.
> - Add the com.ibm.websphere.security.trustassociation.ignoreInitStatus property in the trust association interceptor custom properties. Set the value of this property to **true**, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

`public void cleanup ();`
> This method is called when the application server is stopped. It is used to prepare the interceptor for termination.

`public void setVersion (String s);`
> This method is optional. The method is used to set the version and is for informational purpose only. The default value is `Unspecified`.

You must configure the following methods implemented by the custom interceptor implementation. **This listing only shows the methods and does not include any implementation.**

```
*******************************************************************
import java.util.*;
import javax.servlet.http.HttpServletRequest;
import com.ibm.websphere.security.*;

public class myTAIImpl extends WebSphereBaseTrustAssociationInterceptor
        implements TrustAssociationInterceptor
{

        public myTAIImpl ()
        {
        }

        public boolean isTargetInterceptor (HttpServletRequest req)
            creates WebTrustAssociationException
        {

            //return true if this is the target interceptor, else return false.
        }
```

```
public void validateEstablishedTrust (HttpServletRequest req)
      creates WebTrustAssociationFailedException
{
      //validate if the request is from the trusted proxy server.
      //throw exception if the request is not from the trusted server.

}

public String getAuthenticatedUsername (HttpServletRequest req)
      creates WebTrustAssociationUserException
{
      //Get the user name from the request and if the user is
      //entitled to the requested resource
      //return the user. Otherwise, throw the exception

}

public int init (Properties props)
{
      //initialize the implementation. If successful return 0, else return -1.
}

public void cleanup ()
{
      //Cleanup code.

}

}
**********************************************************************
```

Note: If the init(Properties) method is implemented as described previously in your custom interceptor, this note does not apply to your implementation, and you can move on to the next step. Previous versions of com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor include the public int init (String propsfile) method. This method is no longer required since the interceptor properties are not read from a file. The properties are now entered in the administrative console **Custom Properties** link of the interceptor using the administrative console or scripts. These properties then are made available to your implementation in the init(Properties) method. However, for backward compatibility, the init(String) method still is supported. The init(String) method is called by the default implementation of init(Properties) as shown in the following example.

```
// Default implementation of init(Properties props) method. A Custom
// implementation should override this.
public int init (java.util.Properties props)
{
   String type =
    props.getProperty("com.ibm.websphere.security.trustassociation.types");
   String classfile=
    props.getProperty("com.ibm.websphere.security.trustassociation."
    +type+".config");
   if (classfile != null && classfile.length() > 0 ) {
      return init(classfile);
   } else {
      return -1;
   }
}
```

Change your implementation to implement the init(Properties) method instead of relying on init(String propsfile) method. As shown in the previous example, this default implementation reads the properties

to load the property file. The com.ibm.websphere.security.trustassociation.types property gets the file containing the properties by concatenating .config to its value.

Note: The init(String) method still works if you want to use it instead of implementing the init(Properties) method. The only requirement is that the file name containing the custom trust association properties should now be entered using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using *either* of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

> **Method 1:**
>> The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating the .config to the com.ibm.websphere.security.trustassociation.types property value.
>>
>> If the file name is called myTAI.properties and is located in the *app_server_root*/properties directory, set the following properties:
>> - com.ibm.websphere.security.trustassociation.types = myTAItype
>> - com.ibm.websphere.security.trustassociation.myTAItype.config = *app_server_root*/properties/myTAI.properties

> **Method 2:**
>> You can set the com.ibm.websphere.security.trustassociation.initPropsFile property in the trust association custom properties to the location of the file. For example, set the following property:
>> - com.ibm.websphere.security.trustassociation.initPropsFile= *app_server_root*/properties/myTAI.properties
>>
>> Type the previous code as one continuous line.

The location of the properties file is fully qualified (for example, *app_server_root*/properties/myTAI.properties). Because the location can be different in a Network Deployment environment, use variables such as ${USER_INSTALL_ROOT} to refer to the WebSphere Application Server installation directory. For example, if the file name is called myTAI.properties and it is located in the *app_server_root*/properties directory, then set the following properties:

3. Compile the implementation once you have implemented it. For example, *app_server_root*/java/bin/javac -classpath *install_root*/lib/wssec.jar;<install_root>/lib/j2ee.jar myTAIImpl.java

   a. Copy the class file to a location in the class path (preferably the *app_server_root*/lib/ext directory).

      This file needs to be copied to each node class path and each cell class path.

   b. Restart all the servers.

4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot separated and appears in the class path.

5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the init(Properties) method of your implementation when it extends the com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor as described in the previous step.

6. Save and synchronize (if applicable) the configuration.

7. Restart the servers for the custom interceptor to take effect.

Refer to the Security: Resources for Learning article, which references the WebSphere Application Server version 5 Redbook to view an example of a custom interceptor.

Trust association interceptor support for Subject creation:

The trust association interceptor (TAI) com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface supports several features that are different from the existing com.ibm.websphere.security.TrustAssociationInterceptor interface.

The TAI interface supports a multiphase, negotiated authentication process. For example, some systems require a challenge response protocol back to the client. The two key methods in this interface are:

Key method name

> public boolean isTargetInterceptor (HttpServletRequest req)

> The isTargetInterceptor method determines whether the request originated with the proxy server that is associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server that forwards the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request.

Method result

> A `true` value tells WebSphere Application Server to have the TAI handle the request.

> A `false` value, tells WebSphere Application Server to ignore the TAI.

Key method name

> public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)

> The negotiateValidateandEstablishTrust method determines whether to trust the proxy server from which the request originated. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry that WebSphere Application Serve uses. If the credentials are not valid, the code creates the WebTrustAssociationException exception, which indicates that the proxy server is not trusted and the request is denied. If the credentials are valid, the code returns a TAIResult result, which indicates the status of the request processing with the client identity (Subject and principal name) to use for authorizing the Web resource.

Method result

> Returns a TAIResult result, which indicates the status of the request processing. You can query the Request object and modify the Response object can be modified.

The TAIResult class has three static methods for creating a TAIResult result. The TAIResult create methods take an int type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted in one of the following ways:

- If the value is `HttpServletResponse.SC_OK`, this response tells WebSphere Application Server that the TAI completed its negotiation. The response also tells WebSphere Application Server to use the information in the TAIResult result to create a user identity.
- Other values tell WebSphere Application Server to return the TAI output, which is placed into the HttpServletResponse response, to the Web client. Typically, the Web client provides additional information and then places another call to the TAI.

The created TAIResults results have the following meanings:

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status cannot be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a hashtable, the principal is ignored. The contents of the Subject become part of the eventual user Subject.

All of the following examples are within the negotiateValidateandEstablishTrust method of a TAI.

The following code sample indicates that additional negotiation is required:

```
// Modify the HttpServletResponse object
 //  The response code is meaningful only on the client
 return TAIResult.create(HttpServletResponse.SC_CONTINUE);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the user ID only and queries the user registry for additional information:

```
// modify the HttpServletResponse object
 return TAIResult.create(HttpServletResponse.SC_OK, userid);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the complete user information that is contained in the hashtable. For more information on the hashtable, see Configuring inbound identity mapping. In this code sample, the hashtable is placed in the public credential portion of the Subject:

```
// create Subject and place Hashtable in it
 Subject subject = new Subject;
 subject.getPublicCredentials().add(hashtable);
 //the response code is meaningful only the client
 return TAIResult.create(HttpServletResponse.SC_OK, "ignored", subject);
```

The following code sample indicates that an authentication failure occured. WebSphere Application Server fails the authentication request:

```
//log error message
 // ....
 throw new WebTrustAssociationFailedException("TAI failed for this reason");
```

The following methods are additional methods on the TrustAssociationInterceptor interface. These methods are used for initialization, for shutdown, and for identifying the TAI to WebSphere Application Server. For more information, see the Java documentation.

Method name
>   public int initialize(Properties props)

Method result
>   This method is called during TAI initialization and is called only if custom properties are configured for the interceptor.

Method name
>   public String getVersion()

Method result
>   This method returns the version of the TAI.

Method name
>   public String getType()

Method result
>   This method returns the type of the TAI.

Method name
>   public void cleanup()

Method result
>   This method is called when stopping the WebSphere Application Server process. Stopping the

WebSphere Application Server process provides an opportunity for the TAI to perform any necessary cleanup. This method is not necessary if cleanup is not required.

Plug point for custom password encryption

A plug point for custom password encryption can be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding.

The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret. The WebSphere Application Server runtime stores the encrypted passwords in their existing locations, preceded with {custom:alias} tags instead of {xor} tags. The custom part of the tag indicates that it is a custom algorithm. The alias part of the tag is specified by the custom implementation, which helps to indicate how the password is encrypted. The implementation can include the key alias, encryption algorithm, encryption mode, or encryption padding.

A custom provider of this plug point must implement an interface that is designed to encrypt and decrypt passwords. The interface is called by the WebSphere Application Server runtime whenever the custom plug point is enabled. The custom algorithm becomes one of the supported algorithms when the plug point is enabled. Other supported algorithms include {xor} (standard base64 encoding) and {os400} which is used on the iSeries platform.

The following example illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface:

```
package com.ibm.wsspi.security.crypto;
public interface CustomPasswordEncryption
{

    /**
     * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
     * The byte[] is generated from String.getBytes("UTF-8").
     * An encrypted byte[] is returned from the implementation in the EncryptedInfo
     * object.  Additionally, a logical key alias is returned in the EncryptedInfo
     * objectwhich is passed back into the decrypt method to determine which key was
     * used to encrypt this password. The WebSphere Application Server runtime has
     * no knowledge of the algorithm or the key used to encrypt the data.
     *
     * @param byte[]
     * @return com.ibm.wsspi.security.crypto.EncryptedInfo
     * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
     **/
    public EncryptedInfo encrypt (byte[] decrypted_bytes) throws PasswordEncryptException;

    /**
     * The decrypt operation takes the EncryptedInfo object containing a byte[]
     * and the logical key alias and converts it to the decrypted byte[].  The
     * WebSphere Application Server runtime converts the byte[] to a String
     * using new String (byte[], "UTF-8");
     *
     * @param com.ibm.wsspi.security.crypto.EncryptedInfo
     * @return byte[]
     * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
     **/
    public byte[] decrypt (EncryptedInfo info) throws PasswordDecryptException;

    /**
     * The following is reserved for future use and is currently not
     * called by the WebSphere Application Server runtime.
     *
     * @param java.util.HashMap
     **/
    public void initialize (java.util.HashMap initialization_data);
}
```

The com.ibm.wsspi.security.crypto.EncryptedInfo class contains the encrypted bytes with the user-defined alias that is associated with the encrypted bytes. This information is passed back into the encryption method to help determine how the password was originally encrypted.

```
package com.ibm.wsspi.security.crypto;
public class EncryptedInfo
{
    private byte[] bytes;
    private String alias;

/**
 * This constructor takes the encrypted bytes and a keyAlias as parameters.
 * This constructor is used to pass to or from the WebSphere Application Server
 * runtime to enable the runtime to associate the bytes with a specific key that
 * is used to encrypt the bytes.
 */

    public EncryptedInfo (byte[] encryptedBytes, String keyAlias)
    {
        bytes = encryptedBytes;
        alias = keyAlias;
    }

/**
 * This command returns the encrypted bytes.
 *
 * @return byte[]
 */
    public byte[] getEncryptedBytes()
    {
        return bytes;
    }

/**
 * This command returns the key alias.  The key alias is a logical string that is
 * associated with the encrypted password in the model. The format is
 * {custom:keyAlias}encrypted_password. Typically, just the key alias is placed
 * here, but algorithm information can also be returned.
 *
 * @return String
 */
    public String getKeyAlias()
    {
        return alias;
    }

}
```

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {custom:alias} tag . The custom:alias tag is stripped prior to decryption. For more information, see Enabling custom password encryption.

Enabling custom password encryption:
To view an example code sample that illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface, see Plug point for custom password encryption.

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {custom:alias} tag. The custom:alias tag is stripped prior to decryption.

1. To enable custom password encryption, you must configure two properties:

- **property com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** - Defines the custom class that implements the com.ibm.wsspi.security.crypto.CustomPasswordEncryption password encryption interface.

- **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** - Defines when the custom class is used for default password processing. When the passwordEncryptionEnabled option is not specified or set to `false`, and the passwordEncryptionClass class is specified, the decryption method is called whenever a `{custom:alias}` tag still exists in the configuration repository.

2. If the custom implementation class defaults to the com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl interface, and this class is present in the class path, then encryption is enabled by default. This simplifies the enablement process for all nodes. It is not necessary to define any other properties except for those that the custom implementation requires. To disable encryption, but still use this class for decryption, specify the following class.

- `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false`

3. To configure custom password encryption, configure both of these properties in the `security.xml` file. The custom encryption class (com.acme.myPasswordEncryptionClass) must be placed in a Java archive (JAR) file in the `${WAS_INSTALL_ROOT}/classes` directory in all WebSphere Application Server processes. Every configuration document that contains a password (`security.xml` and any application bindings that contain RunAs passwords), must be saved before all of the passwords become encrypted with the custom encryption class.

Whenever a custom encryption class encryption operation is called, and it creates a run-time exception or a defined PasswordEncryptException exception, the WebSphere Application Server runtime uses the {xor} algorithm to encode the password. This encoding prevents the storage of the password in plain text. After the problem with the custom class has been resolved, it automatically encrypts the password the next time the configuration document is saved.

When a RunAs role is assigned a user ID and password, it currently is encoded using the WebSphere Application Server encoding function. Therefore, after the custom plug point is configured to encrypt the passwords, it encrypts the passwords for the RunAs bindings as well. If the deployed application is moved to a cell that does not have the same encryption keys, or the custom encryption is not yet enabled, a login failure results because the password is not readable.

One of the responsibilities of the custom password encryption implementation is to manage the encryption keys. This class must decrypt any password that it encrypted. Any failure to decrypt a password renders that password to be unusable, and the password must be changed in the configuration. All encryption keys must be available for decryption there no passwords are left using those keys. The master secret must be maintained by the custom password encryption class to protect the encryption keys.

You can manage the master secret by using a stash file for the keystore, or by using a password locator that enables the custom encryption class to locate the password so that it can be locked down.

Naming and directory

Using naming

Naming is used by clients of WebSphere Application Server applications most commonly to obtain references to objects related to those applications, such as Enterprise JavaBeans (EJB) homes.

The Naming service is based on the Java Naming and Directory Interface (JNDI) 1.2.1 Specification and the Object Management Group (OMG) Interoperable Naming (CosNaming) specifications Naming Service Specification, Interoperable Naming Service revised chapters and Common Object Request Broker: Architecture and Specification (CORBA).

1. Develop your application using either JNDI or CORBA CosNaming interfaces. Use these interfaces to look up server application objects that are bound into the name space and obtain references to them.

Most Java developers use the JNDI interface. However, the CORBA CosNaming interface is also available for performing Naming operations on WebSphere Application Server name servers or other CosNaming name servers.

2. Assemble your application using an assembly tool. Application assembly is a packaging and configuration step that is a prerequisite to application deployment. If the application you are assembling is a client to an application running in another process, you should qualify the jndiName values in the deployment descriptors for the objects related to the other application. Otherwise, you may need to override the names with qualified names during application deployment. If the objects have fixed qualified names configured for them, you should use them so that the jndiName values do not depend on the other application's location within the topology of the cell.

3. **Optional:** Verify that your application is assigned the appropriate security role if administrative security is enabled. For more information on the security roles, see "Naming roles" on page 1028.

4. Deploy your application. Put your assembled application onto the application server. If the application you are assembling is a client to an application running in another server process, be sure to qualify the jndiName values for the other application's server objects if they are not already qualified. For more information on qualified names, refer to "Lookup names support in deployment descriptors and thin clients" on page 1023.

5. **Optional:** If your application must access applications in other cells, configure foreign cell bindings for the other cells.

6. Configure name space bindings. This step is necessary in these cases:
   - Your deployed application is to be accessed by legacy client applications running on previous versions of WebSphere Application Server. In this case, you must configure additional name bindings for application objects relative to the default initial context for legacy clients. (Version 5 clients have a different initial context from legacy clients.)
   - The application requires qualified name bindings for such reasons as:
     – It will be accessed by J2EE client applications or server applications running in another server process.
     – It will be accessed by thin client applications.

   In this case, you can configure name bindings as additional bindings for application objects. The qualified names for the configured bindings are *fixed*, meaning they do not contain elements of the cell topology that can change if the application is moved to another server. Objects as bound into the name space by the system can always be qualified with a topology-based name. You must explicitly configure a name binding to use as a fixed qualified name.

   For more information on qualified names, refer to "Lookup names support in deployment descriptors and thin clients" on page 1023. For more information on configured name bindings, refer to "Configured name bindings" on page 1025.

7. Troubleshoot any problems that develop. If a Naming operation is failing and you need to verify whether certain name bindings exist, use the dumpNameSpace tool to generate a dump of the name space.

Naming

Naming is used by clients of WebSphere Application Server applications to obtain references to objects related to those applications, such as enterprise bean (EJB) homes.

These objects are bound into a mostly hierarchical structure, referred to as a *name space*. In this structure, all non-leaf objects are called *contexts*. Leaf objects can be contexts and other types of objects. Naming operations, such as lookups and binds, are performed on contexts. All naming operations begin with obtaining an *initial context*. You can view the initial context as a starting point in the name space.

The name space structure consists of a set of *name bindings*, each consisting of a name relative to a specific context and the object bound with that name. For example, the name myApp/myEJB consists of one non-leaf binding with the name myApp, which is a context. The name also includes one leaf binding with the

name `myEJB`, relative to `myApp`. The object bound with the name `myEJB` in this example happens to be an EJB home reference. The whole name `myApp/myEJB` is relative to the initial context, which you can view as a starting place when performing naming operations.

You can access and manipulate the name space through a *name server*. Users of a name server are referred to as *naming clients*. Naming clients typically use the Java Naming and Directory Interface (JNDI) to perform naming operations. Naming clients can also use the Common Object Request Broker Architecture (CORBA) CosNaming interface.

You can use security to control access to the name space. For more information, see Naming roles.

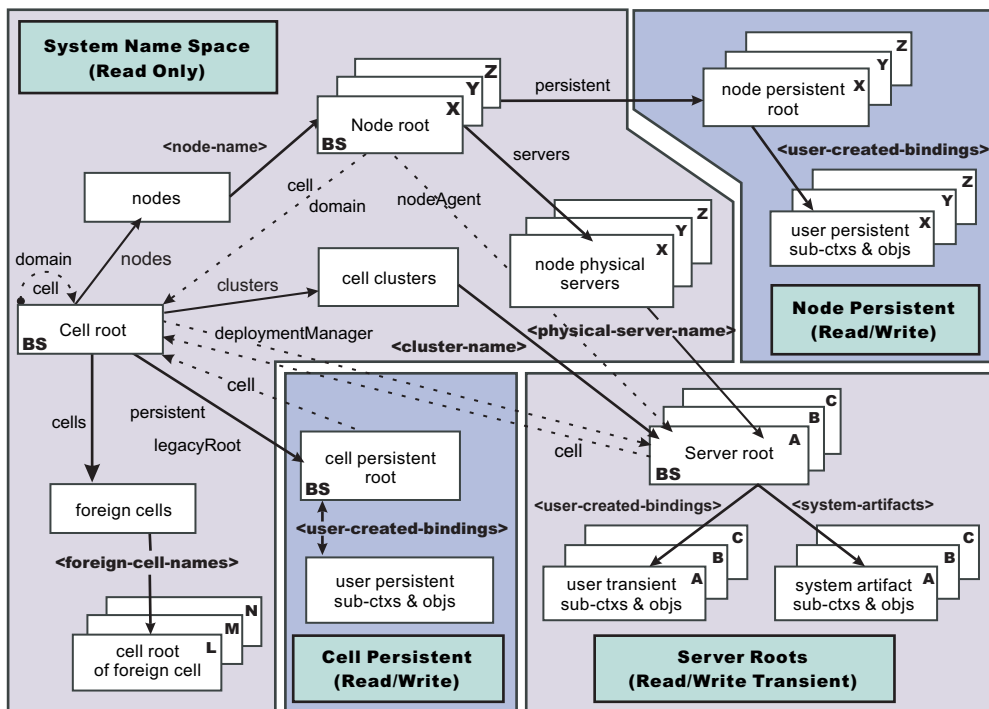
Typically, objects bound to the name space are resources and objects associated with installed applications. These objects are bound by the system, and client applications perform lookup operations to obtain references to them. Occasionally, server and client applications bind objects to the name space. An application can bind objects to transient or persistent partitions, depending on requirements.

In J2EE environments, some JNDI operations are performed with `java:` URL names. Names bound under these names are bound to a completely different name space which is local to the calling process. However, some lookups on the `java:` name space may trigger indirect lookups to the name server.

Name space logical view

The name space for the entire cell is federated among all servers in the cell. Every server process contains a name server. All name servers provide the same logical view of the cell name space.

The various server roots and persistent partitions of the name space are interconnected by a system name space. You can use the system name space structure to traverse to any context in a the cell's name space. A logical view of the name space is shown in the following diagram.

Logical View of a Cell's Name Space


The bindings in the preceding diagram appear with solid arrows, labeled in bold, and dashed arrows, labeled in gray. Solid arrows represent *primary bindings*. A primary binding is formed when the associated subcontext is created. Dashed arrows show *linked bindings*. A linked binding is formed when an existing

context is bound under an additional name. Linked bindings are added for convenience or interoperability with previous WebSphere Application Server versions.

A cell name space is composed of contexts which reside in servers throughout the cell. All name servers in the cell provide the same logical view of the cell name space. A name server constructs this view at startup by reading configuration information. Each name server has its own local in-memory copy of the name space and does not require another running server to function. There are, however, a few exceptions. Server roots for other servers are not replicated among all the servers. The respective server for a server root must be running to access that server root context.

In WebSphere Application Server Network Deployment cells, the cell and node persistent areas can be read even if the deployment manager and respective node agent are not running. However, the deployment manager must be running to update the cell persistent segment, and a node agent must be running to update its respective node persistent segment.

Name space partitions

There are four major partitions in a cell name space:
- System name space partition
- Server roots partition
- Cell persistent partition
- Node persistent partition

System name space partition

> The system name space contains a structure of contexts based on the cell topology. The system structure supports traversal to all parts of a cell name space and to the cell root of other cells, which are configured as foreign cells. The root of this structure is the cell root. In addition to the cell root, the system structure contains a node root for each node in the cell. You can access other contexts of interest specific to a node from the node root, such as the node persistent root and server roots for servers configured in that node.

> All contexts in the system name space are read-only. You cannot add, update, or remove any bindings.

Server roots partition

> Each server in a cell has a server root context. A server root is specific to a particular server. You can view the server roots for all servers in a cell as being in a transient read/write partition of the cell name space. System artifacts, such as EJB homes for server applications and resources, are bound under the server root context of the associated server. A server application can also add bindings under its server root. These bindings are transient. Therefore, the server application creates all required bindings at application startup, so they exist anytime the application is running.

> A server cluster is composed of many servers that are logically equivalent. Each member of the cluster has its own server root. These server roots are not replicated across the cluster. In other words, adding a binding to the server root of one member does not propagate it to the server roots of the other cluster members. To maintain the same view across the cluster, you should create all user bindings under the server root by the server application at application startup so that the bindings are present under the server root of each cluster member. Because of Workload Management (WLM) behavior, a JNDI client outside a cluster has no control over which cluster member's server root context becomes the target of the JNDI operation. Therefore, you should execute bind operations to the server root of a cluster member from within that cluster member process only.

> Server-scoped configured name bindings are relative to a server's server root.

> The name of a cluster member must be unique within a cell and must be different from the cell name.

Cell persistent partition

The root context of the cell persistent partition is the cell persistent root. A binding created under the cell persistent root is saved as part of the cell configuration and continues to exist until it is explicitly removed. Applications that need to create additional persistent bindings of objects generally associated with the cell can bind these objects under the cell persistent root.

It is important to note that the cell persistent area is not designed for transient, rapidly changing bindings. The bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

The cell persistent area can be read even if the deployment manager is not running. However, the deployment manager must be running to update the cell persistent segment. Because every server contains its own copy of the cell persistent partition, any server can look up locally objects bound in the cell persistent partition.

Cell-scoped configured name bindings are relative to a cell's cell persistent root.

Node persistent partition

The node persistent partition is similar to the cell partition except that each node has its own node persistent root. A binding created under a node persistent root is saved as part of that node configuration and continues to exist until it is explicitly removed.

Applications that need to create additional persistent bindings of objects associated with a specific node can bind those objects under that particular node's node persistent root. As with the cell persistent area, it is important to note that the node persistent area is not designed for transient, rapidly changing bindings. These bindings are more static in nature, such as part of an application setup or configuration, and are not created at run time.

The node persistent area for a node can be read from any server in the node even if the respective node agent is not running. However, the node agent must be running to update the node persistent area, or for any server outside the node to read from that node persistent partition. Because every server in a node contains its own copy of the node persistent partition for its node, any server in the node can look up locally objects bound in that node persistent partition.

Node-scoped configured name bindings are relative to a node's node persistent root.

Initial context support

All naming operations begin with obtaining an initial context. You can view the initial context as a starting point in the name space. Use the initial context to perform naming operations, such as looking up and binding objects in the name space.

Initial contexts registered with the ORB as initial references

The server root, cell persistent root, cell root, and node root are registered with the name server's ORB and can be used as an initial context. An initial context is used by CORBA and enterprise bean applications as a starting point for name space lookups. The keys for these roots as recognized by the ORB are shown in the following table:

Root Context	Initial Reference Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot, NameService
Node Root	NameServiceNodeRoot

A server root initial context is the server root context for the specific server you are accessing. Similarly, a node root initial context is the node root for the server being accessed.

You can use the previously mentioned keys in CORBA INS object URLs (corbaloc and corbaname) and as an argument to an ORB `resolve_initial_references` call. For examples, see CORBA and JNDI programming examples, which show how to get an initial context.

Default initial contexts

The default initial context depends on the type of client. Different categories of clients and the corresponding default initial context follow.

- **WebSphere Application Server V5 and later JNDI interface implementation**

  The JNDI interface is used by EJB applications to perform name space lookups. WebSphere Application Server clients by default use the WebSphere Application Server CosNaming JNDI plug-in implementation. The default initial context for clients of this type is the server root of the server specified by the provider URL. For more details, refer to the JNDI programming examples on getting initial contexts.

- **Other JNDI implementation**

  Some applications can perform name space lookups with a non-WebSphere Application Server CosNaming JNDI plug-in implementation. Assuming the key `NameService` is used to obtain the initial context, the default initial context for clients of this type is the cell root.

- **CORBA**

  The standard CORBA client obtains an initial org.omg.CosNaming.NamingContext reference with the key `NameService`. The initial context in this case is the cell root.

Lookup names support in deployment descriptors and thin clients

Server application objects, such as EJB homes, are bound relative to the server root context for the server in which the application is installed. Other objects, such as resources, can also be bound to a specific server root. The names used to look up these objects must be qualified so as to select the correct server root. This topic discusses what relative and qualified names are, when they can be used, and how you can construct them.

Relative names

All names are relative to a context. Therefore, a name that can be resolved from one context in the name space cannot necessarily be resolved from another context in the name space. This point is significant because the system binds objects with names relative to the server root context of the server in which the application is installed. Each server has its own server root context. The initial JNDI context is by default the server root context for the server identified by the provider URL used to obtain the initial context. (Typically, the URL consists of a host and port.) For applications running in a server process, the default initial JNDI context is the server root for that server. A relative name will resolve successfully when the initial context is obtained from the server which contains the target object, but it will not resolve successfully from an initial context obtained from another server.

If all clients of a server application run in the same server process as the application, all objects associated with that application are bound to the same initial context as the clients' initial context. In this case, only names relative to the server's server root context are required to access these server objects. Frequently, however, a server application has clients that run outside the application's server process. The initial context for these clients can be different from the server application's initial context, and lookups on the relative names for server objects may fail. These clients need to use the qualified name for the server objects. This point must be considered when setting up the jndiName values in a J2EE client application deployment descriptors and when constructing lookup names in thin clients. Qualified names resolve successfully from any initial context in the cell.

Qualified names

All names are relative to a context. Here, the term *qualified name* refers to names that can be resolved from any initial context in a cell. This action is accomplished by using names that navigate to the same

context, the cell root. The rest of the qualified name is then relative to the cell root and uniquely identifies an object throughout the cell. All initial contexts in a server (that is, all naming contexts in a server registered with the ORB as an initial reference) contain a binding with the name **cell**, which links back to the cell root context. All qualified names begin with the string **cell/** to navigate from the current initial context back to the cell root context.

A qualified name for an object is the same throughout the cell. The name can be topology-based, or some fixed name bound under the cell persistent root. Topology-based names, described in more detail below, navigate through the system name space to reach the target object. A fixed name bound under the cell persistent root has the same qualified name throughout the cell and is independent of the topology. Creating a fixed name under the cell persistent root for a server application object requires an extra step when the server application is installed, but this step eliminates impacts to clients when the application is moved to a different location in the cell topology. The process for creating a fixed name is described later in this section.

Generally, you **must** use qualified names for EJB jndiName values in a J2EE client application deployment descriptors and for EJB lookup names in thin clients. The only exception is when the initial context is obtained from the server in which the target object resides. For example, a session bean which is a client to an entity bean can use a relative name if the two beans run in the same server. If the session bean and entity beans run in different servers, the jndiName for the entity bean must be qualified in the session bean's deployment descriptors. The same requirement may be true for resources as well, depending on the scope of the resource.

- **Topology-based names**

  The system name space partition in a cell's name space reflects the cell's topology. This structure can be navigated to reach any object bound into the cell's name space. Topology-based qualified names include elements from the topology which reflect the object's location within the cell. For a system-bound object, such as an EJB home, the form for a topology-based qualified name depends on whether the object is bound to a single server or cluster. Both forms are described below.
  Single server
  An object bound in a single server has a topology-based qualified name of the following form:

  `cell/nodes/`*nodeName*`/servers/`*serverName*`/`*relativeJndiName*

  where *nodeName* and *serverName* are the node name and server name for the server where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to its server's server root context.
  Server cluster
  An object bound in a server cluster has a topology-based qualified name of the following form:

  `cell/clusters/`*clusterName*`/`*relativeJndiName*

  where *clusterName* is the name of the server cluster where the object is bound, and *relativeJndiName* is the unqualified name of the object; that is, the object's name relative to a cluster member's server root context.
- **Fixed names**

  It is possible to create a fixed name for a server object so that the qualified name is independent of the cell topology. This quality is desirable when clients of the application run in other server processes or as pure clients. Fixed names have the advantage of not changing if the object is moved to another server. The jndiName values in deployment descriptors for a J2EE client application can reference the qualified fixed name for a server object regardless of the cell topology on which the client or server application is being installed.

  Defining a cell-wide fixed name for a server application object requires an extra step after the server application is installed. That is, a binding for the object must be created under the cell persistent root. A fixed name bound under the cell persistent root can be any name, but all names under the cell persistent root must be unique within the cell because the cell persistent root is global to the entire cell.

  A qualified fixed name has the form:

```
cell/persistent/fixedName
```

where *fixedName* is an arbitrary fixed name.

The binding can be created programmatically (for example, using JNDI). However, it is probably more convenient to configure a cell-scoped binding for the server object.

You must keep the programmatic or configured binding up-to-date. Configured EJB bindings are based on the location of the enterprise bean within the cell topology, and moving the EJB application to another single server or to a server cluster, for example, requires the configured binding to be updated. Similar changes affect an EJB home reference programmatically bound so that the fixed name would need to be rebound with a current reference. However, for J2EE clients, the jndiName value for the object, and for thin clients, the lookup name for the object, remains the same. In other words, clients that access objects by fixed names are not affected by changes to the configuration of server applications they access.

JNDI support in WebSphere Application Server

IBM WebSphere Application Server includes a name server to provide shared access to Java components, and an implementation of the `javax.naming` JNDI package which supports user access to the WebSphere Application Server name server through the JNDI naming interface.

WebSphere Application Server does **not** provide implementations for:
- `javax.naming.directory` or
- `javax.naming.ldap` packages

Also, WebSphere Application Server does **not** support interfaces defined in the `javax.naming.event` package.

However, to provide access to LDAP servers, the development kit shipped with WebSphere Application Server supports the Sun Microsystems implementation of:
- `javax.naming.ldap` and
- `com.sun.jndi.ldap.LdapCtxFactory`

WebSphere Application Server's JNDI implementation is based on version 1.2 of the JNDI interface, and was tested with Version 1.2.1 of the Sun Microsystems JNDI Service Provider Interface (SPI).

The default behavior of this JNDI implementation is adequate for most users. However, users with specific requirements can control certain aspects of JNDI behavior.

Configured name bindings

Administrators can configure bindings into the name space. A configured binding is different from a programmatic binding in that the system creates the binding every time a server is started, even if the target context is in a transient partition.

Administrators can add name bindings to the name space through the configuration. Name servers add these configured bindings to the name space view, by reading the configuration data for the bindings. Configuring bindings is an alternative to creating the bindings from a program. Configured bindings have the advantage of being created each time a server starts, even when the binding is created in a transient partition of the name space. Cell-scoped configured bindings provide a fixed qualified name for server application objects.

Scope

You can configure a binding at one of the following four scopes: cell, node, server, or cluster. Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server. Cluster-scoped bindings are created under the server root context in each member of the selected cluster.

The scope you select for new bindings depends on how the binding is to be used. For example, if the binding is not specific to any particular node, cluster, or server, or if you do not want the binding to be associated with any specific node, cluster, or server, a cell-scoped binding is a suitable scope. Defining fixed names for enterprise beans to create fixed qualified names is just such an application. If a binding is to be used only by clients of an application running on a particular server (or cluster), or if you want to configure a binding with the same name on different servers (or clusters) which resolve to different objects, a server-scoped (or cluster-scoped) binding would be appropriate. Note that two servers or clusters can have configured bindings with the same name but resolve to different objects. At the cell scope, only one binding with a given name can exist.

Intermediate contexts

Intermediate contexts created with configured bindings are read-only. For example, if an EJB home binding is configured with the name `some/compound/name/ejbHome`, the intermediate contexts `some`, `some/compound`, and `some/compound/name` will be created as read-only contexts. You cannot add, update, or remove any read-only bindings.

The configured binding name cannot conflict with existing bindings. However, configured bindings can use the same intermediate context names. Therefore, a configured binding with the name `some/compound/name2/ejbHome2` does not conflict with the previous example name.

Configured binding types

Types of objects that you can bind follow:

EJB: EJB home installed in some server in the cell
The following data is required to configure an EJB home binding:
- JNDI name of the EJB server or server cluster where the enterprise bean is deployed
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

A cell-scoped EJB binding is useful for creating a fixed lookup name for an enterprise bean so that the qualified name is not dependent on the topology.

Note: In standalone servers, an EJB binding resolving to another server cannot be configured because the name server does not read configuration data for other servers. That data is required to construct the binding.

CORBA: CORBA object available from some CosNaming name server
You can identify any CORBA object bound into some INS compliant CosNaming server with a corbaname URL. The referenced object does not have to be available until the binding is actually referenced by some application.

The following data is required in order to configure a CORBA object binding:
- The corbaname URL of the CORBA object
- An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object)
- Target root for the configured binding
- The name of the configured binding, relative to the target root

Indirect: Any object bound in WebSphere Application Server name space accessible with JNDI
Besides CORBA objects, this includes javax.naming.Referenceable, javax.naming.Reference, and java.io.Serializable objects. The target object itself is not bound to the name space. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application. The following data is required in order to configure an indirect JNDI lookup binding:
- JNDI provider URL of name server where object resides
- JNDI lookup name of object

- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root.

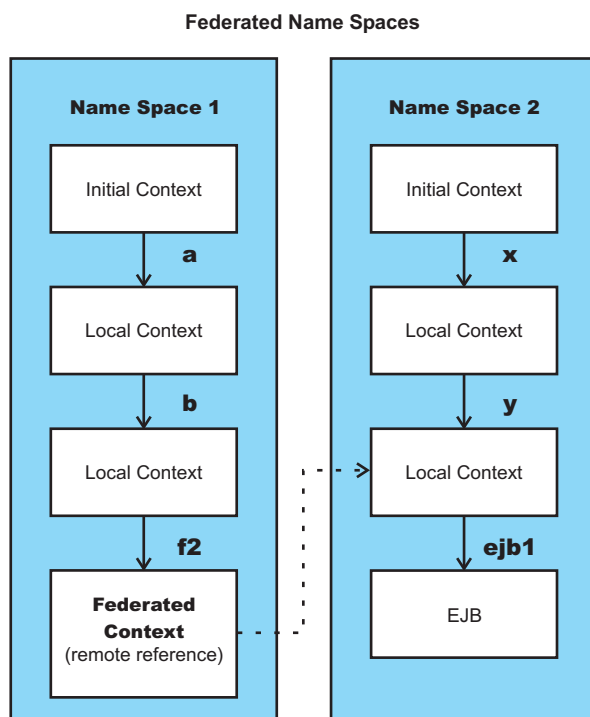
A cell-scoped indirect binding is useful when creating a fixed lookup name for a resource so that the qualified name is not dependent on the topology. You can also achieve this topology by widening the scope of the resource definition.

String: String constant
You can configure a binding of a string constant. The following data is required to configure a string constant binding:
- String constant value
- Target root for the configured binding (scope)
- The name of the configured binding, relative to the target root

Name space federation

Federating name spaces involves binding contexts from one name space into another name space.

For example, assume that a name space, Name Space 1, contains a context under the name `a/b`. Also assume that a second name space, Name Space 2, contains a context under the name `x/y`. (See the following illustration.) If context `x/y` in Name Space 2 is bound into context `a/b` in Name Space 1 under the name `f2`, the two name spaces are federated. Binding `f2` is a federated binding because the context associated with that binding comes from another name space. From Name Space 1, a lookup of the name `a/b/f2` returns the context bound under the name `x/y` in Name Space 2. Furthermore, if context `x/y` contains an enterprise bean (EJB) home bound under the name `ejb1`, the EJB home can be looked up from Name Space 1 with the lookup name `a/b/f2/ejb1`. Notice that the name crosses name spaces. This fact is transparent to the naming client.

Federated Name Spaces


In a WebSphere Application Server name space, you can create federated bindings with the following restrictions:

- Federation is limited to CosNaming name servers. A WebSphere Application Server name server is a Common Object Request Broker Architecture (CORBA) CosNaming implementation. You can create federated bindings to other CosNaming contexts. You cannot, for example, bind contexts from an LDAP name server implementation.

- If you use JNDI to federate the name space, you must use a WebSphere Application Server initial context factory to obtain the reference to the federated context. If you use some other initial context factory implementation, you might not be able to create the binding or the level of transparency might be reduced.

- A federated binding to a non-WebSphere Application Server naming context has the following functional limitations:
  - JNDI operations are restricted to the use of CORBA objects. For example, you can look up EJB homes, but you cannot look up non-CORBA objects such as data sources.
  - JNDI caching is not supported for non-WebSphere Application Server name spaces. This restriction affects the performance of lookup operations only.
  - If security is enabled, WebSphere Application Server does not support federated bindings to non-WebSphereApplication Server name spaces.

- Do not federate two WebSphere Application Server stand-alone server name spaces. Incorrect behavior might result. If you want to federate WebSphere Application Server name spaces, use servers running under the Network Deployment package of WebSphere Application Server.

- When federating the name spaces of two cells running a Network Deployment package of WebSphere Application Server, the names of the cells must be different. Otherwise, incorrect behavior can result.

Naming roles

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization concept is extended to protect the CosNaming service.

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. They affect the content of the name space. Generally two ways are acceptable in which client programs result in CosNaming calls. The first is through the Java Naming and Directory Interface (JNDI) methods. The second is CORBA clients invoking CosNaming methods directly.

The following security roles exist. However, the roles have an authority level from low to high as shown in the following list. The list also provides the security-related interface methods for each role. The interface methods that are not listed are either not supported or not relevant to security.
- **CosNamingRead**. Users who are assigned the CosNamingRead role can do queries of the name space, such as through the JNDI lookup method. The Everyone special-subject is the default policy for this role.

Table 29. CosNamingRead role packages and interface methods

Package	Interface methods
javax.naming	• Context.list • Context.listBindings • Context.lookup • NamingEnumeration.hasMore • NamingEnumeration.next
org.omg.CosNaming	• NamingContext.list • NamingContext.resolve • BindingIterator.next_one • BindingIterator.next_n • BindingIterator.destroy

- **CosNamingWrite**. Users who are assigned the CosNamingWrite role can do write operations (such as JNDI bind, rebind, or unbind) plus CosNamingRead operations. As a default policy, Subjects are not assigned this role.

Table 30. CosNamingWrite role packages and interface methods

Package	Interface methods
javax.naming	• Context.bind • Context.rebind • Context.rename • Context.unbind
org.omg.CosNaming	• NamingContext.bind • NamingContext.bind_context • NamingContext.rebind • NamingContext.rebind_context • NamingContext.unbind

- **CosNamingCreate**. Users who are assigned the CosNamingCreate role are allowed to create new objects in the name space through JNDI createSubcontext operations plus CosNamingWrite operations. As a default policy, Subjects are not assigned this role.

Table 31. CosNamingCreate role packages, interface methods

Package	Interface methods
javax.naming	Context.createSubcontext
org.omg.CosNaming	NamingContext.bind_new_context

- **CosNamingDelete**. Users who are assigned the CosNamingDelete role can destroy objects in the name space, for example byusing the JNDI destroySubcontext method and CosNamingCreate operations. As a default policy, Subjects are not assigned this role.

Table 32. CosNamingDelete role packages and interface methods

Package	Interface methods
javax.naming	Context.destroySubcontext
org.omg.CosNaming	NamingContext.destroy

Important: The `javax.naming` package applies to the CosNaming JNDI service provider only. All of the variants of a JNDI interface method have the same role mapping.

If the caller is not authorized, the packages listed in the previous tables exhibit the following behavior:

javax.naming
> This package creates the javax.naming.NoPermissionException exception, which maps NO_PERMISSION from the CosNaming method invocation to NoPermissionException.

org.omg.CosNaming
> This package creates the org.omg.CORBA.NO_PERMISSION exception.

Users, groups, or the AllAuthenticated and Everyone special subjects can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, you must restart the server for the changes to take effect. A best practice is to map groups or one of the special-subjects, rather than specific users, to Naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

If a user is assigned a particular naming role and that user is a member of a group that is assigned a different naming role, the user is granted the most permissive access between the role that is assigned and the role the group is assigned. For example, assume that the MyUser user is assigned the CosNamingRead role. Also, assume that the MyGroup group is assigned the CosNamingCreate role. If the

MyUser user is a member of the MyGroup group, the MyUser user is assigned the CosNamingCreate role because the user is a member of the MyGroup group. If the MyUser user is not a member of the MyGroup group, is assigned the CosNamingRead role.

The CosNaming authorization policy is only enforced when administrative security is enabled. When administrative security is enabled, attempts to do CosNaming operations without the proper role assignment result in a org.omg.CORBA.NO_PERMISSION exception from the CosNaming server.

In WebSphere Application Server, each CosNaming function is assigned to one role only. Therefore, users who are assigned the CosNamingCreate role cannot query the name space unless they also are assigned the CosNamingRead role. In most cases, a creator needs three roles assigned: CosNamingRead, CosNamingWrite, and CosNamingCreate. The CosNamingRead and CosNamingWrite roles assignment for the creator example in above have been included in CosNamingCreate role. In most cases, WebSphere Application Server administrators do not have to change the roles assignment for every user or group when they move to this release from a previous one.

Although the ability exists to greatly restrict access to the name space by changing the default policy, doing so might result in unexpected org.omg.CORBA.NO_PERMISSION exceptions at runtime. Typically, J2EE applications access the name space and the identity is that of the user that authenticated to WebSphere Application Server when he J2EE application is accessed. Unless the J2EE application provider clearly communicates the expected naming roles, fully consider changing the default naming authorization policy.

Foreign cell bindings

If you have applications in a cell that access other applications in another cell, you can configure a foreign cell name binding for the other cell. A *foreign cell name binding* is a context binding that resolves to the Cell Root context of the other cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Foreign cell bindings limit bootstrap address information for a foreign cell to a single location, instead of placing in the local cell's application deployment data the bootstrap address information contained in every foreign cell reference. If the bootstrap address for the foreign cell changes, you only need to update the foreign cell binding. You do not need to update the deployment data for any application in the local cell that looks up application objects in the foreign cell through the foreign cell binding.

For example, assume the foreign cell CellB has a cell-scoped EJB name space binding configured with a name in the name space of `ejb/AccountHome`. Applications running in CellB would look up the home with a JNDI name of `cell/persistent/ejb/AccountHome`. (J2EE applications would actually use a `java:comp/env` name that maps to that JNDI name through deployment descriptor data.) If you configure a foreign cell binding to CellB in the local cell, applications running in the local cell can look up AccountHome with a JNDI name of `cell/cells/CellB/persistent/ejb/AccountHome`. In both lookup names, the suffix `persistent/ejb/AccountHome` is relative to the Cell Root context in CellB.

The foreign cell and the local cell must have different names.

Naming and directories: Resources for learning

Additional information and guidance on naming and directories is available on various Internet sites.

Use the following links to find relevant supplemental information about naming and directories. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

The naming service provided with WebSphere Application Server Version 6 is the same as that provided for Version 5, thus information on the Version 5 naming and directories applies to Version 6.

The following links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to "Web resources for learning" on page 15 for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

Developing applications that use JNDI

References to EJB homes and other artifacts such as data sources are bound to the WebSphere Application Server name space. These objects can be obtained through the JNDI interface. Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the WebSphere Application Server name space.

The following examples describe how to get an initial context and how to perform lookup operations.
- Getting the default initial context
- Getting an initial context by setting the provider URL property
- Setting the provider URL property to select a different root context as the initial context
- Looking up an EJB home with JNDI
- Looking up a JavaMail session with JNDI

In these examples, the default behavior of features specific to the WebSphere Application Server JNDI Context implementation is used.

The WebSphere Application Server JNDI context implementation includes special features. JNDI caching enhances performance of repeated lookup operations on the same objects. Name syntax options offer a choice of a name syntaxes, one optimized for typical JNDI clients, and one optimized for interoperability with CosNaming applications. Most of the time, the default behavior of these features is the preferred behavior. However, sometimes you should modify the behavior for specific situations.

JNDI caching and name syntax options are associated with a javax.naming.InitialContext instance. To select options for these features, set properties that are recognized by the WebSphere Application Server initial context factory. To set JNDI caching or name syntax properties which will be visible to WebSphere Application Server initial context factory, do the following:

1. **Optional:** Configure JNDI caches

   JNDI caching can greatly increase performance of JNDI lookup operations. By default, JNDI caching is enabled. In most situations, this default is the desired behavior. However, in specific situations, use the other JNDI cache options.

Objects are cached locally as they are looked up. Subsequent lookups on cached objects are resolved locally. However, cache contents can become stale. This situation is not usually a problem, since most objects you look up do not change frequently. If you need to look up objects which change relatively frequently, change your JNDI cache options.

JNDI clients can use several properties to control cache behavior.

You can set properties:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.jndicache.maxentrylife=1440
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.jndicache.cacheobject=none
...
```

Include the file as the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the **PROPS.JNDI_CACHE*** Java constants, defined in the **_com.ibm.websphere.naming.PROPS_** file. The constant definitions follow:

```
public static final String JNDI_CACHE_OBJECT =
 "com.ibm.websphere.naming.jndicache.cacheobject";
public static final String JNDI_CACHE_OBJECT_NONE      = "none";
public static final String JNDI_CACHE_OBJECT_POPULATED = "populated";
public static final String JNDI_CACHE_OBJECT_CLEARED   = "cleared";
public static final String JNDI_CACHE_OBJECT_DEFAULT   =
 JNDI_CACHE_OBJECT_POPULATED;

public static final String JNDI_CACHE_NAME =
 "com.ibm.websphere.naming.jndicache.cachename";
public static final String JNDI_CACHE_NAME_DEFAULT = "providerURL";

public static final String JNDI_CACHE_MAX_LIFE =
 "com.ibm.websphere.naming.jndicache.maxcachelife";
public static final int    JNDI_CACHE_MAX_LIFE_DEFAULT = 0;

public static final String JNDI_CACHE_MAX_ENTRY_LIFE =
 "com.ibm.websphere.naming.jndicache.maxentrylife";
public static final int    JNDI_CACHE_MAX_ENTRY_LIFE_DEFAULT = 0;
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the InitialContext constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...

// Disable caching
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE); ...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

2. **Optional:** Specify the name syntax

Most WebSphere applications use JNDI to look up EJB objects and do not need to look up objects bound by CORBA applications. Therefore, the default name syntax used for JNDI names is the most convenient. If your application needs to look up objects bound by CORBA applications, you may need to change your name syntax so that all CORBA CosNaming names can be represented.

JNDI clients can set the name syntax by setting a property. The property setting is applied by the initial context factory when you instantiate a new java.naming.InitialContext object. Names specified in JNDI operations on the initial context are parsed according to the specified name syntax.

You can set the property:

- From the command line by entering the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.name.syntax=ins
```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.name.syntax=ins
...
```

Include the file at the beginning of the classpath, so that the class loader loads your copy of `jndi.properties` before any other copies.

- Within a Java program by using the PROPS.NAME_SYNTAX* Java constants, defined in the `com.ibm.websphere.naming.PROPS` file. The constant definitions follow:

```
public static final String NAME_SYNTAX =
    "com.ibm.websphere.naming.name.syntax";
public static final String NAME_SYNTAX_JNDI = "jndi";
public static final String NAME_SYNTAX_INS  = "ins";
```

To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the InitialContext constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS); // Set name syntax to INS
...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

Example: Getting the default initial context

There are various ways for a program to get the default initial context.

The following example gets the default initial context. Note that no provider URL is passed to the javax.naming.InitialContext constructor.

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
...
Context initialContext = new InitialContext();
...
```

The default initial context returned depends the runtime environment of the JNDI client. Following are the initial contexts returned in the various environments:

Thin client

> The initial context is the server root context of the server running on the local host at port 2809.

Pure client

> The initial context is the context specified by the java.naming.provider.url property passed to launchClient command with the -CCD command line parameter. The context usually is the server root context of the server at the address specified in the URL, although it is possible to construct a corbaname or corbaloc URL which resolves to some other context.

> If no provider URL is specified, it is the server root context of the server running on the host and port specified by the `-CCproviderURL`, or `-CCBootstrapHost` and `-CCBootstrapPort` command line parameters. The default host is the local host, and the default port is 2809.

Server process

> The initial context is the server root context for that process.

Even though no provider URL is explicitly specified in the above example, the InitialContext constructor might find a provider URL defined in other places that it searches for property settings.

Users of properties which affect ORB initialization should read the rest of this section for a deeper understanding of exactly how initial contexts are obtained.

Determining which server is used to obtain the initial context

WebSphere Application Server name servers are CORBA CosNaming name servers, and WebSphere Application Server provides a CosNaming JNDI plug-in implementation for JNDI clients to perform naming operations on WebSphere Application Server name spaces. The WebSphere Application Server CosNaming plug-in implementation is selected through a JNDI property that is passed to the InitialContext constructor. This property is `java.naming.factory.initial`, and it specifies the initial context factory implementation to use to obtain an initial context. The factory returns a javax.naming.Context instance, which is part of its implementation.

The WebSphere Application Server initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, is typically used by WebSphere Application Server applications to perform JNDI operations. The WebSphere Application Server runtime environment is set up to use this WebSphere Application Server initial context factory if one is not specified explicitly by the JNDI client. When the initial context factory is invoked, an *initial context* is obtained. The following paragraphs explain how the WebSphere Application Server initial context factory obtains the initial context in client and server environments.

- **Registration of initial references in server processes**

  Every WebSphere Application Server has an ORB used to receive and dispatch invocations on objects running in that server. Services running in the server process can register initial references with the ORB. Each initial reference is registered under a key, which is a string value. An initial reference can be any CORBA object. WebSphere Application Server name servers register several initial contexts as initial references under predefined keys. Each name server initial reference is an instance of the interface org.omg.CosNaming.NamingContext.

- **Obtaining initial references in pure client processes**

  Pure JNDI clients, that is, JNDI clients which are not running in a WebSphere Application Server process, also have an ORB instance. This client ORB instance can be passed to the InitialContext constructor, but typically the initial context factory creates and initializes the client ORB instance transparently. A client ORB can be initialized with initial references, but the initial references most likely resolve to objects running in some server. The initial context factory does not define any default initial references when it initializes an ORB. If the `resolve_initial_references` method is invoked on the client ORB when no initial references have been configured, the method invocation fails. This condition is typical for pure client processes. To obtain an initial NamingContext reference, the initial context factory must invoke `string_to_object` with an IIOP type CORBA object URL, such as `corbaloc:iiop:myhost:2809`. The URL specifies the address of the server from which to obtain the initial context. The host and port information is extracted from the provider URL passed to the InitialContext constructor.

  If no provider URL is defined, the WebSphere Application Server initial context factory uses the default provider URL of `corbaloc:iiop:localhost:2809`. The `string_to_object` ORB method resolves the URL and communicates with the target server ORB to obtain the initial reference.

- **Obtaining initial references in server processes**

  If the JNDI client is running in a WebSphere Application Server process, the initial context factory obtains a reference to the server ORB instance if the JNDI client does not provide an ORB instance. Typically, JNDI clients running in server processes use the server ORB instance; that is, they do not pass an ORB instance to the InitialContext constructor. The name server which is running in the server process sets a provider URL as a java.lang.System property to serve as the default provider URL for all JNDI clients in the process. This default provider URL is `corbaloc:rir:/NameServiceServerRoot`. This URL resolves to the server root context for that server. (The URL is equivalent to invoking `resolve_initial_references` on the ORB with a key of NameServiceServerRoot. The name server registers the server root context as an initial reference under that key.)

- **Understanding the legacy ORB protocol**

  Releases previous to WebSphere Application Server Version 5 used a different ORB implementation, which used a legacy protocol in contrast with the Interoperable Name Service (INS) protocol now used. This change has affected the implementation of the WebSphere Application Server initial context factory.

Certain types of pure clients can experience different behavior when getting initial JNDI contexts as compared to previous releases of WebSphere Application Server. This behavior is discussed in more detail below.

The following ORB properties are used with the legacy ORB protocol for ORB initialization and are now deprecated:
– com.ibm.CORBA.BootstrapHost
– com.ibm.CORBA.BootstrapPort

The new INS ORB is different in a major respect, in that it exhibits no default behavior if no initial references are defined.

In the legacy ORB, the bootstrap host and port values defaulted to `localhost` and `900`.

All initial references were obtained from the server running on the bootstrap host and port. So, if the ORB user provided no bootstrap host and port, all initial references are resolved from the server running on the local host at port 900. The INS ORB has no concept of bootstrap host or bootstrap port. All initial references are defined independently. That is, different initial references could resolve to different servers. If `ORB.resolve_initial_references` is invoked with a key such that the ORB is not initialized with an initial reference having that key, the call fails.

In releases of WebSphere Application Server previous to Version 5, the initial context factory invoked `resolve_initial_references` on the ORB in the absence of any provider URL. This action succeeded if a name server at the default bootstrap host and port was running. In the current release, with the INS ORB, this would fail. (Actually, the ORB would fall back to the legacy protocol during the deprecation period, but when the legacy protocol is no longer supported, the operation would fail.)

The initial context factory now uses a default provider URL of `corbaloc:iiop:localhost:2809`, and invokes `string_to_object` with the provider URL.

This operation preserves the behavior that pure clients in previous releases experienced when they set no ORB bootstrap properties or provider URL. **However, this different initial context factory implementation changes the behavior experienced by certain legacy pure clients, which do not specify a provider URL**:
– Clients which set the ORB bootstrap properties listed above when getting an initial context.
– Clients which supply their own ORB instance to the InitialContext constructor.

There are two ways to circumvent this change of behavior:

– Always specify an IIOP type provider URL. This approach does not depend on the bootstrap host and port properties and continues to work when support for the bootstrap host and port properties is removed. For example, you can express bootstrap host and port property values of `myHost` and `2809`, respectively, as `corbaloc:iiop:myHost:2809`.

– Use an rir type provider URL:
  - Specify `corbaloc:rir:/NameServiceServerRoot` if the ORB is initialized to use a WebSphere Application Server 5 server as the bootstrap server.
  - Specify `corbaname:rir:/NameService#domain/legacyRoot` if the ORB is initialized to use a WebSphere Application Server 4.0.x server as the bootstrap server.
  - Specify `corbaloc:rir:/NameService` if the ORB is initialized to use a server other than a WebSphere Application Server 5 or 4.0.x server as the bootstrap server.

  URLs of this type are equivalent to invoking `resolve_initial_references` on the ORB with the specified key. If the bootstrap host and port properties are being used to initialize the ORB, this approach will not work when the bootstrap and host properties are no longer supported.

- **The InitialContext constructor search order for JNDI properties**

If the code snippet shown at the beginning of this section is executed by an application, the bootstrap server depends on the value of the property, java.naming.provider.url. If the property is not set (in server processes the default value is set as a system property), the default host of `localhost` and default port of `2809` are used as the address of the server from which to obtain the initial context. The JNDI specification describes where the InitialContext constructor looks for java.naming.provider.url property settings, but briefly, the property is picked up from the following places in the order shown:

InitialContext constructor

> This does not apply to the above example because the example uses the empty InitalContext constructor.

System environment

> You can add JNDI properties to the system environment as an option on the Java command invocation and by program code. The recommended way to set the provider URL in the system environment is as an option supplied to the Java command invocation. Setting the provider URL in this manner is not temporal, so that getting a default initial context will always yield the same result. It is generally recommended that program code not set the provider URL property in the system environment because as a side-effect, this could adversely affect other, possibly unrelated, code running elsewhere in the same process.

`jndi.properties` file

> There may be many `jndi.properties` files that are within the scope of the class loader in effect. All `jndi.properties` files are used for setting JNDI properties, but the provider URL setting is determined by the first `jndi.properties` file returned by the class loader.

Example: Getting an initial context by setting the provider URL property

In general, JNDI clients should assume the correct environment is already configured so there is no need to explicitly set property values and pass them to the `InitialContext` constructor. However, a JNDI client might need to access a name space other than the one identified in its environment. In this case, it is necessary to explicitly set the java.naming.provider.url (provider URL) property used by the `InitialContext` constructor. A provider URL contains bootstrap server information that the initial context factory can use to obtain an initial context. Any property values passed in directly to the `InitialContext` constructor take precedence over settings of those same properties found elsewhere in the environment.

You can use two different provider URL forms with WebSphere Application Server's initial context factory:
* A CORBA object URL (new for J2EE 1.3)
* An IIOP URL

CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. CORBA object URLs are part of the OMG CosNaming Interoperable Naming Specification. A corbaname URL, for example, can include initial context and lookup name information and can be used as a lookup name without the need to explicitly obtain another initial context. The IIOP URLs are the legacy JNDI format, but are still supported by the WebSphere Application Server initial context factory.

The following examples illustrate the use of these URLs.
* "Using a CORBA object URL"
* "Using a CORBA object URL with multiple name server addresses" on page 1037
* "Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation" on page 1037
* "Using an IIOP URL" on page 1038

Using a CORBA object URL: This example shows a CORBA object URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL with multiple name server addresses: CORBA object URLs can contain more than one bootstrap address. You can use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap addresses for all servers in the cluster in the URL. The operation succeeds if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap address may be used to obtain the initial context even though the server at the first bootstrap address in the list is available.

Multiple-address provider URLs resolving to servers on non-z/OS systems cannot contain bootstrap addresses for node agent processes. The URLs should only contain the bootstrap addresses of members of the same cluster. Otherwise, incorrect behavior might occur. When resolving to servers running on the z/OS operating system, the URL can contain bootstrap addresses for node agent processes.

An example of a corbaloc URL with multiple addresses follows.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
// All of the servers in the provider URL below are members of
// the same cluster.
env.put(Context.PROVIDER_URL,
    "corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation: Initial context factories for CosNaming JNDI plug-in implementations other than the WebSphere Application Server initial context factory most likely obtain an initial context using the object key, NameService. When you use such a context factory to obtain an initial context from a WebSphere Application Server name server, the initial context is the cell root context. Since system artifacts such as EJB homes associated with a server are bound under the server's server root context, names used in JNDI operations must be qualified. If you want to use relative names, ensure your initial context is the server root context under which the target object is bound. In order to make the server root context the initial context, specify a corbaloc provider URL with an object key of NameServiceServerRoot.

This example shows a CORBA object type URL from a non-WebSphere Application Server JNDI implementation. This example assumes full CORBA object URL support by the non-WebSphere Application Server JNDI implementation. The object key of NameServiceServerRoot is specified so that the initial context will be the specified server's server root context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.somecompany.naming.TheirInitialContextFactory");
env.put(Context.PROVIDER_URL,
    "corbaname:iiop:myhost.mycompany.com:9810/NameServiceServerRoot");
Context initialContext = new InitialContext(env);
...
```

If qualified names are used, you can use the default key of NameService.

Using an IIOP URL: The IIOP type of URL is a legacy format which is not as flexible as CORBA object URLs. However, URLs of this type are still supported. The following example shows an IIOP type URL as the provider URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "iiop://myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Example: Setting the provider URL property to select a different root context as the initial context

Each server contains its own server root context, and, when bootstrapping to a server, the server root is the default initial JNDI context. Most of the time, this default is the desired initial context, since system artifacts such as EJB homes are bound there. However, other root contexts exist, which can contain bindings of interest. It is possible to specify a provider URL to select other root contexts.

Examples for selecting other root contexts follow:
* Initial root contexts with a CORBA object URL
* Initial root contexts with the name space root property

Selecting the initial root context with a CORBA object URL: There are several object keys registered with the bootstrap server that you can use to select the root context for the initial context. To select a particular root context with a CORBA object URL object key, set the object key to the corresponding value. The default object key is NameService. Using JNDI yields the server root context. A table that lists the different root contexts and their corresponding object key follows:

Root Context	CORBA Object URL Object Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot
Node Root	NameServiceNodeRoot

The following example shows the use of a corbaloc URL with the object key set to select the cell persistent root context as the initial context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL,
     "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceCellPersistentRoot");
Context initialContext = new InitialContext(env);
...
```

Selecting the initial root context with the name space root property: You can also select the initial root context by passing a name space root property setting to the InitialContext constructor. Generally, the object key setting described above is sufficient. Sometimes a property setting is preferable. For example, you can set the root context property on the Java invocation to make which server root is being used as

the initial context transparent to the application. The default server root property setting is `defaultroot`, which yields the server root context.

Root Context	Name Space Root Property Value
Server Root	bootstrapserverroot
Cell Persistent Root	cellpersistentroot
Cell Root	cellroot
Node Root	bootstrapnoderoot

The initial context factory ignores the name space root property if the provider URL contains an object key other than `NameService`.

The following example shows use of the name space root property to select the cell persistent root context as the initial context. Note that available constants are used instead of hard-coding the property name and value.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
        "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
env.put(PROPS.NAME_SPACE_ROOT, PROPS.NAME_SPACE_ROOT_CELL_PERSISTENT);
Context initialContext = new InitialContext(env);
...
```

Example: Looking up an EJB home with JNDI

Most applications that use JNDI run in a container. Some do not. The name used to look up an object depends on whether or not the application is running in a container. Sometimes it is more convenient for an application to use a corbaname URL as the lookup name. Container-based JNDI clients and thin Java clients can use a corbaname URL.

The following examples show how to perform JNDI lookups from different types of applications.
- "JNDI lookup from an application running in a container"
- "JNDI lookup from an application that does not run in a container" on page 1040
- "JNDI lookup with a corbaname URL" on page 1041

JNDI lookup from an application running in a container

Applications that run in a container can use `java:` lookup names. Lookup names of this form provide a level of indirection such that the lookup name used to look up an object is not dependent on the object's name as it is bound in the name server's name space. The deployment descriptors for the application provide the mapping from the `java:` name and the name server lookup name. The container sets up the `java:` name space based on the deployment descriptor information so that the `java:` name is correctly mapped to the corresponding object.

The following example shows a lookup of an EJB home. The actual home lookup name is determined by the application's deployment descriptors. The enterprise bean (EJB) resides in an EJB container, which provides an interface between the bean and the application server on which it resides.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using the JNDI name
try {
```

```
        java.lang.Object ejbHome =
            initialContext.lookup(
                "java:comp/env/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
        (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
    catch (NamingException e) { // Error getting the home interface
    ...
}
```

JNDI lookup from an application that does not run in a container

Applications that do not run in a container cannot use `java:` lookup names because it is the container which sets the `java:` name space up for the application. Instead, an application of this type must look the object up directly from the name server. Each application server contains a name server. System artifacts such as EJB homes are bound relative to the server root context in that name server. The various name servers are federated by means of a system name space structure. The recommended way to look up objects on different servers is to qualify the name so that the name resolves from any initial context in the cell. If a relative name is used, the initial context must be the same server root context as the one under which the object is bound. The form of the qualified name depends on whether the qualified name is a topology-based name or a fixed name. A topology based name depends on whether the object resides in a single server or a server cluster. Examples of each form of qualified name follow.

- **Topology-based qualified names**

  Topology-based qualified names traverse through the system name space to the server root context under which the target object is bound. A topology-based qualified name resolves from any initial context in the cell. The topology-based qualified name depends on whether the object resides on a single server or server cluster. Examples of each lookup follow.

  Single server

  The following example shows a lookup of an EJB home that is running in the single server, MyServer, configured in the node, Node1.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome = initialContext.lookup(
       "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
       (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
   ...
}
```

  Server cluster

  The example below shows a lookup of an EJB home which is running in the cluster, MyCluster. The name can be resolved if any of the cluster members is running.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
   // Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome = initialContext.lookup(
       "cell/clusters/MyCluster/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
       (org.omg.CORBA.Object) ejbHome, AccountHome.class);
```

```
        }
        catch (NamingException e) { // Error getting the home interface
            ...
        }
```

- **Fixed qualified names**

  If the target object has a cell-scoped fixed name defined for it, you can use its qualified form instead of the topology-based qualified name. Even though the topology-based name works, the fixed name does not change with the specific cell topology or with the movement of the target object to a different server. An example lookup with a qualified fixed name is shown below.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
    java.lang.Object ejbHome = initialContext.lookup(
      "cell/persistent/com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
       (org.omg.CORBA.Object) ejbHome, AccountHome.class);
   }
catch (NamingException e) { // Error getting the home interface
...
}
```

JNDI lookup with a corbaname URL

A corbaname can be useful at times as a lookup name. If, for example, the target object is not a member of the federated name space and cannot be located with a qualifiied name, a corbaname can be a convenient way to look up the object. A lookup with a corbaname URL follows.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using a corbaname URL
try {
    java.lang.Object ejbHome = initialContext.lookup(
       "corbaname:iiop:someHost:2809#com/mycompany/accounting/AccountEJB");
    accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
       (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
    ...
}
```

Example: Looking up a JavaMail session with JNDI
A program can conduct a JNDI lookup of a JavaMail resource. Deployment descriptors of the application determine the lookup name that you specify.

The following example shows a lookup of a JavaMail resource:

```
// Get the initial context as shown above
...
Session session =
    (Session) initialContext.lookup("java:comp/env/mail/MailSession");
```

JNDI interoperability considerations
You must take extra steps to enable your programs to interoperate with non-WebSphere Application Server JNDI clients and to bind resources from MQSeries to a name space.

EJB clients running in an environment other than WebSphere Application Server accessing EJB applications running on WebSphere Application Server V5 or V6 servers

When an EJB application running in WebSphere Application Server V5 or V6 is accessed by a non-WebSphere Application Server EJB client, the JNDI initial context factory is presumed to be a non-WebSphere Application Server implementation. In this case, the default initial context is the cell root. If the JNDI service provider being used supports CORBA object URLs, the corbaname format can be used to look up the EJB home. The construction of the stringified name depends on whether the object is installed on a single server or cluster.

Single server
>Following is a URL that has the bootstrap host **myHost**, the port **2809**, and the enterprise bean installed in the server **server1** in node **node1** and bound in that server under the name **myEJB**:
>```
>initialContext.lookup(
>    "corbaname:iiop:myHost:2809#cell/nodes/node1/servers/server1/myEJB");
>```

Server cluster
>Following is a URL that has the bootstrap host **myHost**, the port **2809**, and the enterprise bean installed in a server cluster named **myCluster** and bound in that cluster under the name **myEJB**:
>```
>initialContext.lookup(
>    "corbaname:iiop:myHost:2809#cell/clusters/myCluster/myEJB");
>```
>
>The lookup works with any name server bootstrap host and port configured in the same cell.
>
>The lookup also works if the bootstrap host and port belong to a member of the cluster itself. To avoid a single point of failure, the bootstrap server host and port for each cluster member can be listed in the URL as follows:
>```
>initialContext.lookup(
>    "corbaname:iiop:host1:9810,:host2:9810#cell/clusters/myCluster/myEJB");
>```
>
>The name prefix **cell/clusters/myCluster/** is not necessary if boostrapping to the cluster itself, but it will work. The prefix is needed, however, when looking up enterprise beans in other clusters. Name bindings under the **clusters** context are implemented on the name server to resolve to the server root of a running cluster member during a lookup; thus avoiding a single point of failure.

Without CORBA object URL support
>If the JNDI initial context factory being used does not support CORBA object URLs, the initial context can be obtained from the server, and the lookup can be performed on the initial context as follows:
>```
>Hashtable env = new Hashtable();
>env.put(CONTEXT.PROVIDER_URL, "iiop://myHost:2809");
>Context ic = new InitialContext(env);
>Object o = ic.lookup("cell/clusters/myCluster/myEJB");
>```

Binding resources from MQSeries 5.2

In releases previous to WebSphere Application Server V5, the MQSeries jmsadmin tool could be used to bind resources to the name space. When used with a WebSphere Application Server V5 or V6 name space, the resource is bound within a transient partition in the name space and does not persist past the life of the server process. Instead of binding the MQSeries resources with the jmsadmin tool, bind them from the WebSphere Application Server administrative console, under **Resources** in the console navigation tree.

JNDI caching
To increase the performance of JNDI operations, the WebSphere Application Server JNDI implementation employs caching to reduce the number of remote calls to the name server for lookup operations. For most cases, use the default cache setting.

When an InitialContext object is instantiated, an association is established between the InitialContext instance and a cache. The initial context and any contexts returned directly or indirectly from a lookup on the initial context are all associated with that same cache instance. By default, the association is based on the provider URL, in particular, the host name and port. The caller can specify the cache name to override this default behavior. A cache instance of a given name is shared by all instances of InitialContext configured to use a cache of that name which were created with the same context class loader in effect. Two EJB applications running in the same server will use their own cache instances, if they are using different context class loaders, even if the cache names are the same.

After an association between an InitialContext instance and cache is established, the association does not change. A `javax.naming.Context` object returned from a lookup operation inherits the cache association of the Context object on which the lookup was performed. Changing cache property values with the `Context.addToEnvironment()` or `Context.removeFromEnvironment()` method does not affect cache behavior. You can change properties affecting a given cache instance with each InitialContext instantiation.

A cache is restricted to a process and does not persist past the life of that process. A cached object is returned from lookup operations until either the maximum cache life for the cache is reached, or the maximum entry life for the object's cache entry is reached. After this time, a lookup on the object causes the cache entry for the object to be refreshed. By default, caches and cache entries have unlimited lifetimes.

Usually, cached objects are relatively static entities, and objects becoming stale is not a problem. However, you can set timeout values on cache entries or on a cache so that cache contents are periodically refreshed.

If a bind or rebind operation is executed on an object, the change is not reflected in any caches other than the one associated with the context from which the bind or rebind was issued. This scenario is most likely to happen when multiple processes are involved, since different processes do not share the same cache, and context objects in all threads in a process typically share the same cache instance for a given name service provider.

JNDI cache settings

Various cache property settings follow. Ensure that all property values are string values.

com.ibm.websphere.naming.jndicache.cachename:

The name of the cache to associate with an initial context instance can be specified with this property.

It is possible to create multiple InitialContext instances, each operating on the name space of a different name server. By default, objects from each bootstrap address are cached separately, since they each involve independent name spaces and name collisions could occur if they used the same cache. The provider URL specified when the initial context is created by default serves as the basis for the cache name. With this property, a JNDI client can specify a cache name. Valid options for cache names follow:

Valid options	Resulting cache behavior
providerURL (default)	Use the value for java.naming.provider.url property as the basis for the cache name. Cache names are based on the bootstrap host and port specified in the URL. The boostrap host is normalized to a fully qualfied name, if possible. For example, ″corbaname:iiop:server1:2809#some/starting/context″ and ″corbaloc:iiop://server1″ are normalized to the same cache name. If no provider URL is specified, a default cache name is used.
Any string	Use the specified string as the cache name. You can use any arbitrary string with a value other than ″providerURL″ as a cache name.

com.ibm.websphere.naming.jndicache.cacheobject:

Turn caching on or off and clear an existing cache with this property.

By default, when an InitialContext is instantiated, it is associated with an existing cache or, if one does not exist, a new one is created. An existing cache is used with its existing contents. In some circumstances, this behavior is not desirable. For example, when objects that are looked up change frequently, they can become stale in the cache. Other options are available. The following table lists these other options along with the corresponding property value.

Valid values	Resulting cache behavior
populated (default)	Use a cache with the specified name. If the cache already exists, leave existing cache entries in the cache; otherwise, create a new cache.
cleared	Use a cache with the specified name. If the cache already exists, clear all cache entries from the cache; otherwise, create a new cache.
none	Do not cache. If this option is specified, the cache name is irrelevant. Therefore, this option will not disable a cache that is already associated with other InitialContext instances. The InitialContext that is instantiated is not associated with any cache.

com.ibm.websphere.naming.jndicache.maxcachelife:

Impose a limit to the age of a cache with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the com.ibm.websphere.naming.jndicache.cacheobject property set to ″cleared″. This property enables a JNDI client to set the maximum life of a cache. This property differs from the maxentrylife property (below) in that the entire cache is cleared when the cache lifetime is reached. The table below lists the various maxcachelife values and their affect on cache behavior:

Valid options	Resulting cache behavior
0 (default)	Make the cache lifetime unlimited.
Positive integer	Set the maximum lifetime of the entire cache, in minutes, to the specified value. When the maximum lifetime for the cache is reached, the next attempt to read any entry from the cache causes the cache to be cleared

com.ibm.websphere.naming.jndicache.maxentrylife:

Impose a limit to the age of individual cache entries with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the com.ibm.websphere.naming.jndicache.cacheobject property set to `cleared`. This property enables a JNDI client to set the maximum lifetime of individual cache entries. This property differs from the maxcachelife property in that individual entries are refreshed individually as their maximum lifetime reached. This might avoid any noticeable change in performance that might occur if the whole cache is cleared at once. The table below lists the various maxentrylife values and their effect on cache behavior:

Valid options	Resulting cache behavior
0 (default)	Lifetime of cache entries is unlimited.
Positive integer	Set the maximum lifetime of individual cache entries, in minutes, to the specified value. When the maximum lifetime for an entry is reached, the next attempt to read the entry from the cache causes the individual cache entry to refresh.

Example: Controlling JNDI cache behavior from a program
You can specify JNDI cache properties in a program to control the behavior of a JNDI cache.

Following are examples that illustrate how you can use JNDI cache properties to achieve the desired cache behavior. Cache properties take effect when an InitialContext object is constructed.

```
import java.util.Hashtable;
import javax.naming.InitialContext;
import javax.naming.Context;
import com.ibm.websphere.naming.PROPS;

/*****
 Caching discussed in this section pertains to the WebSphere Application
 Server initial context factory. Assume the property,
 java.naming.factory.initial, is set to
 "com.ibm.websphere.naming.WsnInitialContextFactory" as a
 java.lang.System property.
*****/

Hashtable env;
Context ctx;

// To clear a cache:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_CLEARED);
ctx = new InitialContext(env);

// To set a cache's maximum cache lifetime to 60 minutes:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_MAX_LIFE, "60");
ctx = new InitialContext(env);

// To turn caching off:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
ctx = new InitialContext(env);

// To use caching and no caching:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_POPULATED);
ctx = new InitialContext(env);
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
Context noCacheCtx = new InitialContext(env);

Object o;

// Use caching to look up home, since the home should rarely change.
o = ctx.lookup("com/mycom/MyEJBHome");
// Narrow, etc. ...

// Do not use cache if data is volatile.
o = noCacheCtx.lookup("com/mycom/VolatileObject");
// ...
```

JNDI name syntax

JNDI name syntax is the default syntax and is suitable for typical JNDI clients.

This syntax includes the following special characters: forward slash (/) and backslash (\). Components in a name are delimited by a forward slash. The backslash is used as the escape character. A forward slash is interpreted literally if it is escaped, that is, preceded by a backslash. Similarly, a backslash is interpreted literally if it is escaped.

INS name syntax

INS syntax is designed for JNDI clients that need to interoperate with CORBA applications.

The INS syntax allows a JNDI client to make the proper mapping to and from a CORBA name. INS syntax is very similar to the JNDI syntax with the additional special character, dot (.). Dots are used to delimit the `id` and `kind` fields in a name component. A dot is interpreted literally when it is escaped. Only one unescaped dot is allowed in a name component. A name component with a non-empty `id` field and empty `kind` field is represented with only the `id` field value and must not end with an unescaped dot. An empty name component (empty `id` and empty `kind` field) is represented with a single unescaped dot. An empty string is not a valid name component representation.

JNDI to CORBA name mapping considerations

WebSphere Application Server name servers are an implementation of the CORBA CosNaming interface. WebSphere Application Server provides a JNDI implementation which you can use to access CosNaming name servers through the JNDI interface. Issues can exist when mapping JNDI name strings to and from CORBA names.

Each component in a CORBA name consists of an `id` and `kind` field, but a JNDI name component consists of no such fields. Each component in a JNDI name is atomic. Typical JNDI clients do not need to make a distinction between the `id` and `kind` fields of a name component, or know how JNDI name strings map to CORBA names. JNDI clients of this sort can use the JNDI syntax described below. When a name is parsed according to JNDI syntax, each name component is mapped to the `id` field of the corresponding CORBA name component. The `kind` field always has an empty value. This basic syntax is the least obtrusive to the JNDI client in that it has the fewest special characters. However, you cannot represent with this syntax a CORBA name with a non-empty `kind` field. This restriction can prevent EJB applications from interoperating with CORBA applications.

Some clients, however must interoperate with CORBA applications which use CORBA names with non-empty `kind` fields. These JNDI clients must make a distinction between `id` and `kind` so that JNDI names are correctly mapped to CORBA names, particularly when the CORBA names contain components with non-empty `kind` fields. Such JNDI clients can use the INS name syntax. With its additional special character, you can use INS to represent any CORBA name. Use of this syntax is not recommended unless it is necessary, because this syntax is more restrictive from the JNDI client's perspective in that the JNDI client must be aware that name components with multiple unescaped dots are syntactically invalid. INS name syntax is part of the OMG CosNaming Interoperable Naming Specification.

Example: Setting the syntax used to parse name strings

JNDI clients that must interoperate with CORBA applications might need to use INS name syntax to represent names in string format.

The name syntax property can be passed to the InitialContext constructor through its parameter, in the System properties, or in a `jndi.properties` file. The initial context and any contexts looked up from that initial context parse name strings based on the specified syntax.

The following example shows how to set the name syntax to make the initial context parse name strings according to INS syntax.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, ...);
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS);
Context initialContext = new InitialContext(env);
// The following name maps to a CORBA name component as follows:
//    id = "a.name", kind = "in.INS.format"
```

```
// The unescaped dot is used as the delimiter.
// Escaped dots are interpreted literally.
java.lang.Object o = initialContext.lookup("a\.name.in\.INS\.format");
...
```

Developing applications that use CosNaming (CORBA Naming interface)

CORBA clients can perform naming operations on WebSphere Application Server name servers through the CosNaming interface.

The following examples show how to obtain an ORB instance and an initial context as well as how to look up an EJB home.
1. Get an initial context.
2. Perform desired CosNaming operations.

Example: Getting an initial context with CosNaming

In WebSphere Application Server, an initial context is obtained from a bootstrap server. The address for the bootstrap server consists of a host and port. To get an initial context, you must know the host and port for the server that is used as the bootstrap server.

Obtaining an initial context consists of two basic steps:
1. Obtain an ORB reference.
2. Use an ORB reference to get an initial context. Alternatively, use an existing ORB and invoke string_to_object with a CORBA object URL with multiple name server addresses to get an initial context.

Obtaining an ORB reference: Pure CosNaming clients, that is clients that are not running in a server process, must create and initialize an ORB instance with which to obtain the initial context. CosNaming clients which run in server processes can obtain a reference to the server ORB with a JNDI lookup. The following examples illustrate how to create and initialize a client ORB and how to obtain a server ORB reference.

Creating a client ORB instance

To create an ORB instance, invoke the static method, org.omg.CORBA.ORB.init. The init method requires a property set to the name of the ORB class you want to instantiate. An ORB implementation with the class name com.ibm.CORBA.iiop.ORB is included with the product. The WebSphere Application Server ORB recognizes additional properties with which you can specify initial references.

The basic steps for creating an ORB are as follows:
1. Create a Properties object.
2. Set the ORB class property to the product's ORB class.
3. Set the initial reference properties.
4. Invoke ORB.init, passing in the Properties object.

Usage scenario

```
...
import java.util.Properties;
import org.omg.CORBA.ORB;
...
Properties props = new Properties();
props.put("org.omg.CORBA.ORBClass", "com.ibm.CORBA.iiop.ORB");
props.put("com.ibm.CORBA.ORBInitRef.NameService",
     "corbaloc:iiop:myhost.mycompany.com:2809/NameService");
```

```
props.put("com.ibm.CORBA.ORBInitRef.NameServiceServerRoot",
      "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceServerRoot");
ORB _orb = ORB.init((String[])null, props);
...
```

Obtaining a reference to the server ORB

CosNaming clients which run in a server process can obtain a reference to the server ORB with a JNDI lookup on a java: name, shown as follows:

Usage scenario

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
import org.omg.CORBA.ORB;
...
Context initialContext = new InitialContext();
ORB orb = (ORB) initialContext.lookup("java:comp/ORB");
...
```

Using an ORB reference to get an initial naming reference: There are two basic ways to get an initial CosNaming context. Both ways involve an ORB method invocation. The first way is to invoke the resolve_initial_references method on the ORB with an initial reference key. For this call to work, the ORB must be initialized with an initial reference for that key. The other way is to invoke the string_to_object method on the ORB, passing in a CORBA object URL with the host and port of the bootstrap server. The following examples illustrate both approaches.

Invoking resolve_initial_references

Once an ORB reference is obtained, invoke the resolve_initial_references method on the ORB to obtain a reference to the initial context. The following code example invokes resolve_initial_reference on an ORB reference.

Usage scenario

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj = _orb.resolve_initial_references("NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Note that the key NameService is passed to the resolve_initial_references method. Other initial context keys are registered in product servers. For example, NameServiceServerRoot can be used to obtain a reference to the server root context in the bootstrap name server. For more information on the initial contexts registered in server ORBs, refer to "Initial context support" on page 1022.

Invoking string_to_object with a CORBA object URL

You can use an INS-compliant ORB to obtain an initial context even if the ORB is not initialized with any initial references or bootstrap properties, or if those property settings are for a different server than the name server from which you want to obtain the initial context. To obtain an initial context by explicitly specifying the bootstrap name server, invoke the string_to_object method on the ORB, passing in a CORBA object URL which contains the bootstrap server host and port.

The code in the example below invokes the string_to_object method on an existing ORB reference, passing in a CORBA object URL which identifies the desired initial context.

Usage scenario

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj =
 orb.string_to_object("corbaloc:iiop:myhost.mycompany.com:2809/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Note that the key NameService is used in the corbaloc URL. Other initial context keys are registered in product servers. For example, you can use NameServiceServerRoot to obtain a reference to the server root context in the bootstrap name server.

Using an existing ORB and invoking string_to_object with a CORBA object URL with multiple name server addresses to get an initial context: CORBA object URLs can contain more than one bootstrap server address. Use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap server addresses for all servers in the cluster in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap server address may be used to obtain the initial context even though the first bootstrap server in the list is available. An example of a corbaloc URL with multiple addresses follows.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Assume orb is an existing ORB instance
org.omg.CORBA.Object obj = orb.string_to_object(
   "corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Example: Looking up an EJB home with CosNaming

You can look up an EJB home or other CORBA object from a WebSphere Application Server name server through the CORBA CosNaming interface.

You can invoke `resolve` or `resolve_str` on the initial context, or you can invoke `string_to_object` on the ORB. You can use a qualified name so that the name resolves regardless of which name server the lookup is executed on, or use an unqualified name that only resolves from the server root context on the name server that actually contains the object binding. (The qualified name traverses the federated system name space to the specified server root context.)

Qualified and unqualified names

Each application server contains a name server. System artifacts such as EJB homes are bound in that name server. The various name servers are federated by means of a system name space structure. The recommended way to look up objects on different servers is to use a qualified name. A qualified name can be a topology-based name, based on the name of the cluster or single server and node that contains the object. You can define fixed qualified names for objects. With qualified names, you can look up objects residing on different servers from the same initial context by traversing the system name space structure. Alternatively, you can use an unqualified name, but an unqualified name will only resolve using the name server associated with the object's application server.

CosNaming.resolve (and resolve_str) vs. ORB.string_to_object

If you have an initial context from any name server in a WebSphere Application Server cell, you can look up any CORBA object with a qualified name. You do not need additional host and port information for the target object's name server.

Alternatively, you can look up an object by invoking `string_to_object` on the ORB, passing in a corbaname URL. Typically, an IIOP type URL is specified, so the bootstrap address information required for an initial context must be contained in the URL. You can use a qualified or unqualified stringified name, but an unqualifed name resolves only if the initial context is from the name server in which the object is bound.

The following examples show CosNaming resolve operations using qualified topology-based lookup names and an unqualified lookup name.

CosNaming resolve operation using a qualified name: The topology-based qualified name for an object depends on whether the object is bound in a single server or a server cluster. Examples of each follow.

Single server

The following example shows the lookup of an EJB home that is running in a single server. The enterprise bean that is being looked up is running in the server, `MyServer`, on the node, `Node1`.

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
  "cell/nodes/Node1/servers/MyServer/mycompany/accounting/AccountEJB");
accountHome =
  (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

Server cluster

The following example shows a lookup of an EJB home that is running in a cluster. The enterprise bean being that is looked up is running in the cluster, Cluster1. The name can be resolved if any of the cluster members is running.

Usage scenario

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
   "cell/clusters/Cluster1/mycompany/accounting/AccountEJB");
accountHome =
   (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

ORB string_to_object operation using an unqualified stringified name: If the resolve operation is being performed on the name server that contains the object, the system name space does not need to be traversed, and you can use an unqualified lookup name. Note that this name does not resolve on other name servers. If an unqualified name is provided, the object key must be NameServiceServerRoot so that the correct initial context is selected. If a qualified name is provided, you can use the default key of NameService.

The following example shows a lookup of an EJB home. The enterprise bean that is being looked up is bound on the name server running on the host `myHost` on port `2809`. Note the object key of `NameServiceServerRoot`.

```
// Assume orb is an existing ORB instance
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = orb.string_to_object(
    "corbaname:iiop:myHost:2809/NameServiceServerRoot#mycompany/accounting");
accountHome =
    (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

Object Request Broker

Managing Object Request Brokers

Use this task to manage Object Request Brokers (ORB). An ORB manages the interaction between clients and servers using the Internet InterORB Protocol (IIOP).

Default property values are set when the product starts and the Java Object Request Broker (ORB) service is initialized. These properties control the run-time behavior of the ORB and can also affect the behavior of product components that are tightly integrated with the ORB, such as security. It might be necessary to modify some ORB settings under certain conditions.

Every request or response exchange consists of a client-side ORB and a server-side ORB. It is important to set the ORB properties for both sides as necessary.

After an ORB instance has been established in a process, changes to ORB properties do not affect the behavior of the running ORB instance. The process must be stopped and restarted for the modified properties to take effect.

A list of possible tasks for managing ORB follows. These steps can be performed in any order.

1. Adjust timeout settings to improve handling of network failures. See "Object Request Broker service settings" on page 1052 for more information. Before making these adjustments, read Object Request Broker tuning guidelines.
2. Adjust thread-pool settings used by the ORB for handling Internet InterORB Protocol (IIOP) connections. See Thread pool settings for more information.
3. If problems with the ORB arise, see "Object request broker troubleshooting tips" on page 1070.

   For help in troubleshooting, see "Object Request Broker communications trace" on page 1063.

Object Request Brokers

An Object Request Broker (ORB) manages the interaction between clients and servers, using the Internet InterORB Protocol (IIOP). It enables clients to make requests and receive responses from servers in a network-distributed environment.

The ORB provides a framework for clients to locate objects in the network and to call operations on those objects as if the remote objects are located in the same running process as the client, providing location transparency. The client calls an operation on a local object, known as a *stub*. The stub forwards the request to the remote object, where the operation runs and the results are returned to the client.

The client-side ORB is responsible for creating an IIOP request that contains the operation and required parameters, and for sending the request on the network. The server-side ORB receives the IIOP request, locates the target object, invokes the requested operation, and returns the results to the client. The client-side ORB demarshals the returned results and passes the result to the stub, which, in turn, returns to the client application, as if the operation had been run locally.

This product uses an ORB to manage communication between client applications and server applications as well as communication among product components. During product installation, default property values are set when the ORB is initialized. These properties control the run-time behavior of the ORB and can also affect the behavior of product components that are tightly integrated with the ORB, such as security. This product does not support the use of multiple ORB instances.

Logical pool distribution

The Logical pool distribution (LPD) thread pool mechanism implements a strategy for improving the performance of requests that have shorter run times. Do not configure LPD unless you have already configured it in a previous release of WebSphere Application Server. LPD is a deprecated function and will be removed in a future version of the product.

The need for LPD is indicated by a mixture of Enterprise JavaBeans (EJB) requests where the run times vary across the request types, and the ORB thread pool must be constrained for performance reasons. In this case, longer run time requests might tend to prolong the response times for shorter requests by denying them adequate access to threads in the thread pool. LPD provides a mechanism that allows shorter requests greater access to the threads.

LPD divides the Object Request Broker (ORB) thread pool into logical pools, as configured by the administrator using ORB custom properties starting that start with the following:

```
com.ibm.websphere.threadpool.strategy.*
```

The size of each pool is a percentage of the maximum number of ORB threads. The sum of the logical pool percentages must equal 100.

When LPD is active, incoming ORB requests are vectored, or pointed, to a pool based on historical run time history for the request type. The request type is determined by the method, which is qualified internally as unique across components. The LPD mechanism adjusts pool targets at runtime to optimize the distribution of requests across logical pools.

The LPD mechanism can be tuned after it is enabled. Response time, throughput measurements, and statistics produced by the LPD mechanism drive the tuning process.

Object Request Broker service settings

Use this page to configure the Java Object Request Broker (ORB) service.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Container services > ORB service** .

Several settings are available for controlling internal Object Request Broker (ORB) processing. You can use these settings to improve application performance in the case of applications that contain enterprise beans. You can make changes to these settings for the default server or any application server that is configured in the administrative domain.

Request timeout:

Specifies the number of seconds to wait before timing out on a request message.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.RequestTimeout.

Data type	int
Units	Seconds
Default	180
Range	0 - largest integer recognized by Java

Request retries count:

Specifies the number of times that the ORB attempts to send a request if a server fails. Retrying sometimes enables recovery from transient network failures. This field is ignored on the z/OS platform.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.requestRetriesCount.

Data type	int
Default	1
Range	1 to 10

Request retries delay:

Specifies the number of milliseconds between request retries. This field is ignored on the z/OS platform.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.requestRetriesDelay.

Data type	int
Units	Milliseconds
Default	0
Range	0 to 60,000

Connection cache maximum:

Specifies the maximum number of entries that can occupy the ORB connection cache before the ORB starts to remove inactive connections from the cache. This field is ignored on the z/OS platform.

It is possible that the number of active connections in the cache will temporarily exceed this threshold value. If necessary, the ORB will continue to add connections as long as resources are available.

For use in command-line scripting, the full name of this system property is com.ibm.CORBA.MaxOpenConnections.

Data type	Integer
Units	Connections
Default	240
Range	10 - largest integer recognized by Java

Connection cache minimum:

Specifies the minimum number of entries in the ORB connection cache. This field is ignored on the z/OS platform.

The ORB will not remove inactive connections when the number of entries is below this value.

For use in command-line scripting, the full name of this system property is com.ibm.CORBA.MinOpenConnections.

Data type	Integer
Units	Connections
Default	100

Range	Any integer that is at least 5 less than the value specified for the Connection cache maximum property.

ORB tracing:

Enables the tracing of ORB General Inter-ORB Protocol (GIOP) messages.

This setting affects two system properties: com.ibm.CORBA.Debug and com.ibm.CORBA.CommTrace. If you set these properties through command-line scripting, you must set both properties to `true` to enable the tracing of GIOP messages.

Data type	Boolean
Default	Not enabled (false)

Locate request timeout:

Specifies the number of seconds to wait before timing out on a LocateRequest message. This field is ignored on the z/OS platform.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.LocateRequestTimeout.

Data type	int
Units	Seconds
Default	180
Range	0 to 300

Force tunneling:

Controls how the client ORB attempts to use HTTP tunneling. This field is ignored on the z/OS platform.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.ForceTunnel.

Data type	String
Default	NEVER
Range	Valid values are ALWAYS, NEVER, or WHENREQUIRED.

Considering the following information when choosing the valid value:

ALWAYS
Use HTTP tunneling immediately, without trying TCP connections first.

NEVER
Disable HTTP tunneling. If a TCP connection fails, a CORBA system exception (COMM_FAILURE) occurs.

WHENREQUIRED
Use HTTP tunneling if TCP connections fail.

Tunnel agent URL:

Specifies the Web address of the servlet to use in support of HTTP tunneling. This field is ignored on the z/OS platform.

This Web address must be a proper format:

http://w3.mycorp.com:81/servlet/com.ibm.CORBA.services.IIOPTunnelServlet

For applets: http://applethost:port/servlet/com.ibm.CORBA.services.IIOPTunnelServlet.

This field is required if HTTP tunneling is set. If you use command-line scripting, the full name of this system property is com.ibm.CORBA.TunnelAgentURL.

Pass by reference:

Specifies how the ORB passes parameters. If enabled, the ORB passes parameters by reference instead of by value, to avoid making an object copy. If you do not enable the pass by reference option, a copy of the parameter passes rather than the parameter object itself. This can be expensive because the ORB must first make a copy of each parameter object.

You can use this option only when the Enterprise JavaBeans (EJB) client and the EJB are on the same classloader. This requirement means that the EJB client and the EJB must be deployed in the same EAR file.

If the Enterprise JavaBeans (EJB) client and server are installed in the same WebSphere Application Server instance, and the client and server use remote interfaces, enabling the pass by reference option can improve performance up to 50%. The pass by reference option helps performance only where non-primitive object types are passed as parameters. Therefore, int and floats are always copied, regardless of the call model.

Important: Enable this property with caution because unexpected behavior can occur. If an object reference is modified by the callee, the caller's object is modified as well, since they are the same object.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.iiop.noLocalCopies.

Data type	Boolean
Default	Not enabled (false)

The use of this option for enterprise beans with remote interfaces violates Enterprise JavaBeans (EJB) Specification, Version 2.0 (see section 5.4). Object references passed to Enterprise JavaBeans (EJB) methods or to EJB home methods are not copied and can be subject to corruption.

Consider the following example:

```
Iterator iterator = collection.iterator();
MyPrimaryKey pk = new MyPrimaryKey();
while (iterator.hasNext()) {
   pk.id = (String) iterator.next();
   MyEJB myEJB = myEJBHome.findByPrimaryKey(pk);
}
```

In this example, a reference to the same MyPrimaryKey object passes into WebSphere Application Server with a different ID value each time. Running this code with pass by reference enabled causes a problem within the application server because multiple enterprise beans are referencing the same MyPrimaryKey object. To avoid this problem, set the com.ibm.websphere.ejbcontainer.allowPrimaryKeyMutation system property to `true` when the pass by reference option is enabled. Setting the pass by reference option to `true` causes the EJB container to make a local copy of the PrimaryKey object. As a result, however, a small portion of the performance advantage of setting the pass by reference option is lost.

As a general rule, any application code that passes an object reference as a parameter to an enterprise bean method or to an EJB home method must be scrutinized to determine if passing that object reference results in loss of data integrity or in other problems.

After examining your code, you can enable the pass by reference option by setting the com.ibm.CORBA.iiop.noLocalCopies system property to `true`. You can also enable the pass by reference option in the administrative console. Click **Servers > Application servers >** *server_name* **> Container services > ORB Service** and select **Pass by reference**.

Object Request Broker custom properties

There are several ways to configure an ORB. For example, you can use ORB custom property settings, or system property settings to configure an ORB, or you can provide objects during ORB initialization.

If you use ORB custom properties to configure an ORB, you must understand that there are two types of default values for some of these properties: JDK default values and WebSphere Application Server default values. The JDK default is the value that the ORB uses for a property if the property is not specified in any way. The WebSphere Application Server default is the value that WebSphere Application Server sets for a property in one of the following files:
* The orb.properties file when an application server is installed.
* The server.xml when an application server is configured.

Because WebSphere Application Server explicitly sets its default value, if both a WebSphere Application Server and a JDK default value is defined for a property, the WebSphere Application Server default takes precedence over the JDK default.

For more information about the different ways to specify ORB properties and the precedence order, see the JDK Diagnostic Guide for the version of the JDK that you are using. These guides are available at http://www-128.ibm.com/developerworks/java/jdk/diagnosis/.

The WebSphere Application Server orb.properties file, that is located in the WebSphere Application Server *was_home*/java/jre/lib directory, contains WebSphere Application server ORB custom properties that are initially set to WebSphere Application Server default values during the WebSphere Application Server installation process.

You can specify new values for the ORB custom properties in the administrative console. Any value you specify takes precedence over any JDK or WebSphere Application Server default values for these properties. The ORB custom properties settings that you specify in the administrative console are stored in the WebSphere Application Server server.xml system file and are passed to an ORB in a properties object whenever an ORB is initialized.

To use the administrative console to set ORB custom properties, in the administrative console, click **Servers >Application servers >** *server_name* **>Container services > ORB service >Custom properties**. You can then change the setting of one of the listed custom properties or click **New** to add a new property to the list. Then click **Apply** to save your change. When you finish making changes, click **OK** and then click **Save** to save your changes.

To use the `java` command on a command line, use the `-D` option. For example:

```
java -Dcom.ibm.CORBA.propname1=value1 -Dcom.ibm.CORBA.propname2=value2 ... application name
```

To use the `launchclient` command on a command line, prefix the property with `-CC`. For example:

```
launchclient yourapp.ear -CCDcom.ibm.CORBA.propname1=value1 -CCDcom.ibm.CORBA.propname2=value2
   ... optional application arguments
```

The Custom properties page might already include Secure Sockets Layer (SSL) properties that were added during WebSphere Application Server installation. A list of additional properties associated with the Java ORB service follows. Unless otherwise indicated, the default values provided in the descriptions of these properties are the JDK default values.

com.ibm.CORBA.BootstrapHost:

Specifies the domain name service (DNS) host name or IP address of the machine on which initial server contact for this client resides. This setting is deprecated and is scheduled for removal in a future release.

For a command-line or programmatic alternative, see "Client-side programming tips for the Java Object Request Broker service" on page 1066.

com.ibm.CORBA.BootstrapPort:

Specifies the port to which the ORB connects for bootstrapping, the port of the machine on which the initial server contact for this client listens. This setting is deprecated and is scheduled for removal in a future release.

For a command-line or programmatic alternative, see "Client-side programming tips for the Java Object Request Broker service" on page 1066.

Default	2809

com.ibm.CORBA.ConnectTimeout:

The com.ibm.CORBA.ConnectTimeout property specifies the maximum time in seconds that the client ORB waits before timing out when attempting to establish an IIOP connection with a remote server ORB. Generally, client applications use this property. The property is not used by the application server by default. However, if necessary, you can specify the property for each individual application server through the administrative console.

Client applications can specify the com.ibm.CORBA.ConnectTimeout property in one of two ways:
- By including it in the orb.properties file.
- By using the -CCD option to set the property with the launchclient script. This example specifies a maximum timeout value of ten seconds:

```
launchclient clientapp.ear -CCDcom.ibm.com.CORBA.ConnectTimeout=10...
```

Begin by setting your timeout value to 20-30 seconds, but consider factors such as network congestion and application server load and capacity. Lower values can provide better failover performance, but can result in exceptions if the remote server does not have enough time to complete the connection.

Valid Range	0-300 (seconds)
Default	0 (the client ORB waits indefinitely)

com.ibm.CORBA.ConnectionInterceptorName:

Specifies the connection interceptor class that is used to determine the type of outbound IIOP connection to use for a request, and if secure, the quality of protection characteristics associated with the request.

WebSphere Application Server default	com.ibm.ISecurityLocalObjectBaseL13Impl.SecurityConnectionInterceptor
JDK default	None.

com.ibm.CORBA.enableLocateRequest:

Specifies whether the ORB uses the locate request mechanism to find objects in a WebSphere Application Server cell. Use this property for performance tuning.

When this property is set to true, the ORB first sends a short message to the server to find the object that it needs to access. This first contact is called the *locate request*. If most of your initial method invocations

are very small, setting this property to false might improve performance because this setting change can reduce the GIOP traffic by as much as half. If most of your initial method invocations are large, you should set this property to true so that the small locate request message is sent instead of the large message. The large message is then sent to the proper target after the desired object is found.

WebSphere Application Server default	true
JDK default	false

com.ibm.CORBA.FragmentSize:

Specifies the size of General Inter-ORB Protocol (GIOP) fragments used by the ORB. If the total size of a request exceeds the set value, the ORB breaks up and sends multiple fragments until the entire request is sent. Set this property on the client side with a -D system property if you use a stand-alone Java application.

Adjust the `com.ibm.CORBA.FragmentSize` property if the amount of data that is sent over Internet Inter-ORB Protocol (IIOP) in most General Inter-ORB Protocol (GIOP) requests exceeds one kilobyte or if thread dumps show that most client-side threads seem to be waiting while sending or receiving data. Adjust this property so that most messages have few or no fragments.

If you want to instruct the ORB not to break up any of the requests or replies it sends, set this property to `0` (zero). However, setting the value to zero does not prevent the ORB from receiving GIOP fragments in requests or replies sent by another existing ORB.

Units	Bytes.
Default	1024
Range	From 64 to the largest value of a Java integer type that is divisible by 8

com.ibm.CORBA.ListenerPort:

Specifies the port on which this server listens for incoming requests. The setting of this property is valid for client-side ORBs only.

Default	Next available system-assigned port number
Range	0 to 2147483647

com.ibm.CORBA.LocalHost:

Specifies the host name or IP address of the system on which the server ORB is running. If you do not specify a value for this property, during ORB initialization WebSphere Application Server sets this property to the host name or IP address specified for the BOOTSTRAP_ADDRESS end point in serverindex.xml. For client applications, if no value is specified for this property, the ORB obtains a value at run time by calling InetAddress.getLocalHost().getHostAddress() method.

com.ibm.CORBA.numJNIReaders:

Specifies the number of JNI reader threads to be allocated in the ORB's JNI reader thread pool. Each thread can handle up to 1024 connections.

Attention: Before setting this property, make sure that a JSSE provider has been selected as the provider for the SSL repertoire associated with the port on which the ORB service listens for incoming requests. IBMJSSE2 is the default provider setting for SSL repertoires and does not provide the file descriptor that JNIReader Threads require.

Valid Range	1-2147483647
Default	4

com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl:

Specifies that JNI reader threads will be used. The property name specifies the class name of the ORB component that manages the pool of JNI reader threads and interacts with the native OS library used to process multiple connections simultaneously.

Attention:

- Make sure the library is in the WebSphere Application Server bin directory.

  For an Intel platform, the library is Selector.dll and for a UNIX platform, it is libSelector.a or libSelector.so.

  For the UNIX platform, if the prefix ″lib″ is missing, the file should be renamed.

- When specifying this property using the administrative console, enter com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl for the property name and an empty string (″″) for the value.

  When specifying this property on the java command, do not include a value:

  ```
  -Dcom.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl
  ```

Valid Range	not applicable
Default	none

com.ibm.CORBA.RasManager:

Specifies an alternative to the default RAS manager of the ORB. This property must be set to com.ibm.websphere.ras.WsOrbRasManager before the ORB can be integrated with the rest of WebSphere Application Server RAS processing.

WebSphere Application Server default	com.ibm.websphere.ras.WsOrbRasManager
JDK default	None.

com.ibm.CORBA.ServerSocketQueueDepth:

Specifies the maximum number of connection requests that can remain unhandled by the WebSphere Application Server ORB before the Application Server starts to reject new incoming connection requests. This property corresponds to the `backlog` argument to a ServerSocket constructor and is handled directly by TCP/IP.

If you see a ″connection refused″ message in a trace log, usually either the port on the target machine isn't open, or the server is overloaded with queued-up connection requests. Increasing the value specified for this property can help alleviate this problem if there does not appear to be any other problem in the system.

Default	50
Range	From 50 to the largest value of the Java int type

com.ibm.CORBA.ShortExceptionDetails:

Specifies that the exception detail message that is returned whenever the server ORB encounters a CORBA system exception contains a short description of the exception as returned by the toString method

of java.lang.Throwable class. Otherwise, the message contains the complete stack trace as returned by the printStackTrace method of java.lang.Throwable class.

com.ibm.CORBA.WSSSLClientSocketFactoryName:

Specifies the class that the ORB uses to create SSL sockets for secure outbound IIOP connections.

WebSphere Application Server dfault	com.ibm.ws.security.orbssl.WSSSLClientSocketFactoryImpl
JDK default	None.

com.ibm.CORBA.WSSSLServerSocketFactoryName:

Specifies the class that the ORB uses to create SSL sockets for inbound IIOP connections.

WebSphere Application Server default	com.ibm.ws.security.orbssl.WSSSLServerSocketFactoryImpl
JDK default	None.

com.ibm.websphere.ObjectIDVersionCompatibility:

This property applies when you have a mixed release cluster for which you are performing an incremental cell upgrade, and at least one of the releases is earlier than V5.1.1.

In an environment that includes mixed release cells, the migration program automatically sets this property to 1.

After you upgrade all of the cluster members to the same release, you can removing this property from the list of ORB custom properties or you can change the value that is specified for the property to 2. Either action improves performance.

When this property is set to 1, the ORB runs using version 1 object identities, which are required for mixed cells that contain application servers with releases prior to V5.1.1. If you do not specify a value for this property or if you set this property to 2, the ORB runs using version 2 object identities, which cannot be used with pre-V5.1.1 application servers.

See the *Migrating, coexisting, and interoperating* PDF for instructions on how to perform an incremental cell upgrade.

com.ibm.websphere.threadpool.strategy.implementation:

Specifies the logical pool distribution (LPD) thread pool strategy the next time you start the application server, and is enabled if set to com.ibm.ws.threadpool.strategy.LogicalPoolDistribution.

Attention: This is a deprecated function and will be removed in a future version of the product. Do not configure logical pool distribution unless you have already configured it for a previous release of WebSphere Application Server.

Some requests have shorter start times than others. LPD is a mechanism for providing these shorter requests greater access to start threads. For more information, see the information center.

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.calcinterval:

Specifies how often the logical pool distribution (LPD) mechanism readjusts the pool start target times. This property cannot be turned off after this support is installed.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see com.ibm.websphere.threadpool.strategy.implementation).

Data type	Integer
Units	Milliseconds
Default	30
Range	20,000 milliseconds minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.lruinterval:

Specifies how long the logical pool distribution internal data is kept for inactive requests. The mechanism tracks several statistics for each request type that is received. Consider removing requests that have been inactive for awhile.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see com.ibm.websphere.threadpool.strategy.implementation).

Data type	Integer
Units	Milliseconds
Default	300,000 (5 minutes)
Range	60,000 (1 minute) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.outqueues:

Specifies how many pools are created and how many threads are allocated to each pool in the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

The ORB parameter for max threads controls the total number of threads. The outqueues parameter is specified as a comma separated list of percentages that add up to 100. For example, the list 25,25,25,25 sets up 4 pools, each allocated 25% of the available ORB thread pool. The pools are indexed left to right from 0 to n-1. Each outqueue is dynamically assigned a target start time by the calculation mechanism. Target start times are assigned to outqueues in increasing order so pool 0 gets the requests with the least start time and pool n-1 gets requests with the highest start times.

LPD must be enabled (see com.ibm.websphere.threadpool.strategy.implementation).

Data type	Integers in comma separated list
Default	25,25,25,25
Range	Percentages in list must total 100 percent

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.statsinterval:

Specifies that statistics are dumped to stdout after this interval expires, but only if requests are processed. This process keeps the mechanism from filling the log files with redundant information. These statistics are beneficial for tuning the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see com.ibm.websphere.threadpool.strategy.implementation).

Data type	Integer
Units	Milliseconds
Default	0 (off)
Range	30,000 (30 seconds) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.workqueue:

Specifies the size of a new queue where incoming requests wait for dispatch. Pertains to the logical pool distribution mechanism.

Attention: Do not configure logical pool distribution unless you have already configured it with a previous release of WebSphere Application Server. This function is deprecated and will be removed in a future version of the product.

LPD must be enabled (see com.ibm.websphere.threadpool.strategy.implementation).

Data type	Integer
Default	96
Range	10 minimum

com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint:

Specifies the maximum number of connections that the IIOP Tunnel Servlet should maintain in its connection cache for each target host or port. If the number of concurrent client requests to a single host or port exceeds the setting for this property, the IIOP Tunnel Servlet opens a temporary connection to the target server for each extra client request, and then closes the connection after it receives the reply. Connections that are opened but not used within five minutes are removed from the cache for the IIOP Tunnel Servlet.

WebSphere Application Server default	3
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.services.redirector.RequestTimeout:

Specifies the number of seconds that the IIOP Tunnel Servlet waits for a reply from the target server on behalf of a client before timing out. If a value is not specified for this property, or is improperly specified, the com.ibm.CORBA.RequestTimeout property setting for the application server on which the IIOP Tunnel Servlet is installed is used as the setting for the com.ibm.ws.orb.services.redirector.RequestTimeout property.

The value you specify for this property should be at least as high as the highest client setting for the com.ibm.CORBA.RequestTimeout property, otherwise the IIOP Tunnel Servlet might timeout more quickly than the client would normally timeout while waiting for a reply. If this property is set to zero, the IIOP

Tunnel Servlet does not time out.

WebSphere Application Server default	com.ibm.CORBA.RequestTimeout property setting for the application server on which the IIOP Tunnel Servlet is installed.
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.transport.useMultiHome:

Specifies whether the WebSphere Application Server ORB binds to all network interfaces in the system. If true is specified, the ORB binds to all network interfaces that are available to it. If false is specified, the ORB only binds to the network interface specified for the com.ibm.CORBA.LocalHost system property.

WebSphere Application Server default	true
JDK default	true

javax.rmi.CORBA.UtilClass:

Specifies the name of the Java class that WebSphere Application Server uses to implement the javax.rmi.CORBA.UtilDelegate interface.

This property supports delegation for method implementations in the javax.rmi.CORBA.Util class. The javax.rmi.CORBA.Util class provides utility methods that can be used by stubs and ties to perform common operations. The delegate is a singleton instance of a class that implements this interface and provides a replacement implementation for all of the methods of javax.rmi.CORBA.Util. To enable a delegate, provide the class name of the delegate as the value of the javax.rmi.CORBA.UtilClass system property. The default value provides support for the com.ibm.CORBA.iiop.noLocalCopies property.

WebSphere Application Server default	com.ibm.ws.orb.WSUtilDelegateImpl
JDK default	None.

Object Request Broker communications trace

The Object Request Broker (ORB) communications trace, typically referred to as *CommTrace*, contains the sequence of General InterORB Protocol (GIOP) messages sent and received by the ORB when the application is running.

It might be necessary to understand the low-level sequence of client-to-server or server-to-server interactions during problem determination. This topic uses trace entries from log examples to explain the contents of the log and help you understand the interaction sequence. It focuses only in the GIOP messages and does not discuss in detail additional trace information that displays when intervening with the GIOP-message boundaries.

Location

When ORB tracing is enabled, this information is placed in the *app_server_root*/profiles/*profile_name*/logs/*server_name*/trace.log directory.

About the ORB trace file

The following are properties of the file that is created when ORB tracing is enabled.
* Read-only
* Updated by the administrative function
* Use this file to localize and resolve ORB-related problems.

How to interpret the output

The following sections refer to sample log output found later in this topic.

Identifying information

The start of a GIOP message is identified by a line that contains either OUT GOING: or IN COMING: depending on whether the message is sent or received by the process.

Following the identifying line entry is a series of items, formatted for convenience, with information extracted from the raw message that identifies the endpoints in this particular message interaction. See lines 3-13 in both examples. The formatted items include the following:
- GIOP message type (line 3)
- Date and time that the message was recorded (line 4)
- Information that is useful to identify the thread that is running when the message records, and other thread-specific information (line 5)
- Local and remote TCP/IP ports used for the interaction (lines 6 through 9)
- GIOP version, byte order, an indication of whether the message is a fragment, and message size (lines 10 through 13)

Request ID, response expected and reply status

Following the introductory message information, the request ID is an integer generated by the ORB. It is used to identify and associate each request with its corresponding reply. This association is necessary because the ORB can receive requests from multiple clients and must be able to associate each reply with the corresponding originating request.
- Lines 15-17 in the request example show the request ID, followed by an indication to the receiving endpoint that a response is expected (CORBA supports sending one-way requests for which a response is not expected.)
- Line 15 in the *Sample Log Entry - GIOP Reply* shows the request ID; line 33 shows the reply status received after completing the previously sent request.

Object Key

Lines 18-20 in the request example show the object key, the internal representation used by the ORB to identify and locate the target object intended to receive the request message. Object keys are not standardized.

Operation

Line 21 in the request example shows the name of the operation that the target object starts in the receiving endpoint. In this example, the specific operation requested is named _get_value.

Service context information

The service contexts in the message are also formatted for convenience. Each GIOP message might contain a sequence of service contexts sent and received by each endpoint. Service contexts, identified uniquely with an ID, contain data used in the specific interaction, such as security, character code set conversion, and ORB version information. The content of some of the service contexts is standardized and specified by OMG, while other service contexts are proprietary and specified by each vendor. IBM-specific service contexts are identified with IDs that begin with 0x4942.

Lines 22-41 in the request example illustrate typical service context entries. Three service contexts are in the request message, as shown in line 22. The ID, length of data, and raw data for each service context is printed next. Lines 23-25 show an IBM-proprietary context, as indicated by the 0x49424D12 ID. Lines 26-41 show two standard service contexts, identified by 0x6 ID (line 26) and the 0x1 ID (line 39).

Lines 16-32 in the *Sample Log Entry - GIOP Reply* illustrate two service contexts, one IBM-proprietary (line 17) and one standardized (line 20).

For the definition of the standardized service contexts, see the CORBA specification. Service context 0x1 (CORBA::IOP::CodeSets) is used to publish the character code sets supported by the ORB in order to negotiate and determine the code set used to transmit character data. Service context 0x6 (CORBA::IOP::SendingContextRunTime) is used by Remote Method Invocation over the Internet Inter-ORB Protocol (RMI-IIOP) to provide the receiving endpoint with the IOR for the

SendingContextRuntime object. IBM service context 0x49424D12 is used to publish ORB PartnerVersion information to support release-to-release interoperability between sending and receiving ORBs.

Data offset

Line 42 in the request example shows the offset, relative to the beginning of the GIOP message, where the remainder body of the request or reply message is located. This portion of the message is specific to each operation and varies from operation to operation. Therefore, it is not formatted, as the specific contents are not known by the ORB. The offset is printed as an aid to quickly locating the operation-specific data in the raw GIOP message dump, which follows the data offset.

Raw GIOP message dump

Starting at line 45 in the request example and line 36 in the *Sample Log Entry - GIOP Reply*, a raw dump of the entire GIOP message is printed in hexadecimal format. Request messages contain the parameters required by the given operation and reply messages contain the return values and content of output parameters as required by the given operation. For brevity, not all of the raw data is in the figures.

Client-side programming tips for the Java Object Request Broker service

This topic includes programming tips for applications that communicate with the client-side Object Request Broker (ORB) that is part of the Java ORB service.

Resolution of initial references to services

Client applications can use the ORBInitRef and ORBDefaultInitRef properties to configure the network location that the Java ORB service uses to find a service such as naming. When set, these properties are included in the parameters that are used to initialize the ORB, as illustrated in the following example:

```
org.omg.CORBA.ORB.init(java.lang.String[] args,
                       java.util.Properties props)
```

You can set these properties in client code or by command-line argument. It is possible to specify more than one service location by using multiple ORBInitRef property settings (one for each service), but only a single ORBDefaultInitRef value can be specified.

For setting in client code, these properties are com.ibm.CORBA.ORBInitRef.*service_name* and com.ibm.CORBA.ORBDefaultInitRef, respectively. For example, to specify that the naming service

(NameService) is located in sample.server.com at port 2809, set the
com.ibm.CORBA.ORBInitRef.NameService property to corbaloc::sample.server.com:2809/NameService.

For setting by command-line argument, these properties are -ORBInitRef and -ORBDefaultInitRef,
respectively. To locate the same naming service specified previously, use the following Java command:

After these properties are set for services that the ORB supports, Java 2 Platform, Enterprise Edition
(J2EE) applications can call the resolve_initial_references function on the ORB, as defined in the
CORBA/IIOP specification, to obtain the initial reference to a given service.

Preferred API for obtaining an ORB instance

For J2EE applications, you can use either of the following approaches. However, it is strongly
recommended that you use the Java Naming and Directory Interface (JNDI) approach to ensure that the
same ORB instance is used throughout the client application; you avoid the unintended inconsistencies
that might occur when different ORB instances are used.

JNDI approach: For J2EE applications (including enterprise beans, J2EE clients and servlets), you can
obtain an ORB instance by creating a JNDI InitialContext object and looking up the ORB under the
java:comp/ORB name , as illustrated in the following example:

```
javax.naming.Context ctx = new javax.naming.InitialContext();
org.omg.CORBA.ORB orb =
   (org.omg.CORBA.ORB)javax.rmi.PortableRemoteObject.narrow(ctx.lookup("java:comp/ORB"),
                                                    org.omg.CORBA.ORB.class);
```

The ORB instance obtained using JNDI is a singleton object, shared by all the J2EE components that are
running in the same Java virtual machine process.

CORBA approach: Because thin-client applications do not run in a J2EE container, they cannot use JNDI
interfaces to look up the ORB. In this case, you can obtain an ORB instance by using CORBA
programming interfaces, as follows:

```
java.util.Properties props = new java.util.Properties();
java.lang.String[] args = new java.lang.String[0];
org.omg.CORBA.ORB orb = org.omg.CORBA.ORB.init(args, props);
```

In contrast to the JNDI approach, the CORBA specification requires that a new ORB instance be created
each time the ORB.init method is called. If necessary to change the ORB default settings, you can add
ORB property settings to the Properties object that is passed in the ORB.init method call.

The use of the com.ibm.ejs.oa.EJSORB.getORBinstance method, supported in previous releases of this
product is deprecated.

API restrictions with sharing an ORB instance among J2EE application components

For performance reasons, it often makes sense to share a single ORB instance among components in a
J2EE application. As required by the J2EE Specification, Version 1.3, all Web and EJB containers provide
an ORB instance in the JNDI namespace as java:comp/ORB. Each container can share this instance
among application components but is not required to. For proper isolation between application
components, application code must comply with the following restrictions:
• Do not call the ORB shutdown or destroy methods
• Do not call org.omg.CORBA_2_3.ORB methods register_value_factory, or unregister_value_factory

In addition, do not share an ORB instance among application components in different J2EE applications.

Required use of rmic and idlj that ship with the IBM Developer Kit

The Java Runtime Environment (JRE) used by this product includes the **rmic** and **idlj** tools. You use the tools to generate Java language bindings for the CORBA/IIOP protocol.

During product installation, the tools are installed in the *app_server_root*/java/ibm_bin directory. Versions of these tools included with Java development kits in the $JAVA_HOME/bin directory other than the IBM Developer Kit installed with this product are incompatible with this product.

When you install this product, the *app_server_root*/java/ibm_bin directory is included in the $PATH search order to enable use of the rmic and idlj scripts provided by IBM. Because the scripts are in the *app_server_root*/java/ibm_bin directory instead of the JRE standard *app_server_root*/java/bin directory, it is unlikely that you can overwrite them when applying maintenance to a JRE not provided by IBM.

In addition to the rmic and idlj tools, the JRE also includes Interface Definition Language (IDL) files. The files are based on those defined by the Object Management Group (OMG) and can be used by applications that need an IDL definition of selected ORB interfaces. The files are placed in the *app_server_root*/java/ibm_lib directory.

Before using either the rmic or idlj tool, ensure that the *app_server_root*/java/ibm_bin directory is included in the proper PATH variable search order in the environment. If your application uses IDL files in the *app_server_root*/java/ibm_lib directory, also ensure that the directory is included in the PATH variable.

Character code set conversion support for the Java Object Request Broker service

The CORBA/IIOP specification defines a framework for negotiation and conversion of character code sets used by the Java Object Request Broker (ORB) service.

This product supports the framework and provides the following system properties for modifying the default settings:

com.ibm.CORBA.ORBCharEncoding
> Specifies the name of the native code set that the ORB uses for character data (referred to as *NCS-C* in the CORBA/IIOP specification). By default, the ORB uses UTF8. Valid code set values for this property are shown in the table that follows this list; values that are valid only for ORBWCharDefault are indicated.

com.ibm.CORBA.ORBWCharDefault
> Specifies the default code set that the ORB uses for transmission of wide character data when no code set for wide character data is found in the tagged component in the Interoperable Object Reference (IOR) or in the GIOP service context. If no code set for wide character data is found and this property is not set, the ORB raises an exception, as specified in the CORBA specification. No default value is set for this property. The only valid code set values for this property are UCS2 or UTF16.

The CORBA code set negotiation and conversion framework specifies the use of code set registry IDs as defined in the Open Software Foundation (OSF) code set registry. The ORB translates the Java file.encoding names shown in the following table to the corresponding OSF registry IDs. These IDs are then used by the ORB in the IOR Code set tagged component and GIOP code set service context as specified in the CORBA and IIOP specification.

Java name	OSF registry ID	Comments
ASCII	0x00010020	
ISO8859_1	0x00010001

Object Request Brokers: Resources for learning

Use the following links to find relevant supplemental information about Object Request Brokers (ORBs). The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information about:

Object request broker troubleshooting tips
Use these tips to diagnose problems related to the WebSphere Application Server Object Request Broker (ORB).
- "Enabling tracing for the Object Request Broker component"
- "Log files and messages associated with Object Request Broker" on page 1071
- "Adjusting object request broker timeout values" on page 1072
- "Java packages containing the Object Request Broker service" on page 1072
- "Tools used with Object Request Broker" on page 1073
- "Object Request Broker properties" on page 1073
- "CORBA minor codes" on page 1073

Enabling tracing for the Object Request Broker component

The object request broker (ORB) service is one of the WebSphere Application Server run time services. Tracing messages sent and received by the ORB is a useful starting point for troubleshooting the ORB service. You can selectively enable or disable tracing of ORB messages for each server in a WebSphere Application Server installation, and for each application client.

This tracing is referred to by WebSphere Application Server support as a *comm trace*, and is different from the general purpose trace facility. The trace facility, which shows the detailed run-time behavior of product components, may be used alongside comm trace for other product components, or for the ORB component. The trace string associated with the ORB service is `ORBRas=all=enabled`.

You can enable and disable comm tracing using the administrative console or by manually editing the server.xml file for the server be trace. You must stop and restart the server for the configuration change to take effect.

For example, using the administrative console:
- Click **Servers > Application servers >** *server_name* **> Container services > ORB service**, and select the ORB tracing. Click **OK**, and then click **Save** to save your settings. Restart the server for the new settings to take effect. Or,
- Locate the server.xml file for the selected server, for example: *profile_root*/config/cells/*node_name*/nodes/*node_name*/servers/*server_name*/server.xml.
- Locate the services entry for the ORB service, `xmi:type=orb:ObjectRequestBroker`, and set `commTraceEnabled=true`.

ORB tracing for client applications requires that both the ORBRas component trace and the ORB comm trace are enabled. If only the ORB comm trace is enabled, no trace output is generated for client-side ORB traces. You can use one of the following options to enable both traces in the command line used to launch the client application:
- If you are using the WebSphere Application Server launcher, launchClient, use the **-CCD** option.
- If you are using the **java** command specify these parameters:

```
-trace=ORBRas=all=enabled
-tracefile=filename
-Dcom.ibm.CORBA.Debug=true
-Dcom.ibm.CORBA.CommTrace=true
```

ORB tracing output for thin clients can be directed by setting the `com.ibm.CORBA.Debug.Output =` `debugOutputFilename` parameter in the command line.

Important: When using launchClient on operating systems like AIX or Linux, because ORB tracing is integrated with the WebSphere Application Server general component trace, both the component and comm ORB traces are written to the same file as the rest of the WebSphere Application Server traces. The name of this file is specified on the `-CCtracefile=`*filename* parameter.

When using launchClient on a Windows operating systems, you get a separate ORB trace file, called orbtrc.*timestamp*.txt. This file is located in the current directory.

Log files and messages associated with Object Request Broker

Messages and trace information for the ORB are saved in the following logs:
- The *profile_root*/logs/*server_name*/trace.log file for output from communications tracing and tracing the behavior of the ORBRas component
- The JVM logs for each application server, for WebSphere Application Server error and warning messages

The following message in the SystemOut.log file indicates the successful start of the application server and its ORB service:

WSVR0001I: Server server1 open for e-business

When communications tracing is enabled, a message similar to the following example in the *profile_root*/logs/*server_name*/trace.log file, indicates that the ORB service has started successfully. The message also shows the start of a listener thread, which is waiting for requests on the specified local port.

com.ibm.ws.orbimpl.transport.WSTransport startListening(ServerConnectionData connectionData) P=693799:O=0:CT a new ListenerThread has been started for ServerSocket[addr=0.0.0.0/ 0.0.0.0,port=0,localport=1360]

When the `com.ibm.ejs.oa.*=all=enabled` parameter is specified, tracing of the Object Adapter is enabled. The following message in the trace.log indicates that the ORB service started successfully:

EJSORBImpl < initializeORB

The ORB service is one of the first services started during the WebSphere Application Server initialization process. If it is not properly configured, other components such as naming, security, and node agent, are not likely to start successfully. This is obvious in the JVM logs or trace.log of the affected application server.

Adjusting object request broker timeout values

If Web clients that access Java applications running in the product environment are consistently experiencing problems with their requests, and the problem cannot be traced to other sources and addressed through other solutions, consider setting an ORB timeout value and adjusting it for your environment. A list of timeout scenarios follows:
*   Web browsers vary in their language for indicating that they have timed out. Usually, the problem is announced as a connection failure or a no-path-to-server message.
*   Set an ORB timeout value to less than the time after which a Web client eventually times out. Because it can be difficult to tell how long Web clients wait before timing out, setting an ORB timeout value requires experimentation. The ideal testing environment features some simulated network failures for testing the proposed setting value.
*   Empirical results from limited testing indicate that 30 seconds is a reasonable starting value. Ensure that this setting is not too low. To fine tune the setting, find a value that is not too low. Gradually decrease the setting until reaching the threshold at which the value becomes too low. Set the value a little higher than the threshold.
*   When an ORB timeout value is set too low, the symptom is numerous CORBA NO_RESPONSE exceptions, which occur even for some valid requests. The value is likely to be too low if requests that should have been successful, for example, the server is not down, are being lost or refused.

Timeout adjustments: Do not adjust an ORB timeout value unless you have a problem. Configuring a value that is inappropriate for the environment can create a problem. An incorrect value can produce results worse than the original problem.

You can adjust timeout intervals for the product Java ORB through the following administrative settings:
*   **Request timeout**, the number of seconds to wait before timing out on most pending ORB requests if the network fails
*   **Locate request timeout**, the number of seconds to wait before timing out on a locate-request message

See "Object Request Broker service settings" on page 1052 for more information.

Java packages containing the Object Request Broker service

The ORB service resides in the following Java packages:
*   com.ibm.com.CORBA.*
*   com.ibm.rmi.*
*   com.ibm.ws.orb.*
*   com.ibm.ws.orbimpl.*
*   org.omg.CORBA.*
*   javax.rmi.CORBA.*

JAR files that contain the previously mentioned packages include:
*   *app_server_root*/java/jre/lib/ext/ibmorb.jar
*   *app_server_root*/java/jre/lib/ext/iwsorbutil.jar
*   *app_server_root*/lib/iwsorb.jar

Tools used with Object Request Broker

The tools used to compile Java remote interfaces to generate language bindings used by the ORB at runtime reside in the following Java packages:
- com.ibm.tools.rmic.*
- com.ibm.idl.*

The JAR file that contains the packages is *app_server_root*/java/lib/ibmtools.jar.

Object Request Broker properties

The ORB service requires a number of ORB properties for correct operation. It is not necessary for most users to modify these properties, and it is recommended that only your system administrator modify them when required.. Consult IBM Support personnel for assistance. The properties reside in the orb.properties file, located in *app_server_root*/java/jre/lib/orb.properties.

CORBA minor codes

The CORBA specification defines standard minor exception codes for use by the ORB when a system exception is thrown. In addition, the object management group (OMG) assigns each vendor a unique prefix value for use in vendor-proprietary minor exception codes. Minor code values assigned to IBM and used by the ORB in the WebSphere Application Server follow. The minor code value is in decimal and hexadecimal formats. The column labeled minor code reason gives a short description of the condition causing the exception. Currently there is no documentation for these errors beyond the minor code reason. If you require technical support from IBM, the minor code helps support engineers determine the source of the problem.

Table 33. Decimal minor exception codes 1229066320 to 1229066364

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).

If you do not find your problem listed there, contact IBM Support.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. You should also refer to this page before opening a PMR because it contains documents that can save you time gathering information needed to resolve a problem.

Transactions

Using the transaction service

These topics provide information about using transactions with WebSphere applications

WebSphere applications can use transactions to coordinate multiple updates to resources as atomic units (as indivisible units of work) such that all or none of the updates are made permanent.

In WebSphere Application Server, transactions are handled by three main components:
- A transaction manager. The transaction manager supports the enlistment of recoverable XAResources and ensures that each such resource is driven to a consistent outcome either at the end of a transaction or after a failure and restart of the application server.
- A container in which the J2EE application runs. The container manages the enlistment of XAResources on behalf of the application when the application performs updates to transactional resource managers (for example, databases). Optionally, the container can control the demarcation of transactions for enterprise beans configured for container-managed transactions.
- An application programming interface (UserTransaction) that is available to bean-managed enterprise beans and servlets. This allows such application components to control the demarcation of their own transactions.

For more information about using transactions with WebSphere applications, see the following topics:

Transaction support in WebSphere Application Server

This topic provides conceptual information about the support for transactions provided by the Transaction Service of WebSphere Application Server.

A transaction is unit of activity within which multiple updates to resources can be made atomic (as an indivisible unit of work) such that all or none of the updates are made permanent. For example, multiple SQL statements to a relational database are committed atomically by the database during the processing of an SQL COMMIT statement. In this case, the transaction is contained entirely within the database manager and can be thought of as a *resource manager local transaction (RMLT)*. In some contexts, a transaction is referred to as a *logical unit of work* (LUW). If a transaction involves multiple resource managers, for example multiple database managers, then an external transaction manager is required to coordinate the individual resource managers. A transaction that spans multiple resource managers are

referred to as a *global transaction*. WebSphere Application Server is a transaction manager that can coordinate global transactions, be a participant in a received global transaction and also provides an environment in which resource manager local transactions can run.

The way that applications use transactions depends on the type of application component, as follows:
* A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
* Entity beans use container-managed transactions.
* Web components (servlets) and application client components use component-managed transactions.

WebSphere Application Server is a transaction manager that supports the coordination of resource managers through their XAResource interface and participates in distributed global transactions with transaction managers that support the CORBA Object Transaction Service (OTS) protocol or Web Service Atomic Transaction (WS-AtomicTransaction) protocol. WebSphere Application Server also participates in transactions imported through J2EE Connector 1.5 resource adapters. You can also configure WebSphere applications to interact with databases, JMS queues, and JCA connectors through their *local transaction* support, when you do not require distributed transaction coordination.

Resource managers that offer transaction support can be categorized into those that support two-phase coordination (by offering an XAResource interface) and those that support only one-phase coordination (for example through a LocalTransaction interface). The WebSphere Application Server transaction support provides coordination, within a transaction, for any number of two-phase capable resource managers. It also enables a single one-phase capable resource manager to be used within a transaction in the absence of any other resource managers, although a WebSphere transaction is not necessary in this case.

Under normal circumstances you cannot mix one-phase commit capable resources and two-phase commit capable resources in the same global transaction, because one-phase commit resources cannot support the prepare phase of two-phase commit. There are some special circumstances where it is possible to include mixed-capability resources in the same global transaction:

* In scenarios where there is only a single one-phase commit resource provider that participates in the transaction and where all the two-phase commit resource-providers that participate in the transaction are used in a read-only fashion. In this case, the two-phase commit resources all vote read-only during the prepare phase of two-phase commit. Because the one-phase commit resource provider is the only provider to actually perform any updates, the one-phase commit resource does not need to be prepared.

* In scenarios where there is only a single one-phase commit resource provider that participates in the transaction with one of more two-phase commit resource providers and where *last participant support* is enabled. Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. For more information about last participant support, see Using one-phase and two-phase commit resources in the same transaction.

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. It is a distributed context that can be used to coordinate multiple one-phase resource managers. The WebSphere EJB container and deployment tooling support ActivitySessions as an extension to the J2EE programming model. EJBs can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An application can then interact with a resource manager for the period of a client-scoped ActivitySession, rather than only the duration of an EJB method, and have the resource manager's local transaction outcome directed by the ActivitySession. For more information about ActivitySessions, see Using the ActivitySession service.

Resource manager local transaction (RMLT):

A resource manager local transaction (RMLT) is a resource manager's view of a local transaction; that is, it represents a unit of recovery on a single connection that is managed by the resource manager.

Resource managers include:
- Enterprise Information Systems that are accessed through a resource adapter, as described in the J2EE Connector Architecture 1.0.
- Relational databases that are accessed through a JDBC datasource.
- JMS queue and topic destinations.

Resource managers offer specific interfaces to enable control of their RMLTs. J2EE connector resource adapters that include support for local transactions provide a LocalTransaction interface to enable applications to request that the resource adapter commit or rollback RMLTs. JDBC datasources provide a Connection interface for the same purpose.

The boundary at which all RMLTs must be complete is defined in WebSphere Application Server by a local transaction containment (LTC).

Global transactions:

If an application uses two or more resources, then an external transaction manager is needed to coordinate the updates to both resource managers in a *global tansaction*.

Global transaction support is available to web and enterprise bean J2EE components and, with some limitation, to application client components. Enterprise bean components can be subdivided into beans that exploit container-managed transactions (CMT) or bean-managed transactions (BMT).

BMT enterprise beans, application client components, and web components can use the Java Transaction API (JTA) UserTransaction interface to define the demarcation of a global transaction. The UserTransaction interface can be obtained by a JNDI lookup of `java:comp/UserTransaction` or from the SessionContext object using the getUserTransaction method..

The UserTransaction is not available to the following components:
- CMT enterprise beans. Any attempt by such beans to obtain the interface results in an exception in accordance with the EJB specification.

Ensure that programs that perform a JNDI lookup of the UserTransaction interface, use an InitialContext that resolves to a local implementation of the interface. Also ensure that such programs use a JNDI location appropriate for the EJB version.

Before the EJB 1.1 specification, the JNDI location of the UserTransaction interface was not specified. Each EJB container implementor defined it in an implementation-specific manner. Earlier versions of WebSphere Application Server, up to and including Version 3.5.x (without EJB 1.1), bind the UserTransaction interface to a JNDI location of jta/usertransaction. WebSphere Application Server Version 4, and later releases, bind the UserTransaction interface at the location defined by EJB 1.1, which is java:comp/UserTransaction. WebSphere Application Server, from Version 5 no longer provides the jta/usertransaction binding within Web and EJB containers to applications at a J2EE level of 1.3 or later. For example, from EJB 2.0 applications can use only the java:comp/UserTransaction location.

A web component or enterprise bean (CMT or BMT) can get the ExtendedJTATransaction interface through a lookup of `java:comp/websphere/ExtendedJTATransaction`. This interface provides access to the transaction identity and a mechanism to receive notification of transaction completion.

Local transaction containment (LTC):

A *local transaction containment (LTC)* is used to define the application server behavior in an unspecified transaction context.

(Unspecified transaction context is defined in the Enterprise JavaBeans 2.0 (or later) specification; for example, at http://java.sun.com/products/ejb/2.0.html.)

A LTC is a bounded unit-of-work scope within which zero, one, or more resource manager local transactions (RMLTs) can be accessed. The LTC defines the boundary at which all RMLTs must be complete; any incomplete RMLTs are resolved, according to policy, by the container. An LTC is local to a bean instance; it is not shared across beans even if those beans are managed by the same container. LTCs are started by the container before dispatching a method on a J2EE component (such as an enterprise bean or servlet) whenever the dispatch occurs in the absence of a global transaction context. LTCs are completed by the container depending on the application-configured LTC boundary; for example at the end of the method dispatch. There is no programmatic interface to the LTC support; rather LTCs are managed exclusively by the container and configured by the application deployer through transaction attributes in the application deployment descriptor.

A local transaction containment cannot exist concurrently with a global transaction. If application component dispatch occurs in the absence of a global transaction, the container always establishes an LTC for J2EE components at J2EE 1.3 or later. The only exceptions to this are as follows:
- Where application component dispatch occurs without container interposition; for example, for a stateless session bean `create` or a servlet-initiated thread.
- J2EE 1.2 web components.
- J2EE 1.2 BMT enterprise beans.

A local transaction containment can be scoped to an ActivitySession context that lives longer than the enterprise bean method in which it is started, as described in ActivitySessions and transaction contexts.

Local and global transaction considerations: Applications use resources, such as JDBC data sources or connection factories, that are configured through the Resources view of the WebSphere Application Server Administrative Console. How these resources participate in a global transaction depends on the underlying transaction support of the resource provider. For example, most JDBC providers can provide either XA or non-XA versions of a data source. A non-XA data source can support only resource manager local transactions (RMLTs), but an XA data source can support two-phase commit coordination, as well as local transactions.

If an application uses two or more resource providers that support only RMLTs, then atomicity cannot be assured because of the one-phase nature of these resources. To ensure atomic behavior, the application should use resources that support XA coordination and should access them within a global transaction.

If an application uses only one RMLT, the atomic behavior can be guaranteed by the resource manager, which can be accessed under a local transaction containment context.

An application can also access a single resource manager under a global transaction context, even if that resource manager does not support the XA coordination. An application can do this, because WebSphere Application Server performs an "only resource optimization" and interacts with the resource manager under a RMLT. Within a global transaction context, any attempt to use more than one resource provider that supports only RMLTs causes the global transaction to be rolled back.

At any moment, an instance of an enterprise bean can have work outstanding in either a global transaction context or a local transaction containment context, but never both. An instance of an enterprise bean can change from running under one type of context to the other (in either direction), if all outstanding work in the original context is complete. Any violation of this principle causes an exception to be thrown when the enterprise bean tries to start the new context.

Client support for transactions:

This topic describes the support of application clients for the use of transactions.

Application clients running in a J2EE client container can explicitly demarcate transaction boundaries as described in Using component-managed transactions. Application clients cannot perform, directly within the client container, transactional work in the context of any global transaction that they start, because the client container is not a recoverable process.

Application clients can make requests to remote objects, such as enterprise beans, within the context of a client-initiated transaction. Any transactional work performed in a remote, recoverable server process is coordinated as part of the client-initiated transaction. The transaction coordinator is created on the first server process to which the client-initiated transaction is propagated.

A client can begin a transaction then, for example, access a JDBC data source directly in the client process. In such cases, any work performed through the JDBC provider is not coordinated as part of the global transaction. Instead, the work runs under a resource manager local transaction. The client container process is non-recoverable and contains no transaction coordinator with which a resource manager can be enlisted.

A client can begin a transaction then call a remote application component, such as an enterprise bean. In such cases, the client-initiated transaction context is implicitly propagated to the remote application server where a transaction coordinator is created. Any resource managers accessed on the recoverable application server (or any other application server hosting application components invoked by the client) are enlisted in the global transaction.

Client application components need to be aware that locally-accessed resource managers are not coordinated by client-initiated transactions. Client applications acknowledge this through a deployment option that enables access to the UserTransaction interface in the client container. By default, access to the UserTransaction interface in the client container is not enabled. To enable UserTransaction demarcation for an application client component, set the **Allow JTA Demarcation** extension property in the client deployment descriptor. For information about editing the client deployment descriptor, refer to the Application Server Toolkit information, in the navigation pane of this infocenter.

Transactional high availability:

The high availability of the transaction service enables any server in a cluster to recover the transactional work for any other server in the same cluster. This facility forms part of the overall WebSphere Application Server high availability (HA) strategy.

As a vital part of providing recovery for transactions, the transaction service logs information about active transactional work in the *transaction recovery log*. The transaction recovery log stores the information in a persistent form, which means that any transactional work in progress at the time of a server failure can be resolved when the server is restarted. This activity is known as *transaction recovery processing*. In addition to completing outstanding transactions, this processing also ensures that any locks held in the associated resource managers are released.

Peer recovery processing

The standard recovery process that is performed when an application server restarts is for the server to retrieve and process the logged transaction information, recover transactional work and complete in-doubt transactions. Completion of the transactional work (and hence the release of any database locks held by the transactions) takes place after the server successfully restarts and processes its transaction logs. If the server is slow to recover or requires manual intervention, the transactional work cannot be completed and access to associated databases is disrupted.

To minimize such disruption to transactional work and the associated databases, WebSphere Application Server provides a high availability strategy known as *transaction peer recovery*.

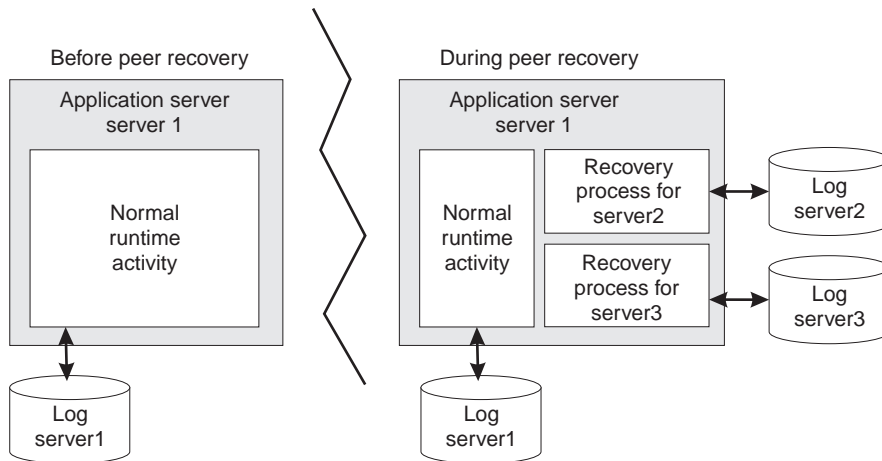
Peer recovery is provided within a server cluster. A peer server (another cluster member) can process the recovery logs of a failed server while the peer continues to manage its own transactional workload. You do not have to wait for the failed server to restart, or start a new application server specifically to recover the failed server.


Figure 13. Peer recovery

The peer recovery process is the logical equivalent to restarting the failed server, but does not constitute a complete restart of the failed server within the peer server. The peer recovery process provides an opportunity to complete outstanding work; it cannot start new work beyond recovery processing. No forward processing is possible for the failed server.

Peer recovery moves the high availability requirements away from individual servers and onto the server cluster. After such failures, the management system of the cluster dispatches new work onto the remaining servers; the only difference is the potential drop in overall system throughput. If a server fails, all that is required is to complete work that was active on the failed server and redirect requests to an alternate server.

By default, peer recovery is disabled until you enable failover of transaction log recovery in the cluster configuration, and restart the cluster members. After you enable transaction log recovery, WebSphere Application Server supports two styles for the initiation of transaction peer recovery: automated and manual. You determine which style is more appropriate, based on your deployment considerations, and specify that style by configuring the appropriate high availability policy. This high availability policy is referred to elsewhere in these topics as the *policy for the transaction service*.

Automated peer recovery
This style is the default for peer recovery initiation. If an application server fails, WebSphere Application Server automatically selects a server to perform peer recovery processing on its behalf, and passes recovery back to the failed server when it restarts. To use this model, all you have to do is enable transaction log recovery and configure the recovery log location for each cluster member.

Manual peer recovery
You must explicitly configure this style of peer recovery. If an application server fails, you use the administrative console to select a server to perform recovery processing on its behalf.

Peer recovery example

The following diagrams illustrate the peer recovery process that takes place if a single server fails. Figure 2 shows three stable servers running in a WebSphere Application Server cluster. The workload is balanced between these servers, which results in locks held by the back-end database on behalf of each server.
Figure 14. Server cluster up and running, just before server failure

Figure 3 shows the state of the system after server 1 fails without clearing locks from the database. Servers 2 and 3 can run their existing transactions to completion and release existing locks in the back-end database, but further access might be impaired because of the locks still held on behalf of server 1. In practice, some level of access by servers 2 and 3 is still possible, assuming appropriately configured lock granularity, but for this example assume that servers 2 and 3 attempt to access locked records and become blocked.
Figure 15. Server 1 fails. Servers 2 and 3 become blocked as a result.

Figure 4 shows a peer recovery process for server 1 running inside server 3. The transaction service portion of the recovery process retrieves the information that is persisted by server 1, and uses that information to complete any in-doubt transactions. In this figure, the peer recovery process is partially complete as some locks are still held by the database on behalf of server 1.
Figure 16. Peer recovery process started in server 3

Figure 5 shows the state of the server cluster when the peer recovery process is complete. The system is in a stable state with just two servers, between which the workload is balanced. Server 1 can be restarted, and will have no recovery processing of its own to perform.
Figure 17. Server cluster stable again with just two servers: server 2 and server 3.

Deployment considerations for transactional high availability:

Before you use the high availability (HA) function, you must consider deployment issues such as your file system type, or where you plan to store the transaction recovery logs. In particular, your file system type can have important consequences for your recovery configuration.

Common configuration

Transaction peer recovery requires a common configuration of the resource providers between the participating server members to perform peer recovery between servers. Therefore, peer recovery processing can only take place between members of the same server cluster. Although a cluster can contain servers that are at different versions of WebSphere Application Server, peer recovery can only be performed between servers in the cluster that are at Version 6 or later.

Physical storage

For application servers to perform transaction peer recovery for each other, they must be able to access the transaction recovery logs of all the other members in the cluster. Ensure that the log files are stored on a medium that is accessible by all members of the cluster. This medium, and access to it, for example

through a local area network (LAN), must support the file-based force operation that is used by the recovery log service to force data to disk. After the force operation is complete, information must be persistently stored on physical disk media.

For example, you can use IBM Network attached storage (NAS) (http://www.ibm.com/servers/storage/nas/index.html) mounted on each node, and shared SCSI drives, but not simple network share. All nodes must have read and write access to the recovery logs.
Figure 18. Recovery logs on NAS storage are available to all servers

In addition, configure the mechanism by which the remote log files are accessed, to exploit any fault tolerance in the underlying file system. For example, by using the Network File System (NFS) and hard mounting the remote directory containing the log files using the -o hard option of the NFS mount command, the NFS client will retry a failed operation until the NFS server becomes available again.

Two types of potential server failure exist: software failure and hardware failure. Software failures generally do not affect other application servers directly. Even servers on the same physical hardware can perform peer recovery processing. If a hardware failure occurs, all the servers that are deployed on the failed hardware become unavailable. Servers on other hardware are required to handle peer recovery processing. Any HA configuration requires that servers are deployed across multiple and discrete hardware systems.

File system

The file system type is an important deployment consideration as it is the main factor in deciding whether to use automated or manual peer recovery. For more information, see "How to choose between automated and manual transaction peer recovery."

How to choose between automated and manual transaction peer recovery:

Your type of file system is the dominant factor in deciding which kind of transaction peer recovery to use. Different file systems have different behaviors, and the file locking behavior in particular is important when choosing between automated and manual peer recovery.

WebSphere Application Server high availability (HA) support uses a heartbeat mechanism to determine whether servers are still running. Servers are considered failed if they stop responding to heartbeat requests. Some scenarios, such as system overloading and network partitioning (explained elsewhere in this topic), can cause servers to stop responding to heartbeats, even though the servers are still running. WebSphere Application Server uses file locking technology to prevent such events from causing concurrent access to transaction recovery logs, because access to a recovery log by more than one server can lead to loss of data integrity.

However, not all file systems provide the necessary file locking semantics, specifically that file locks are released when a server fails. For example, Network File System Version 4 (NFSv4) provides this release behavior, whereas Network File System Version 3 (NFSv3) does not.

NFSv4 releases locks held on behalf of a host in case that host fails. Peer recovery can occur automatically without the need to restart the failed hardware. Therefore, this version of NFS is better suited for use with automated peer recovery.

NFSv3 holds file locks on behalf of a failed host until that host can restart. In this context, the host is the physical machine running the application server that requested the lock and it is the restart of the host, not the application server, that eventually triggers the locks to release.

To illustrate file locking on NFSv3, consider the behavior when a cluster member fails:

1. Server H is running on host H and holds an exclusive file lock for its own recovery log files.
2. Server P is running on host P and holds an exclusive file lock for its own recovery log files.
3. Host H fails, taking server H with it. The NFS lock manager on the file server holds the locks that are granted to server H on its behalf.
4. A peer recovery event is triggered in server P for server H by WebSphere Application Server.
5. Server P attempts to gain an exclusive file lock for this peer recovery log, but is unable to do so as it is held on behalf of server H. The peer recovery process is blocked.
6. At an unspecified time, host H is restarted. The locks held on its behalf are released.
7. The peer recovery process in server P is unblocked and granted the exclusive file locks that are needed to perform peer recovery.
8. Peer recovery takes place in server P for server H.
9. Server H is restarted.
10. If peer recovery is still in progress in server P, the recovery is halted.
11. Server P releases the exclusive lock on the recovery logs and returns ownership of the recovery logs back to server H.
12. Server H obtains the exclusive lock and can now perform standard transaction logging.

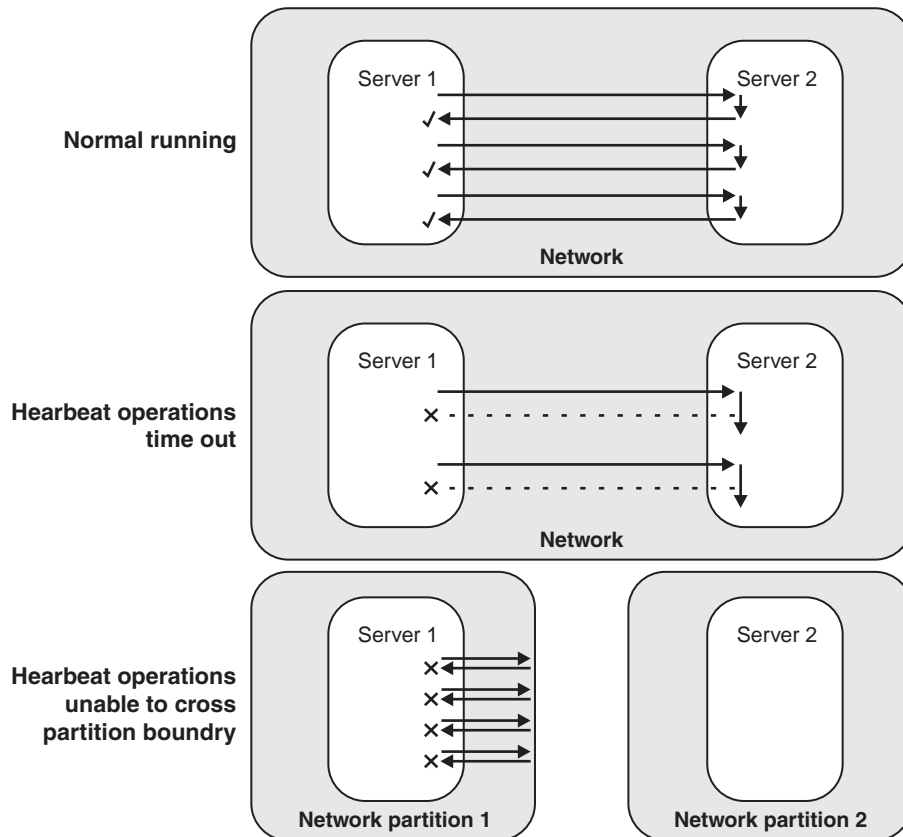
Because of this behavior, on NFSv3 you must disable file locking to use automated peer recovery. Disabling file locking can lead to concurrent access to recovery logs so it is vital that you protect your system from system overloading and network partitioning first. Alternatively, you can configure manual peer recovery, where you prevent concurrent access by manually triggering peer recovery processing only for servers that have actually failed.

System overloading

System overloading occurs when a machine becomes very heavily loaded such that response times are extremely poor and requests begin to time out. Several potential causes exist for such overloading, including:

- The server is underpowered and cannot handle the workload.
- The server received a temporary surge of requests.
- Insufficient physical memory is available. As a result, the operating system is too busy paging to give the application server the required CPU time.

Network partitioning

Network partitioning occurs when a communications failure in a network results in two smaller networks that are independent and cannot contact each other.


During normal running, two servers on the network exchange heartbeats. During system overloading, heartbeat operations time out, giving the appearance of a server failure. After network partitioning, each server is in a separate network and heartbeats cannot pass between them, also giving the appearance of a server failure.

Figure 19. Heartbeats in a system running normally, compared to heartbeats after the apparent server failures of system overloading and network partitioning

High availability policies for the transaction service:

WebSphere Application Server provides integrated high availability (HA) support in which system subcomponents, such as the transaction service, are made highly available. An HA policy provides the logic that governs the manner in which each WebSphere Application Server HA component behaves within the overall HA framework. In the case of the transaction service, the transaction HA policy provides the logic to determine which servers own a recovery log at any time.

Typically, transaction policies assign ownership of a recovery log to the server that originally created it (the home server) and that server can then use the recovery log for both recovery and normal transactional activity. In the event that the home server is unavailable or fails, ownership can pass to a peer server to perform recovery processing.

Conceptually, a policy can be thought of as consisting of two key components, a policy type and a policy configuration.

Policy type

The policy type determines whether peer recovery initiation is manual or automated. The policy essentially provides the logic for determining updated recovery log ownership in the event of a server failure. The following WebSphere Application Server policy types are used for transaction peer recovery (other HA policy types exist, but are not used by the transaction service):

Static Ownership of the recovery log is defined in the WebSphere Application Server configuration. At run time, the static policy assigns ownership accordingly. Any changes to ownership require a change to the static configuration and therefore this policy type is used for manually initiated peer recovery.

One-of-N
Ownership of the recovery log is determined dynamically by the WebSphere Application Server HA framework and assigned to exactly one of the N cluster members. This policy type is used for automated peer recovery.

Transaction compensation and business activity support:

A *business activity* is a collection of tasks that are linked together so that they have an agreed outcome. Unlike atomic transactions, activities such as sending an e-mail can be difficult or impossible to roll back atomically, and therefore require a compensation process in the event of an error. The WebSphere Application Server business activity support provides this compensation ability through *business activity scopes*.

When to use business activity support

Use the business activity support when you have an application that requires compensation. An application requires compensation if its operations cannot be atomically rolled back. Typically, this scenario is due to one of the following reasons:

* The application uses multiple non-extended-architecture (XA) resources.
* The application uses more than one atomic transaction, for example, enterprise beans that have **Requires new** as the setting for the **Transaction** field in the container transaction deployment descriptor.
* The application does not run under a global transaction.

The following diagram shows a simple Web service application that uses the business activity support. The Retailer, Warehouse and Manufacturing services are running in non-WebSphere Application Server environments. The Retailer service calls the Supplier service, running on WebSphere Application Server, which delegates tasks to the Warehouse and Manufacturing services. The implementation of the Supplier service contains a stateless session bean, which calls other stateless session beans that are associated with the Warehouse and Manufacturing services, and that perform compensatable work. These other session beans each have a *compensation handler*; a piece of logic that is associated with an application component at run time, and performs compensation activity such as resending an e-mail.

Application design considerations

Business activity contexts are propagated with application messages, and can therefore be distributed between application components that are not co-located in the same server. Unlike atomic transaction contexts, business activity contexts are propagated on both synchronous (blocking) call-response messages and asynchronous one-way messages. An application component that runs under a business activity scope is responsible for ensuring that any asynchronous work it initiates is complete before the component's own processing is complete. An application that initiates asynchronous work using a fire-and-forget message pattern must not use business activity scopes, because such applications have no means of detecting whether this asynchronous processing has completed.

Only enterprise beans that have container-managed transactions can use the business activity functionality. Enterprise beans that exploit business activity scopes can offer Web service interfaces, but can also offer standard enterprise bean local or remote Java interfaces. Business activity context is propagated in Web service messages using a standard, interoperable Web Services Business Activity `CoordinationContext` element. WebSphere Application Server can also propagate business activity context on RMI calls to enterprise beans when Web services are not being used, but this form of the context is not interoperable with non-WebSphere Application Server environments. You might want to use this homogeneous scenario if you require compensation for an application that is internal to your business. If you want to use business activity compensation in a heterogeneous environment, expose your application components as Web services.

Business activity contexts can be propagated across firewalls and outside the WebSphere Application Server domain. The topology that you use to achieve this propagation can affect the high availability and affinity behavior of the business activity transaction.

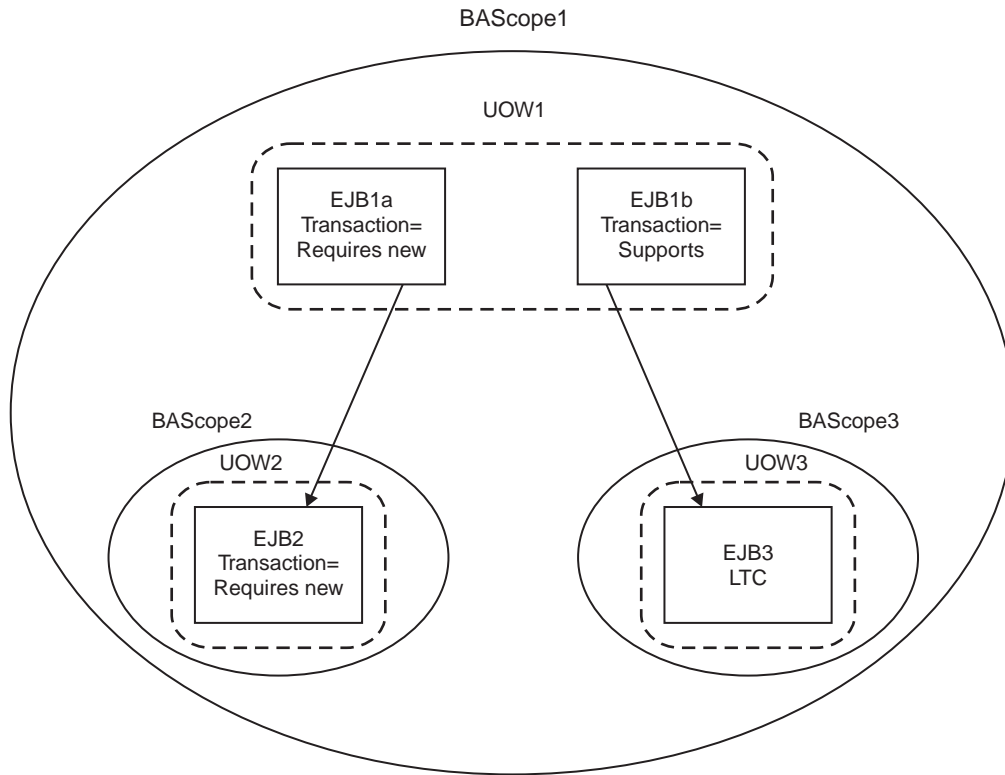
Application development and deployment considerations

WebSphere Application Server provides a programming model for creating business activity scopes, and for associating compensation handlers with those business activity scopes. WebSphere Application Server also provides an application programming interface to specify compensation data, and check or alter the status of a business activity. To use the business activity support you must set certain application deployment descriptors appropriately, provide a compensation handler class if required, and enable business activity support on any servers that run the application.

Note: Applications can exploit the business activity support only if you deploy them to a WebSphere Application Server Version 6.1 server. Applications cannot use the business activity support if you deploy them to a cluster that includes WebSphere Application Server Version 6.0.x servers.

Business activity scopes

The scope of a business activity is that of a core WebSphere Application Server unit of work: a global transaction, an activity session, or local transaction containment (LTC). A business activity scope is not a new unit of work (UOW); it is an attribute of an existing core UOW. Therefore, a one-to-one relationship exists between a business activity scope and a UOW.

Any core UOW can have a business activity scope associated with it. If a component running under a UOW that is associated with a business activity scope calls another component, that request propagates the business activity scope; any work done by the new component is associated with the same business activity scope as the calling component. The called component can create a new UOW, for example if an enterprise bean has a **Transaction** setting of **Requires new**, or runs under the same UOW as the calling component. If a new UOW is started then a new business activity scope is created and associated with the new UOW. The newly created business activity scope is a child of the business activity scope associated with the calling UOW. In the following diagram, EJB1a running under UOW1 calls two components: EJB1b that also runs under UOW1, and EJB2 that creates a new UOW, UOW2. The enterprise bean EJB1b, calls another enterprise bean, EJB3, which creates another new UOW, UOW3. Because each new UOW is created by a calling component whose UOW already has an association with business activity scope BAScope1, the newly created UOWs are associated with new inner business activity scopes, BAScope2 and BAScope3.


Inner business activity scopes must complete before the outer business activity scope completes. Inner business activity scopes, for example BAScope2, have an association with the outer business activity scope, in this case BAScope1. Each business activity scope is directed to close if its associated UOW completes successfully, or to compensate if its associated UOW fails. If BAScope2 completes successfully, any active compensation handlers that are owned by BAScope2 are moved to BAScope1, and are directed in the same way as the completion direction of BAScope1: either compensate or close. If BAScope2 fails, the active compensation handlers are compensated automatically, and nothing is moved to the outer BAScope1. When an inner business activity scope fails, as a result of its associated UOW failing, an application server exception is thrown to the to calling application component, running in the outer UOW.

For example, if the inner UOW fails it might throw a TransactionRolledBackException exception. If the calling application can handle the exception, for example by retrying the called component or by calling another component, then the calling UOW, and its associated business activity scope, can complete successfully even though the inner business activity scope failed. If the application design requires the calling UOW to fail, and for its associated business activity scope to be compensated, then the calling application component must cause its UOW to fail, for example by allowing any system exception from the UOW that failed to be handled by its container.

When the outer business activity scope completes, its success or failure determines the completion direction (close or compensate) of any active compensation handlers that are owned by the outer business activity scope, including those promoted by the successful completion of inner business activity scopes. If the outer business activity scope completes successfully, it drives all active compensation handlers to close. If the outer business activity scope fails, it drives all active compensation handlers to compensate.

This compensation behavior is summarized in the following table.

Table 39. Compensation behavior for a single business activity scope

Inner business activity scope	Outer business activity scope	Compensation behavior
Succeeds	Succeeds	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW succeeds, the outer business activity scope drives all compensation handlers to close.
Fails	Succeeds	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is caught, when the outer UOW succeeds, the outer business activity scope drives all remaining active compensation handlers to close.
Fails	Fails	Any active compensation handlers that are owned by the inner business activity scope are compensated. An exception is thrown to the outer UOW; if this exception is not caught, the outer business activity scope fails. When the outer business activity scope fails, either because of the unhandled exception or for some other reason, all remaining active compensation handlers are compensated.
Succeeds	Fails	Any compensation handlers that are owned by the inner business activity scope wait for the outer UOW to complete. When the outer UOW fails, the outer business activity scope drives all compensation handlers to compensate.

When a UOW with an associated business activity scope completes, the business activity scope always completes in the same direction as the UOW that it is associated with. The only way that you can influence the direction of the business activity scope is to influence the UOW that it is associated with, which you can do by using the setCompensateOnly method of the business activity API.

A compensation handler that is registered within a transactional UOW might be inactive initially, depending on the method invoked from the business activity API. Inactive handlers in this situation become active when the UOW in which that handler is declared completes successfully. A compensation handler that is registered outside a transactional UOW always becomes active immediately. For more information, see "The business activity API" on page 1107.

Each business activity scope in the diagram represents a business activity. For example, the outer business activity running under BAScope1 can be a holiday booking scenario, with BAScope2 being a flight booking activity and BAScope3 a hotel booking. If either the flight or hotel bookings fail, the overall holiday booking by default also fails. Alternatively if, for example, the flight booking fails, you might want your application to try booking a flight using another component that represents a different airline. If the overall holiday booking fails, the application can use compensation handlers to cancel any flights or hotels that are already successfully booked.

Use of business activity scopes by application components

Application components do not use business activity scopes by default. You use the WebSphere Application Server assembly tools to specify the use of a business activity scope and to identify any compensation handler class for the component:

Default configuration
> If a business activity context is present on a request received by a component with no business activity scope configuration, the context is stored by the container but never used during the method scope of the target component. A new business activity scope is not created. If the target component invokes another component, the stored business activity context is propagated and can be used by other compensating components.

Run enterprise bean methods under a business activity scope

Any business activity context present on the incoming request is received by the container and made available to the target component. If a new UOW is created for the target method, for example because the enterprise bean method has a **Transaction** setting of **Requires new**, the received business activity scope becomes an outer business activity scope to a newly created business activity. If the UOW is propagated from the calling component and used by the method, then the received business activity scope is used by the method. If a business activity scope does not exist on the invocation, a new business activity scope is created and used by the method.

To create a business activity scope when an enterprise bean is invoked, you must configure the enterprise bean to run enterprise bean methods under a business activity scope. You must also configure the deployment descriptors for the method being invoked, to specify the creation of a new UOW upon invocation. For instructions on how to perform these actions, see "Creating an application that exploits the business activity support" on page 1114.

The effect of application server shutdown on active transactions and later recovery: When an application server shuts down, any active transactions are rolled back. If all transactions are successfully completed in this way, message WTRN0105I is logged, and on the next server restart no recovery activity is needed. If message CWWTR0105I is not logged for an application server shutdown, this does not indicate that there has been a failure, only that recovery activity is required when the server restarts.

A clean shutdown of all application servers should be achieved before the product is uninstalled, to avoid data integrity problems.

Extended JTA support: Extended JTA support provides application programming interfaces additional to the UserTransaction interface that is defined in the JTA as part of the J2EE specification. Specifically, the API extensions provide the following functionality:

- Access to global and local transaction identifiers associated with the thread.

  The global id is based on the tid in CosTransactions::PropagationContext: and the local id identifies the transaction uniquely within the local JVM.

- A transaction synchronization callback that enables any J2EE component to register an interest in transaction completion.

  This can be used by advanced applications to flush updates before transaction completion and clear up state after transaction completion. J2EE (and related) specifications position this function generally as the domain of the J2EE containers.

An application uses a JNDI lookup of java:comp/websphere/ExtendedJTATransaction to get an ExtendedJTATransaction object, which it then uses as follows:

```
ExtendedJTATransaction exJTA = (ExtendedJTATransaction)ctx.lookup("
 java:comp/websphere/ExtendedJTATransaction");
SynchronizationCallback sync = new SynchronizationCallback();
exJTA.registerSynchronizationCallback(sync);
```

The ExtendedJTATransaction object supports the registration of one or more application-provided SynchronizationCallbacks. Depending on how the callback is registered, each registered callback is called at one of the following points:

- At the end of every transaction that runs on the application server (whether the transaction is started locally or imported).
- At the end of the transaction for which the callback was registered.

The following information provides an overview of the interfaces provided by the Extended JTA support. For more detailed information, see the Javadoc.

SynchronizationCallback interface

An object implementing this interface is enlisted once through the ExtendedJTATransaction interface, and receives notification of transaction completion.

Although an object implementing this interface can run in a J2EE server, there is no specific J2EE component active when this object is called. So, the object has limited direct access to any J2EE resources. Specifically, it has no access to the java: namespace or to any container-mediated resource. Such an object can cache a reference to a J2EE component (for example, a stateless session bean) that it delegates to. The object would then have all the normal access to J2EE resources and could be used, for example, to acquire a JDBC connection and flush updates to a database during beforeCompletion.

ExtendedJTATransaction interface

A WebSphere programming model extension to the J2EE JTA support. An object implementing this interface is bound, by WebSphere J2EE containers that support this interface, at java:comp/websphere/ExtendedJTATransaction. Access to this object, when called from an EJB container, is not restricted to component-managed transactions.

Support for Web Services protocols:

WebSphere Application Server supports a number of Web Services protocols. These protocols provide standard ways of defining Web service applications, allowing the applications to operate independently of the product, platform or programming language used.

Web Services protocols are defined by the Oasis group. Refer to the Oasis Web site, http://www.oasis-open.org, for specifications and further information on each protocol. Use the sub-topics below to find out more information about the support for each protocol in WebSphere Application Server.
* "Web Services Atomic Transaction support in WebSphere Application Server"
* "Web Services Business Activity support in WebSphere Application Server" on page 1103
* "Web Services transactions, firewalls and intermediary nodes" on page 1103

Web Services Atomic Transaction support in WebSphere Application Server:

The Web Services Atomic Transaction support in WebSphere Application Server provides transactional quality of service to the Web services environment. This enables distributed Web service applications, and the resources they use, to take part in distributed global transactions.

The Web Services Atomic Transaction (WS-AT) support is an implementation of the following specifications on WebSphere Application Server. These specifications define a set of Web services that enable Web service applications to participate in global transactions distributed across the heterogeneous Web service environment.
* Web Services Atomic Transaction (WS-AT), at http://www-106.ibm.com/developerworks/webservices/library/ws-atomtran/

    WS-AT is a specific coordination type that defines protocols for atomic transactions.
* Web Service Coordination (WS-COOR), at http://www-106.ibm.com/developerworks/webservices/library/ws-coor/

    WS-COOR specifies a CoordinationContext and a Registration service with which Participant web services may enlist to take part in the protocols offered by specific coordination types.

The WS-AT support is an interoperability protocol that introduces no new programming interfaces for transactional support. Global transaction demarcation is provided by standard J2EE use of the JTA UserTransaction interface. If a Web service request is made by an application component running under a

global transaction, then a WS-AT CoordinationContext is implicitly propagated to the target Web service, but only if the appropriate application deployment descriptors have been set as described in "Configuring transactional deployment attributes" on page 1111.

If WebSphere Application Server is the system hosting the target endpoint for a Web service request that contains a WS-AT CoordinationContext, then WebSphere automatically establishes a subordinate JTA transaction in the target runtime environment that becomes the transactional context under which the target Web service application executes.

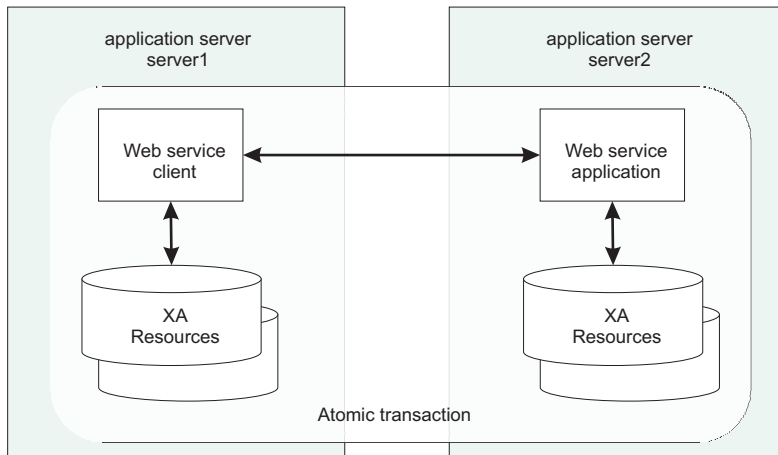
The following figure, Figure 20, shows a transaction context shared between two WebSphere application servers for a Web service request that contains a WS-AT CoordinationContext.


Figure 20. Transaction context shared between two WebSphere application servers.

WS-AT support restrictions

In this version of WebSphere Application Server, WS-AT contexts cannot be started from a non-recoverable client process.

Application design considerations

WS-AT is a two-phase commit transaction protocol and is suitable for short duration transactions only.

Because the purpose of an atomic transaction is to coordinate resource managers that isolate transactional updates by holding transactional locks on resources, it is generally not recommended that WS-AT transactions be distributed across enterprise domains. Inter-enterprise transactions typically require a looser semantic than two-phase commit and, in such scenarios, it can be more appropriate to use a compensating business transaction, for example a Web Services Business Activity or as part of a BPEL process.

WS-AT is most appropriate for distributing transaction context across Web services deployed within a single enterprise. Only request-response message exchange patterns carry transaction context since the originator (application or container) of a transaction needs to be sure that all business tasks executed under that transaction have finished before requesting the completion of a transaction. Web services invoked by a one-way request never run under the transaction of the requesting client.

Application development considerations

There are no specific development tasks required for Web service applications to take advantage of WS-AT. There are some application deployment descriptors that need to be set appropriately, as described in "Configuring transactional deployment attributes" on page 1111.

Application developers do not need to explicitly register WS-AT participants. The WebSphere Application Server runtime takes responsibility for the registration of WS-AT participants, in the same way as the registration of XAResources in the JTA transaction to which the WS-AT transaction is federated. At transaction completion time, all XAResources and WS-AT participants are atomically coordinated by the WebSphere Application Server transaction service.

If a JTA transaction is active on the thread when a Web service Application request is made, the transaction is propagated across on the Web service request and established in the target environment. This is analogous to the distribution of transaction context over IIOP as described in the EJB specification. Any transactional work performed in the target environment becomes part of the same global transaction.

Web Services Business Activity support in WebSphere Application Server:

With Web Services Business Activity (WS-BA) support in WebSphere Application Server, Web services on disparate systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process in the event of an error.

The Web Services Business Activity (WS-BA) support is an implementation of the following specifications in WebSphere Application Server. These specifications define a set of protocols that enable Web service applications to participate in loosely coupled business processes that are distributed across the heterogeneous Web service environment, with the ability to compensate actions if an error occurs. For example, an application that sends an e-mail cannot unsend it following a failure. The application can, however, provide a business-level compensation handler that sends another e-mail advising of the new circumstances. A *business activity* is a group of general tasks that you want to link together so that the tasks have an agreed outcome.

- Web Services Business Activity (WS-BA), at http://www-106.ibm.com/developerworks/library/ specification/ws-tx/#ba

  WS-BA is a specific coordination type that defines protocols for business activities.

- Web Service Coordination (WS-COOR), at http://www-106.ibm.com/developerworks/webservices/library/ ws-coor/

  WS-COOR specifies a CoordinationContext and a registration service with which participant Web services can enlist to take part in the protocols that are offered by specific coordination types.

In addition to supporting the WS-BA interoperability protocol, WebSphere Application Server provides a programming interface for creating business activities and compensation handlers. With this programming interface, you can specify compensation data and check or alter the status of a business activity.

You can also use this compensation ability with applications that are not Web services, as long as these applications involve communication between WebSphere Application Servers only. See the related topics for more information.

Web Services transactions, firewalls and intermediary nodes:

You can configure your system to enable propagation of Web Services Atomic Transactions (WS-AT) message contexts and Web Service Business Activities (WS-BA) message contexts across firewalls or outside the WebSphere Application Server domain. With this configuration you can distribute Web service applications that use WS-AT or WS-BA across disparate systems. The topology that you use can have an effect on the high availability and affinity behavior of the transactions.

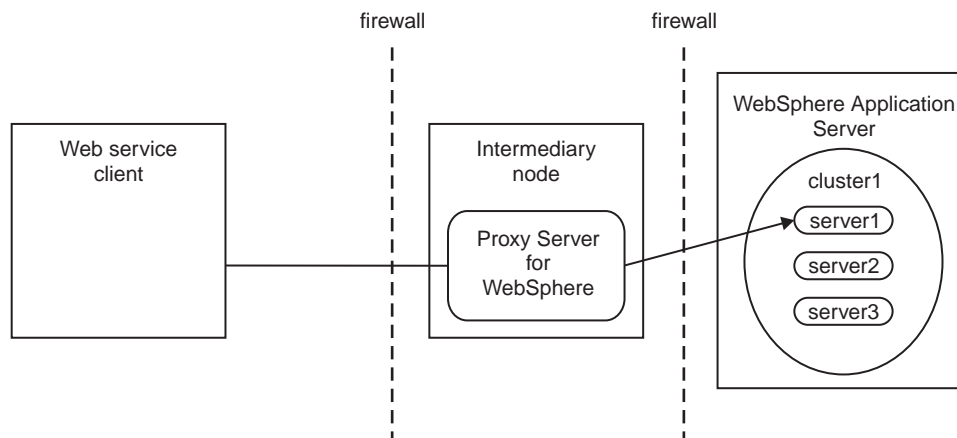
The topologies that are available to you are as follows:

Direct connection

No intermediary node exists in this topology. The client communicates directly with a specific WebSphere Application Server. This topology supports high availability for transactions on requests made within a cluster, and affinity of transactions.

Proxy Server for IBM WebSphere Application Server

In this topology, the client communicates with a Proxy Server for IBM WebSphere Application Server, which dynamically routes the client requests to the appropriate server within a WebSphere Application Server cluster.

The proxy server supports high availability, workload management, and affinity of transactions. After you create the proxy server you do not have to perform any extra additional steps to enable these features.


HTTP server, such as IBM HTTP Server

In this topology, the client communicates with an HTTP server, which always routes the client requests to a specific server within a WebSphere Application Server cluster. You configure the HTTP server to specify the WebSphere Application Server to route requests to.

The HTTP server cannot provide either affinity or high availability for transactions. However, transactional integrity is assured because recovery processing occurs after the failed server restarts.

Note: You can still enable high availability on the WebSphere Application Server. Clients accessing this server through an HTTP server cannot have high availability of transactions, however other clients accessing the same server can.

```
If you have an existing HTTP server, but want the high availability and workload management capabilities of a Proxy Server for WebSphere, create a Proxy Server for IBM WebSphere Application Server and configure the HTTP server to route all requests to the proxy server, as in the following scenario.

HTTP server in conjunction with a Proxy Server for IBM WebSphere Application Server

The client communicates with an HTTP server, which you configure to forward the client's requests to a Proxy Server for IBM WebSphere Application Server. The proxy then dynamically routes the requests to the appropriate server within WebSphere Application Server.

The proxy server provides the client with the high availability and affinity behavior that the HTTP server cannot.

firewall   firewall

```
Use of local transactions

Local transaction containment (LTC) support, and its configuration through local transaction extended deployment descriptors, gives IBM WebSphere Application Server application programmers a number of advantages. This topic describes those advantages and how they relate to the settings of the local transaction extended deployment descriptors. This topic also describes points to consider to help you best configure transaction support for some example scenarios that use local transactions.

Develop an enterprise bean or servlet that accesses one or more databases that are independent and require no coordination.

If an enterprise bean does not need to use global transactions, it is often more efficient to deploy the bean with the Container Transaction deployment descriptor **Transaction** attribute set to `Not supported` instead of `Required`.

With the extended local transaction support of IBM WebSphere Application Server, applications can perform the same business logic in an unspecific transaction context as they can under a global transaction. An enterprise bean, for example, runs under an unspecified transaction context if it is deployed with a **Transaction** attribute of `Not supported` or `Never`.

The extended local transaction support provides a container-managed, implicit local transaction boundary within which application updates can be committed and their connections cleaned up by the container. Applications can then be designed with a greater degree of independence from deployment concerns. This makes using a **Transaction** attribute of `Supports` much simpler, for example, when the business logic may be called either with or without a global transaction context.

An application can follow a get-use-close pattern of connection usage regardless of whether or not the application runs under a transaction. The application can depend on the close behaving in the same way and not causing a rollback to occur on the connection if there is no global transaction.

There are many scenarios where ACID coordination of multiple resource managers is not needed. In such scenarios running business logic under a **Transaction** policy of `Not supported` performs better than if it had been run under a `Required` policy. This benefit is exploited through the **Local Transactions - Resolution-control** extended deployment setting of `ContainerAtBoundary`. With this setting, application interactions with resource providers (such as databases) are managed within implicit RMLTs that are both started and ended by the container. The RMLTs are committed by the container at the configured **Local Transactions - Boundary**; for example at the end of a method. If the application returns control to the container by an exception, the container rolls back any RMLTs that it has started.

This usage applies to both servlets and enterprise beans.

Use local transactions in a managed environment that guarantees clean-up.

Applications that want to control RMLTs, by starting and ending them explicitly, can use the default **Local Transactions - Resolution-control** extended deployment setting of `Application`. In this case, the container ensures connection cleanup at the boundary of the local transaction context.

J2EE specifications that describe application use of local transactions do so in the manner provided by the default setting of **Local Transactions - Resolution-control**=`Application` and **Local Transactions - Unresolved-action**=`Rollback`. By configuring the **Local Transactions - Unresolved-action** extended deployment setting to `Commit`, then any RMLTs started by the application but not completed when the local transaction containment ends (for example, when the method ends) are committed by the container. This usage applies to both servlets and enterprise beans.

Extend the duration of a local transaction beyond the duration of an EJB component method.

The J2EE specifications restrict the use of RMLTs to single EJB methods. This restriction is because the specifications have no scoping device, beyond a container-imposed method boundary, to which an RMLT can be extended. You can exploit the **Local Transactions - Boundary** extended deployment setting to give the following advantages:

- Significantly extend the use-cases of RMLTs
- Make conversational interactions with one-phase resource managers possible through ActivitySession support.

You can use an ActivitySession to provide a distributed context with a boundary that is longer than a single method. You can extend the use of RMLTs over the longer ActivitySession boundary, which can be controlled by a client. The ActivitySession boundary reduces the need to use distributed transactions where ACID operations on multiple resources are not needed. This benefit is exploited through the **Local Transactions - Boundary** extended deployment setting of `ActivitySession`. Such extended RMLTs can remain under the control of the application or be managed by the container depending on the use of the **Local Transactions - Resolution-control** deployment descriptor setting.

Coordinate multiple one-phase resource managers.

For resource managers that do not support XA transaction coordination, a client can exploit ActivitySession-bounded local transaction contexts. Such contexts give a client the same ability to control the completion direction of the resource updates by the resource managers as the client

has for transactional resource managers. A client can start an ActivitySession and call its entity beans under that context. Those beans can perform their RMLTs within the scope of that ActivitySession and return without completing the RMLTs. The client can later complete the ActivitySession in a commit or rollback direction and cause the container to drive the ActivitySession-bounded RMLTs in that coordinated direction.

To determine how best to configure the transaction support for an application, depending on what you want to do with transactions, consider the following points.

General points

- You want to start and end global transactions explicitly in the application (BMT session beans and servlets only).

  For a session bean, set the **Transaction type** to `Bean` (to use bean-managed transactions) in the component's deployment descriptor. (You do not need to do this for servlets.)

- You want to access only one XA or non-XA resource in a method.

  In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `ContainerAtBoundary`. In the Container transaction deployment descriptor, set **Transaction** to `Supports`.

- You want to access several XA resources atomically across one or more bean methods.

  In the Container transaction deployment descriptor, set **Transaction** to `Required`, `Requires new`, or `Mandatory`.

- You want to access several non-XA resource in a method without having to worry about managing your own local transactions.

  In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `ContainerAtBoundary`. In the Container transaction deployment descriptor, set **Transaction** to `Not supported`.

- You want to access several non-XA resources in a method and want to manage them independently.

  In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `Application` and set **Local Transactions - Unresolved-action** to **Rollback**. In the Container transaction deployment descriptor, set **Transaction** to `Not supported`.

- You want to access one of more non-XA resources across multiple EJB method calls without having to worry about managing your own local transactions.

  In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `ContainerAtBoundary`, **Local Transactions - Boundary** to `ActivitySession`, and **Bean Cache - Activate at** to `ActivitySession`. In the Container transaction deployment descriptor, set **Transaction** to `Not supported` and set **ActivitySession** attribute to `Required`, `Requires new`, or `Mandatory`.

- You want to access several non-XA resources across multiple EJB method calls and want to manage them independently.

  In the component's deployment descriptor, set **Local Transactions - Resolution-control** to `Application`, **Local Transactions - Boundary** to `ActivitySession`, and **Bean Cache - Activate at** to `ActivitySession`. In the Container Transaction deployment descriptor, set **Transaction** to `Not supported` and set **ActivitySession** attribute to `Required`, `Requires new`, or `Mandatory`.

- You want to use a single non-XA resource and one or more XAResources.

  Use the *Last Participant Support*.

The business activity API

Use the business activity API to create business activities and compensation handlers for an application component, and to log data that is required for compensating an activity in the event of a failure.

Overview

The business activity support provides a UserBusinessActivity API, a CompensationHandler interface and two exceptions: RetryCompensationHandlerException and CompensationHandlerFailedException. You can

look up the UserBusinessActivity interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

If an application component is running work that might require compensating upon failure, you must provide a compensation handler class that is assembled as part of the deployed application. This new Java class must implement the com.ibm.websphere.wsba.CompensationHandler interface, which supports the close and compensate methods, which take a parameter of a Service Data Object (SDO). During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in an SDO representing the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the compensate or the close method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in the SDO DataObject; using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and compensate or close in an appropriate manner, for example by undoing changes made to database rows in the event of a failure. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

Active and inactive compensation handlers

You implement the CompensationHandler interface for any application component that executes code that might need to be compensated within a business activity scope. CompensationHandler objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the UserBusinessActivity API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler registered within a transactional UOW might be initially inactive until the transaction commits, at which point it becomes active (see below). A compensation handler registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives active compensation handlers only. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing upon completion of the business activity. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

`setCompensationDataAtCommit()`

Call this method if the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the CompensationHandler object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not need to be involved. If the global transaction commits successfully, the compensation handler becomes active because it is required to compensate the durable work that is completed by the global transaction, if the overall business activity fails. The setCompensationDataAtCommit method configures the CompensationHandler instance to perform this compensation function.

- If a global transaction is not present when this method is called, the compensation handler becomes active immediately.

For example, using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

setCompensationDataImmediate()

Call this method if the application does not expect a global transaction on the thread.

The setCompensationDataImmediate method makes a CompensationHandler instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the setCompensationDataImmediate method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but is not governed by the transaction. For example, sending an e-mail. The compensation handler must be active immediately so if a failure occurs within a business activity, this non-transactional work is always compensated.

Although these two compensation data logging methods, if called within the same enterprise bean, use the same CompensationHandler class, they create two separate instances of the CompensationHandler class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

A CompensationHandler instance is not added to a business activity automatically when a business-activity-enabled enterprise bean is invoked. The association is done explicitly through the business activity API, using one of the compensation data logging methods described previously. If such a method is called passing in `null` as a parameter, the CompensationHandler instance is added to the current business activity, and `null` is passed later to either the `compensate` or the close method upon completion of the business activity scope. With this process, you can add the compensation handler to the business activity, and code default behavior within the compensation handler. It is your responsibility to handle the case of `null`s that pass back to your CompensationHandler instance. This scenario happens only if you call a compensation data logging method with `null` as a parameter.

As described previously, the business activity support adds a CompensationHandler instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean using that business activity. At the same time, a snapshot of the J2EE context is taken and logged with the compensation data. Upon completion of the business activity, all the compensation handlers that were added to the business activity are driven to compensate or close. The code that you create within the CompensationHandler class is guaranteed to run wiithin the same J2EE context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see the WebSphere Application Server application programming interface reference information.

Transaction service exceptions

This topic lists the exceptions that can be thrown by the WebSphere Application Server transaction service. The exceptions are listed in the following groups:
- Standard exceptions
- Heuristic exceptions

If the EJB container catches a system exception from the business method of an enterprise bean, and the method is running within a container-managed transaction, the container rolls back the transaction before passing the exception on to the client. For more information about how the container handles the exceptions thrown by the business methods for beans with container-managed transaction demarcation, see the section *Exception handling* in the Enterprise JavaBeans 2.0 specification. That section specifies

the container's action as a function of the condition under which the business method executes and the exception thrown by the business method. It also illustrates the exception that the client receives and how the client can recover from the exception.

Standard exceptions

The standard exceptions such as TransactionRequiredException, TransactionRolledbackException, and InvalidTransactionException are defined in the Java Transaction API (JTA) 1.0.1 Specification.

InvalidTransactionException

This exception indicates that the request carried an invalid transaction context.

TransactionRequiredException exception

This exception indicates that a request carried a null transaction context, but the target object requires an active transaction.

TransactionRolledbackException exception

This exception indicates that the transaction associated with processing of the request has been rolled back, or marked for roll back. Thus the requested operation either could not be performed or was not performed because further computation on behalf of the transaction would be fruitless.

Heuristic exceptions

A heuristic decision is a unilateral decision made by one or more participants in a transaction to commit or rollback updates without first obtaining the consensus outcome determined by the Transaction Service. Heuristic decisions are an issue only after the participant has been prepared and the second phase of commit processing is underway. Heuristic decisions are normally made only in unusual circumstances, such as repeated failures by the transaction manager to communicate with a resource manage during two-phase commit. If a heuristic decision is taken, there is a risk that the decision differs from the consensus outcome, resulting in a loss of data integrity.

The following list provides a summary of the heuristic exceptions. For more detail, see the Java Transaction API (JTA) 1.0.1 Specification.

HeuristicRollback exception

This exception is raised on the commit operation to report that a heuristic decision was made and that all relevant updates have been rolled back.

HeuristicMixed exception

This exception is raised on the commit operation to report that a heuristic decision was made and that some relevant updates have been committed and others have been rolled back.

UserTransaction interface - methods available

For details about the methods available with the UserTransaction interface, see the WebSphere Application Server application programming interface reference information (Javadoc) or the Java Transaction API (JTA) 1.0.1 Specification.

Developing components to use transactions

These topics provide information about developing WebSphere application components to use transactions

The way that applications use transactions depends on the type of application component, as follows:
- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) and application client components use component-managed transactions.

You configure whether EJB components use container- or bean-managed transactions by setting an appropriate value on the Transaction type deployment attribute, as described in Configuring transactional deployment attributes. You can also configure other transactional deployment descriptor attributes.

If you want a session bean, Web component, or application client component to manage its own transactions, you must write the code that explicitly demarcates the boundaries of a transaction as described in Using component-managed transactions. There are some limitations to the transaction support available to application client components, as described in Client support for transactions.

Configuring transactional deployment attributes

Use this task to configure the transactional deployment descriptor attributes associated with an EJB or Web module, to enable a J2EE application to use transactions.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.

This topic describes the use of the Application Server Toolkit (AST) to configure the deployment attributes of an application. This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about assembling applications, see Chapter 7, "Assembling applications," on page 1345.

To set transactional attributes in the deployment descriptor for an application component (enterprise bean or servlet), complete the following steps:

1. Start the assembly tool. For information about starting the AST, refer to the AST infocenter.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File-> Import-> EAR file**
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.
3. In the J2EE Hierarchy view, right-click the component instance, then click **Open With > Deployment Descriptor Editor**. For example:
   - For a session bean, expand **EJB Modules->** *ejb_module_instance***-> Deployment Descriptor-> Session Beans** then select the bean instance.
   - For a servlet, expand **Web Modules->** *web_application***-> Deployment Descriptor->** *web component* then select the servlet instance.

   A property dialog notebook for the component's deployment descriptor is displayed in the property pane.
4. **[For session beans only]** Set the **Transaction type** attribute, which defines the transactional manner in which the container invokes a method. You can set this attribute to Container or Bean, as follows:
   - To use container-managed transactions, set Container
   - To use bean-managed transactions, set Bean
5. In the deployment descriptor notebook, select the Bean tab. Under **WebSphere Extensions**, optionally configure **Local Transaction**. To enable management of local transaction containments, configure the following component extensions attributes. These attributes configure, for the component, the behavior of the container's local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present.
   Boundary

      This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are **Bean method** or **ActivitySession**.
      - BeanMethod: This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started.
      - [For EJB components only] ActivitySession: RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started.

Note: The ActivitySession option is not supported in the web container.

Resolver

This setting specifies the component responsible for initiating and ending RMLTs. Possible values are **Application** or **ContainerAtBoundary**.

- Application: This is the default value. The application is responsible for starting RMLTs and for completing them within the local transaction containment (LTC) boundary. Any RMLTs that are not completed by the end of the LTC boundary are cleaned up by the container according to the value of the Unresolved action attribute.
- ContainerAtBoundary: The container is responsible for starting RMLTs and for completing them within the LTC boundary. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope. If Boundary is set to ActivitySession, the RMLTs are enlisted as ActivitySession resources and directed to complete by the ActivitySession. If Boundary is set to BeanMethod, the RMLTs are committed at the end of the method by the container.

Unresolved action

Specifies the direction that the container requests RMLTs to take, if they are unresolved at the end of the LTC boundary scope and the Resolver is set to Application. Possible values are **Rollback** or **Commit**.

- Rollback: This is the default value. At end of the LTC boundary scope, the container instructs all unresolved RMLTs to roll back.
- Commit: At the end of the LTC boundary scope, the container instructs all unresolved RMLTs to commit. The container will instruct the RMLTs to commit only in the absence of an un-handled exception. If the application method executing under the local transaction context ends with an exception, any unresolved RMLTs are rolled back by the container. (This is the same behavior as for global transactions.)

6. Continuing in WebSphere Extensions, configure **Global Transaction**. These attributes configure, for the component, behavior in the presence of a global transaction.

Component Transaction Timeout

[For enterprise beans using container managed transactions only.] Specifies the transaction timeout, in seconds, for any new global transaction started by the container on behalf of the enterprise bean. Any value specified overrides, for transactions started on behalf of the component, the default transaction timeout configured on the application server.

Use Web Services Atomic Transaction

[For enterprise beans only.] Specifies whether the application component, if it makes any Web service requests, expects any transaction context to be propagated with the Web service requests in accordance with the WebSphere WS-AtomicTransaction support described in "Web Services Atomic Transaction support in WebSphere Application Server" on page 1101. Unless specified using this attribute, Web service requests do not carry transaction context.

Send Web Services Atomic Transaction on requests

[For web components only.] Specifies whether the application component, if it makes any Web service requests, expects any transaction context to be propagated with the Web service requests in accordance with the WebSphere WS-AtomicTransaction support described in "Web Services Atomic Transaction support in WebSphere Application Server" on page 1101. Unless specified using this attribute, Web service requests do not carry transaction context.

Execute using Web Services Atomic Transaction on incoming requests

[For web components only.] Specifies whether web application components are prepared to run under a received WS-AtomicTransaction context. Unless specified using this attribute, the web application component's container suspends any received transaction context in a similar manner to the EJB container's behavior for an enterprise bean deployed with a **Container transaction type** of `NotSupported`. Setting this attribute enables a web application component

to run under a received WS-AtomicTransaction context in a similar fashion to an enterprise bean deployed with a **Container transaction type** of `Supports`.

7. [For EJB components only] For container-managed transactions, configure how the container must manage the transaction boundaries when delegating a method invocation to an enterprise bean's business method:

   a. In the deployment descriptor notebook, select the Assembly tab. The **Container Transactions** box displays a table of the methods for enterprise beans.

   b. For each method of the enterprise bean set the **Container transaction type** to an appropriate value. The default value for the Container transaction type is `Required`, meaning that the method invocation occurs in the context of a transaction. This transaction is either the (local or remote) client component's transaction or, if the client component does not execute under a transaction, a new transaction started by the component's container.

   If the application uses ActivitySessions, how the container manages transaction boundaries when delegating a method invocation depends on both the **Container transaction type** set in this task, and the **ActivitySession kind** attribute as described in "Setting EJB module ActivitySession deployment attributes" on page 1136. For more detail about the relationship between these two properties, see "Combining transaction and ActivitySession container policies" on page 1125.

8. [For Web service applications that use a SOAP/JMS binding and participates in WS-AtomicTransactions] Ensure that the **Container transaction type** of the message-driven bean named `JMS router MDB` is set, as described in the previous step, to a value of `NotSupported`. Web service applications that use a SOAP/JMS binding include in the assembled EAR a router message-driven bean named `JMS router MDB`. If a Web service uses a SOAP/JMS binding and participates in WS-AtomicTransactions, as described in "Web Services Atomic Transaction support in WebSphere Application Server" on page 1101, then the **Container transaction type** of the `JMS router MDB` must be set, as described in the previous step, to a value of `NotSupported`. Note that there is no equivalent action neccessary for Web service applications that use a SOAP/HTTP binding and participate in WS-AtomicTransactions.

9. [For client application components only] Enable, if required, support for transaction demarcation by the client. In the deployment descriptor notebook, select the option **Allow JTA demarcation**. This directs the client container to bind the JTA UserTransaction interface into JNDI at java:comp/UserTransaction for the client component. There are constraints on the capabilities of the transaction support in the client container described in "Client support for transactions" on page 1087.

10. Save your changes to the deployment descriptor.

    a. Close the deployment descriptor editor.

    b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

11. Verify the archive files. For more information about verifying files using the AST, refer to the AST infocenter.

12. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

13. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Web Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

    Important

    Important: Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Web Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Chapter 9, "Deploying and administering applications," on page 1363.

Using component-managed transactions

This topic describes how to enable a session bean, servlet, or application client component to use component-managed transactions, to manage its own transactions directly instead of letting the container manage the transactions.

Note: Entity beans cannot manage transactions (so cannot use bean-managed transactions).

To enable a session bean, servlet, or application client component to use component-managed transactions, complete the following steps:

1. For session beans, set the **Transaction type** attribute in the component's deployment descriptor to `Bean`, as described in Setting transactional attributes in the deployment descriptor.

2. For application client components, enable support for transaction demarcation by setting the **Allow JTA Demarcation** attribute in the component's deployment descriptor, as described in Setting transactional attributes in the deployment descriptor.

3. Write the component code to actively manage transactions

   For stateful session beans, a transaction started in a given method does not need to be completed (that is, committed or rolled back) before completing that method. The transaction can be completed at a later time, for example on a subsequent call to the same method, or even within a different method. However, constructing the application so a transaction is begun and completed within the same method call is usually preferred, because it simplifies application debugging and maintenance.

   The following code extract shows the standard code required to obtain an object encapsulating the transaction context, and involves the following basic steps:
   - A javax.transaction.UserTransaction object is created by calling a lookup on "java:comp/UserTransaction".
   - The UserTransaction object is used to demarcate the boundary of a transaction by using transaction methods such as begin and commit as needed. If an application component begins a transaction, it must also complete that transaction either by invoking the commit method or the rollback method.

   Code example: Getting an object that encapsulates a transaction context

```
...
import javax.transaction.*;
import javax.naming.InitialContext;
import javax.naming.NamingException;
...
    public float doSomething(long arg1)throws NamingException {
        InitialContext initCtx = new InitialContext();
        UserTransaction userTran = (UserTransaction)initCtx.lookup(
            "java:comp/UserTransaction");
        ...
        //Use userTran object to call transaction methods
        userTran.begin ();
        //Do transactional work
        ...
        userTran.commit ();
        ...
    }
    ...
}
```

Creating an application that exploits the business activity support

To create an application component that uses the business activity support, you must set **Run EJB methods under a Business Activity scope** in the deployment descriptor of the relevant application component, and if required, create and specify a compensation handler for the application to use in the

event of an error. You then build the component into the application and deploy the application onto a server that has the business activity support enabled. The application component can be either an enterprise bean or a Web service that is implemented as an enterprise bean.

For information about editing deployment descriptors, refer topics such as ″Application Deployment Descriptor editor″, in the Application Server Toolkit documentation, accessible from the Contents view.

Perform this task to for an application that runs on a business-activity-enabled sever to exploit the business activity support at run time, and to perform work that might later be compensated by a compensation handler. If the application requires compensation when a business activity scope ends, the application passes data that is required by the compensation process, in the form of a Service Data Object (SDO), to a compensation handler indirectly by using the business activity API.

1. Design the application component that requires the business activity support. In particular, define the application component requirements for compensation and close activities. If the application component requires compensation, define the nature of the data in the SDO that the application component passes to the compensation handler.

2. Using the information from your application design, create the compensation handler for the application component, if required. This handler defines the close and compensation logic that runs upon completion of a business activity scope that has the handler added to it through an application component.

   a. Open your chosen WebSphere Application Server assembly tool.

   b. Create a new Java class that implements the com.ibm.websphere.wsba.CompensationHandler interface.

   c. Implement the close and compensate methods on the new compensation handler object, to perform appropriate actions depending on the SDO data that passes to the handler when it is invoked.

   The compensation handler class is now ready for the application component to reference, and for assembly into an application.

3. Open the application component in the assembly tool.

4. Open the deployment descriptor for the application component in the deployment descriptor viewer.

5. Scroll to the **Compensation** section and select the **Run EJB methods under a Business Activity scope** check box.

6. In the **Compensation handler class** text field, type the fully qualified class name of the compensation handler class that you created earlier.

7. Save the deployment descriptor.

8. Build the application, including both the application component and the compensation handler. If the application is a Web service, the application must be compliant with the Java Specification Request (JSR) 109 standard.

9. Deploy the application onto an application server that is business-activity-enabled.

The application is now business-activity-enabled, and can exploit the business activity support at run time through the business activity API. The application component has a compensation handler associated with it, and can therefore call the setCompensationDataImmediate and setCompensationDataAtCommit methods at run time to add the compensation handler to the business activity scope. For more information about these methods, see "The business activity API" on page 1107. If the unit of work with which the business activity scope is associated fails, the compensation handler performs actions to compensate for the error.

Ensure that the compensation handler class is on the application class path for the WebSphere Application Server runtime environment.

Using one-phase and two-phase commit resources in the same transaction

Use these topics to help you coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

You can coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved. This coordination is enabled by the *last participant support*.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

For more information about using one-phase and two-phase commit resources within the same transaction, see the following topics:
- "Coordinating access to one-phase commit and two-phase commit capable resources within the same transaction"
- "Assembling an application to use one-phase and two-phase commit resources in the same transaction" on page 1117
- "Configuring an application server to log heuristic reporting" on page 1119

Coordinating access to one-phase commit and two-phase commit capable resources within the same transaction

Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

Note: If the global transaction is distributed across multiple application servers *that are all running at WebSphere Application Server version 5.1 or later*, you can coordinate access to one-phase and two-phase commit capable resources within the same transaction.

Note: If the global transaction is distributed across multiple application servers *that are all running at WebSphere Application Server version 5.1 or later* then you can exploit last participant support to coordinate a one-phase commit capable resource and any number of two-phase commit capable resources within the same transaction, in a limited number of scenarios.

- The main scenario is where the one-phase commit resource provider is accessed in the application server process (the "transaction root" server) in which the transaction is started.

  In this scenario, last participant support can coordinate a one-phase commit capable resource and any number of two-phase commit capable resources within the same transaction.

- If the one-phase commit resource provider is accessed in a different application server (a "transaction subordinate" server) from the one in which the transaction was started; for example, as a result of a transactional invocation on a remote EJB interface where the EJB implementation accesses a one-phase commit resource provider.

  In this scenario, the transaction typically cannot be committed. To be able to commit (as part of a global transaction) a one-phase commit resource enlisted on a transaction subordinate server,

the transaction service must delegate coordination responsibility from the transaction root to the subordinate server. This occurs only if no other resources were registered with the transaction root server.

Last participant support introduces an increased risk of an heuristic outcome to the transaction. That is, the transaction manager cannot be sure that all resources were completed in the same direction (either committed or rolled back). For this reason, to enable an application to coordinate access to one-phase and two-phase commit capable resources within the same transaction, you configure the application to accept the increased risk of an heuristic outcome.

An heuristic outcome occurs if the transaction service (JTS) receives no response from the commit one-phase flow on the one-phase commit resource. In this situation the transaction service cannot determine whether changes for the one-phase commit resource were committed or rolled back, so cannot drive reliably the correct outcome of the global transaction on the other two-phase commit resources.

You can configure the transaction service for an application server to indicate whether or not to log that it is about to commit the one-phase commit resource. This does not reduce the heuristic hazard, but ensures that any failure, and subsequent recovery, of the application server during the one-phase commit phase occurs with knowledge of whether or not the one-phase commit resource was asked to commit:
- If the one-phase commit resource was asked to commit, a heuristic outcome is reported to the activity log.
- If the one-phase commit resource was not asked to commit, then the transaction is rolled back consistently.

Assembling an application to use one-phase and two-phase commit resources in the same transaction

Use this task to assemble an application to use one-phase and two-phase commit resources within the same transaction.

To enable an application to use one-phase and two-phase commit capable resources within the same transaction, you must configure the deployment attributes of the application to accept the increased risk of an heuristic outcome.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.

This task description assumes that you have an EAR file for an application component, that can be deployed in WebSphere Application Server. For more details about assembling applications, see Chapter 7, "Assembling applications," on page 1345.

To configure an application to indicate that you accept the increased risk of an heuristic outcome, complete the following steps:

1. Start the assembly tool. For more information about starting the AST, refer to the AST infocenter.
2. Create or edit the application EAR file.

   Note: Ensure that you set the target server as WebSphere Application Server version 6.1.

   For example, to change attributes of an existing application, use the import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File-> Import-> EAR file**
   b. Click **Next**, then select the EAR file.
   c. In the Target server field, select `WebSphere Application Server v6.1`
   d. Click **Finish**
3. In the J2EE Hierarchy view, complete the following steps:
   a. Expand the Enterprise Application instance.

b. Right click on the Deployment Descriptor.

   c. Click **Open With > Deployment Descriptor Editor**.

   A property dialog notebook for the component is displayed in the property pane.

4. In the property pane, select the Extended Services tab.

5. In the Last Participant Support section, select the **Last participant support** checkbox.

6. Save your changes to the deployment descriptor.

   a. Close the Deployment Descriptor Editor.

   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

7. Verify the archive files. For more information about verifying files using the AST, refer to the AST infocenter.

8. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

9. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Web Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

   Important

   Important: Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Web Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Chapter 9, "Deploying and administering applications," on page 1363.

Last participant support extension settings:

Use this page to configure settings for last participant support. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources. Values on this panel are ignored if you select **Use configuration information in binary** on the Application binaries panel.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **[Detail Properties] Last participant support extension**

Accept heuristic hazard:

Specifies whether an application accepts the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource.

Default	Cleared
Range	**Selected**
	The application accepts the increased risk of an heuristic outcome.
	Cleared
	The application does not accept the increased risk of an heuristic outcome.

Configuring an application server to log heuristic reporting

To enable an application server to log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources, use the Administrative console to complete the following steps:

1. Start the Administrative console
2. In the navigation pane, select **Servers-> Manage Application Servers-> *your_app_server*** This displays the properties of the application server, *your_app_server*, in the content pane.
3. Select the Transaction Service tab, to display the properties page for the transaction service, as two notebook pages:

   Configuration
   > The values of properties defined in the configuration file. If you change these properties, the new values are applied when the application server next starts.

   Runtime
   > The runtime values of properties. If you change these properties, the new values are applied immediately, but are overwritten with the Configuration values when the application server next starts.

4. Select the Configuration tab, to display the transaction-related configuration properties.
5. Select the **Enable logging for heuristic reporting** checkbox.
6. Click **OK**.
7. Stop then restart the application server.

Exceptions thrown for transactions involving both single- and two-phase commit resources

The exceptions that can be thrown by transactions that involve single- and two-phase commit resources are the same as those that can be thrown by transactions involving only two-phase commit resources.

The exceptions that can be thrown are listed in the "Reference: Generated API documentation" on page 26.

Last Participant Support: Resources for learning

Use the links in this topic to find relevant supplemental information about Last Participant Support. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Learn about WebSphere programming extensions

Use this section as a starting point to investigate the WebSphere programming model extensions for enhancing your application development and deployment.

See "Learn about WebSphere applications: Overview and new features" on page 1 for a brief description of each WebSphere extension.

In addition, now your applications can use the Eclipse extension framework. Your applications are extensible as soon as you define an extension point and provide the extension processing code for the extensible area of the application. You can also plug an application into another extensible application by defining an extension that adheres to the target extension point requirements. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis.

The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement Eclipse tools and to provide plug-in modules to contribute functionality such as actions, tasks, menu items, and links at predefined extension points in the WebSphere application. For more information about this feature, see "Application extension registry" on page 97.

ActivitySessions

Using the ActivitySession service
These topics provide information about implementing WebSphere enterprise applications that use ActivitySessions.

The ActivitySession service provides an alternative unit-of-work scope to the scope that is provided by global transaction contexts. ActivitySessions provide a scoping mechanism for units of work, and both an ActivitySession and a transaction have the same following characteristics:
- They can be bean-managed or container-managed
- They can be distributed across application servers
- They can be used as the context for managing EJB activation policy and lifecycle

An ActivitySession differs significantly from a transaction in the manner of its interaction with resource managers. An ActivitySession is used to scope or coordinate local transactions. That is, an ActivitySession can be used to request multiple one-phase resource managers to come to an application- or container-determined outcome. Unlike a transaction, an ActivitySession has no notion of a prepare phase or any notion of recovery at a service level.

The WebSphere EJB container and deployment tools support ActivitySessions as an extension to the J2EE programming model. Enterprise beans can be deployed with lifecycles that are influenced by ActivitySession context, as an alternative to transaction context. An enterprise bean with an ActivitySession-scoped lifecycle can participate in a resource manager local transaction (RMLT) that has a duration of the ActivitySession rather than an individual method on the bean (which is all that is possible under the standard J2EE model). Applications can then be composed of several enterprise beans with ActivitySession-based activation, with each bean participating in extended local transactions with one or more resource managers. At the end of the ActivitySession each of the local transactions can be directed to a common outcome by the ActivitySession manager.

You can configure the WebSphere containers and deployable applications to support enterprise beans that operate under application- or container-initiated ActivitySessions rather than, or in addition to, transactions.

For more information about implementing WebSphere enterprise applications that use ActivitySessions, see the following topics:
- "The ActivitySession service" on page 1121
  - "ActivitySession and transaction contexts" on page 1124

- "Setting Web module ActivitySession deployment attributes" on page 1138
- Disabling or enabling the ActivitySession service
- Configuring the default ActivitySession timeout for an application server
- Troubleshooting ActivitySessions

The ActivitySession service:

The ActivitySession service provides an alternative unit-of-work (UOW) scope to that provided by global transaction contexts. An ActivitySession context can be longer-lived than a global transaction context and can encapsulate global transactions.

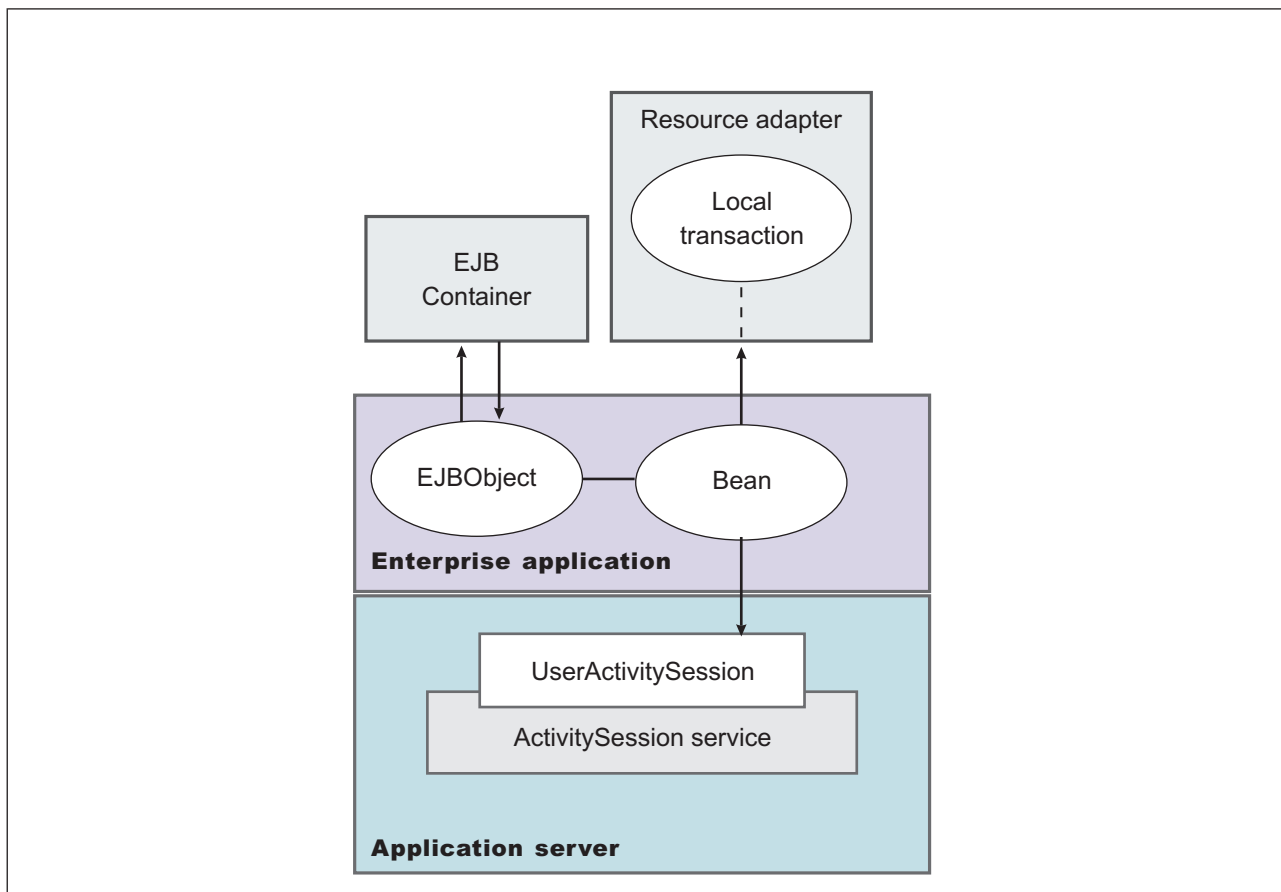
Support for the ActivitySession service is shown in the following figure:


Figure 21. The ActivitySession service. This figure shows the main components of the ActivitySession service within WebSphere Application server. For an overview of these components, see the text that accompanies this figure.

Although the purpose of a global transaction is to coordinate multiple resource managers, global transaction context is often used by J2EE applications as a "session" context through which to access EJB instances. An ActivitySession context is such a session context, and can be used in preference to a global transaction in cases where coordination of two-phase commit resource managers is not needed. Further, an ActivitySession can be associated with an HttpSession to extend a "client session" to an HTTP client.

ActivitySession support is available to Web, EJB, and J2EE-client components. EJB components can be divided into beans that exploit container-managed ActivitySessions and beans that use bean-managed ActivitySessions.

The ActivitySession service provides a UserActivitySession application programming interface available to J2EE components that use bean-managed ActivitySessions for application-managed demarcation of ActivitySession context. The ActivitySession service also provides a system programming interface for container-managed demarcation of ActivitySession context and for container-managed enlistment of one-phase resources (RMLTs) in such contexts.

The UserActivitySession interface is obtained by a JNDI lookup of java:comp/websphere/UserActivitySession. This interface is not available to enterprise beans that use container-managed ActivitySessions, and any attempt by such beans to obtain the interface results in a NotFound exception.

A common scenario is a J2EE application accessing one or more enterprise beans backed by non-transactional (one-phase commit) resources. The application, or its container, uses the UserActivitySession interface to define the demarcation boundaries within which operations against the enterprise beans are grouped and to control whether those grouped operations should be checkpointed or discarded. The business logic of the enterprise beans does not need to use any ActivitySession interfaces. The container into which the enterprise beans are deployed ensures that updates to the underlying one-phase resource managers are coordinated.

The application can checkpoint an ActivitySession to create a new point of consistency within the ActivitySession without ending the ActivitySession. The application can also use a reset operation to return work performed in the ActivitySession back to the last point of consistency. The application can end the ActivitySession with an operation to either checkpoint or reset all resources.

Using ActivitySessions with HTTP sessions:

This topic describes how a web application that runs in the WebSphere Web container can participate in an ActivitySession context.

If the web application is designed such that several servlet invocations occur as part of the same logical application, then the servlets can use the HttpSession to preserve state across servlet invocations. The ActivitySession context is one state that can be suspended into the HttpSession and resumed on a future invocation of a servlet that accesses the HttpSession.

An ActivitySession is associated automatically with an HttpSession, so can be used to extend access to the ActivitySession over multiple HTTP invocations, over inclusion or forwarding of servlets, and to support EJB activation periods that can be determined by the lifecycle of the web HTTP client. An ActivitySession context stored in an HttpSession can also be used to relate work for the ActivitySession back to a specific web HTTP client.

The Web container manages ActivitySessions based on deployment descriptor attributes associated with servlets in the Web application module. The two usage models are:
- The Web container starts and ends ActivitySessions.

  The Web application invokes a servlet that has been configured for container control of ActivitySessions.
  - If an HttpSession exists then it has an associated ActivitySession.
  - If an HttpSession does not exist, the servlet can start an HttpSession, which causes an ActivitySession to be started automatically and associated with the HttpSession.

  A servlet cannot start a new HttpSession until an existing HttpSession has been ended. Within an HttpSession, the Web application can invoke other servlets that can use the associated ActivitySession context. When the Web application invokes a servlet that ends the HttpSession, the ActivitySession is ended automatically. This is shown in the following diagram:

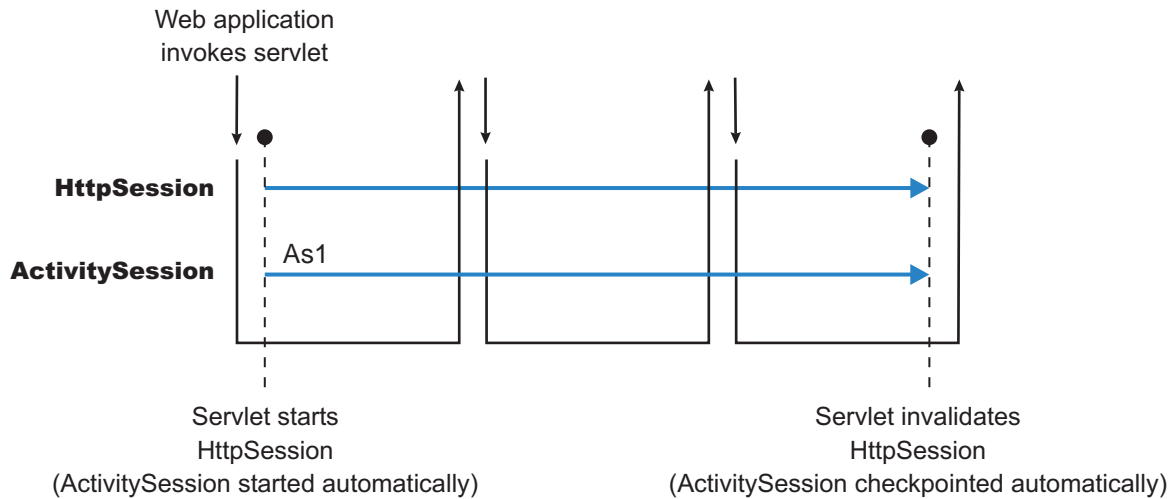
Web application
invokes servlet

HttpSession

ActivitySession

As1

Servlet starts
HttpSession
(ActivitySession started automatically)

Servlet invalidates
HttpSession
(ActivitySession checkpointed automatically)


- The Web application starts and ends ActivitySessions.

  The Web application invokes a servlet that has been configured for application control of ActivitySesions.
  - If an HttpSession exists and has an associated ActivitySession, the servlet can use or end that ActivitySession context.
  - If an HttpSession does not exist, the servlet can start an HttpSession, but this does not automatically start an ActivitySession.
  - If an HttpSession exists but does not have an associated ActivitySession, the servlet can start a new ActivitySession. This automatically associates the ActivitySession with the HttpSession. The ActivitySession lasts either until the ActivitySession is specifically ended or until the HttpSession is ended.

  The servlet cannot start a new ActivitySession until an existing ActivitySession has been ended. The servlet cannot start a new HttpSession until an existing HttpSession has been ended.

  Within an HttpSession, the Web application can invoke other servlets that can use or end an existing ActivitySession context or, if no ActivitySession exists start a new ActivitySession. When the Web application invokes a servlet that ends the HttpSession, the ActivitySession is ended automatically. This is shown in the following diagram:

Web application
invokes servlet

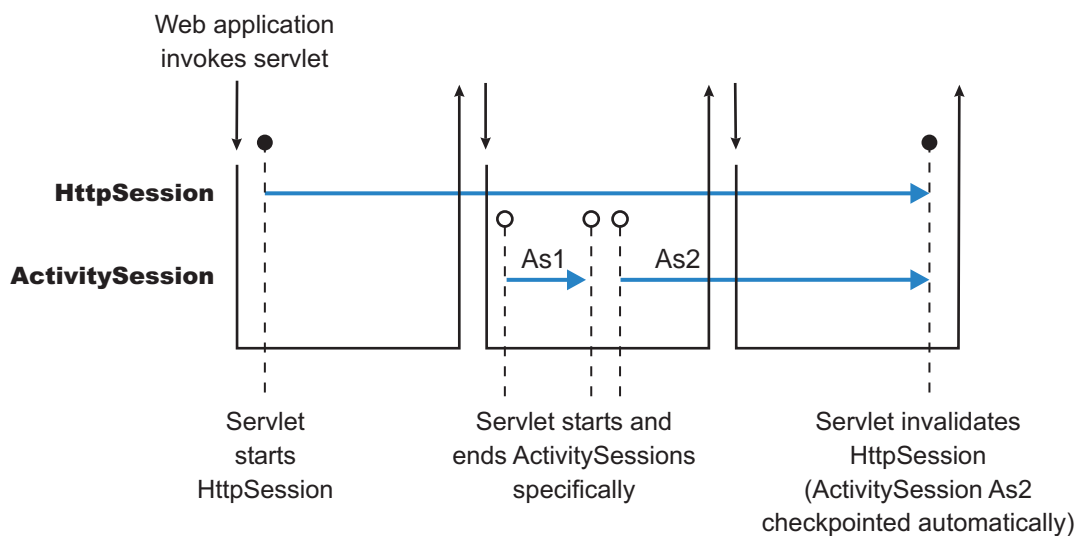
HttpSession

ActivitySession

As1   As2

Servlet
starts
HttpSession

Servlet starts and
ends ActivitySessions
specifically

Servlet invalidates
HttpSession
(ActivitySession As2
checkpointed automatically)


A Web application can invoke servlets configured for either usage model.

The following points apply to both usage models:
* To end an HttpSession (and any associated ActivitySession), the Web application must invalidate that session. This causes the ActivitySession to be checkpointed.
* Any downstream EJBs activated within the context of an ActivitySession can be held in memory rather than passivated between servlet invocations, because the client effectively becomes the web HTTP client.
* Web applications can be composed of many servlets, and each servlet in the Web application can be configured with a value for ActivitySessionControl. ActivitySessionControl determines whether the servlet or its container starts any ActivitySessions.
* An ActivitySession context that encapsulates an active transaction context cannot be associated with an HttpSession, because a transaction can hold database locks and should be designed to be shortlived. If an application moves an active transaction to an HttpSession, the transaction is rolled back and the ActivitySession is suspended into the HTTPSession. In general, you should design applications to use ActivitySessions or other constructs as the long-lived entities and ACID transactions as short-duration entities within these.
* Only one ActivitySession can be associated with an HttpSession at any time, for the duration of the ActivitySession. An ActivitySession associated with an HttpSession remains associated for the duration of that ActivitySession, and cannot be replaced with another until the first ActivitySession is completed. The ActivitySession can be accessed by multiple servlets if they have shared access to the HttpSession.
* ActivitySessions are not persistent. If a persistent HttpSession exists longer than the server hosting it, any cached ActivitySession is terminated when the hosting server ends.
* If the HttpSession times out before the associated ActivitySession has ended, then the ActivitySession is reset[5]. This rolls back the ActivitySession resources to the last point of consistency:
  – If the Web application invoked a servlet that has been configured for container control of ActivitySessions, the ActivitySession resources are rolled back completely.
  – If the Web application invoked a servlet that has been configured for application control of ActivitySessions, the ActivitySession resources are rolled back to the last checkpoint taken by the servlet, or completely if no checkpoint has been taken.
* If the ActivitySession times out, it is reset to the last point of consistency (see previous item), then the HttpSession is ended.

ActivitySession and transaction contexts:

This topic describes the hierarchical relationship between transaction and ActivitySession contexts. This relationship, defined by the ActivitySession service, requires that any transaction context be either wholly inside or wholly outside an ActivitySession context.

An ActivitySession context is very similar to a transaction context and extends the lifecycle choices for activation of enterprise beans; it can encapsulate one or more transactions. The ActivitySession context is a distributed context that, like the transaction context, can be bean- or container-managed. An ActivitySession context is used mainly by a client to scope the lifecycle of an enterprise bean that it uses either beyond or in the absence of individual transactions started by that client.

ActivitySessions have a lower overhead than transactions and can be used instead of transactions that are only used to scope the lifecycle of a called enterprise bean. For a bean with an activation policy of ActivitySession, the duration of any resource manager local transactions (RMLTs) started by that bean can be bounded by the duration of the ActivitySession instead of the bean method in which the RMLT was started. This provides flexibility and potential for using RMLTs in an enterprise bean beyond the scenarios

---

5. Resetting an ActivitySession causes all the resources involved in the current ActivitySession to be rolled back to the last point of consistency, but allows further work within the ActivitySession. When the reset completes, the thread is associated with the same ActivitySession as it was before the reset was called. The ActivitySession resources remain associated with the ActivitySession although they cannot participate further in the ActivitySession

described in the J2EE specifications. The J2EE specifications define that RMLTs need to be completed before the end of the bean method, because the bean method is the only containment boundary for local transactions available in those specifications.

The following rules defines the relationship between transactions and ActivitySessions.
- The EJB or Web container always uses a local transaction containment (LTC) if there is no global transaction present. An LTC can be method-scoped or ActivitySession-scoped.
- Before a method dispatch, the container ensures that there is always either an LTC or global transaction context, but never both contexts.
- ActivitySessions cannot be nested within each other. Any attempt to start a nested ActivitySession results in a com.ibm.websphere.ActivitySession.NotSupportedException on UserActivitySession.beginSession().
- An ActivitySession can wholly encapsulate one or more global transactions.
- The application can end an ActivitySession with an operation to either checkpoint or reset all resources. The endSession(EndModeCheckpoint) operation checkpoints the work coordinated under the ActivitySession then ends the context. The endSession(EndModeReset) operation resets, to the last point of consistency, the work coordinated under the ActivitySession then ends the context.
- An ActivitySession cannot be encapsulated by a global transaction nor should ActivitySession and global transaction boundaries overlap. Any attempt to start an ActivitySession in the presence of a global transaction context results in a com.ibm.websphere.ActivitySession.NotSupportedException on UserActivitySession.beginSession(). Any attempt to call endSession(EndModeCheckpoint) on an ActivitySession that contains an incomplete global transaction results in a com.ibm.websphere.ActivitySession.ContextPendingException. Neither the global transaction nor the ActivitySession context are affected. If endSession(EndModeReset) is called then the ActivitySession is reset and the global transactions marked rollback_only.
- Each global transaction wholly encapsulated by an ActivitySession is independent of every other global transaction within that ActivitySession. A rollback of one global transaction does not affect any others or the ActivitySession itself.
- ActivitySession and global transaction contexts can coexist with an ActivitySession encapsulating one or more serially-executing global transactions.

Combining transaction and ActivitySession container policies:

This topic provides details about the relationship between the deployment descriptor properties that determine how the container manages ActivitySession boundaries.

If an enterprise bean uses ActivitySessions, how the EJB container manages ActivitySession boundaries when delegating a method invocation depends on both the **ActivitySession kind** and **Container transaction type** deployment descriptor attributes configured for the enterprise bean. The following table lists the relationship between these two properties.

In each row, the final column describes the behavior that the EJB container takes with respect to global transaction and ActivitySession context, based on the following abbreviations:
S*n*   An ActivitySession, where *n* indicates the ActivitySession instance.
T*n*   A transaction, where *n* indicates the transaction instance.

In every case where the container does not start or leave a global transaction context associated with the thread, it starts (or obtains from the bean instance) a local transaction containment and associates that with the thread. The duration of the local transaction containment is determined by a combination of the local-transaction boundary descriptor (configured as part of the application deployment descriptor, and not shown in the following table) and the presence or not of an ActivitySession context, as described in ActivitySessions and transaction contexts.

The rows highlighted in bold are not allowed.

Table 40. Container behavior for activitysession and transaction policies deployment settings

Bean ActivitySession policy(ActivitySession kind)	Bean transaction policy(Container transaction type)	Received contexts	Container behavior
Required	Required	None	Start S1, Start T1
		S1	Start T1
		T1	Suspend T1, Start S1, Start T2
		S1, T1	No Action

The ActivitySession service application programming interfaces:

The ActivitySession service consists of an application programming interface available to Web applications, session EJBs, and J2EE client applications for application-managed demarcation of ActivitySession context.

Applications use the UserActivitySession interface, which provides demarcation scope methods.

ActivitySession API

The ActivitySession service provides the UserActivitySession interface for use by EJB Session beans using bean-managed context demarcation, Web application components configured with **ActivitySession control**=`Web Application`, and J2EE client applications. This UserActivitySession interface defines the set

of ActivitySession operations available to an application component. An implementation of this interface is obtained via a JNDI lookup of the URL ″java:comp/websphere/UserActivitySession″. It is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.

For more information about the ActivitySession API, see WebSphere Application Server application programming interface reference information (Javadoc).

The ActivitySession API and the implementation of its interfaces is contained in the com.ibm.websphere.ActivitySession package.

Programming Examples

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas = (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

Samples: ActivitySessions:

This topic describes the ActivitySession samples provided with WebSphere Application Server.
MasterMind sample
> This sample is based on the game MasterMind. It consists of the following components:
> - A servlet, configured with ActivitySession contol set to Container, that accesses a stateful session bean.
> - A stateful session bean, configured with an activation policy of ActivitySession containing transient state data.
>
> The servlet begins an HttpSession at the start of each new game, and ends it at the end of each game; therefore an ActivitySession lasts for the duration of each game. The ActivitySession activation policy stops the bean from being passivated and therefore the transient data remains in memory. This is to demonstrate HttpSession/ActivationSession association in the web container, and an ActivitySession-scoped activation policy.

J2EE client container application and a CMP entity bean backed by a one-phase commit datasource
> In this sample, the entity bean is configured with the following properties:
> - TX_NOT_SUPPORTED
> - An ActivitySession container managed policy of REQUIRES
> - An LTC boundary of ActivitySession
> - An LTC Resolution Control of ContainerAtBoundary
>
> The client accesses the UserActivitySession, begins an ActivitySession, updates two instances of the bean, then ends the ActivitySession. It does this twice using EndModeReset then EndModeCheckpoint. This sample demonstrates the following functionality:
> - Client access to the UserActivitySession interface
> - Multiple RMLTs being scoped to the ActivitySession and automatically taking their completion direction from that of the ActivitySession

The entity bean also holds a transient variable incremented by each method call (gets and sets for the persistent data). This value is checked before the end of the ActivitySession to show that the same bean instance is used. The client checks for the correct results.

A J2EE client container application and two session beans with different ActivitySession types
This sample consists of a J2EE client container application and the following session beans:
- SLB1, a stateless session bean configured with an ActivitySession Type of Bean.
- SFB2, a stateful session bean configured with ActivitySession Type of Requires, an LTC boundary of ActivitySession, LTC Resolution Contol of APPLICATION, and an LTC Unresolved Action of ROLLBACK.

Both beans are configured with TX_NOTSUPPORTED.

This sample performs the following steps:
1. The client starts SLB1
2. SLB1 accesses the UserActivitySession interface, begins an ActivitySession, then calls a method on SFB2
3. SFB2 accesses the UserActivitySession interface, begins an ActivitySession, calls a method on SFB2
4. SFB2 gets a connection (setAutoCommit false) then uses JDBC to update a single-phase datasource.
5. SLB1 then optionally calls a seperate method on SFB2 to finish the work either committing or rolling-back the RMLT.
6. SLB1 then ends the ActivitySession with an EndModeCheckpoint.

This sample demonstrates the following functionality:
- The ActivitySession completion direction is unconnected to the direction of the RMLTs, although the RMLTs containment is bound to the ActivitySession.
- The container using the unresolved action when an RMLT is not completed.
- A bean-managed ActivitySessions bean using the UserActivitySession interface.

The sample checks for correct results and reports them back to the client.

ActivitySession service: Resources for learning:

Use the links in this topic to find relevant supplemental information about ActivitySessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Developing a J2EE application to use ActivitySessions

This topic provides an overview of the scenarios for which you would develop a J2EE application to use an ActivitySession.

The following common J2EE application scenarios make use of an ActivitySession:
- Developing a J2EE application to use one or more enterprise beans that are persisted to non-transactional datastores.

  This scenario can be used by an application that needs to coordinate multiple one-phase resource managers; for example, for two or more entity EJBs whose persistence is delegated to LocalTransaction resource adapters.

  In this scenario, the enterprise beans used by the application have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of ContainerAtBoundary. The synchronization of the EJB state data is synchronized, by the container, with the one-phase resource managers at ActivitySession completion and no application code is required to be aware of ActivitySession support.
- Developing a J2EE application in which an enterprise bean accesses a resource manager multiple times in different business methods.

  This scenario can be used by an application that needs to extend a resource manager local transaction (RMLT) over several business methods of an enterprise bean instance.

  In this scenario, the enterprise beans used by the application have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of Application. The application logic starts and ends the RMLTs, for example using the javax.resource.cci.LocalTransaction interface offered by a LocalTransaction Connector, but is not constrained to start and commit the LocalTransaction in the same method.
- Developing a J2EE client application to use an ActivitySession to scope EJB activation and load-balancing.

  This scenario can be used by an application client that needs to access an entity bean instance several times in the same client session, either without needing to run under a transaction context, or with the need to run under a number of distinct and serially-executed transactions.

  In this scenario, the enterprise beans used by the application client have an Activation policy of ActivitySession and a local transaction containment policy appropriate to the function of the enterprise bean. The J2EE client application can represent a period of user activity, for example a signon period, during which a number of interactions occur with one or more enterprise beans. If the J2EE client application begins an ActivitySession and invokes the enterprise beans within the scope of the UOW represented by the ActivitySession, then the enterprise bean instances are activated by the container on the ActivitySession boundary and remain in the active state until passivated by the container at the end of the ActivitySession. Workload affinity management based on the ActivitySession is a platform quality of service. Global transactions can begin and end within the ActivitySession, if they are wholly encapsulated by the ActivitySession and run serially. EJB instances activated at the ActivitySession boundary remain active across the serial global transactions.
- Developing a Web application client to participate in an ActivitySession context.

  A web application that runs in the WebSphere Web container can participate in an ActivitySession context. Web applications can use the UserActivitySession interface to begin and end an ActivitySession context. Also, the ActivitySession can be associated with an HttpSession, thereby extending access to the ActivitySession over multiple HTTP invocations and supporting EJB activation periods that can be determined by the lifecycle of the web HTTP client.

  The Web container manages ActivitySessions based on deployment descriptor attributes associated with the Web application module.

General considerations:
- An application that is accessed under an ActivitySession context can receive a javax.transaction.InvalidTransactionException RemoteException, thrown by the EJB container when

servicing any application method. This exception occurs when an instance of an enterprise bean that has an ActivitySession-based activation policy becomes involved with concurrent global and local transactions.

- To enable an enterprise bean to participate in an ActivitySession context and support ActivitySession-based operations, it must be configured with an ActivationPolicy of ACTIVITY_SESSION. A bean configured with ActivationPolicy of either TRANSACTION or ONCE cannot participate in an ActivitySession context.
- A session bean can either use container-managed ActivitySessions or implement bean-managed ActivitySessions; entity beans can only use container-managed ActivitySessions. A bean is deployed to be bean-managed or container-managed with respect to ActivitySession management by setting its transaction type deployment attribute to be bean-managed or container-managed when deploying the enterprise bean. A bean that uses bean-managed transactions can use bean-managed ActivitySessions; a bean that uses container-managed transactions can use container-managed ActivitySessions.
- If you want a session bean or J2EE client to manage its own ActivitySessions, you must write the code that explicitly demarcates the boundaries of an ActivitySession, as described in Developing an enterprise bean or J2EE client to manage ActivitySessions.

For examples of using ActivitySessions in J2EE applications, see ActivitySessions samples.

Developing an enterprise bean or J2EE client to manage ActivitySessions

Use this task to write the code needed by a session EJB or J2EE client application to manage an ActivitySession, based on the example code extract provided.

In most situations, an enterprise bean can depend on the EJB container to manage ActivitySessions within the bean. In these situations, all you need to do is set the appropriate ActivitySession attributes in the EJB module deployment descriptor, as described in Configuring EJB module ActivitySession deployment attributes. Further, in general, it is practical to design your enterprise beans so that all ActivitySession management is handled at the enterprise bean level.

However, in some cases you may need to have a session bean or J2EE client participate directly in ActivitySessions. You then need to write the code needed by the session bean or J2EE client application to manage its own ActivitySessions.

Note: Session beans that use BMT and have an **Activate at** setting of `Activity session` can manage ActivitySessions. Entity beans cannot manage ActivitySessions; the EJB container always manages ActivitySessions within entity beans.

When preparing to write code needed by a session bean or J2EE client application to manage ActivitySessions, consider the points described in ActivitySessions and transaction contexts.

To write the code needed by a session EJB or J2EE client application to manage an ActivitySession, complete the following steps based on the example code extract below:

1. Get an initial context for the ActivitySession.
2. Get an implementation of the UserActivitySession interface, by a JNDI lookup of the URL java:comp/websphere/UserActivitySession. The UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.
3. Set the timeout, in seconds, after which any subsequently started ActivitySessions are automatically completed by the ActivitySession service. If the session bean or J2EE client does not specifically set this value, the default timeout (300 seconds) is used.

   The default timeout can also be overridden for each application server, on the ***server->* Activity Session Service** panel of the administrative console.
4. Start the ActivitySession, by calling the beginSession() method of the UserActivitySession.

5. Within the ActivitySession, call business methods to do the work needed. You can also call other methods of UserActivitySession to manage the ActivitySession; for example, to get the status of the ActivitySession or to checkpoint all the ActivitySession resources involved in the ActivitySession.

6. End the ActivitySession, by calling the endSession() method of the UserActivitySession.

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas = (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

Setting EJB module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for an enterprise bean to enable the bean to participate in an ActivitySession context and support ActivitySession-based operations.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.

This topic describes the use of the Application Server Toolkit (AST) to configure the ActivitySession deployment attributes. These attributes are in addition to other deployment attributes, like Load at (which specifies when the bean loads its state from the database). This task description assumes that you have an EAR file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details about assembling applications, see assembling applications. For more detail about the fields in the assembly tool, and for associated task help, see the help information provided with the toolkit.

To set the ActivitySession deployment attributes for an enterprise bean, complete the following steps:

1. Start the assembly tool. For more information about starting the AST, refer to the AST infocenter.
2. Create or edit the application EAR file.

   Note: Ensure that you set the target server as WebSphere Application Server version 6.1.

   For example, to change attributes of an existing application, use the import wizard to import the EAR file into the assembly tool. To start the import wizard:

   a. Click **File-> Import-> EAR file**
   b. Click **Next**, then select the EAR file.
   c. In the Target server field, select `WebSphere Application Server v6.1`
   d. Click **Finish**

3. In the J2EE Hierarchy view of the J2EE perspective, right-click the EJB module for the enterprise bean instance, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the enterprise bean instance is displayed in the property pane.
4. In the property pane, select the Beans tab.
5. Select the bean that you want to change.
6. In the WebSphere Extensions section, under **Bean Cache**, set the **Activate at** attribute to **ActivitySession**:

An enterprise bean with this activation policy is activated and passivated as follows:

- On an ActivitySession boundary, if an ActivitySession context is present on activation.
- On a transaction boundary, if a transaction context, but no ActivitySession context, is present on activation.
- Otherwise on an invocation boundary.

7. In the Local Transactions group box, set the **Boundary** attribute to **ActivitySession**: When this setting is used, the local transaction must be resolved within the scope of any ActivitySession in which it was started or, if no ActivitySession context is present, within the same bean method in which it was started.

8. For entity beans, or session beans, set the ActivitySessions properties for each EJB method.

   a. In the property pane, select the ActivitySession tab.

   b. In the **Configure ActivitySession policies** field, click **Add** or **Edit** to set the **ActivitySession kind** attribute for methods of the enterprise bean. This specifies how the container must manage the ActivitySession boundaries when delegating a method invocation to an enterprise bean's business method:

   Never   The container invokes bean methods without an ActivitySession context.
   - If the client invokes a bean method from within an ActivitySession context, the container throws an InvalidActivityException exception, which is a javax.rmi.RemoteException.
   - If the client invokes a bean method from outside an ActivitySession context, the container behaves in the same way as if the **Not Supported** value was set. The client must call the method without an ActivitySession context.

   Mandatory

   The container always invokes the bean method within the ActivitySession context associated with the client. If the client attempts to invoke the bean method without an ActivitySession context, the container throws an ActivityRequiredException exception to the client. The ActivitySession context is passed to any EJB object or resource accessed by an enterprise bean method.

   The ActivityRequiredException exception is javax.rmi.RemoteException.

   Requires new

   The container always invokes the bean method within a new ActivitySession context, regardless of whether the client invokes the method within or outside an ActivitySession context. The new ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

   Any received ActivitySession context is suspended for the duration of the method and resumed after the method ends. The container starts a new ActivitySession before method dispatch and completes it after the method ends.

   Required

   The container invokes the bean method within an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container invokes the bean method within the client ActivitySession context. If a client invokes a bean method outside an ActivitySession context, the container creates a new ActivitySession context and invokes the bean method from within that context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

   Not supported

   The container invokes bean methods without an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container suspends the association between the ActivitySession and the current thread before invoking the method on the enterprise bean instance. The container then resumes the suspended association when the method invocation returns. The suspended ActivitySession context is not passed to any enterprise bean objects or resources that are used by this bean method.

   Supports

   If the client invokes the bean method within an ActivitySession, the container invokes the

bean method within an ActivitySession context. If the client invokes the bean method without a ActivitySession context, the container invokes the bean method without an ActivitySession context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

c. Click **Next**.

d. Select the methods to which the ActivitySession kind policy is to be applied.

e. Click **Finish**.

How the container manages the ActivitySession boundaries when delegating a method invocation depends on both the **ActivitySession kind** set here, and the **Container transaction type** as described in "Configuring transactional deployment attributes" on page 1111. For more detail about the relationship between these two properties, see "Combining transaction and ActivitySession container policies" on page 1125.

9. Save your changes to the deployment descriptor.

a. Close the Deployment Descriptor Editor.

b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

10. Verify the archive files. For more information about verifying files using the AST, refer to the AST infocenter.

11. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

12. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Web Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

Important: Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Web Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console as described in Chapter 9, "Deploying and administering applications," on page 1363.

Setting Web module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for a Web application to start UserActivitySessions and perform work scoped within ActivitySessions.

You can configure the deployment attributes of an application by using an assembly tool such as the Application Server Toolkit (AST) or Rational Web Developer.

This topic describes the use of the Application Server Toolkit (AST) to configure the deployment attributes. This task description assumes that you have an EAR file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details about assembling applications, see Assembling applications.

To set the ActivitySession deployment attributes for a Web application, complete the following steps:

1. Start the assembly tool. For more information about starting the AST, refer to the AST infocenter.

2. Create or edit the Web module. For example, to change attributes of an existing module, click **File-> Open** then select the archive file for the module. For example, to change attributes of an existing module, use the import wizard to import the EAR or WAR file into the assembly tool. To start the import wizard:

a. Click **File-> Import-> WAR file**

b. Click **Next**, then select the WAR file.

c. Click **Finish**

3. In the J2EE Hierarchy view, right-click the Web module, then click **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Web module is displayed in the property pane.

4. In the property pane, select the Extended services tab.

5. Select the servlet that you want to change.

6. In the ActivitySession section, set the **ActivitySession control kind** attribute to either Application, Container, or None.

Application

The Web application is responsible for starting and ending ActivitySessions, as follows:

- If an HttpSession is active when an application begins an ActivitySession, then the container associates the ActivitySession with the HttpSession.
- If an ActivitySession is started in the absence of an HttpSession, then the application must ensure it is completed before the dispatched method completes; otherwise, an exception results.
- If an HttpSession is associated with a request dispatched to an application with this ActivitySession control value, and if that HttpSession has an ActivitySession associated with it, then the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.
- A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the web component that started them and within the same request dispatch.

Container

A servlet has no access to UserActivitySessions. Any HttpSession started by the servlet has an ActivitySession automatically associated with it by the container, and this ActivitySession is put onto the thread of execution. If such a servlet is dispatched by a request that has an HttpSession containing no ActivitySession, then the container starts an ActivitySession and associates it with the HttpSession and the thread.

A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the web component that started them and within the same request dispatch.

None A servlet has no access to UserActivitySession. An HttpSession started by the servlet does not have an ActivitySession automatically associated with it by the container. If such a servlet is dispatched by a request that has an HttpSession containing an ActivitySession, then the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.

7. To apply the changes and close the assembly tool, click **OK**. Otherwise, to apply the values but keep the property dialog open for additional edits, click **Apply**.

8. Save your changes to the deployment descriptor.

a. Close the deployment descriptor editor.

b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

9. Verify the archive files. For more information about verifying files using the AST, refer to the AST infocenter.

10. From the popup menu of the project, click **Deploy** to generate EJB deployment code.

11. **Optional:** Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard. Note that **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only; you cannot deploy remotely from the Application Server Toolkit (AST) or Rational Web Developer to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important

> **Important:** Use **Run On Server** for unit testing only. The Application Server Toolkit (AST) or Rational Web Developer controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

After assembling your application, use a systems management tool to deploy the WAR file; for example, using the administrative console as described in Deploying and managing applications.

Application profiling

Task overview: Application profiling

You can use application profiling to configure multiple access intent policies on the same entity bean.

Application profiling reflects the fact that different units of work have different use patterns for enlisted entities and can require different kinds of support from the server runtime environment. For more information, see Application Profiling.

1. Assembling applications for application profiles. This topic describes how to configure tasks, create application profiles, and configure tasks on profiles.
2. Managing application profiles. This topic describes how to add and remove tasks from application profiles using the administrative console.
3. Using the TaskNameManager API. This topic describes how to programmatically set the current task name, but you should use this technique sparingly. Wherever possible, use the declarative method instead, which results in more portable function.

Application profiling:

You can use application profiling to identify particular units of work to the WebSphere Application Server runtime environment. The run time can tailor its support to the exact requirements of that unit of work.

Access intent is currently the only runtime component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two new concepts in order to achieve this function: *tasks* and *profiles*.

Tasks A task is a configurable name for a unit of work. *Unit of work* in this case means either a transaction or an ActivitySession. The task name is typically assigned declaratively on a J2EE component that can initiate a unit of work. Most commonly, the task is configured on a method of an Enterprise JavaBeans file that is declared either for container-managed transactions or bean-managed transactions. Any unit of work that begins in the scope of a configured task is associated with that task name. A unit of work can only be named when it is initiated, and the name cannot change for the lifetime of that unit of work. A unit of work ignores any subsequent task name configurations at any point after it has begun. The task is used for the duration of its unit of work to identify configured policies specific to that unit of work.

> **Note:** If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

Profiles

A profile is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a CMR getter, or a dynamic query) requires data to be retrieved from the back end system, the current task associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent. If a request is operating in the absence of a task, the runtime environment uses either a method-level access intent (if any) or a bean-level default access intent.

Note: The application profile configuration is application scope configuration data. If any Enterprise JavaBean (EJB) module contains an application profile configuration, all other EJB modules are implicitly regulated by the Application Profiling service even if they do not contain application profile configuration data.

For example, an application has two EJB modules: EJBModule1 and EJBModule2.

The EJBModule1 has an application profile named AppProfile1. This AppProfile1 is registered by a task named task1. This task1 becomes a *known-to-application task* and is honored when associated with a unit of work within this application. With the presence of any known-to-application task, method level access intent configurations are ignored and only bean level access intent configurations are applied.

The EJBModule2 contains no application profile configuration data. All entity beans are **not** configured with bean level access intent explicitly, but some methods have method level access intent configurations. If an entity bean in the EJBModule2 is loaded in a unit of work that is associated with task1, the bean-level access intent configuration is applied and method level access intent configuration is ignored. Because the bean level access intent is not set explicitly, the default bean level access intent, which is wsPessimisticUpdate-WeakestLockAtLoad, is applied.

Tasks and units of work considerations:

The application profiling function works under the unit of work (UOW) concept. UOW in this case means either a transaction or an ActivitySession.

The task name on a method is used only when a UOW is begun, because of that method being invoked. This gives it a more predictable data access pattern based on the active unit of work. To be more specific, this approach ensures that a bean type with only one configured access intent is loaded within a UOW, because a bean is configured with only one access intent within an application profile. This configured access intent for a bean type is determined at assembly time and is enforced by the Application Profile service.

A task name is always associated with a unit of work, and that task name does not change for the duration of that UOW. When a UOW associated with a method is begun because of that method being invoked, if a task name is associated with the method then that task name is used to name the UOW. A task assigned to a unit of work is considered a named UOW.

If a task name is not associated with the method that began the UOW, then a default access intent is used and the UOW is unnamed. A unit of work can only be named when the UOW is begun and that task name remains for the life of the UOW. Furthermore, the task assigned to a UOW can never be changed for the

life of that UOW. Any task names associated with a method are ignored if that method does not begin a UOW (either container managed or component managed).

It is not possible to change the task name assigned to a unit of work. However, it is possible that in a call sequence consisting of many different application calls a different task name might need to be used for different calls. In this case it is important for the deployer to begin a new UOW and associate with the UOW the necessary task name. For example, assume you have the following beans: sb1 is a session bean, eb2 and eb3 are container managed persistence (CMP) entity beans. When sb1 is called, a transaction is begun and task 't1' is associated with it. Further assume that sb1 then calls eb2 and eb3. If neither eb2 or eb3 create a unit of work, then these beans execute within the UOW context from sb1 and as such its task name (t1). If eb2 or eb3 need to execute within a task name other than t1, then these beans must define a unit of work and associate with it the appropriate task name.

Note that if an application deployer does not specifically configure a transaction on a method, WebSphere Application Server creates a global transaction by default. This is important because if a task is defined on a method, but a UOW is not specifically configured on that method, the EJB container automatically creates a global transaction on behalf of that method. As such, this task name is associated with the UOW and any application profiles mapped to this task are used.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

Application profiles:

An application profile is the set of access intent policies that should be selectively applied for a particular unit of work (a transaction or *ActivitySession*).

Application profiling enables applications to run under different sets of policies depending on the active task under which the application is operating.

The active task depends upon the current unit of work mechanism. If the current unit of work is a global transaction, then the task is the name associated with that transaction. If the global transaction was not named when it was initiated, then there is no active task anywhere in the scope of that transaction.

If the current unit of work is a local transaction associated with an ActivitySession, then the task is the name associated with that ActivitySession. If the ActivitySession was not named when it was initiated, then there is no active task for any local transaction bound to that ActivitySession. If the current unit of work is a local transaction that is not associated with an ActivitySession, then the task is the name associated with that local transaction. If the local transaction was not associated with a task when the local transaction was initiated, then there is no active task for the duration of that local transaction. In other words, the active task is the task associated with the unit of work on the thread that is coordinating database resources. If the controlling unit of work was not associated with a task when that unit of work was initiated, then there is no active task in the scope of that unit of work.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

Consider an application that centralizes the student records for a school district. These records are frequently accessed by the school district's central office in order to generate reports. The report generation process would be optimized if it held no locks with the back end system, and if the records could be read into memory with as few back end operations as possible. Occasionally, however, the records are updated by the students' instructors. Without the ability to distinguish between transactions, the developer is forced to assume a worst-case scenario and, wishing to use pessimistic concurrency, lock the records for all transactions.

Using the application profiling service, the developer can configure in as many ways as necessary the access intent under which the students' records are loaded. Under one profile, the records can be configured with an exclusive pessimistic update intent, not only locking-out competing transactions but ensuring that the student is not removed from the system before the transaction completes. Under another profile, the records can be configured with an optimistic intent as part of an object graph that is read from the back end system in a single database operation. The task represented by the pessimistic profile receives the strong-locking semantics required for certain transactions, while the task represented by the optimistic profile receives the performance benefits appropriate for other transactions.

Application profiling performance considerations:

Application profiling enables assembly configuration techniques that improve your application run time, performance and scalability. You can configure tasks that identify incoming requests, identify access intents determining concurrency and other data access characteristics, and profiles that map the tasks to the access intents.

The capability to configure the application server can improve performance, efficiency and scalability, while reducing development and maintenance costs. The application profiling service has no tuning parameters, other than a checkbox for disabling the service if the service is not necessary. However, the overhead for the application profile service is small and should not be disabled, or unpredictable results can occur.

Access intents enable you to specify data access characteristics. The WebSphere runtime environment uses these hints to optimize the access to the data, by setting the appropriate isolation level and concurrency. Various access intent hints can be grouped together in an access intent policy.

In WebSphere Application Server, it is recommended that you configure bean level access intent for loading a given bean. Application profiling enables you to configure multiple access intent policies on the entity bean, if desired. Some callers can load a bean with the intent to read data, while others can load the bean for update. The capability to configure the application server can improve performance, efficiency, and scalability, while reducing development and maintenance costs.

Access intents enable the EJB container to be configured providing optimal performance based on the specific type of enterprise bean used. Various access intent hints can be specified declaratively at deployment time to indicate to WebSphere resources, such as the container and persistence manager, to provide the appropriate access intent services for every EJB request.

The application profiling service improves overall entity bean performance and throughput by fine tuning the run time behavior. The application profiling service enables EJB optimizations to be customized for multiple user access patterns without resorting to ″worst case″ choices, such as pessimistic update on a bean accessed with the findByPrimaryKey method, regardless of whether the client needs it for read or for an update.

Application profiling provides the capability to define the following hierarchy: **Container-Managed Tasks** > **Application Profiles** > **Access Intent Policies** > **Access Intent Overrides**. Container-managed tasks identify units of work (UOW) and are associated with a method or a set of methods. When a method associated with the task is invoked, the task name is propagated with the request. For example, a UOW refers to a unique path within the application that can correspond to a transaction or ActivitySession. The name of the task is assigned declaratively to a J2EE client or servlet, or to the method of an enterprise bean. The task name identifies the starting point of a call graph or subgraph; the task name flows from the starting point of the graph downstream on all subsequent IIOP requests, identifying each subsequent invocation along the graph as belonging to the configured task. As a best practice, wherever a UOW starts, for example, a transaction or an ActivitySession, assign a task to that starting point.

The application profile service associates the propagated tasks with access intent policies. When a bean is loaded and data is retrieved, the characteristics used for the retrieval of the data are dictated by the application profile. The application profile configures the access intent policy and the overrides that should be used to access data for a specific task.

Access intent policies determine how beans are loaded for specific tasks and how data is accessed during the transaction. The access intent policy is a named group of access intent hints. The hints can be used, depending on the characteristics of the database and resource manager. Various access intent hints applied to the data access operation govern data integrity. The general rule is, the more data integrity, the more overhead. More overhead causes lower throughput and the opportunity for simultaneous data access from multiple clients.

If specified, access intent overrides provide further configuration for the access intent policy.

Best practices

Application profiling is effective in a variety of different scenarios. The following are example situations where application profiling is useful
- **The same bean is loaded with different data access patterns**

  The same bean or set of beans can be reused across applications, but each of those applications has differing requirements for the bean or for beans within the invocation graph. One application can require that beans be loaded for update, while another application requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.
- **Different clients have different data access requirements**

  The same bean or set of beans can be used for different types of client requests. When those clients have different requirements for the bean, or for beans within the invocation graph, application profiling can be used to tailor the bean loading characteristics to the requirements of the client. One client can require beans be loaded for update, while another client requires beans be loaded for read only. Application profiling enables deploy time configuration for beans to distinguish between EJB loading requirements.

Monitoring tools

You can use the Tivoli Performance Viewer, database and logs as monitoring tools.

You can use the Tivoli Performance Viewer to monitor various metrics associated with beans in an application profiling configuration. The following sections describe at a high level the Tivoli Performance Viewer metrics that reflect changes when access intents and application profiling are used:
- **Collection scope**

  The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor this information to determine the difference between using the ActivitySession scope versus the transaction scope. For the transaction scope, depending on how the container transactions are defined, activates and passivates can be associated with method

invocations. The application could use the ActivitySession scope to reduce the frequency of activates and passivates. For more information, see "Using the ActivitySession service."

- **Collection increment**

  The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor *Num Activates* to watch the number of enterprise beans activated for a particular findByPrimaryKey operation. For example, if the collection increment is set to 10, rather than the default 25, the *Num Activates* value shows 25 for the initial findByPrimaryKey, before any result set iterator runs. If the number of activates rarely exceeds the collection increment, consider reducing the collection increment setting.

- **Resource manager prefetch increment**

  The resource manager prefetch increment is a hint acted upon by the database engine to depend upon the database. The Tivoli Performance Viewer does not have a metric available to show the effect of the resource manager prefetch increment setting.

- **Read ahead hint**

  The enterprise beans group contains EJB life cycle information, either a cumulative value for a group of beans, or for specific beans. You can monitor *Num Activates* to watch the number of enterprise beans activated for a particular request. If a read ahead association is not in use, the *Num Activates* value shows a lower initial number. If a read ahead association is in use, the *Num Activates* value represents the number of activates for the entire call graph.

Database tools are helpful in monitoring the different bean loading characteristics that introduce contention and concurrency issues. These issues can be solved by application profiling, or can be made worse by the misapplication of access intent policies.

Database tools are useful for monitoring locking and contention characteristics, such as locks, deadlocks and connections open. For example, for locks the DB2 Snapshot Monitor can show statistics for lock waits, lock time-outs and lock escalations. If excessive lock waits and time-outs are occurring, application profiling can define specific client tasks that require a more string level of locking, and other client tasks that do not require locking. Or, a different access intent policy with less restrictive locking could be applied. After applying this configuration change, the snapshot monitor shows less locking behavior. Refer to information about the database you are using on how to monitor for locking and contention.

The **application server logs** can be monitored for information about rollbacks, deadlocks, and other data access or transaction characteristics that can degrade performance or cause the application to fail.

Application profiling tasks:

Tasks are named units of work. They are the mechanism by which the runtime environment determines which access intent policies to apply when an entity bean's data is loaded from the back end system.

Application profiles enable developers to configure an entity bean with multiple access intent policies; if there are *n* instances of profiles in a given application, each bean can be configured with as many as *n* access intent policies.

A task is associated with a transaction or an ActivitySession at the initiation of the unit of work. The task, which cannot change for the lifetime of the unit of work, is always available anywhere within the scope of that unit of work to apply the access intent policy configured for that particular unit of work.

If an enterprise application is configured to use application profiling in any part of the application, then application profiling is active and method-level access intent configurations are ignored when units of works are associated with known-to-application tasks.

If an entity bean is loaded in a unit of work that is not associated with a task, or is associated with a task that is unassociated with an application profile, the default bean-level access intent or the method-level

access intent configuration is applied. If a unit of work is associated with a task that is configured with an application profile, the bean-level access intent configuration within the appropriate application profile is applied.

Note: The application profile configuration is application scope configuration data. If any enterprise Javabean (EJB) module contains an application profile configuration, all other EJB modules are implicitly regulated by the Application Profiling service even if they do not contain application profile configuration data.

For example, an application has two EJB modules: EJBModule1 and EJBModule2.

The EJBModule1 has an application profile named AppProfile1. This AppProfile1 is registered by a task named task1. This task1 becomes a *known-to-application task* and is honored when associated with a unit of work within this application. With the presence of any known-to-application task, method level access intent configurations are ignored and only bean level access intent configurations are applied.

The EJBModule2 contains no application profile configuration data. All entity beans are **not** configured with bean level access intent explicitly, but some methods have method level access intent configurations. If an entity bean in the EJBModule2 is loaded in a unit of work that is associated with task1, the bean-level access intent configuration is applied and method level access intent configuration is ignored. Because the bean level access intent is not set explicitly, the default bean level access intent, which is wsPessimisticUpdate-WeakestLockAtLoad, is applied.

The active task depends upon the current unit of work mechanism. If the current unit of work is a global transaction, then the task is the name associated with that transaction. If the global transaction was not named when it was initiated, then there is no active task anywhere in the scope of that transaction.

If the current unit of work is a local transaction associated with an ActivitySession, then the task is the name associated with that ActivitySession. If the ActivitySession was not named when it was initiated, then there is no active task for any local transaction bound to that ActivitySession. If the current unit of work is a local transaction that is not associated with an ActivitySession, then the task is the name associated with that local transaction. If the local transaction was not associated with a task when the local transaction was initiated, then there is no active task for the duration of that local transaction. In other words, the active task is the task associated with the unit of work on the thread that is coordinating database resources. If the controlling unit of work was not associated with a task when that unit of work was initiated, then there is no active task in the scope of that unit of work.

For example, consider a school district application that calls through a session bean in order to interact with student records. One method on the session bean allows administrators to modify the students' records; another method supports student requests to view their own records. Without application profiling, the two tasks would operate anonymously and the runtime environment would be unable to distinguish work operating on behalf of one task or the other. To optimize the application, a developer can configure one of the methods on the session bean with the task ″updateRecords″ and the other method on the session bean with the task ″readRecords″. When registered with an application profile that has the student bean configured with the appropriate locking access intent, the ″updateRecords″ task is assured that it is not unnecessarily blocking transactions that need to only read the records. For more information about the relationships between tasks and units of work, see "Tasks and units of work considerations" on page 1141.

Tasks can be configured to be managed by the container or to be programmatically established by the application. Container managed tasks can be configured on servlets, JavaServer Pages (JSP) files, application clients, and the methods of Enterprise JavaBeans (EJB). Configured container-managed tasks are only associated with units of work that the container initiates after the task name is set. Application managed tasks can be configured on all J2EE components. In the case of enterprise beans they must be bean managed transactions.″

best-practices: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

Application profiling interoperability:

Using application profiling with 5.x compatibility mode or in a clustered environment with mixed WebSphere Application Server product versions and mixed platforms can affect its behavior in different ways.

The effect of 5.x Compatibility Mode

Application profiling supports *forward* compatibility. Application profiles created in previous versions of WebSphere Application Server (Enterprise Edition 5.0 or WebSphere Business Integration Server Foundation 5.1) can only run in WebSphere Application Server Version 6 or later if the Application Profiling 5.x Compatibility Mode attribute is turned on. If the 5.x Compatibility Mode attribute is off, Version 5 application profiles might display unexpected behavior.

Similarly, application profiles that you create using the latest version of WebSphere Application Server are not compatible with Version 5 or earlier versions. Even applications configured with application profiles run on Version 6.x servers with the Application Profiling 5.x Compatibility Mode attribute turned on cannot interact with applications configured with profiles run on Version 5 servers.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.x client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to **true** in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the *launchClient* command.

Considerations for a clustered environment

In a clustered environment with mixed WebSphere Application Server product versions and mixed platforms, applications configured with application profiles might exhibit unexpected behavior because previous versions of server members cannot support the application profiling of Version 6.x.

If a clustered environment contains both Version 5.x and 6.x server members, and if any applications are configured with application profiles, the Application Profiling 5.x Compatibility Mode attribute must be turned on in Version 6 server members. Still, this cluster can only support Version 5 application profiling behavior. To support applications configured with Version 6 application profiles in a cluster environment, all server members in the cluster must be at the Version 6.x level.

WebSphere Application Server Enterprise Edition Version 5.0.2

If you use WebSphere Application Server Enterprise Edition 5.0.2, you must apply WebSphere Application Server Version 5 service pack 7 or later service pack to enable Application Profiling interoperability.

Assembling applications for application profiling

To enable application profiling, you must configure tasks, create an application profile, and declaratively configure a unit of work on necessary methods.

Application profiling enables multiple access intent policies to be configured on the same entity bean, each specified for a particular unit of work. You can use the one of the default policies or create your own. To create your own access intent policy, see Creating a custom access intent policy.

1. Configuring tasks. Declaratively configure tasks as described in the following topics:
   - Configuring container-managed tasks for Enterprise Java Beans.
   - Configuring container-managed tasks for web components.
   - Configuring container-managed tasks for application clients.

   On rare occasions, you might find it necessary to configure tasks *programmatically*. Application profiling supports this requirement with a simple interface that enables a task name to be set before a unit of work is programmatically initiated. Setting a task name and then initiating a transaction or ActivitySession causes the task to be associated with the new unit of work. This interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. See Using the TaskNameManager interface.

   Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

   For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

2. Creating an application profile.

3. Declaratively configure a unit of work on necessary methods. In step one of this article, you defined a task on a method. The task defined on a method only becomes active when a unit of work is begun on that method's behalf. The method must begin a new unit of work for the configured task to be applied. If the method runs under an imported unit of work, then the configured task on the method is ignored and the task (if any) associated with the imported unit of work is used. If the container begins a new unit of work when the method executes, then it is associated with the configured task name. Therefore, the last step in assembling applications for application profiling is to define a unit of work on any method that has a task name (and eventually an Application Profile) associated with it. A unit of work can either be a transaction or an ActivitySession. "Defining container transactions for EJB modules" on page 196 describes how to configure a transaction on an EJB module. "Configuring transactional deployment attributes" on page 1111 describes how to define other transaction attributes. "Using the ActivitySession service" on page 1120 describes how to use and create an ActivitySession unit of work. For more information about the relationships between tasks and units of work, see "Tasks and units of work considerations" on page 1141.

Automatic configuration of application profiling:

The Application Server Toolkit (AST) includes a static analysis engine that can assist you in configuring application profiling. The tool examines the compiled classes and the deployment descriptor of a Java 2 Platform, Enterprise Edition (J2EE) application to determine the entry point of transactions, calculate the set of entities enlisted in each transaction, and determine whether the entities are read or updated during the course of each identified transaction.

Application profiling requires accurate knowledge of an application's transactional configuration and the interaction of the application with its persistent state during the course of each transaction.

You can execute the analysis in either *closed world* or *open world* mode. A closed-world analysis assumes that all possible clients of the application are included in the analysis and that the resulting analysis is complete and correct. The results of a closed-world analysis report the set of all transactions that can be invoked by a web, JMS, or application client. The results exclude many potential transactions that never execute at run time.

An open-world analysis assumes that not all clients are available for analysis or that the analysis cannot return complete or accurate results. An open-world analysis returns the complete set of possible transactions.

The results of an analysis persist as an application profiling configuration. The tool establishes container managed tasks for servlets, JavaServer Pages (JSP) files, application clients, and Message Driven Beans (MDBs). Application profiles for the tasks are constructed with the appropriate access intent for the entities enlisted in the transaction represented by the task. However, in practice, there are many situations where the tool returns at best incomplete results. Not all applications are amenable to static analysis. Some factory and command patterns make it impossible to determine the call graphs. The tool does not support the analysis of *ActivitySessions*.

You should examine the results of the analysis very carefully. In many cases you must manually modify them to meet the requirements of the application. However, the tool can be an effective starting place for most applications and may offer a complete and quick configuration of application profiles for some applications.

Automatically configuring application profiles and tasks:

You can automatically configure application profiling for an application through static analysis.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server Version 6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server V6.0* type of Server Runtime.
   e. Select **Finish**
5. Be sure that the application and its modules successfully compile. To include JavaServer Pages (JSP) files in the analysis, you must precompile the pages. Also, be sure that you have configured all transactional attributes before analyzing.

6. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: Enterprise Application Name** under the Enterprise Application, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Enterprise Application project is displayed in the property pane.

7. In the property pane, select the **Extended Services** tab.

8. Beneath the *Application Profiling* table, select **Auto...**.

9. Select the projects to be analyzed and configured. Select **Next**.

10. To limit the returned results of the analysis, choose *closed world analysis*. Closed world analysis generates application profiles only if a client entry point in a message driven bean (MDB), servlet, JSP, or application client is resolved that begins a transaction and enlists entities. If closed world is not selected, the analysis returns the set of application profiles for all possible transactions represented by the application.

    Note: At this point you can also choose the **Clean** attribute. If you set this attribute, the existing configuration of selected modules is removed and the new configuration is applied. If you do not select this option, the new configuration is merged into the existing configuration.

11. Choose the concurrency for the default configuration of the access intent for generated application profiles.

12. Select **Analyze > Next**.

13. Examine the results of the analysis. Each top-level entry in the table represents a transaction identified by the analysis. The nested entries represent the callers of the transaction, the entities enlisted by the transaction, and the attributes read or modified during the course of the transaction.

14. Select **Finish** to automatically configure the container-managed tasks and application profiles represented by the analysis.

Applying profile-scoped access intent policies to entity beans:

You can configure entities with access intent for an application profile.

1. Start the Application Server Toolkit.

2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).

4. Create a new application EAR file or edit an existing one.

    For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

    a. Select **File > Import > EAR file > Next**

    b. Select the EAR file.

    c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.

    d. In the *Target server* field, select *WebSphere Application Server V6.0* type of Server Runtime.

    e. Select **Finish**

5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the application profile instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.

6. Select the **Extended Access** tab.

7. Select the **application profile** for which you want to specify the access intent.

8. Beneath the **Access Intent for Entities 2.x (Profile Level)** panel, select **Add...**

9. Select the **entities** to configure and click **Next...**.

10. Select the **access intent policy** to apply. Select **Read Ahead Hint** if a read ahead hint is desired.

11. Select **Next**.

12. **Optional:** Specify the **collection scope**

    Transaction

    > This is the default. Collections of entities cannot be used beyond the scope of the transaction in which you create the collection.

    ActivitySession

    > Collections of entities cannot be used beyond the scope of the *ActivitySession* in which you create the collection. The collection can be used in a new transaction if that transaction is nested under the original *ActivitySession*, although you might have to reload the object by querying the underlying data store.

13. **Optional:** Specify the **collection increment**. Specify a valid integer to define the chunks that populate a remote collection. This value only applies to *remote* collections and is ignored by local collections. The default for access types that result in U locks is 1. Otherwise, the default is 25.

14. **Optional:**

15. Specify the **resource manager prefetch increment**. Specify a valid integer to set as the fetch size on the JDBC statement when you execute queries for a bean type. The default is 0.

16. Select **Next**.

17. If you selected *read ahead*, choose the **preload path**.

18. Select **Finish** to apply.

19. Select **OK**.

Creating a custom access intent policy:

You can define a custom access intent policy, which can be configured for 2.x entity beans.

1. Start the Application Server Toolkit.

2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).

4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**

   b. Select the EAR file.

   c. Create a WebSphere Application Server Version 6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.

   d. In the *Target server* field, select *WebSphere Application Server V6.0* type of Server Runtime.

   e. Select **Finish**

5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.

6. In the property pane, select the **Extended Access** tab.

7. Beneath the **Defined Access Intent Policies** panel, select **Add**.

8. Specify a **unique name** by which the policy is referenced when applied to entity beans.

9. **Optional:** Specify a **description** of the policy.

10. Specify an **access type**.

11. Specify the **collection scope**.

Transaction

> This is the default. Collections of entities cannot be used beyond the scope of the transaction in which the collection is created.

ActivitySession

> Collections of entities cannot be used beyond the scope of the *ActivitySession* in which the collection is created. The collection can be used in a new transaction if that transaction is nested under the original *ActivitySession*, although you might need to reload the object by querying the underlying data store.

12. Specify the **collection increment**. Specify a valid integer to define the chunks that populate a remote collection. This value only applies to *remote* collections and is ignored by local collections. The default value for access types that result in U locks is 1. Otherwise, the default is 25.

13. Specify the **resource manager prefetch increment**. Specify a valid integer to set as the fetch size on the JDBC statement when executing queries for a bean type. The default value is 0.

Applying access intent policies to entity beans.

Creating an application profile:

An application profile contains a set of access intent policies applied to an application's entity beans. The access intent policies are only applied for requests that are associated with tasks configured on the application profile.

1. Start the Application Server Toolkit.

2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).

4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**.

   b. Select the EAR file.

   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.

   d. In the *Target server* field, select *WebSphere Application Server V6.0* type of Server Runtime.

   e. Select **Finish**.

5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.

6. In the property pane, select the **Extended Access** tab.

7. Beneath the **Application Profiles** table, select **Add...**

8. Select or type the **name** of the task for which this profile applies. You cannot map the task to any other profile within the module. The task name should have been configured already as a task on a web component (container managed task, application managed task), an application client (container managed task, application managed task), or the method of an EJB (container managed task, application managed task).

9. **Optional:** Specify a **description** of the task.

10. Select **Next**.

11. Select the entities that are enlisted in the unit of work represented by the application profile. You can add additional entities as a separate task after the profile has been created.

12. Select **Finish**.

Configuring access intent for application profiles.

Configuring container-managed tasks for application clients:

For application clients that programmatically begin either a transaction or ActivitySession only, you must configure an application client's container-managed task to associate requests from the client with an application profile.

If a unit of work is not begun, then the configured task is ignored. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: Application Client Module Name** under the application client module, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Application Client project is displayed in the property pane.
6. Select the **Extended Services** tab.
7. Enter the **name** and **description** of the task in the **Container-Managed Task** section. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

   The description is provided for your convenience; it is not used by the runtime environment.
8. Select **OK**.

Configuring container-managed tasks for Web components:

For Web components that programmatically begin either a transaction or ActivitySession only, you can configure a Web component's container-managed task to associate requests from a servlet or JavaServer Pages (JSP) file with an application profile.

If a unit of work is not begun, then the configured task is ignored. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: Web Module Name** under the web module, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the web project is displayed in the property pane.
6. Select the **Servlets** tab.
7. Select the servlet or JSP that you want to change.
8. Expand the WebSphere Programming Model Extensions section.
9. Enter the **name** and **description** of the task in the **Container-Managed Task** section. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

   The description is provided for your convenience; it is not used by the runtime environment.
10. Select **OK**.

Configuring container-managed tasks for Enterprise JavaBeans:

For methods that cause a new transaction or ActivitySession to be started either by the container or programmatically by the Enterprise JavaBean (EJB) developer, you can configure an enterprise bean's container-managed tasks to associate requests from the bean with application profiles.

Units of work begun during the execution of a method configured with a task are associated with the task name. If the method is executed under an imported transaction, then the configured task is ignored. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:
   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Extended Access** tab.
7. Beneath the **Container-Managed Tasks** table, select **Add...**.
8. Select the **bean** for which you want to configure the task.
9. Select **Next**.
10. Select the **method** for which you want to configure the task. . This method must begin a new unit of work in order for the configured task to be applied. If the method runs under an imported unit of work, then the configured task on the method is ignored. If the container begins a new unit of work when the method executes, then it is associated with the configured task name. If the method's implementation programmatically begins a new unit of work, then that unit of work is associated with the configured task name.
11. Select **Next**.
12. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

    The description is provided for your convenience; it is not used by the runtime environment.
13. Select **OK**.

Configuring application-managed tasks for application clients:

For application clients that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession, you must configure application-managed tasks so that an application client can associate requests from the client with application profiles.

If a unit of work is not begun after the task is set, then the set task is ignored. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime..
   e. Select **Finish**

5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: Application Client Module Name** under the application client module, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the Application Client project is displayed in the property pane.
6. Select the **Extended Services** tab.
7. Beneath the **Application-Managed Tasks** panel, select **Add...**.
8. Specify the name of the **task reference**. The task reference name is used programmatically by the application client. The task reference is the logical representation of the task that is used by the run time environment.
9. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

   The description is provided for your convenience, it is not used by the run time environment.
10. Select **OK**.

Configuring application-managed tasks for Web components:

For Web components that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure Web components application-managed tasks to associate requests from a servlet or JavaServer Pages (JSP) file with application profiles.

If a unit of work is not begun after the task is set, then the set task is ignored. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: Web Module Name** under the web module, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the web project is displayed in the property pane.
6. Select the **Servlets** tab.
7. Select the servlet or JSP that you want to change.
8. Expand the WebSphere Programming Model Extensions section.
9. Beneath the **Application-Managed Tasks** table, select **Add...**.
10. Specify the name of the **task reference**. The task reference name is used programmatically by the servlet or JSP. The task reference is the logical representation of the task that is used by the run time environment.
11. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

    The description is provided for your convenience; it is not used by the runtime environment.

12. Select **OK**.

Configuring application-managed tasks for Enterprise JavaBeans:

For Enterprise JavaBeans (EJB) that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure EJB application-managed tasks to associate requests from the bean with application profiles.

If a unit of work is not begun after the task is set, then the task is ignored. The task must not be performed for an enterprise bean that uses container-managed transactions or container-managed ActivitySessions. For more information about using tasks, see "Application profiling tasks" on page 1145 and "Tasks and units of work considerations" on page 1141.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**) .
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Extended Access** tab.
7. Beneath the **Application-Managed Tasks** table, select **Add...**.
8. Select the bean for which you want to configure the task.
9. Type the **name** of the task reference. The task reference name is used programmatically by the bean. The task reference is the logical representation of the task used by the runtime environment.
10. Enter the **name** and **description** of the task. The task name is mapped to application profiles and used by the run time to determine the appropriate access intent to use for enlisted entities. Task names do not have to be unique within an application. However, task names should be shared consciously and conservatively. At run time, all tasks with the same name are treated the same way, regardless of where you configured the task.

    The description is provided for your convenience; it is not used by the runtime environment.

11. Select **OK**.

Asynchronous beans

Using asynchronous beans

The asynchronous beans feature adds a new set of APIs that enable Java 2 Platform Enterprise Edition J2EE applications to run asynchronously inside an Integration Server.

This topic provides a brief overview of the tasks involved in using asynchronous beans. For a more detailed description of the asynchronous beans model, review the conceptual topic Asynchronous beans. For detailed information on the programming model for supported asynchronous beans interfaces, see the topic Work managers.

1. Configure work managers.
2. Configure timer managers.
3. Assemble applications that use asynchronous beans work managers.
4. Develop work objects to run code in parallel.
5. Develop event listeners.
6. Develop asynchronous scopes.

Asynchronous beans:

An asynchronous bean is a Java object or enterprise bean that can run asynchronously by a Java 2 Platform Enterprise Edition (J2EE) application, using the J2EE context of the asynchronous bean creator.

Asynchronous beans can improve performance by enabling a J2EE program to decompose operations into parallel tasks. Asynchronous beans support the construction of stateful, active J2EE applications. These applications address a segment of the application space that J2EE has not previously addressed (that is, advanced applications that require application threading, active agents within a server application, or distributed monitoring capabilities).

Asynchronous beans can run using the J2EE security context of the creator J2EE component. These beans also can run with copies of other J2EE contexts, such as:
* Internationalization context
* Application profiles, which are not supported for J2EE 1.4 applications and deprecated for J2EE 1.3 applications
* Work areas

Asynchronous bean interfaces

Four types of asynchronous beans exist:

Work object
> There are two work interfaces that essentially accomplish the same goal. The legacy Asynchronous Beans work interface is com.ibm.websphere.asynchbeans.Work, and the CommonJ work interface is commonj.work.Work. A work object runs parallel to its caller using the work manager `startWork` or `schedule` method (`startWork` for legacy Asynchronous Beans and `schedule` for CommonJ). Applications implement work objects to run code blocks asynchronously. For more information on the Work interface, see the API documentation.

Timer listener
> This interface is an object that implements the commonj\timers\TimerListener interface. Timer listeners are called when a high-speed transient timer expires. For more information on the TimerListener interface, see the API documentation.

Alarm listener
> An alarm listener is an object that implements the com.ibm.websphere.asynchbeans.AlarmListener

interface. Alarm listeners are called when a high-speed transient alarm expires. For more information on the AlarmListener interface, see the API documentation.

Event listener

An event listener can implement any interface. An event listener is a lightweight, asynchronous notification mechanism for asynchronous events within a single Java virtual machine (JVM). An event listener typically enables J2EE components within a single application to notify each other about various asynchronous events.

Supporting interfaces

Work manager

Work managers are thread pools that administrators create for J2EE applications. The administrator specifies the properties of the thread pool and a policy that determines which J2EE contexts the asynchronous bean inherits.

CommonJ Work manager

The CommonJ work manager is similar to the work manager. The difference between the two is that the CommonJ work manager contains a subset of the asynchronous beans work manager methods. Although CommonJ work manager functions in a J2EE 1.4 environment, each JNDI lookup of a work manager does not return a new instance of the WorkManager. All the JNDI lookup of work managers within a scope have the same instance.

Timer manager

Timer managers implement the commonj.timers.TimerManager interface, which enables J2EE applications, including servlets, EJB applications, and JCA Resource Adapters, to schedule future timer notifications and receive timer notifications. The timer manager for Application Servers specification provides an application-server supported alternative to using the J2SE `java.util.Timer` class, which is inappropriate for managed environments.

Event source

An event source implements the com.ibm.websphere.asynchbeans.EventSource interface. An event source is a system-provided object that supports a generic, type-safe asynchronous notification server within a single JVM. The event source enables event listener objects, which implement any interface to be registered. For more information on the EventSource interface, see the API documentation.

Event source events

Every event source can generate its own events, such as listener count changed. An application can register an event listener object that implements the class com.ibm.websphere.asynchbeans.EventSourceEvents. This action enables the application to catch events such as listeners being added or removed, or a listener throwing an unexpected exception. For more information on the EventSourceEvents class, see the API documentation.

Additional interfaces, including alarms and subsystem monitors, are introduced in the topic Developing Asynchronous scopes, which discusses some of the advanced applications of asynchronous beans.

Transactions

Every asynchronous bean method is called using its own transaction, much like container-managed transactions in typical enterprise beans. It is very similar to the situation when an Enterprise Java Beans (EJB) method is called with TX_NOT_SUPPORTED. The runtime starts a local transaction before invoking the method. The asynchronous bean method is free to start its own global transaction if this transaction is possible for the calling J2EE component. For example, if an enterprise bean creates the component, the method that creates the asynchronous bean must be TX_BEAN_MANAGED.

When you call an entity bean from within an asynchronous bean, for example, you must have a global transactional context available on the current thread. Because asynchronous bean objects start local transactional contexts, you can encapsulate all entity bean logic in a session bean that has a method marked as TX_REQUIRES or equivalent. This process establishes a global transactional context from which you can access one or more entity bean methods.

If the asynchronous bean method throws an exception, any local transactions are rolled back. If the method returns normally, any incomplete local transactions are completed according to the unresolved action policy configured for the bean. EJB methods can configure this policy using their deployment descriptor. If the asynchronous bean method starts its own global transaction and does not commit this global transaction, the transaction is rolled back when the method returns.

Access to J2EE component metadata

If an asynchronous bean is a J2EE component, such as a session bean, its own metadata is active when a method is called. If an asynchronous bean is a simple Java object, the J2EE component metadata of the creating component is available to the bean. Like its creator, the asynchronous bean can look up the java:comp namespace. This look up enables the bean to access connection factories and enterprise beans, just as it would if it were any other J2EE component. The environment properties of the creating component also are available to the asynchronous bean.

The `java:comp` namespace is identical to the one available for the creating component; the same restrictions apply. For example, if the enterprise bean or servlet has an EJB reference of `java:comp/env/ejb/MyEJB`, this EJB reference is available to the asynchronous bean. In addition, all of the connection factories use the same resource-sharing scope as the creating component.

Connection management

An asynchronous bean method can use the connections that its creating J2EE component obtained using java:comp resource references. (For more information on resource references, see References). However, the bean method must access those connections using a get, use or close pattern. There is no connection caching between method calls on an asynchronous bean. The connection factories or datasources can be cached, but the connections must be retrieved on every method call, used, and then closed. While the asynchronous bean method can look up connection factories using a global Java Naming and Directory Interface (JNDI) name, this is not recommended for the following reasons:
- The JNDI name is hard coded in the application (for example, as a property or string literal).
- The connection factories are not shared because there is no way to specify a sharing scope.

For code examples that demonstrate both the correct and the incorrect ways to access connections from asynchronous bean methods, see the topic Example: Asynchronous bean connection management.

Deferred start of Asynchronous Beans

Asynchronous beans support deferred start by allowing serialization of J2EE service context information. The `WorkWithExecutionContext createWorkWithExecutionContext(Work r)` method on the WorkManager interface will create a snapshot of the J2EE service contexts enabled on the WorkManager. The resulting `WorkWithExecutionContext` object can then be serialized and stored in a database or file. This is useful when it is necessary to store J2EE service contexts such as the current security identity or Locale and later inflate them and run some work within this context. The `WorkWithExecutionContext` object can run using the startWork() and doWork() methods on the WorkManager interface.

All `WorkWithExecutionContext` objects must be deserialized by the same application that serialized it. All EJBs and classes must be present in order for Java to successfully inflate the objects contained within.

Deferred start and security

The asynchronous beans security service context might require Common Secure Interoperability Version 2 (CSIv2) identity assertion to be enabled. Identity assertion is required when a `WorkWithExecutionContext` object is deserialized and run to Java Authentication and Authorization Service (JAAS) subject identity credential assignment. Review the following topics to better understand if you need to enable identity assertion, when using a `WorkWithExecutionContext` object:

- Configuring Common Secure Interoperability Version 2 and Security Authentication Service authentication protocol
- Identity Assertion

There are also issues with interoperating with `WorkWithExecutionContext` objects from different versions of the product. See Interoperating with asynchronous beans .

Work managers:

A work manager is a thread pool created for J2EE applications that use asynchronous beans.

Using the administrative console, an administrator can configure any number of work managers. The administrator specifies the properties of the work manager, including the J2EE context inheritance policy for any asynchronous beans that use the work manager. The administrator binds each work manager to a unique place in Java Naming and Directory Interface (JNDI). You can use work manager objects in any one of the following interfaces:

- Asynchronous beans
- CommonJ work manager (For details, see the CommonJ work manager section in this article.)

The selected type of interface is resolved during the JNDI lookup time. The interface type is the value that you specify in the ResourceRef, rather than the interface type specified in the configuration object. For example, you can have one ResourceRef for each interface per configuration object, and each ResourceRef lookup returns that appropriate type of instance.

The work managers provide a programming model for the J2EE 1.4 applications. For more information, see the Programming model section in this article.

When writing a Web or EJB component that uses asynchronous beans, the developer should include a resource reference in each component that needs access to a work manager. For more information on resource references, see the article References. The component looks up a work manager using a logical name in the component, java:comp namespace, just as it looks up a data source, enterprise bean or connection factory.

The deployer binds physical work managers to logical work managers when the application is deployed.

For example, if a developer needs three thread pools to partition work between bronze, silver, and gold levels, the developer writes the component to pick a logical pool based on an attribute in the client application profile. The deployer has the flexibility to decide how to map this request for three thread pools. The deployer might decide to use a single thread pool on a small machine. In this case, the deployer binds all three resource references to the same work manager instance (that is, the same JNDI name). A larger machine might support three thread pools, so the deployer binds each resource reference to a different work manager. Work managers can be shared between multiple J2EE applications installed on the same server.

An application developer can use as many logical work managers as necessary. The deployer chooses whether to map one physical work manager or several to the logical work manager defined in the application.

All J2EE components that need to share asynchronous scope objects must use the same work manager. These scope objects have an affinity with a single work manager. An application that uses asynchronous scopes should verify that all of the components using scope objects use the same work manager.

When multiple work managers are defined, the underlying thread pools are created in a Java virtual machine (JVM) only if an application within that JVM looks up the work manager. For example, there might be ten thread pools (work managers) defined, but none are actually created until an application looks these pools up.

Note: Asynchronous beans do not support submitting work to remote JVMs.

CommonJ Work Manager

The CommonJ work manager is similar to the work manager. The difference between the two is that the CommonJ work manager contains a subset of the asynchronous beans work manager methods. Although CommonJ work manager functions in a J2EE 1.4 environment, the interface does not return a new instance for each JNDI naming lookup, since this specification is not included in the J2EE specification.

Remote start of work. The CommonJ Work specification optional feature for work running remotely is not supported. Even if a unit of work implements the `java.io.Serializable` interface, the unit of work does not run remotely.

How to look up a work manager

An application can look up a work manager as follows. Here, the component contains a resource reference named `wm/myWorkManager`, which was bound to a physical work manager when the component was deployed:

```
InitialContext ic = new InitialContext();
WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
```

Inheritance J2EE contexts

Asynchronous beans can inherit the following J2EE contexts.
Internationalization context
When this option is selected and the internationalization service is enabled, and the internationalization context that exists on the scheduling thread is available on the target thread.
Work area
When this option is selected, the work area context for every work area partition that exists on the scheduling thread is available on the target thread.
Application profile (deprecated)
Application profile context is not supported and not available for J2EE 1.4 applications. For J2EE 1.3 applications, when this option is selected, the application profile service is enabled, and the application profile service property, **5.x compatibility mode**, is selected. The application profile task that is associated with the scheduling thread is available on the target thread for J2EE 1.3 applications. For J2EE 1.4 applications, the application profile task is a property of its associated unit of work, rather than a thread. This option has no effect on the behavior of the task in J2EE 1.4 applications. The scheduled work that runs in a J2EE 1.4 application does not receive the application profiling task of the scheduling thread.
Security
The asynchronous bean can be run as anonymous or as the client authenticated on the thread that created it. This behavior is useful because the asynchronous bean can do only what the caller can do. This action is more useful than a RUN_AS mechanism, for example, which prevents this kind of behavior. When you select the **Security** option, the JAAS subject that exists on the scheduling thread is available on the target thread. If not selected, the thread runs anonymously.
Component metadata
Component metadata is relevant only when the asynchronous bean is a simple Java object. If the bean is a J2EE component, such as an enterprise bean, the component metadata is active.

The contexts that can be inherited depend on the work manager used by the application that creates the asynchronous bean. Using the administrative console, the administrator defines the sticky context policy of a work manager by selecting the services on which the work manager is to be made available.

Programming model

Work managers support the following programming models.

- **CommonJ Specification**. The Application Server Version 6.0 CommonJ programming model uses the WorkManager and TimerManager to manage threads and timers asynchronously in the J2EE 1.4 environment.
- **Asynchronous beans and CommonJ specification extensions**. The current asynchronous beans Event Source, asynchronous scopes, subsystem monitors and J2EEContext interfaces are a part of the CommonJ extension.

The following table describes the method mapping between the CommonJ and Asynchronous beans APIs. You can change the current asynchronous beans interfaces to use the CommonJ interface, while maintaining the same functions.

CommonJ package	API	Asynchronous beans package	API
Work manager		Work manager	
Asynchronous beans	Field - IMMEDIATE (long)		Field - IMMEDIATE (int)
	Field - INDEFINITE		Field - INDEFINITE
	schedule(Work) throws WorkException, IllegalArgumentException		startWork(Work) throws WorkException, IllegalArgumentException
	schedule(Work, WorkListener) throws WorkException, IllegalArgumentException **Note:** Configure the work manager work timeout property to the value you previously specified as `timeout_ms` on `startWork`. The default timeout value is INDEFINITE.		startWork(Work, timeout_ms, WorkListener) throws WorkException, IllegalArgumentException
	waitForAll(workItems, timeout_ms)		join(workItems, JOIN_AND, timeout_ms)
	waitForAny(workItems, timeout_ms)		join(workItems, JOIN_OR, timeout_ms)
WorkItem		WorkItem

	 col1.add(item1);
	 col1.add(item2);
	 wm.waitForAll(col1, WorkManager.IMMEDIATE);
	 // when the works are done
	 System.out.println("work1 data="+work1.getData());
	 System.out.println("work2 data="+work2.getData());
	
	 // case 2: wait for any of the items to complete.
	 Collection finished = wm.waitForAny(col1,
	 // check the workItems status
	 if (finished != null) {
	   Iterator I = finished.iterator();
	   if (i.hasNext()) {
	     WorkItem wi = (WorkItem) i.next();
	      if (wi.equals(item1)) {
	        System.out.println("work1 =
	     "+ work1.getData());
	      } else if (wi.equals(item2)) {
	        System.out.println("work1 =
	     "+ work1.getData());
	      }
	   }
	 }
	``

Table 44. Create a timer manager

Asynchronous beans	CommonJ
| ```
InitialContext ctx  = new InitialContext();
com.ibm.websphere.asynchbeans.WorkManager wm  =
    (com.ibm.websphere.asynchbeans.WorkManager)
      ctx.lookup("java:comp/env/wm/MyWorkMgr");

AsynchScope ascope;
Try {
  Ascope = wm.createAsynchScope("ABScope");
} Catch (DuplicateKeyException ex)
{
   Ascope = wm.findAsynchScope("ABScope");
   ex.printStackTrace();
}

// get an AlarmManager
AlarmManager  aMgr= ascope.getAlarmManager();
``` | ```
InitialContext ctx  = new InitialContext();
Commonj.timers.TimerManager tm =
(commonj.timers.TimerManager)
ctx.lookup("java:comp/env/tm/MyTimerManager");
``` |

Table 45. Fire the timer

Asynchronous beans	CommonJ
| ```
// create alarm
ABAlarmListener listener = new ABAlarmListener();
Alarm am =
  aMgr.create(listener, "SomeContext", 1000*60);
``` | ```
// create Timer
TimerListener listener =
new StockQuoteTimerListener("qqq",
"johndoe@example.com");
Timer timer = tm.schedule(listener, 1000*60);

// Fixed-delay: schedule timer to expire in
// 60 seconds from now and repeat every
// hour thereafter.
Timer timer = tm.schedule(listener, 1000*60,
1000*30);

// Fixed-rate: schedule timer to expire in
// 60 seconds from now and repeat every
// hour thereafter
Timer timer = tm.scheduleAtFixedRate(listener,
1000*60, 1000*30);
``` |

Timer managers:

The timer manager combines the functions of the asynchronous beans alarm manager and asynchronous scope. So, when a timer manager is created, it internally uses an asynchronous scope to provide the timer manager life cycle functions.

You can look up the timer manager in the JNDI name space. This capability is different from the alarm manager that is retrieved through the asynchronous beans scope. Each lookup of the timer manager returns a new logical timer manager that can be destroyed independently of all other timer managers.

A timer manager can be configured with a number of thread pools through the administrative console. For deployment you can bind this timer manager to a resource reference at assembly time, so the resource reference can be used by the application to look up the timer manager.

The Java code to look up the timer manager is:

```
InitialContext ic = new InitialContext();
TimerManager tm = (TimerManager)ic.lookup("java:comp/env/tm/TimerManager");
```

The programming model for setting up the alarm listener and the timer listener is different. The following code example shows that difference.

Table 46. Set up the timer listener

Asynchronous beans	CommonJ
<pre> public class ABAlarmListener implements
AlarmListener {
     public void fired(Alarm alarm) {
        System.out.println("Alarm fired.
Context =" + alarm.getContext());
     }</pre> | <pre> public class StockQuoteTimerListener implements
 TimerListener {
 String context;
 String url;
   public StockQuoteTimerListener(String context,
   String url){
      this.context = context;
      This.url = url;
   }
   public void timerExpired(Timer timer) {
      System.out.println("Timer fired. Context ="+
((StockQuoteTimerListener)timer.getTimerListener())
.getContext());

 }
    public String getContext() {
     return context;
    }
 }</pre> |

Example: Using connections with asynchronous beans:

An asynchronous bean method can use the connections that its creating Java 2 Platform Enterprise Edition (J2EE) component obtained using java:comp resource references.

For more information on resource references, see the topic References. The following is an example of an asynchronous bean that uses connections correctly:

```
class GoodAsynchBean
{
 DataSource ds;
 public GoodAsynchBean()
  throws NamingException
 {
  // ok to cache a connection factory or datasource
  // as class instance data.
  InitialContext ic = new InitialContext();
  // it is assumed that the created J2EE component has this
  // resource reference defined in its deployment descriptor.
  ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
 }
 // When the asynchronous bean method is called, get a connection,
 //  use it, then close it.
 void anEventListener()
 {
  Connection c = null;
  try
  {
   c = ds.getConnection();
   // use the connection now...
  }
  finally
  {
   if(c != null) c.close();
  }
 }
}
```

The following example of an asynchronous bean that uses connections incorrectly:

```
class BadAsynchBean
{
 DataSource ds;
 // Do not do this. You cannot cache connections across asynch method calls.
 Connection c;

 public BadAsynchBean()
  throws NamingException
 {
  // ok to cache a connection factory or datasource as
  // class instance data.
  InitialContext ic = new InitialContext();
  ds = (DataSource)ic.lookup("java:comp/env/jdbc/myDataSource");
  // here, you broke the rules...
  c = ds.getConnection();
 }
 // Now when the asynch method is called, illegally use the cached connection
 // and you likely see J2C related exceptions at run time.
 // close it.
 void someAsynchMethod()
 {
  // use the connection now...
 }
}
```

Work manager service settings:

Use this page to enable or disable the work manager service that manages work manager resources used by the server.

To view this administrative console page, click **Servers > Application Servers >** *server_name* **> Work Manager Service** .

Startup:

Specifies whether the server attempts to start the work manager service.

Default	Selected
Range	**Selected**
	When the application server starts, it attempts to start the work manager service automatically.
	Cleared
	The server does not try to start the work manager service. If work manager resources are to be used on this server, the system administrator must start the work manager service manually or select this property then restart the server.

Assembling applications that use work managers and timer managers

The work manager and timer manager objects are both supported for assembling applications that implement the asynchronous bean technology. You can assemble either work managers or time managers.

Configure at least one work manager or timer manager using the administrative console.

Complete the steps to either assemble work managers or time managers.

1. Assemble applications that use asynchronous beans work managers.
2. Assemble applications that use CommonJ work managers.

3. Assemble applications that use CommonJ timer managers.

Assembling applications that use a CommonJ WorkManager:

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work manager.

Your administrator needs to configure at least one work manager using the administrative console.

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer.

1. Declare a resource reference for each work manager (required action by the application developer). This forms an EAR file. (For more information on resource references, see the topic References.)
2. Bind each resource reference to a physical work manager, using an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer.
3. Add a resource reference with the type commonj.work.WorkManager to the application deployment descriptor. The application can look up this work manager using its resource reference name in java:comp. Now, you can use an assembly tool or Rational Application Developer to specify which resource references are bound to the physical commonj.work.WorkManager.

   Note: The previous steps outline the same process used for data sources.

Assembling applications that use timer managers:

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical timer.

Your administrator needs to configure at least one timer manager using the administrative console.

If your application references one or more logical timer managers, the logical timer managers must be bound to one or more physical timer managers using an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer.

1. Declare a resource reference for each timer manager (required action by the application developer). This forms an EAR file. (For more information on resource references, see the topic References.)
2. Bind each resource reference to a physical timer manager, using an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer.
3. Add a resource reference with the type commonj.timers.TimerManager to the application deployment descriptor. The application then can look up this timer manager using its resource reference name in java:comp. The assembly tool or Rational Application Developer then can specify which resource references are bound to a physical timer manager.

   Note: The previous steps outline the same process used for data sources.

Assembling applications that use asynchronous beans work managers:

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work managers.

Your administrator needs to configure at least one work manager using the administrative console.

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer.

The CommonJ 1.1 interfaces are supported. Both asynchronous beans and CommonJ interfaces can use one configuration work manager object. The type of interface implemented is resolved during the JNDI lookup time. The type of interface used is determined by the one specified in the resource-reference, instead of the one specified in the configuration object. So, there can be one resource-reference for each interface, per configuration object. Each resource-reference lookup returns the appropriate type of instance. For example, there are two resource-references defined for the `wm/MyWorkManager`: `wm/ABWorkMgr` and `wm/CommonJWorkMgr`. The WebSphere Application Server run time returns the correct interface for each resource-reference lookup.

1. Declare a resource reference for each work manager (required action by the application developer). This action results in an EAR file. For more information on resource references, see the topic References.

2. Use an assembly tool, such as the Application Server Toolkit (AST) or Rational Web Developer to bind each resource reference to a physical work manager.

3. Add a resource reference with the type com.ibm.websphere.asynchbeans.WorkManager to the application deployment descriptor. The application then can look up this work manager using its resource reference name in java:comp. The assembly tool or Rational Application Developer then can specify which resource references are bound to a physical work manager.

   Note: Use the same previous steps to configure data sources.

Developing work objects to run code in parallel

You can run work objects in parallel, or in a different J2EE context, by wrapping the code in a work object.

Your administrator must have configured at least one work manager using the administrative console.

To run code in parallel, wrap the code in a work object.

1. Create a work object.

   A work object implements the com.ibm.websphere.asynchbeans.Work interface. For example:

   ```
   class SampleWork implements Work
   ```

2. Determine the number of work managers needed by this application component.

3. Look up the work manager or managers using the work manager resource reference (or logical name) in the java:comp namespace. (For more information on resource references, see the topic References.)

   ```
   InitialContext ic = new InitialContext();
   WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
   ```

   The resource reference for the work manager (in this case, `wm/myWorkManager`) must be declared as a resource reference in the application deployment descriptor.

4. Call the WorkManager.startWork() method using the work object as a parameter. For example:

   ```
   Work w = new MyWork(...);
   WorkItem wi = wm.startWork(w);
   ```

   The startWork() method can take a startTimeout parameter. This specifies a hard time limit for the Work object to be started. The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object.

5. [Optional] If your application component needs to wait for one or more of its running work objects to complete, call the WorkManager.join() method. For example:

   ```
   WorkItem wiA = wm.start(workA);
   WorkItem wiB = wm.start(workB);
   ArrayList l = new ArrayList();
   ```

```
l.add(wiA);
l.add(wiB);
if(wm.join(l, wm.JOIN_AND, 5000)) // block for up to 5 seconds
{

// both wiA and wiB finished
}
else
{

// timeout

// we can check wiA.getStatus or wiB.getStatus to see which, if any, finished.
}
```

This method takes an array list of work items which your component wants to wait on and a flag that indicates whether the component will wait for one or all of the work objects to complete. You also can specify a timeout value.

6. Use the release() method to signal the unit of work to stop running. The unit of work then attempts to stop running as soon as possible. Typically, this action is completed by toggling a flag using a thread-safe approach like the following example:

```
public synchronized void release()
{
 released = true;
}
```

The Work.run() method can periodically examine this variable to check whether the loop exits or not.

Work objects:

A work object is a type of asynchronous bean used by application components to run code in parallel or in a different J2EE context.

A work object implements the com.ibm.websphere.asynchbeans.Work interface. A work object is essentially a java.lang.Runnable object that is serializable and provides additional methods. For details, see the Interface Work in the Javadoc.

A component wanting to run work in parallel, or in a different J2EE context, locates a work manager in JNDI, then calls the WorkManager.startWork() method using the work object as a parameter.

The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object. The work item object is typically used when the component needs to wait for one or more of its running work objects to complete. The WorkManager.join() method takes an array list of work items that the component wants to wait on, and a flag indicating whether the component will wait for all or one of the work objects to complete. A timeout can be specified, which prevents the component from waiting indefinitely.

The application does not create Java 2 Developer Kit threads because they are not managed threads. Plus, these threads are not affiliated with the J2EE environment, which makes them useless inside an application server. In addition, these threads have no J2EE context (for example, a java:comp) and are not authenticated when they fire. Work object threads are fully supported by the application server and have the same properties as other asynchronous beans.

Example: Work object:

You can create a work object that dynamically subscribes to a topic and any component that has access to the event source can add an event on demand.

The following is an example of a work object that dynamically subscribes to a topic:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;

 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
  released = false;
  this.targetTopic = targetTopic;
  this.es = es;
  this.tcf = tcf;
 }

 synchronized boolean getReleased()
 {
  return released;
 }

 public void run()
 {
  try
  {
   // setup our JMS stuff.
   TopicConnection tc = tcf.createConnection();
   TopicSession sess = tc.createSession(false, Session.AUTOACK);
   tc.start();

   MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
   while(!getReleased())
   {
    // block for up to 5 seconds.
    Message msg = sess.receiveMessage(5000);
    if(msg != null)
    {
     // fire an event when we get a message
     proxy.onMessage(msg);
    }
   }
   tc.close();
  }
  catch (JMSException ex)
  {
   // handle the exception here
   throw ex;
  }
  finally
  {
   if (tc != null)
   {
    try
    {
     tc.close();
    }
    catch (JMSExceptin ex1)
    {
     // handle exception
    }
   }
  }
 }

 // called when we want to stop the Work object.
 public synchronized void release()
```

```
 {
  released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. See the Samples Gallery for details.

Developing event listeners

Application components that listen for events can use the EventSource.addListener() method to register an event listener object (a type of asynchronous bean) with the event source to which the events will be published. An event source also can fire events in a type-safe manner using any interface.

Notifications between components within a single EAR file are handled by a special event source. See the topic, Using the application notification service.

1. Create an event listener object, which can be any type. For example, see the following interface code:

   ```
   interface SampleEventGroup
   {

   void finished(String message);
   }

   class myListener implements SampleEventGroup
   {

   public void finished(String message)

   {

   // This will be called when we 'finish'.

   }
   }
   ```

2. Register the event listener object with the event source. For example, see the following code:

   ```
   InitialContext ic = ...;
   EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
   myListener l = new myListener();
   es.addListener(l);
   ```

   This enables the myListener.finished() method to be called whenever the event is fired. The following code example shows how this event might be fired:

   ```
   InitialContext ic = ...;
   EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
   myListener proxy = es.getEventTrigger(myListener.class);
   // fire the 'event' by calling the method
   // representing the event on the proxy
   proxy.finished("done");
   ```

Using the application notification service:

During the application lifetime, individual J2EE components (servlets or enterprise beans) within a single EAR file might need to signal each other. There is an event source in the java:comp namespace that is bound into all components within an EAR file that can be used for notification.

The JNDI name for this event source, in the java:comp namespace that is bound into all components within an EAR file, is:

```
java:comp/websphere/ApplicationNotificationService
```

Components within the same application can fire asynchronous events and register event listeners using this application notification service. Startup beans can be used to register these event listeners at application startup or they can be registered dynamically at run time.

To have your enterprise bean or servlet use the application notification service, write code similar to the following example:

```
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
  ic.lookup("java:comp/websphere/ApplicationNotificationService");
// now, the application can add a listener using the EventSource.addListener method.
// MyEventType is an interface.
MyEventType myListener = ...;
AppES.addListener(myListener);

// later another component can fire events as follows
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
ic.lookup("java:comp/websphere/ApplicationNotificationService");

// This highlights a constant string on the EventSource interface which
// specifies the 'java:comp/websphere/ApplicationNotificationService' string.
ic.lookup(appES.APPLICATION_NOTIFICATION_EVENT_SOURCE)
// now, the application can add a listener using the EventSource.addListener method.
MyEventType proxy = appES.getEventTrigger(MyEventType.class, false);
proxy.someEvent(someArguments);
```

Example: Event listener:

You can fire a listenerCountChanged event that produces a proxy for the interface on which the method fires. Calling the method corresponding to the event on the proxy implements the EventSourceEvents interface. The same proxy can be used to send multiple events simultaneously.

The following code example demonstrates how to fire a listenerCountChanged event:

```
// imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
 {
  try
  {
    InitialContext ic = new InitialContext();
  // Here, the asynchronous bean can access an environment variable of
  // the component which created it.
    int i = (Integer)ic.lookup("java:comp/env/countValue").intValue());
   if(newCount == i)
   {
    // do something interesting
   }
   // call this event when the following code executes:
  }
  catch(NamingException e)
  {
  }
 }
 void listenerExceptionThrown( EventSource es, Object listener,
       String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
```

```
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
    es.getEventTrigger(EventSourceEvents.class, false);

proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

The output in this example is a proxy for the interface on which the method fires. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the EventSourceEvents interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the getEventTrigger() method is `sameTransaction`. When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the event() method is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, then the current transaction (if any) on the thread is used for all of the event listeners. The event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. The order that listeners are called is undefined, and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called, which means that this action is a synchronous operation.

The parameters that references and listeners pass do not interfere with the function of these references, unless you configure the method to do so. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the sameTransaction parameter is `false` because the parameters can be accessed by multiple threads.

Developing asynchronous scopes

`Asynchronous scopes` are units of scoping that comprise a set of alarms, subsystem monitors, and child asynchronous scopes. You can create asynchronous scopes, starting with the parent.

Using asynchronous scopes can involve some or all of the following steps:

1. Create asynchronous scopes. Create the parent asynchronous scope object by using a unique parameter name that calls the AsynchScopeManager.createAsynchScope() method. You can store properties in an asynchronous scope object. This storage provides Java 2 Enterprise Edition (J2EE) applications with a way to store a non-serializable state that otherwise cannot be stored in a session bean. You also can create child asynchronous scopes, which is useful for scoping data beneath the parent.

2. Listen for alarm notifications

   a. Create a listener object by implementing the AlarmListener interface. For more information, see the AlarmListener interface in the Javadoc.

   b. Supply this object to the AlarmManager.create() method, as the target for the alarm. The create() method takes the following parameters:

      Target for the alarm
         The target on which the fired() method is called when the alarm is fired.
      Context
         The context object for the alarm. This object is useful for supplying alarm-specific data to the listener and supports a single listener for multiple alarms.

Interval

The number of milliseconds before the alarm fires.

After the specified interval, the alarm fires and the fired() method of the listener is called with the firing alarm as a parameter. The alarm object is returned. By calling methods on this object, you can cancel or reschedule the alarm.

3. Monitor remote systems.

   a. Implement a mechanism for detecting messages sent from the remote system. For example, publish and subscribe messaging.

   b. Create a subsystem manager object by calling the SubsystemMonitorManager.create() method with the following parameters:

Name Each subsystem monitor must have a unique name.

Heartbeat interval

The expected interval, in milliseconds, between heartbeats.

Missed heart beats until stale or suspect

The number of heartbeats that can be missed before the subsystem is marked as stale.

Missed heart beats until dead

The number of heartbeats that can be missed before the system is marked as dead.

   c. Create an object that implements the SubsystemMonitorEvents interface. For more information, see the SubsystemMonitorEvents in the Javadoc.

   d. Add an instance of this object to the subsystem monitor using the SubsystemMonitor.addListener() method.

   e. Whenever a heartbeat message arrives from the remote system, call the SubsystemMonitor ping() method.

The subsystem monitor configures alarms to track the heartbeat status of the remote system. When the ping() method is called, the alarms are reset. If an alarm fires, the ping() method is not called; that is, the application did not receive a heartbeat from the monitored subsystem.

Asynchronous scopes are useful in stateful server applications. An application can have a startup bean that creates an asynchronous scope on a named work manager. The application also might create subsystem monitors to monitor the health of any remote systems on which the application is dependent.

When a client attaches to the server, the application creates a child asynchronous scope that is owned by the application asynchronous scope for the client and named using the client ID. A subsystem monitor for monitoring the client might be created on the client asynchronous scope. If the client times out, a callback can clean up the client state on the server. Callbacks can be attached to the application subsystem monitors, on behalf of the client. When a remote system becomes unavailable, the client code in the server is notified and an event is sent to the client to warn that a critical remote system has failed. For example, the failure might be a data feed in an electronic trading application.

Asynchronous scopes:

An asynchronous scope (AsynchScope object) is a unit of scoping provided for use with asynchronous beans.

Asynchronous scopes are collections of alarms, subsystem monitors, and child asynchronous scopes that enable a relationship to form. Each asynchronous scope uses a single work manager.

Each AsynchScope object owns and controls the life cycle of the following objects:

Child asynchronous scopes

Each AsynchScope object extends the AsynchScopeManager interface, which is a factory for AsynchScope objects. (For more information on the AsynchScopeManager interface, see the API documentation). Any asynchronous scope can therefore create named asynchronous scopes

(children). Child asynchronous scopes can be useful for scoping data underneath the parent. All of the child asynchronous scopes must be uniquely named. These children are destroyed if the parent asynchronous scope is destroyed.

Alarms

Each asynchronous scope has an associated alarm manager. All of the alarms created by the alarm manager are automatically cancelled if the associated asynchronous scope is destroyed.

Subsystem monitors

Each asynchronous scope has a subsystem monitor manager, which manages a set of subsystem monitors associated with the asynchronous scope. When the asynchronous scope is destroyed, all of the associated subsystem monitors also are destroyed.

In summary, asynchronous scopes can be organized into an acyclic tree. The life cycle of each asynchronous scope is directly coupled to that of its parent asynchronous scope. Each asynchronous scope is associated with a set of alarms and subsystem monitors, and an optional set of child asynchronous scopes. These objects are cancelled and destroyed when the asynchronous scope is destroyed.

Asynchronous scope state

Each asynchronous scope has an associated map, in which applications can store their state in the form of name and value pairs.

Asynchronous scope events

Each asynchronous scope is also an event source. Applications can therefore register event listeners against the asynchronous scope. The event listeners can receive notification if, for example, the AsynchScope object is about to be destroyed.

Applications also can use this event source to fire events only to listeners of this asynchronous scope. For example, an AsynchScope object created for a client session might be used to fire asynchronous events to parties interested in that client.

Alarms:

An alarm runs Java 2 Enterprise Edition (J2EE) context-aware code at a given time interval. Alarm objects are fine-grained, nonpersistent, transient, and can fire at millisecond intervals.

Alarms are run using a thread pool associated with the work manager that owns the associated asynchronous scope. You must create a work manager instance to create an alarm. See the topic Configuring work managers for more information.

The AlarmManager.createAlarm() method takes an application-written object that implements the AlarmListener interface. For more information on the AlarmListener interface, see the Javadoc. The fired method is called when the alarm expires. The createAlarm() method returns a non-serializable handle, which can be used to cancel or reset the alarm. All of the pending alarms are cancelled when its associated AsynchScope object is destroyed.

best-practices: The Java 2 Software Development Kit (SDK) already has a timer mechanism, so why create a new one? The Java 2 SDK is a Java 2 Platform Standard Edition (J2SE) feature that knows nothing about the J2EE environment. Timers fired by the J2SE feature do not run on a managed thread and are therefore unusable inside an application server. These timers also lack a J2EE context (that is, a java:comp value) and are not authenticated when they fire. The asynchronous scope alarms are fully supported by the product and have the same properties as any other asynchronous bean.

Alarm performance

The alarm subsystem is designed to handle a large number of alarms. However, do not expect alarms to process heavy loads when they are firing because this activity slows the processing of later alarms. If an alarm needs to process a heavy load, design a work object that is activated by a work manager. This procedure moves the heavy processing to a different thread and enables the alarm threads to process alarms unhampered. All of the alarms owned by asynchronous scopes that are owned by a single work manager share a common thread pool. The properties of this thread pool can be tuned at the work manager level using the administrative console.

Subsystem monitors:

A subsystem monitor is an object that monitors the health of a remote system. It uses an event source to inform all registered listeners of the health of the system.

Advanced Java 2 Platform Enterprise Edition (J2EE) applications often rely on remote, non-managed, non-J2EE systems. These remote systems can periodically send clients a message to indicate that they are working. A subsystem monitor is a set of alarms that tracks indicator messages or heart beats from a remote system.

An application creates a subsystem monitor by calling the SubsystemMonitorManager.create() method with the following parameters:

Name   Each subsystem monitor must be uniquely named.

Heart beat interval
> The time period, in milliseconds, between arriving heart beat messages.

Missed heart beats until stale or suspect
> The number of heart beats that can be missed before the subsystem is marked as stale. This designation indicates that the subsystem might be having problems.

Missed heart beats until dead
> The number of heart beats that can be missed before the system is considered down. The system then is marked as dead.

The subsystem monitor configures alarms to track the heart beat status. Whenever the ping() method is called, the alarms are reset. If an alarm fires, the ping() method has not been called; that is, the application did not receive a heart beat from the monitored subsystem. When the number of **Missed heart beats until stale** value has elapsed without a ping, a stale event is fired. Later, if the number of **Missed heart beats until dead** value elapses without a ping, a dead event is fired. If a ping is received after a stale or dead notification, a fresh event is sent, which indicates that the subsystem is alive again.

Make the **Missed heart beats until dead** value greater or equal to the **Missed heart beats until stale** value. If **Missed heart beats until stale** value equals the **Missed heart beats until dead** value, then a stale event is not published. Only a dead event is published.

You can register a listener that implements the SubsystemMonitorEvents interface for applications that require notification of events. For more information on the SybsystemMonitorEvents interface, see the Javadoc.

Heart beat messages can be transmitted using a variety of mechanisms. The application must call the SubsystemMonitor ping() method whenever a heart beat message arrives from a remote system, but the method used to detect these messages is up to the application. For example, you might use a Java Message Service (JMS) publish or subscribe implementation or even a third-party Java messaging product that does not implement JMS.

Asynchronous scopes: Dynamic message bean scenario:

Java 2 Platform Enterprise Edition (J2EE) now supports message-driven beans, but the beans are static. This scenario provides information about how to set up the environment to enable the dynamic message bean.

All of the message sources must be known in advance and bound at deployment time. This action is not always viable, especially in fluid messaging environments such as those found in brokerages. Some environments have publish-subscribe topic spaces that are continually changing and clients need servers that can subscribe on demand to an arbitrary topic.

An asynchronous bean application can create a work object that performs a blocking receive on a Java Message Service (JMS) topic and then publishes the message as an event on an application-defined event source. Clients requiring a subscription to that message can add an event listener to the event source. The event source can inform the work object when there are no listeners. Then, the event source can shut down and make the JMS and thread resources available. The work object registers a listener with its own event source. When the count is one again, the work object knows that it is the only listener and it is time to shut down the work object. The WebSphere Trader Sample (see your installed Samples Gallery) uses this pattern to dynamically subscribe to JMS topics at run time to gather stock prices. For more information, see an overview of the samples.

How does the server catch clients that disconnect or crash? It creates a subsystem monitor to watch the client and adds an event listener to catch dead events. When a dead event occurs, the server application can clean up the client server state. For example, the server application can remove the client event listener from the dynamic message bean, thereby allowing the server to subscribe to a dynamic topic only when it is needed.

Dynamic cache

Task overview: Using the dynamic cache service to improve performance
Use the dynamic cache service to improve application performance by caching the output of servlets, commands, and JavaServer Pages (JSP) files.

The dynamic cache service works within an application server Java virtual machine (JVM), intercepting calls to cacheable objects. For example, it intercepts calls through a servlet service method or a command execute method, and either stores the output of the object to the cache or serves the content of the object from the dynamic cache.

1. Enable the dynamic cache service globally. To use the features associated with dynamic caching, you must enable the service in the administrative console. See Enabling the dynamic cache service for more information.
2. Configure the type of caching that you are using:
    *   Configuring servlet caching.
    *   Configuring portlet fragment caching.
    *   Configuring Edge Side Include caching.
    *   Configuring command caching.
    *   "Example: Caching Web services" on page 1182.
    *   Configuring the Web services client cache.
3. Monitor the results of your configuration using the dynamic cache monitor. For more information, see Displaying cache information.
4. If you have any problems with your configuration, see the *Troubleshooting and support* PDF.

To use the DistributedMap and DistributedObjectCache interfaces for the dynamic cache, see "Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache" on page 1196.

Dynamic cache:

Caching the output of servlets, commands, and JavaServer Pages (JSP) improves application performance. WebSphere Application Server consolidates several caching activities including servlets, Web services, and WebSphere commands into one service called the *dynamic cache*. These caching

activities work together to improve application performance, and share many configuration parameters that are set in the dynamic cache service of an application server.

You can use the dynamic cache to improve the performance of servlet and JSP files by serving requests from an in-memory cache. Cache entries contain servlet output, the results of a servlet after it runs, and metadata.

Eviction policies using the disk cache garbage collector:

The disk cache garbage collector is responsible for evicting objects out of the disk cache, based on a specified eviction policy.

The garbage collector keeps a certain amount of space on disk available, which is governed by the configuration attribute that limits the amount of disk space that is used for caching objects. To enable the eviction policy, enable the Limit disk cache size in GB and/or Limit disk cache size in entries options in the administrative console.

The garbage collector is triggered when the disk space reaches a specified high threshold (a percentage of the Limit disk cache size in entries or in GB) and evicts objects, based on the eviction policy, from the disk in the background until the disk cache size reaches a specified low threshold (a percentage of the Limit disk cache size in entries or in GB). Eviction triggers when one or both of the high thresholds is reached for Limit disk cache size in GB and Limit disk cache size in entries. The supported policies are:

- None: This is the default policy. Objects are evicted only when they expire, or if they are invalidated.
- Random: The expired objects are removed first. If the disk size still has not reached the low threshold limit, objects are picked from the disk cache in random order and removed until the disk size reaches a low threshold limit.
- Size: The expired objects are removed first. If the disk size still has not reached the low threshold limit, then largest-sized objects are removed until the disk size reaches a low threshold limit.

Limit disk cache size in GB and High Threshold determines when to trigger eviction and when the disk cache is considered near full. It is computed as a function of the user-specified limit. If the specified limit is *10* GB (3 GB is the minimum), the cache subsystem initially creates three files that can grow to 1 GB in size for cache data, dependency ID information, and template information. Each time more space is needed to contain cache data, dependency ID information, or template information, a new file is created. Each of these files grow in 1 GB increments until the total number of files that are created is equal to disk cache in size in GB (in this case ten). Although the initial size of the new file may be much smaller than 1 GB, the dynamic cache service always rounds up to the next GB.

Eviction triggers when the cache data size reaches the high threshold and continues until the cache data size reaches the low threshold. Calculation of cache data size is dynamic. The following formula describes how to calculate the actual cache data size limit:

```
cache data size limit = disk cache size (in GB) - number of dependency files per GB - number of template files
```

When the cache data size limit is defined, the trigger point is calculated as follows:

```
eviction trigger point = cache data size limit * high threshold
size of evicted entries = cache data size * (high threshold - low threshold)
```

Consider the following scenarios:
- **Scenario 1**
  - Disk cache size in GB = 10 GB
  - High threshold = 90%
  - Low Threshold = 80%
  Initially, there is one file for dependency ID and template ID.

```
cache data size limit = 10-(1+1) = 8 GB
eviction trigger point = 8 * 90% = 7.2 GB
size of evicted entries = 8 * (90% - 80%) = 0.8 GB
```

In the above scenario, eviction starts when the data cache size reaches 7.2 GB and continues until the cache size is 6.4 GB (7.2 - 0.8).

- **Scenario 2**

  In scenario 1, if the dependency files grow to more than 1 GB, an additional dependency file generates. The eviction trigger point launches dynamically as follows:

```
cache data size limit = 10 - (2+1) = 7GB
eviction trigger point = 7 * 90% = 6.3GB
size of evicted entries = 7 * (90% - 80%) = 0.7GB
```

  In the above scenario, eviction starts when the data cache size reaches 6.3 GB, and continues until the cache size in 5.6 GB (6.3 - 0.7).

Disk cache eviction for limit disk cache size in entries. Consider the following scenario:

- Disk cache size in entries = 100000

- High threshold = 90%

- Low threshold = 80%

```
eviction trigger point = 100000 * 90% = 90000
number of entries evicted = 100000 * (90% - 80%) = 10000
```

In this scenario, eviction starts when the number of cache entries reaches 90000 and 10000 entries are evicted from the cache.

Example: Caching Web services:

This topic includes examples of building a set of cache policies and SOAP messages for a Web services application.

The following is a example of building a set of cache policies for a simple Web services application. The application in this example stores stock quotes and has operations to read, update the price of, and buy a given stock symbol.

Following are two SOAP message examples that the application can receive, with accompanying HTTP Request headers.

The first message sample contains a SOAP message for a GetQuote operation, requesting a quote for IBM. This is a read-only operation that gets its data from the back end, and is a good candidate for caching. In this example the SOAP message is cached and a timeout is placed on its entries to guarantee the quotes it returns are current.

Message example 1

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-lookup
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:getQuote xmlns:m="urn:stockquote">
<symbol>IBM</symbol>
</m:getQuote>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The SOAPAction HTTP header in the request is defined in the SOAP specification and is used by HTTP proxy servers to dispatch requests to particular HTTP servers. WebSphere Application Server dynamic cache can use this header in its cache policies to build IDs without having to parse the SOAP message.

Message example 2 illustrates a SOAP message for a BuyQuote operation. While message 1 is cacheable, this message is not, because it updates the back end database.

Message example 2

```
POST /soap/servlet/soaprouter
HTTP/1.1
Host: www.myhost.com
Content-Type: text/xml; charset="utf-8"
SOAPAction: urn:stockquote-update
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<m:buyStock xmlns:m="urn:stockquote">
<symbol>IBM</symbol>
</m:buyStock>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The following graphic illustrates how to invoke methods with the SOAP messages. In Web services terms, especially Web Service Definition Language (WSDL), a service is a collection of operations such as getQuote and buyStock. A body element namespace (urn:stockquote in the example) defines a service, and the name of the first body element indicates the operation.

The following is an example of WSDL for the getQuote operation:

```
<?xml version="1.0"?>
<definitions name="StockQuoteService-interface"
targetNamespace="http://www.getquote.com/StockQuoteService-interface"
xmlns:tns="http://www.getquote.com/StockQuoteService-interface"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns=soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns="http://schemas.xmlsoap.org/wsdl/"
<message name="SymbolRequest">
<part name="return" type="xsd:string"/>
</message>
<portType name="StockQuoteService">
<operation name="getQuote">
<input message="tns:SymbolRequest"/>
<output message="tns:QuoteResponse"/>
</operation>
</portType>
<binding name="StockQuoteServiceBinding"
type="tns:StockQuoteService">
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
<operation name="getQuote">
```

```
<soap:operation soapAction="urn:stockquote-lookup"/>
<input>
<soap:body use="encoded" namespace="urn:stockquote"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
</input>
<output>
<soap:body use="encoded" namespace="urn:stockquotes"
encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
</output>
</operation>
</binding>
</definition>
```

To build a set of cache policies for a Web services application, configure WebSphere Application Server dynamic cache to recognize cacheable service operation of the operation.

WebSphere Application Server inspects the HTTP request to determine whether or not an incoming message can be cached based on the cache policies defined for an application. In this example, buyStock and stock-update are not cached, but stockquote-lookup is cached. In the `cachespec.xml` file for this Web application, the cache policies need defining for these services so that the dynamic cache can handle both SOAPAction and service operation.

WebSphere Application Server uses the operation and the message body in Web services cache IDs, each of which has a component associated with them. Therefore, each Web services `<cache-id>` rule contains only two components. The first is for the operation. Because you can perform the stockquote-lookup operation by either using a SOAPAction header or a service operation in the body, you must define two different `<cache-id>` elements, one for each method. The second component is of type "body", and defines how WebSphere Application Server should incorporate the message body into the cache ID. You can use a hash of the body, although it is legal to use the literal incoming message in the ID.

The incoming HTTP request is analyzed by WebSphere Application Server to determine which of the `<cache-id>` rules match. Then, the rules are applied to form cache or invalidation IDs.

The following is sample code of a `cachespec.xml` file defining SOAPAction and servicesOperation rules:

```
<cache>
<cache-entry>
 <class>webservice</class>
 <name>/soap/servlet/soaprouter</name>
 <sharing-policy>not-shared</sharing-policy>
 <cache-id>
  <component id="" type="SOAPAction">
   <value>urn:stockquote-lookup</value>

   <priority>1</priority>
  </component>
 </cache-id>
</cache-entry>
</cache>
```

Dynamic cache MBean statistics:

The dynamic cache service provides an MBean interface to access cache statistics.

Access cache statistics with the MBean interface, using JACL

- Obtain the MBean identifier with the **queryNames** command, for example:

  ```
  $AdminControl queryNames type=DynaCache,*  // Returns a list of the available dynamic cache MBeans
  ```

  Select your dynamic cache MBean and run the following command:

  ```
  set mbean <dynamic_cache_mbean>
  ```

- Retrieve the names of the available cache statistics:

  ```
  $AdminControl invoke $mbean getCacheStatisticNames
  ```

- Retrieve the names of the available cache instances:

  ```
  $AdminControl invoke $mbean getCacheInstanceNames
  ```

- Retrieve all of the available cache statistics for the base cache instance:

  ```
  $AdminControl invoke $mbean getAllCacheStatistics
  ```

- Retrieve all of the available cache statistics for the named cache instance:

  ```
  $AdminControl invoke $mbean getAllCacheStatistics "services/cache/servletInstance_4"
  ```

- Retrieve cache statistics that are specified by the names array for the base cache instance:

  ```
  $AdminControl invoke $mbean getCacheStatistics
   {"DiskCacheSizeInMB ObjectsReadFromDisk4000K RemoteObjectMisses"}
  ```

  Note: This command should all be entered on one line. It is broken here for printing purposes.

- Retrieve cache statistics that are specified by the names array for the named cache instance:

  ```
  $AdminControl invoke $mbean getCacheStatistics
   {services/cache/servletInstance_4 "ExplicitInvalidationsLocal CacheHits"}
  ```

  Note: This command should all be entered on one line. It is broken here for printing purposes.

Example: Configuring the dynamic cache:

This example puts all the steps together for configuring the dynamic cache with the `cachespec.xml` file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose that a servlet is used to manage a simple news site. This servlet uses the query parameter ″action″ to determine if the request is being used to ″view″ news or ″update″ news (used by the administrator). Another query parameter ″category″ is used to select the news category. Suppose that this site supports an optional customized layout that is stored in the user's session using the attribute name ″layout″. Here are example URL requests to this servlet:

http://*yourhost/yourwebapp*/newscontroller?action=view&category=sports (Returns a news page for the sports category)

http://*yourhost/yourwebapp*/newscontroller?action=view&category=money (Returns a news page for the money category)

http://*yourhost/yourwebapp*/newscontroller?action=update&category=fashion (Allows the administrator to update news in the fashion category)

Here are the steps for configuring dynamic cache for this example with the `cachespec.xml` file:
1. Define the <cache-entry> elements necessary to identify the servlet. In this case, the servlet's URI is ″newscontroller″ so this is the cache-entry's <name> element. Because this example caches a servlet or JavaServer Pages (JSP) file, the cache entry class is ″servlet″.

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet  </class>
 </cache-entry>
```

2. Define cache ID generation rules. This servlet is cached only when action=view, so one component of the cache ID is the parameter ″action″ when the value equals ″view″. The news category is also an essential part of the cache ID. Finally, the optional session attribute for the user's layout is included in the cache ID. The cache entry now is :

```
<cache-entry>
 <name> /newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
</cache-entry>
```

3. Define dependency ID rules. For this servlet, a dependency ID is added for the category. Later, when the category is invalidated due to an update event, all views of that news category are invalidated. Following is an example of the cache entry after adding the dependency-id:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

4. Define invalidation rules. Since a category dependency ID is already defined, define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, we will add ″ignore-value″ components into the invalidation rule. These components do not add to the output of the invalidation ID, but only determine whether or not the invalidation ID is created and run. The final cache-entry now looks like this:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
```

```
    <component id="layout" type="session">
     <required>false</required>
    </component>
   </cache-id>
   <dependency-id>category
    <component id="category" type="parameter">
     <required>true</required>
    </component>
   </dependency-id>
   <invalidation>category
    <component id="action" type="parameter" ignore-value="true">
     <value>update</value>
     <required>true</required>
    </component>
    <component id="category" type="parameter">
     <required>true</required>
        </component>
   </invalidation>
  </cache-entry>
```

Accessing dynamic cache PMI counters:

The dynamic cache statistics interface is defined as WSDynamicCacheStats under the
com\ibm\websphere\pmi\stat package.

Dynamic cache statistics are structured as follows in the Performance Monitoring Infrastructure (PMI) tree:

```
__Dynamic Caching+
  |
  |__<Servlet: instance_1>
   |__Templates+
      |__<template_1>
      |__<template_2>
   |__Disk+
      |__<Disk Offload Enabled>
  |
  |__<Object: instance_2>
   |__Object Cache+
      |__<Counters>
+ indicates logical group
```

StatDescriptor locates and accesses particular statistics in the PMI tree. For example:

1. StatDescriptor to represent statistics for cache servlet: `instance_1 templates group template_1:` new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, ″Servlet: instance1″, WSDynamicCacheStats.TEMPLATE_GROUP, ″template_1″});

2. StatDescriptor to represent statistics for cache servlet: `instance_1 disk group Disk Offload Enabled:` new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, ″Servlet: instance_1″, WSDynamicCacheStats.DISK_GROUP, WSDynamicCacheStats.DISK_OFFLOAD_ENABLED});

3. StatDescriptor to represent statistics for cache object: `instance2 object cache group Counters:` new StatDescriptor (new String[] {WSDynamicCacheStats.NAME, ″Object: instance_2″, WSDynamicCacheStats.OBJECT_GROUP, WSDynamicCacheStats.OBJECT_COUNTERS});

Important: Cache instance names are prepended with cache type (″Servlet: ″ or ″Object: ″).

Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache

By using the DistributedMap or DistributedObjectCache interfaces, Java 2 platform, Enterprise Edition (J2EE) applications and system components can cache and share Java objects by storing a reference to the object in the cache.

Enable the dynamic cache service. See Enabling the dynamic cache service for more information.

The DistributedMap and DistributedObjectCache interfaces are simple interfaces for the dynamic cache. Using these interfaces, J2EE applications and system components can cache and share Java objects by storing a reference to the object in the cache. The default dynamic cache instance is created if the dynamic cache service is enabled in the administrative console. This default instance is bound to the global Java Naming and Directory Interface (JNDI) namespace using the name services/cache/distributedmap.

Multiple instances of the DistributedMap and DistributedObjectCache interfaces on the same Java virtual machine (JVM) enable applications to separately configure cache instances as needed. Each instance of the DistributedMap interface has its own properties that can be set using "Object cache instance settings" on page 1198.

Tip: For more information about the DistributedMap and DistributedObjectCache interfaces, see the API documentation for the com.ibm.websphere.cache package. See "Reference: Generated API documentation" on page 26 for more information.

Important: If you are using custom object keys, you must place your classes in a shared library. You can define the shared library at cell, node, or server level. Then, in each server create a class loader and associate it with the shared library that you defined. See the *Setting up the application serving environment* PDF for more information.

There are three methods for configuring and using cache instances.

- **Method 1 - Administrative console** You can create additional cache instances using the administrative console.

    1. In the administrative console, select **Resources > Object cache instances** and create a new object cache instance.

    If you defined two object cache instances in the administrative console with JNDI names of **services/cache/instance_one** and **services/cache/instance_two**, you can use the following code to look up the cache instances:

    ```
     InitialContext ic = new InitialContext();
    DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");

    DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");

    // or

    InitialContext ic = new InitialContext();
    DistributedObjectCache dm1 = (DistributedObjectCache)ic.lookup("services/cache/instance_one");

    DistributedObjectCache dm2 = (DistributedObjectCache)ic.lookup("services/cache/instance_two");
    ```

- **Method 2 - Properties file** You can create cache instances using the `cacheinstances.properties` file and package the file in your Enterprise Archive (EAR) file.

    Following is an example of how you can create additional cache instances using the `cacheinstances.properties` file:

    ```
    cache.instance.0=/services/cache/instance_one

    cache.instance.0.cacheSize=1000
    ```

```
cache.instance.0.enableDiskOffload=true

cache.instance.0.diskOffloadLocation=${app_server_root}/diskOffload

cache.instance.0.flushToDiskOnStop=true

cache.instance.0.useListenerContext=true

cache.instance.0.enableCacheReplication=false

cache.instance.0.disableDependencyId=false

cache.instance.0.htodCleanupFrequency=60

cache.instance.1=/services/cache/instance_two

cache.instance.1.cacheSize=1500

cache.instance.1.enableDiskOffload=false

cache.instance.1.flushToDiskOnStop=false

cache.instance.1.useListenerContext=false

cache.instance.1.enableCacheReplication=true

cache.instance.1.replicationDomain=DynaCacheCluster

cache.instance.1.disableDependencyId=true
```
The preceding example creates two cache instances named `instance_one` and `instance_two`. `instance_one` has a cache entry size of 1,000 and `instance_two` has a cache entry size of 1,500. Disk offload is enabled in `instance_one` and disabled in `instance_two`. Use listener context is enabled in `instance_one` and disabled in `instance_two`. Flush to disk on stop is enabled in `instance_one` and disabled in `instance_two`. Cache replication is enabled in `instance_two` and disabled in `instance_one`. The name of the data replication domain for `instance_two` is DynaCacheCluster. Dependency ID support is disabled in `instance_two`.

You must place the `cacheinstances.properties` file in either your application server or application class path. For example, you can use your application `WAR` file, `WEB-INF\classes` directory, or `was_root\classes` directory. The first entry in the properties file (`cache.instance.0`) specifies the JNDI name for the cache instance in the global namespace. You can use the following code to look up the cache instance:

```
InitialContext ic = new InitialContext();
DistributedMap dm1 = (DistributedMap)ic.lookup("services/cache/instance_one");
DistributedMap dm2 = (DistributedMap)ic.lookup("services/cache/instance_two");
```

For more information about the DistributedMap and DistributedObjectCache interfaces, see the API documentation for the `com.ibm.websphere.cache` package.

- **Method 3 - Resource references**

Note: Method three is an extension to method one or method two, listed above. First use either method one or method two.

Define a resource-ref in your module deployment descriptor (`web.xml` and `ibm-web-bnd.xmi` files) and look up the cache using the `java:comp` namespace.

Resource-ref example:
File: web.xml
```
<resource-ref id="ResourceRef_1">
  <res-ref-name>dmap/LayoutCache</res-ref-name>
  <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
  <res-auth>Container</res-auth>
  <res-sharing-scope>Shareable</res-sharing-scope>
```

```
   </resource-ref>
   <resource-ref id="ResourceRef_2">
     <res-ref-name>dmap/UserCache</res-ref-name>
     <res-type>com.ibm.websphere.cache.DistributedMap</res-type>
     <res-auth>Container</res-auth>
     <res-sharing-scope>Shareable</res-sharing-scope>
   </resource-ref>

   File: ibm-web-bnd.xmi
   <?xml version="1.0" encoding="UTF-8"?>
   <webappbnd:WebAppBinding xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
   xmlns:webappbnd="webappbnd.xmi"
   xmlns:webapplication="webapplication.xmi" xmlns:commonbnd="commonbnd.xmi"
   xmlns:common="common.xmi"
   xmi:id="WebApp_ID_Bnd" virtualHostName="default_host">
     <webapp href="WEB-INF/web.xml#WebApp_ID"/>
     <resRefBindings xmi:id="ResourceRefBinding_1" jndiName="services/cache/instance_one">
       <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_1"/>
     </resRefBindings>
     <resRefBindings xmi:id="ResourceRefBinding_2" jndiName="services/cache/instance_two">
       <bindingResourceRef href="WEB-INF/web.xml#ResourceRef_2"/>
     </resRefBindings>
   </webappbnd:WebAppBinding>
```

The following example shows how to look up the resource-ref:

```
InitialContext ic = new InitialContext();
  DistributedMap dm1a =(DistributedMap)ic.lookup("java:comp/env/dmap/LayoutCache");
  DistributedMap dm2a =(DistributedMap)ic.lookup("java:comp/env/dmap/UserCache");
// or
  DistributedObjectCache dm1a =(DistributedObjectCache)ic.lookup("java:comp/env/dmap/LayoutCache");
  DistributedObjectCache dm2a =(DistributedObjectCache)ic.lookup("java:comp/env/dmap/UserCache");
```

The previous resource-ref example maps `java:comp/env/dmap/LayoutCache` to `/services/cache/instance_one` and `java:comp/env/dmap/UserCache` to `/services/cache/instance_two`. In the examples, `DistributedMap dm1` and `dm1a` are the same object. `DistributedMap dm2` and `dm2a` are the same object.

Restriction: DistributedMap and DistributedObjectCache do not have authorization or access control associated with the cache entries.

To learn how to share cached objects in a clustered environment, see "Shared cached objects in a clustered environment."

Shared cached objects in a clustered environment:

This section discusses what you should do when sharing cached objects in a clustered environment.

In a clustered environment, the content you place in cache might be shared with other servers in the cluster. The content might also be offloaded to disk. If you intend to have the cached objects shared or offloaded to disk, you must make these particular objects serializable. If the objects you place in cache are non-serializable, you must specify that the sharing policy for these objects is not shared. The DistributedMap interface DistributedMap interface contains information about how to specify the sharing policy for a cached object. Specifying a sharing policy other than not shared for non-serializable objects can result in poor system performance.

Object cache instance settings:

An object cache instance is a location, in addition to the default shared dynamic cache, where any Java 2 Platform, Enterprise Edition (J2EE) application can store, distribute, and share data. This gives applications greater flexibility and better tuning of the cache resources. Use the DistributedMap programming interface to access this cache instance. See the API documentation for more information.

To view this administrative console page, click **Resources > Cache instances > Object cache instances > *cache_instance_name*.**

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The results return a `DistributedMap` object.

Description:

Specifies a description for the resource. This field is optional.

Category:

Specifies a category string to classify or group the resource. This field is optional.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands.

Default	2000
Range	100 - 200,000

Default priority:

Specifies the default priority for servlets that can be cached. This value determines how long an entry stays in a full cache.

The recommended value is one. The range is one through 255.

Enable disk offload:

Specifies if disk offloading is enabled.

If you have disk offload disabled, when a new entry is created while the cache is full, the priorities are configured for each entry and the least recently used algorithm are used to remove the entry from the cache in memory. If you enable disk offload, the entry that would be removed from the cache is copied to the local file system. The location of the file is specified by the disk offload location.

Default	false

Offload location:

Specifies the directory that is used for disk offload.

If disk offload location is not specified, the default location, `${WAS_TEMP_DIR}/`*node*`/`*server name*`/_dynacache/`*cache JNDI name* will be used. If disk offload location is specified, the node, server name, and cache instance name are appended. For example, `${USER_INSTALL_ROOT}/diskoffload` generates the location as `${USER_INSTALL_ROOT}/diskoffload/`*node*`/`*server name*`/`*cache JNDI name*. This value is ignored if disk offload is not enabled.

The default value of the ${WAS_TEMP_DIR} property is ${USER_INSTALL_ROOT}/temp. If you change the value of the ${WAS_TEMP_DIR} property after starting WebSphere Application Server, but do not move the disk cache contents to the new location:

- The Application Server creates a new disk cache file at the new disk offload location.
- If the Flush to disk setting is enabled, all the disk cache content at the old location is lost when you restart the Application Server

Flush to disk:

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if `Enable Disk Offload` is not selected.

Default	false

Limit disk cache size in GB:

Specifies a value for the maximum disk cache size in GB. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.

Limit disk cache size in entries:

Specifies a value for the maximum disk cache size in number of entries. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.

Limit disk cache entry size:

Specifies a value for the maximum size of an individual cache entry in MB. Any cache entry larger than this, when evicted from memory, will not be offloaded to disk. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.

Performance settings:

Specifies the level of performance that is required by the disk cache. This setting applies only if **enableDiskOffload** is specified for the cache. Performance levels determine how memory resources should be used on background activity such as cache cleanup, expiration, garbage collection, and so on. This setting applies only if enable disk offload is specified for the cache.

High performance and high memory usage	Indicates that all metadata will be kept in memory.
Balanced performance and balanced memory usage	Indicates some metadata will be kept in memory. This is the default performance setting and will provide an optimal balance of performance and memory usage for most users.
Low performance and low memory usage	Indicates that limited metadata will be kept in memory.

Custom performance	Indicates that the administrator will explicitly configure the memory settings that will be used to support the above background activity. The administrator sets these values using the **DiskCacheCustomPerformanceSettings** object.

Disk cache cleanup frequency:

Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.

Value	0 to 1440

Maximum buffer for cache identifiers per metaentry:

Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk offload performance level is custom.

Value	100 to MAXINT

Maximum buffer for dependency identifiers:

Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	100 to MAXINT

Maximum buffer for templates:

Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	10 to MAXINT

Eviction policy algorithm:

Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached. This setting applies only if enable disk offload is specified for the cache.

None	No eviction policy, so the disk cache can grow until it reaches its limit at which time the dynamic cache service stops writing to disk
Random	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and randomly picks entries on the disk and evicts them until the size reaches a low threshold limit.

Size	When the disk size reaches a high threshold limit, the disk cache garbge collector wakes up and picks the largest entries on the disk and evicts them until the disk size reaches a low threshold limit.

High threshold:

Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The disk cache garbage collector is awaken when the disk size exceeds high threshold limit. The lower value limits disk cache size in GB and disk cache size in entries. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100

Low threshold:

Specifies when the eviction policy ends. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value limits disk cache size in GB and disk cache size in entries. The disk cache garbage collector, when awaken, evicts entries until the disk size reaches the low threshold limit. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100

Use listener context:

Set this value to true to have invalidation events sent to registered invalidation listeners using the Java 2 Platform, Enterprise Edition (J2EE) context of the listener. If you want to use listener J2EE context for callback, set this value to **true**. If you want to use the caller thread context for callback, set this to **false**.

Dependency ID support:

Specifies that the dynamic cache service, supports cache entry dependency IDs. Disable this option if you do not need to use dependency IDs. Dependency IDs specify additional cache group identifiers that associate multiple cache entries to the same group identifier in your cache policy.

This option might not be available for cache instances that were created with a previous version of WebSphere Application Server.

Default	true

Enable cache replication:

Use cache replication to enable sharing of cache IDs, cache entries, and cache invalidations with other servers in the same replication domain.

This option might be unavailable for cache instances created with a previous version of WebSphere Application Server.

Full group replication domain:

Specifies a replication domain from which your data is replicated.

Specifies a replication domain from which your data is replicated. Choose from any replication domains that have been defined. If there are no replication domains listed, you must create one during cluster

creation or manually in the administrative console by clicking **Environment > Internal replication domains > New**. The replication domain you choose to use with the dynamic cache service must be using a Full group replica. Do not share replication domains between replication consumers. Dynamic cache should use a different replication domain from session manager or stateful session beans.

Replication type:

Specifies the global sharing policy for this cache instance.

The following settings are available:
- **Both push and pull** sends the cache ID of newly updated content to other servers in the replication domain. Then, if one of the other servers requests the content, and that server has the ID of the cache entry for the previously updated content, it will retrieve the content from the publishing server. If a request is made for an ID which has not been previously published, the server assumes it does not exist in the cluster and creates a new entry.
- **Pull only** shares cache entries for this object between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
- **Push only** sends the cache ID and cache content of new content to all other servers in the replication domain.
- The sharing policy of **Not Shared** results in the cache ID and cache content not being shared with other servers in the replication domain.

The default setting for a an environment without clustering is **Not Shared**. When enabling replication, the default value is **Not Shared**.

Push frequency:

Specifies the time, in seconds, to wait before pushing new or modified cache entries to other servers.

A value of 0 (zero) sends the cache entries immediately. Setting this property to a value greater than 0 (zero) results in a ″batch″ push of all cache entries that are created or modified during the time period. The default is 1 (one).

Object cache instance collection:

Use this page to configure and manage object cache instances, which in addition to the default shared dynamic cache, can store, distribute, and share data for Java 2 Platform, Enterprise Edition (J2EE) applications. Use cache instances to give applications better flexibility and tuning of the cache resources.

To view this administrative console page, click **Resources > Cache instances > Object cache instances**.

Use the DistributedObjectCache programming interface to access the cache instances. For more information about the DistributedObjectCache application programming interface, see the API documentation.

Scope:

Specify CELL SCOPE to view and configure cache instances that are available to all servers within the cell. Specify NODE SCOPE to view and configure cache instances that are available to all servers with the particular node. Specify SERVER SCOPE to view and configure cache instances that are available only on the specific server.

Name:

Specifies the required display name for the resource.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource. Use this name when looking up a reference to this cache instance. The results return a `DistributedMap` object.

Cache size:

Specifies a positive integer for the maximum number of entries the cache holds. The cache size is usually in the thousands. The default is 2000.

The minimum value is 100, with no set maximum value.

Invalidation listeners:

Invalidation listener mechanism uses Java events for alerting applications when contents are removed from the cache.

Applications implement the InvalidationListener interface (defined in the `com.ibm.websphere.cache` package) and register it to the cache using the DistributedMap interface. Listeners receive InvalidationEvents (defined in the `com.ibm.websphere.cache` package) when entries from the cache are removed, due to an explicit user invalidation, timeout, least recently used (LRU) eviction, cache clear, or disk timeout. Applications can immediately recalculate the invalidated data and prime the cache before the next user request.

Enable listener support in DistributedMap before registering listeners. DistributedMap can also be configured to use the invalidation listener Java 2 Platform, Enterprise Edition (J2EE) context from registration time during callbacks. Setting the value of the custom property useListenerContext to true enables the invalidation listener J2EE context for callbacks. See Cache instance settings for more information.

The following example shows how to set up an invalidation listener:

```
dmap.enableListener(true);  // Enable cache invalidation listener.
InvalidationListener listener = new MyListenerImpl();  //Create invalidation listener object.
dmap.addInvalidationListener(listener);  //Add invalidation listener.
     :
     :
     :
dmap.removeInvalidationListener(listener);  //Remove the invalidation listener.
//This increases performance.
dmap.enableListener(false);  // Disable cache invalidation listener.
//This increases performance.
```

For more information about invalidation listeners, see "Reference: Generated API documentation" on page 26 for the `com.ibm.websphere.cache` package.

Dynamic query

Using EJB query

The EJB query language is used to specify a query over container-managed entity beans. The language is similar to SQL. An EJB query is independent of the bean's mapping to a persistent store.

An EJB query can be used in three situations:

- To define a finder method of an EJB entity bean.
- To define a select method of an EJB entity bean.
- To dynamically specify a query using the `executeQuery()` dynamic API.

Finder and select queries are specified in the bean's deployment descriptor using the `<ejb-ql>` tag; they are compiled into SQL during deployment. Dynamic queries are included within the application code itself.

WebSphere's EJB query language is compliant with the EJB QL defined in Sun's EJB 2.1 specification and has additional capabilities as listed in the topic Comparison of EJB 2.x specification and WebSphere Query Language.

- Before using EJB query, familiarize yourself with query language concepts, starting with the topic, EJB Query Language.
- Define an EJB query in one of the following ways:
  - **Application Server Toolkit.** When defining an EJB 2.1 entity bean in an EJB deployment descriptor editor, on the **Beans** page click **Add** under **Queries** and, in the Add Finder Descriptor wizard, define a `find` or `ejbSelect` method. See the online **Application Server Toolkit information** for documentation on wizard options.
  - **Rational Application Developer.** When defining an entity bean, specify the `<ejb-ql>` tag for the finder or select method.
  - **Dynamic query service.** Add the executeQuery() method to your application.

See the topic Example: EJB queries.

EJB query language: An EJB query is a string that contains the following elements:
- a SELECT clause that specifies the enterprise beans or values to return;
- a FROM clause that names the bean collections;
- an optional WHERE clause that contains search predicates over the collections;
- an optional GROUP BY and HAVING clause (see Aggregation functions);
- an optional ORDER BY clause that specifies the ordering of the result collection.

Collections of entity beans are identified in EJB queries through the use of their abstract schema name in the query FROM clause.

The elements of EJB query language are discussed in more detail in the following related topics.

Example: EJB queries:

Here is an example EJB schema, followed by a set of example queries:

Table 47. DeptBean schema

Entity bean name (EJB name)	DeptEJB (not used in query)
Abstract schema name	DeptBean
Implementation class	com.acme.hr.deptBean (not used in query)
Persistent attributes (cmp fields)	- deptno - Integer (key) - name - String - budget - BigDecimal
Relationships	- emps - 1:Many with EmpEJB - mgr - Many:1 with EmpEJB

Table 48. EmpBean schema

Entity bean name (EJB name)	EmpEJB (not used in query)
Abstract schema name	EmpBean
Implementation class	com.acme.hr.empBean (not used in query)

Table 48. EmpBean schema (continued)

Persistent attributes (cmp fields)	• empid - Integer (key) • name - String • salary - BigDecimal • bonus - BigDecimal • hireDate - java.sql.Date • birthDate - java.util.Calendar • address - com.acme.hr.Address
Relationships	• dept - Many:1 with DeptEJB • manages - 1:Many with DeptEJB

Address is a serializable object used as cmp field in EmpBean. The definition of address is as follows:

```
    public class com.acme.hr.Address  extends Object implements Serializable {
public String street;
public String state;
public String city;
public Integer zip;
    public double distance (String start_location) { ... } ;
    public  String format ( ) { ... } ;
}
```

The following query returns all departments:

```
SELECT OBJECT(d) FROM DeptBean d
```

The following query returns departments whose name begins with the letters ″Web″. Sort the result by name:

```
SELECT OBJECT(d) FROM DeptBean d WHERE  d.name LIKE  'Web%' ORDER BY d.name
```

The keywords SELECT and FROM are shown in uppercase in the examples but are case insensitive. If a name used in a query is a reserved word, the name must be enclosed in double quotes to be used in the query. You can find a list of reserved words in "EJB query: Reserved words" on page 1226. Identifiers enclosed in double quotes are case sensitive. This example shows how to use a cmp field that is a reserved word:

```
SELECT OBJECT(d) FROM DeptBean d  WHERE  d."select" > 5
```

The following query returns all employees who are managed by Bob. This example shows how to navigate relationships using a path expression:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name='Bob'
```

A query can contain a parameter which refers to the corresponding value of the finder or select method. Query parameters are numbered starting with 1:

```
SELECT OBJECT (e) FROM EmpBean e WHERE e.dept.mgr.name= ?1
```

This query shows navigation of a multivalued relationship and returns all departments that have an employee that earns at least 50000 but not more than 90000:

```
SELECT OBJECT(d) FROM DeptBean d,  IN (d.emps) AS e
WHERE e.salary BETWEEN 50000 and 90000
```

There is a join operation implied in this query between each department object and its related collection of employees. If a department has no employees, the department does not appear in the result. If a department has more than one employee that earns more than 50000, that department appears multiple times in the result.

The following query eliminates the duplicate departments:

```
SELECT DISTINCT OBJECT(d) from DeptBean d,  IN (d.emps) AS e  WHERE e.salary > 50000
```

Find employees whose bonus is more than 40% of their salary:

```
SELECT OBJECT(e) FROM EmpBean e where e.bonus > 0.40 * e.salary
```

Find departments where the sum of salary and bonus of employees in the department exceeds the department budget:

```
SELECT OBJECT(d) FROM DeptBean d where d.budget <
( SELECT SUM(e.salary+e.bonus) FROM IN(d.emps) AS e )
```

A query can contain DB2 style date-time arithmetic expressions if you use java.sql.* datatypes as CMP fields and your datastore is DB2. Find all employees who have worked at least 20 years as of January 1st, 2000:

```
SELECT OBJECT(e) FROM EmpBean e where year(  '2000-01-01' - e.hireDate ) >= 20
```

If the datastore is not DB2 or if you prefer to use java.util.Calendar as the CMP field, then you can use the java millsecond value in queries. The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate <  631180800232
```

Find departments with no employees:

```
SELECT OBJECT(d) from DeptBean d where d.emps IS EMPTY
```

Find all employees whose earn more than Bob:

```
SELECT OBJECT(e) FROM EmpBean e, EmpBean b
WHERE b.name = 'Bob' AND e.salary + e.bonus > b.salary + b.bonus
```

Find the employee with the largest bonus:

```
SELECT OBJECT(e) from EmpBean e  WHERE e.bonus =
(SELECT MAX(e1.bonus) from EmpBean e1)
```

The above queries all return EJB objects. A finder method query must always return an EJB Object for the home. A select method query can in addition return CMP fields or other EJB Objects not belonging to the home.

The following would be valid select method queries for EmpBean. Return the manager for each department:

```
SELECT  d.mgr FROM DeptBean d
```

Return department 42 manager's name:

```
SELECT  d.mgr.name FROM DeptBean d WHERE  d.deptno = 42
```

Return the names of employees in department 42:

```
SELECT e.name FROM EmpBean e WHERE  e.dept.deptno=42
```

Another way to write the same query is:

```
SELECT e.name from DeptBean d, IN (d.emps) AS e WHERE d.deptno=42
```

Finder and select queries allow only a single CMP field or EJBObject in the SELECT clause. A select query can return aggregate values in Enterprise JavaBeans 2.1 using SUM, MIN, MAX, AVG and COUNT.

```
SELECT max(e.salary) FROM EmpBean e WHERE e.dept.deptno=42
```

The dynamic query API allows multiple expressions in the SELECT clause. The following query would be a valid dynamic query, but not a valid select or finder query:

```
SELECT  e.name, e.salary+e.bonus as total_pay , object(e), e.dept.mgr
FROM  EmpBean e
ORDER BY 2
```

The following dynamic query returns the number of employees in each department:

```
SELECT e.dept.deptno as department_number , count(*) as employee_count
FROM  EmpBean e
GROUP BY  by e.dept.deptno
ORDER BY 1
```

The dynamic query API allows queries that contain bean or value object methods:

```
SELECT object(e), e.address.format( )
FROM EmpBean e EmpBean e
```

FROM clause: The FROM clause specifies the collections of objects to which the query is to be applied. Each collection is specified either by an abstract schema name (ASN) or by a path expression identifying a relationship. An identification variable is defined for each collection.

Conceptually, the semantics of the query is to form a temporary collection of tuples, **R**, with elements consisting of all possible combinations of objects from the collections. This collection is subject to the constraints imposed by any path relationships and by the JOIN operation. The JOIN can be either an *inner* or *outer* join.

The identification variables are bound to elements of the tuple. After forming the temporary collection, the search conditions of the WHERE clause are applied to R, and yield a new temporary collection, **R1**. The ORDER BY, GROUP BY, HAVING, and SELECT clauses are applied to R1 to yield the final result.

```
from_clause::=FROM identification_variable_declaration [, {identification_variable_declaration |
                      collection_member_declaration } ]*
```

```
identification_variable_declaration::= range_variable_declaration [join]*
```

```
join := [ { LEFT [OUTER] | INNER }]  JOIN {collection_valued_path_expression | single_valued_path_expression}
 [AS] identifier
```

Examples: Joining collections

`DeptBean` contains records 10, 20, and 30. `EmpBean` contains records 1, 2, and 3 that are related to department 10, and records 4 and 5 that are related to department 20. Department 30 has no employees.

```
SELECT d FROM  DeptBean AS d, EmpBean AS e
WHERE d.name = e.name
```

The comma syntax performs an inner join resulting in all possible combinations. In this example, R would consist of 15 tuples (3 departments x 5 employees). If any collection is empty, then R is also empty. The keyword *AS* is optional.

This example shows that a collection can be joined with itself.

```
SELECT d FROM DeptBean AS d, DeptBean AS d1
```

R would consist of 9 tuples (3 departments x 3 departments).

Examples: Relationship joins

A collection can be a relationship based on a previously declared identifier as in

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

R would contain 5 tuples. Department 30 would not appear in R because it contains no employees. Department 10 would appear in 3 tuples and department 20 would appear in 2 tuples. IN can only refer to multi-valued relationships. The following is not valid

```
SELECT m FROM EmpBean e,  IN( e.dept.mgr) as m   INVALID
```

When joining with a relationship the alternate syntax INNER JOIN (keyword INNER is optional) can also be used, as shown here.

```
SELECT e FROM DeptBean AS d INNER JOIN d.emps AS e
```

An ASN declaration (**d** in the above query) can be followed by one or more join clauses. The relationship following the JOIN keyword must be related (directly or indirectly) to the ASN declaration. Unlike the case with the IN clause, relationships used in a join clause can be single- or multi-valued. This query has the same semantics as the query

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

You can use multiple joins together.

```
SELECT m FROM EmpBean e JOIN e.dept d JOIN d.mgr m
```

This is equivalent to

```
SELECT m FROM EmpBean e JOIN e.dept.mgr m
```

Examples: OUTER JOIN

An OUTER JOIN results in a temporary collection that contains combinations of the *left* and *right* operands, subject to the relationship constraints and such that the left operand always appears in R. In the example an outer join results in a temporary collection R that contains department 30, even though the collection **d.emps** is empty. The tuple contains Department 30 along with a NULL value. References to **e** in the query yields a null value.

```
SELECT e FROM DeptBean AS d LEFT OUTER JOIN d.emps AS e
```

The keyword OUTER is optional, as shown here..

```
SELECT e FROM DeptBean AS d LEFT JOIN d.emps AS e
```

You can also use combinations of INNER and OUTER JOIN.

```
SELECT m FROM EmpBean e JOIN e.dept d LEFT JOIN d.mgr m
```

Inheritance in EJB query: If an EJB inheritance hierarchy has been defined for an abstract schema, using the abstract schema name in a query statement implies the collection of objects for that abstract schema as well as all subtypes.

Example: Inheritance

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy. The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

Path expressions: An identification variable followed by the navigation operator (.) and a cmp or relationship name is a path expression.

A path expression that leads to a cmr field can be further navigated if the cmr field is single-valued. If the path expression leads to a multi-valued relationship, then the path expression is terminal and cannot be further navigated. If the path expression leads to a cmp field whose type is a value object, it is possible to navigate to attributes of the value object.

Example: Value object

Assume that `address` is a cmp field for `EmpBean`, which is a value object.

```
SELECT  object(e)  FROM EmpBean e
WHERE  e.address.distance('San Jose') < 10  and e.address.zip = 95037
```

It is best to use the composer pattern to map value object attributes to relational columns if you intend to search on value attributes. If you store value objects in serialized format, then each value object must be retrieved from the database and deserialized. Value object methods can only be done in dynamic queries.

A path expression can also navigate to a bean method. The method must be defined on either the remote or local bean interface. Methods can only be used in dynamic queries. You cannot mix both remote and local methods in a single query statement.

If the query contains remote methods, the dynamic query must be executed using the query remote interface. Using the query remote interface causes the query service to activate beans and create instances of the remote bean interface

Likewise, a query statement with local bean methods must be executed with the query local interface. This causes the query service to activate beans and local interface instances.

Do not use get methods to access cmp and cmr fields of a bean.

If a method has overloaded definitions, the overloaded methods must have different number of parameters.

Methods must have non-void return types and method arguments and return types must be either primitive types byte, short, int, long, float, double, boolean, char or wrapper types from the following list:

Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.sql.Date, java.sql.Time, java.sql.Timestamp, java.util.Date

If any input argument to a method is NULL, it is assumed the method returns a NULL value and the method is not invoked.

A collection valued path expression can be used in the FROM clause as a collection member declaration, and with the IS EMPTY, MEMBER OF, and EXISTS predicates in the WHERE clause.

`FROM EmpBean e WHERE e.dept.mgr.name='Bob'`	OK
`FROM EmpBean e WHERE e.dept.emps.name='BOB'`	INVALID -- cannot navigate through emps because it is multivalued
`FROM EmpBean e,  IN (e.dept.emps) e1` `WHERE e1.name='BOB'`	OK
`FROM EmpBean e WHERE e.dept.emps IS EMPTY`	OK

WHERE clause: The WHERE clause contains search conditions composed of the following:
• literal values
• input parameters
• expressions
• basic predicates
• quantified predicates
• BETWEEN predicate
• IN predicate
• LIKE predicate
• NULL predicate
• EMPTY collection predicate
• MEMBER OF predicate
• EXISTS predicate
• IS OF TYPE predicate

If the search condition evaluates to TRUE, the tuple is added to the result set.

Literals: A string literal is enclosed in single quotes. A single quote that occurs within a string literal is represented by two single quotes; For example: 'Tom''s'. A string literal cannot exceed the maximum length that is supported by the underlying persistent datastore.

A numeric literal can be any of the following:
* an exact value such as 57, -957, +66
* any value supported by Java long
* a decimal literal such as 57.5, -47.02
* an approximate numeric value such as 7E3, -57.4E-2

A decimal or approximate numeric value must be in the range supported by the underlying persistent datastore.

A boolean literal can be the keyword TRUE or FALSE and is case insensitive.

Input parameters: Input parameters are designated by the question mark followed by a number; For example: ?2

Input parameters are numbered starting at 1 and correspond to the arguments of the finder or select method; therefore, a query must not contain an input parameter that exceeds the number of input arguments.

An input parameter can be a primitive type of byte, short, int, long, float, double, boolean, char or wrapper types of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, an EJBObject, or a binary data string in the form of Java byte[].

An input parameter must not have a NULL value. To search for the occurrence of a NULL value the NULL predicate should be used.

Expressions: Conditional expressions can consist of comparison operators and logical operators (AND, OR, NOT).

Arithmetic expressions can be used in comparison expressions and can be composed of arithmetic operations and functions, path expressions that evaluate to a numeric value and numeric literals and numeric input parameters.

String expressions can be used in comparison expressions and can be composed of string functions, path expressions that evaluate to a string value and string literals and string input parameters. A cmp field of type char is handled as if it were a string of length 1.

Binary expressions can be used in comparison expressions and can be composed of path expressions that evaluate to the Java byte[] type as well as input parameters of type byte[].

Boolean expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a boolean value and TRUE and FALSE keywords and boolean input parameters.

Reference expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a cmr field, an identification variable and an input parameter whose type is an EJB reference

Four different expression types are supported for working with date-time types. For portability the java.util.Calendar type should be used. DB2 style date, time and timestamp expressions are supported if the datastore is DB2 and the CMP field is of type java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp. If you use DB2 UDB, you might obtain a syntax error when using the java.sql.Timestamp.ojbect. You must use the syntax TIMESTAMP 'yyyy-mm-dd hh:mm:ss.nnnn'.

A Calendar type can be compared to another Calendar type, an exact numeric literal or input parameter of type long whose value is the standard Java long millisecond value.

The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate <  631180800232
```

Date expressions can be used in comparison expressions and can be composed of operators + - , date duration expressions and date functions, path expressions that evaluate to a date value, string representation of a date and date input parameters.

Time expressions can be used in comparison expressions and can be composed of operators + - , time duration expressions and time functions, path expressions that evaluate to a time value, string representation of time and time input parameters.

Timestamp expressions can be used in comparison expressions and can be composed of operators + - , timestamp duration expressions and timestamp functions, path expressions that evaluate to a timestamp value, string representation of a timestamp and timestamp input parameters.

Standard bracketing ( ) for ordering expression evaluation is supported.

The operators and their precedence order from highest to lowest are:
- Navigation operator (.)
- Arithmetic operators in precedence order:
  - + - unary
  - * / multiply, divide
  - + - add, subtract
- Comparison operators: =, >, <, >=, <=, <>(not equal)
- Logical operator NOT
- Logical operator AND
- Logical operator OR

Null value semantics: The following describe the semantics of NULL values:
- Comparison or arithmetic operations with an unknown (NULL) value yield an unknown value
- In a Java 2 platform, Enterprise Edition (J2EE) version 1.3 application, a path expression uses an outer-join semantic where a NULL field or cmr value evaluates to NULL. In J2EE version 1.4, the path expression uses an inner-join semantic.
- The IS NULL and IS NOT NULL operators can be applied to path expressions and return TRUE or FALSE. Boolean operators AND, OR and NOT use three valued logic.

AND	True	False	Unknown
True	True	False	Unknown
False	False	False	False
Unknown	Unknown	False	Unknown

OR	True	False	Unknown
True	True	True	True
False	True	False	Unknown
Unknown	True	Unknown	Unknown

	NOT
True	False
False	True

NOT	
Unknown	Unknown

Example: Null value semantics

```
select object(e) from EmpBean where e.salary > 10  and e.dept.budget > 100
```

If salary is NULL the evaluation of `e.salary` > 10 returns unknown and the employee object is not returned. If the cmr field dept or budget is NULL evaluation of `e.dept.budget` > 100 returns unknown and the employee object is not returned.

```
select object(e) from EmpBean where e.dept.budget is null
```

In J2EE 1.3 if dept or budget is NULL evaluation of `e.dept.budget` is null returns TRUE and the employee object is returned. In J2EE 1.4 the employee object is returned only if budget is NULL.

```
select object(e) from EmpBean e ,  in (e.dept.emps) e1 where e1.salary > 10
```

If dept is NULL, then the multivalued path expression `e.dept.emps` results in an empty collection (not a collection that contains a NULL value). An employee with a null dept value will not be returned.

```
select object(e) from EmpBean e where  e.dept.emps is empty
```

If dept is NULL the evaluation of the predicate in unknown and the employee object is not returned.

```
select object(e) from EmpBean e , EmpBean e1  where e member of  e1.dept.emps
```

If dept is NULL evaluation of the member of predicate returns unknown and the employee is not returned.

Date time arithmetic and comparisons: DATE, TIME and TIMESTAMP values may be compared with another value of the same type. Comparisons are chronological. Date time values can also be incremented, decremented, and subtracted.

If the datastore is DB2, then DB2 string representation of DATE, TIME and TIMESTAMP types can also be used. A string representation of a date or time can use ISO, USA, EUR or JIS format. A string representation of a timestamp uses ISO format.

Format	Date format	Date examples	Time format	Time examples
ISO	yyyy-mm-dd	1987-02-24 1987-2-24	hh.mm.ss	13.50.00 13.50
USA	mm/dd/yyyy	2/24/1987	hh:mm AM or PM	1:50 pm 02:10 AM
EUR	dd.mm.yyyy	24.02.1987 24.2.1987	hh.mm.ss	13.50.00 13.55
JIS	yyyy-mm-dd	1987-02-24	hh:mm:ss	13:50 13:50:05

Example 1: Date time arithmetic comparisons

```
e.hiredate > '1990-02-24'
```

The timestamp of February 24th, 1990 1:50 pm can be represented as follows:

```
'1990-02-24-13.50.00.000000'  or
'1990-02-24-13.50.00'
```

If the datastore is DB2, DB2 decimal durations can be used in expressions and comparisons. A date duration is a decimal(8,0) number that represents the difference between two dates in the format YYYYMMDD. A time duration is a decimal(6,0) number that represents the difference between two time values as HHMMSS. A timestamp duration is a decimal(20,6) number representing the differences between two timestamp values as YYYYMMDDHHMMSS.ZZZZZZ (ZZZZZZ is the number of microseconds and is to the right of the decimal point) .

Two date values (or time values or timestamp values) can be subtracted to yield a duration. If the second operand is greater than the first the duration is a negative decimal number. A duration can be added or subtracted from a datetime value to yield a new datetime value.

Example 2: Date time arithmetic comparisons

`DATE('3/15/2000') - '12/31/1999'` results in a decimal number 215 which is a duration of 0 years, 2 months and 15 days.

Durations are really decimal numbers and can be used in arithmetic expressions and comparisons.

`( DATE('3/15/2000') - '12/31/1999' ) + 14 > 215` evaluates to TRUE.

`DATE('12/31/1999') + DECIMAL(215,8,0)` results in a date value 3/15/2000.

`TIME('11:02:26') - '00:32:56'` results in a decimal number 102930 which is a time duration of 10 hours, 29 minutes and 30 seconds.

`TIME('00:32:56') + DECIMAL(102930,6,0)` results in a time value of 11:02:26.

`TIME('00:00:59') + DECIMAL(240000,6,0)` results in a time value of 00:00:59.

`e.hiredate + DECIMAL(500,8,0) > '2000-10-01'` means compare the hiredate plus 5 months to the date 10/01/2000.

Basic predicates: Basic predicates can be of two forms

```
expression-1  comparison-operator  expression-2
expression-3  comparison-operator ( subselect )
```

The subselect must not return more than one value and the subselect can not return a type of an EJB reference. Boolean types and reference types only support = and <> comparisons.

Example: Basic predicates
```
d.name='Java Development'
e.salary > 20000
e.salary > ( select avg(e.salary) from EmpBean e)
```

Quantified predicates: A quantified predicate compares a value with a set of values produced by a subselect.

```
expression   comparison-operator   SOME  |  ANY  |   ALL   ( subselect )
```

The expression must not evaluate to a reference type.

When SOME or ANY is specified the result of the predicate is as follows:
• TRUE if the comparison is true for at least one value returned by the subselect.
• FALSE if the subselect is empty or if the comparison is false for every value returned by the subselect.
• UNKNOWN if the comparison is not true for all of the values returned by the subselect and at least one of the comparisons is unknown because of a null value.

When ALL is specified the result of the predicate is as follows:
• TRUE if the subselect returns empty or if the comparison is true to every value returned by the subselect.
• FALSE if the comparison is false for at least one value returned by the subselect.
• UNKNOWN if the comparison is not false for all values returned by the subselect and at least one comparison is unknown because of a null value.

BETWEEN predicate: The BETWEEN predicate determines whether a given value lies between two other given values.

```
expression  [NOT]   BETWEEN expression-2  AND expression-3
```

The expression must not evaluate to a boolean or reference type.

Example: BETWEEN predicate

```
e.salary BETWEEN 50000 AND 60000
```

is equivalent to:

```
e.salary >= 50000  AND e.salary <= 60000
```

```
e.name NOT BETWEEN 'A' AND 'B'
```

is equivalent to:

```
e.name < 'A'  OR e.name > 'B'
```

IN predicate: The IN predicate compares a value to a set of values and can have one of two forms:

```
expression [NOT] IN  ( subselect )
```

```
expression [NOT] IN  ( value1, value2,  .... )
```

ValueN can either be a literal value or an input parameter. The expression can not evaluate to a reference type.

Example: IN predicate

```
e.salary IN ( 10000, 15000 )
```

is equivalent to

```
( e.salary = 10000  OR  e.salary = 15000 )
```

```
e.salary IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary = ANY   ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

```
e.salary NOT IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary <> ALL    ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

LIKE predicate: The LIKE predicate searches a string value for a certain pattern.

```
string-expression   [NOT]  LIKE  pattern    [ ESCAPE escape-character ]
```

The pattern value is a string literal or parameter marker of type string in which the underscore (_) stands for any single character and percent (%) stands for any sequence of characters (including empty sequence). Any other character stands for itself. The escape character can be used to search for character _ and %. The escape character can be specified as a string literal or an input parameter.

If the string-expression is null, then the result is unknown.

If both string-expression and pattern are empty, then the result is true.

Example: LIKE predicate

- '' LIKE '' is true
- '' LIKE '%' is true
- e.name LIKE '12%3' is true for '123' '12993' and false for '1234'
- e.name LIKE 's_me' is true for 'some' and 'same', false for 'soome'

- e.name LIKE '/_foo' escape '/' is true for '_foo', false for 'afoo'
- e.name LIKE '//_foo' escape '/' is true for '/afoo' and for '/bfoo'
- e.name LIKE '///_foo' escape '/' is true for '/_foo' but false for '/afoo'

NULL predicate: The NULL predicate tests for null values.

```
single-valued-path-expression IS [NOT] NULL
```

Example: NULL predicate

```
e.name IS NULL

e.dept.name IS NOT NULL

e.dept IS NOT NULL
```

EMPTY collection predicate: To test if a multivalued relationship is empty, use the following syntax:

```
collection-valued-path-expression  IS [NOT]  EMPTY
```

Example: Empty collection predicate

To find all departments with no employees:

```
SELECT OBJECT(d) FROM DeptBean d  WHERE  d.emps IS EMPTY
```

MEMBER OF predicate: This expression tests whether the object reference specified by the single valued path expression or input parameter is a member of the designated collection. If the collection valued path expression designates an empty collection the value of the MEMBER OF expression is FALSE.

```
{ single-valued-path-expression | input_parameter } [ NOT ] MEMBER [ OF ] collection-valued-path-expression
```

Example: MEMBER OF predicate

Find employees that are not members of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e , DeptBean d
WHERE e NOT MEMBER OF d.emps AND d.deptno = ?1
```

Find employees whose manager is a member of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e, DeptBean d
WHERE e.dept.mgr MEMBER  OF d.emps  and d.deptno=?1
```

EXISTS predicate: The exists predicate tests for the presence or absence of a condition specified by a subselect.

```
EXISTS ( subselect )
```
```
EXISTS collection-valued-path-expression
```

The result of EXISTS is true if the subselect returns at least one value or the path expression evaluates to a nonempty collection, otherwise the result is false.

To negate an EXISTS predicate, precede it with the logical operator NOT.

Example: EXISTS predicate

Return departments that have at least one employee earning more than 1000000:

```
SELECT  OBJECT(d) FROM  DeptBean d
WHERE EXISTS ( SELECT  1  FROM IN (d.emps) e WHERE  e.salary > 1000000 )
```

Return departments that have no employees:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE NOT EXISTS  ( SELECT 1 FROM IN (d.emps) e)
```

The above query can also be written as follows:

```
SELECT OBJECT(d) FROM DeptBean d WHERE NOT EXISTS d.emps
```

IS OF TYPE predicate: The IS OF TYPE predicate is used to test the type of an EJB reference. It is similar in function to the Java instance of operator. IS OF TYPE is used when several abstract beans have been grouped into an EJB inheritance hierarchy. The type names specified in the predicate are the bean abstract names. The ONLY option can be used to specify that the reference must be exactly this type and not a subtype.

```
identification-variable IS OF TYPE ( [ONLY] type-1, [ONLY] type-2, ..... )
```

Example: IS OF TYPE predicate

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy.

The following query returns employees as well as managers and executives:

```
SELECT  OBJECT(e) FROM EmpBean e
```

If you are interested in objects which are employees and not managers and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ONLY EmpBean )
```

If you are interested in object which are managers or executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ManagerBean)
```

The above query is equivalent to the following query:

```
SELECT  OBJECT(e) FROM ManagerBean e
```

If you are interested in managers only and not executives:

```
SELECT  OBJECT(e) FROM  EmpBean e WHERE e IS OF TYPE( ONLY ManagerBean)
```

or:

```
SELECT  OBJECT(e) FROM  ManagerBean e
WHERE  e IS OF TYPE (ONLY ManagerBean)
```

Scalar functions: EJB query contains scalar functions for doing type conversions, string manipulation, and for manipulating date-time values. The list of scalar functions is documented in the topic EJB query: Scalar functions.

Example: Scalar functions

Find employees hired in 1999:

```
SELECT OBJECT(e) FROM EmpBean e where YEAR(e.hireDate) = 1999
```

The only scalar functions that are guaranteed to be portable across backend datastore vendors are the following:
- ABS
- MOD
- SQRT
- CONCAT
- LENGTH
- LOCATE
- SUBSTRING
- UCASE
- LCASE

The other scalar functions should be used only when DB2 is the backend datastore.

EJB query: Scalar functions: EJB query contains scalar built-in functions, as listed below, for doing type conversions, string manipulation, and for manipulating date-time values.

Numeric functions
```
ABS ( < any numeric datatype > ) -> < any numeric datatype >
MOD ( <int>, <int> ) -> int
SQRT ( < any numeric datatype > ) -> Double
```

Type conversion functions
```
CHAR ( < any  numeric datatype > ) ->  string
CHAR ( <  string  > ) ->  string
CHAR ( < any datetime  datatype >  [, Keyword k ]) ->  string
```

Datetime datatype is converted to its string representation in a format specified by the keyword k. The valid keywords values are ISO, USA, EUR or JIS. If k is not specified the default is ISO.
```
BIGINT ( < any numeric datatype > ) -> Long
BIGINT ( < string > ) -> Long
```

The function in the second line of the following code converts the argument to an integer n by truncation, and returns the date that is n-1 days after January 1, 0001:
```
DATE ( < date string > ) -> Date
DATE (   < any numeric datatype>) -> Date
```

The following function returns date portion of a timestamp:
```
DATE( timestamp ) -> Date
DATE ( < timestamp-string > ) -> Date
```

The following function converts number to decimal with optional precision p and scale s.
```
DECIMAL ( < any numeric datatype > [, p [ ,s ] ] ) -> Decimal
```

The following function converts string to decimal with optional precision p and scale s.
```
DECIMAL ( < string > [ , p [ , s ] ] ) -> Decimal
DOUBLE ( < any numeric datatype > ) -> Double
DOUBLE ( < string > ) -> Double
FLOAT ( < any numeric datatype > ) -> Double
FLOAT ( < string > ) -> Double
```

Float is a synonym for DOUBLE.
```
INTEGER ( < any numeric datatype > ) -> Integer
INTEGER ( < string > ) -> Integer
REAL ( < any numeric datatype > ) -> Float
SMALLINT ( < any numeric datatype ) -> Short
SMALLINT ( < string > ) -> Short
TIME ( < time > ) -> Time
TIME ( < time-string  > ) -> Time
TIME ( < timestamp > ) -> Time
TIME ( < timestamp-string  > ) -> Time
TIMESTAMP ( < timestamp > ) -> Timestamp
TIMESTAMP ( < timestamp-string > ) -> Timestamp
```

String functions
```
CONCAT ( <string>, <string>  ) -> String
```

The following function returns a character string representing absolute value of the argument not including its sign or decimal point. For example, `digits( -42.35)` is ″4235″.
```
DIGITS ( Decimal d  ) -> String
```

The following function returns the length of the argument in bytes. If the argument is a numeric or datetime type, it returns the length of internal representation.
```
LENGTH ( < string >  ) -> Integer
```

The following function returns a copy of the argument string where all upper case characters have been converted to lower case.
```
LCASE ( < string > ) -> String
```

The following function returns the starting position of the first occurrence of argument 1 inside argument 2 with optional start position. If not found, it returns 0.
```
LOCATE ( String s1 , String s2  [, Integer start ] ) -> Integer
```

The following function returns a substring of s beginning at character m and containing n characters. If n is omitted, the substring contains the remainder of string s. The result string is padded with blanks if needed to make a string of length n.
```
SUBSTRING ( String s ,  Integer m [ , Integer n ] ) -> String
```

The following function returns a copy of the argument string where all lower case characters have been converted to upper case.
```
UCASE ( < string > ) -> String
```

Date - time functions

The following function returns the day portion of its argument. For a duration, the return value can be -99 to 99.
```
DAY (  Date ) ->  Integer
DAY ( < date-string > ) ->  Integer
DAY ( < date-duration > ) -> Integer
DAY ( Timestamp  ) ->  Integer
DAY ( < timestamp-string > ) ->  Integer
DAY ( < timestamp-duration > ) -> Integer
```

The following function returns one more than number of days from January 1, 0001 to its argument.
```
DAYS ( Date  ) ->  Integer
DAYS ( < Date-string > ) ->  Integer
DAYS ( Timestamp  ) ->  Integer
DAYS ( < timestamp-string > ) ->  Integer
```

The following function returns the hour part of its argument. For a duration, the return value can be -99 to 99.
```
HOUR ( Time ) -> Integer
HOUR ( < time-string > ) -> Integer
HOUR ( < time-duration > ) ->  Integer
HOUR ( Timestamp ) -> Integer
HOUR ( < timestamp-string > ) -> Integer
HOUR ( < timestamp-duration >  ) -> Integer
```

The following function returns the microsecond part of its argument.
```
MICROSECOND ( Timestamp ) -> Integer
MICROSECOND ( < timestamp-string > ) -> Integer
MICROSECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the minute part of its argument. For a duration, the return value can be -99 to 99.

```
MINUTE ( Time ) -> Integer
MINUTE ( < time-string > ) -> Integer
MINUTE ( < time-duration > ) ->  Integer
MINUTE ( Timestamp ) -> Integer
MINUTE ( < timestamp-string > ) -> Integer
MINUTE ( < timestamp-duration >  ) -> Integer
```

The following function returns the month portion of its argument. For a duration, the return value can be -99 to 99.

```
MONTH (  Date ) ->  Integer
MONTH ( < date-string > ) ->  Integer
MONTH ( < date-duration > ) -> Integer
MONTH ( Timestamp  ) ->  Integer
MONTH ( < timestamp-string > ) ->  Integer
MONTH ( < timestamp-duration > ) -> Integer
```

The following function returns the second part of its argument. For a duration, the return value can be -99 to 99.

```
SECOND ( Time ) -> Integer
SECOND ( < time-string > ) -> Integer
SECOND ( < time-duration > ) ->  Integer
SECOND ( Timestamp ) -> Integer
SECOND ( < timestamp-string > ) -> Integer
SECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the year portion of its argument. For a duration, the return value can be -9999 to 9999.

```
YEAR (  Date ) ->  Integer
YEAR ( < date-string > ) ->  Integer
YEAR ( < date-duration > ) -> Integer
YEAR ( Timestamp  ) ->  Integer
YEAR ( < timestamp-string > ) ->  Integer
YEAR ( < timestamp-duration > ) -> Integer
```

Aggregation functions: Aggregation functions operate on a set of values to return a single scalar value. You can use these functions in the select and subselect methods. The following example illustrates an aggregation:

```
SELECT  SUM (e.salary) FROM EmpBean e WHERE e.dept.deptno =20
```

This aggregation computes the total salary for department 20.

The aggregation functions are AVG, COUNT, MAX, MIN, and SUM. The syntax of an aggregation function is illustrated in the following example:

```
aggregation-function  (    [ ALL |  DISTINCT ]  expression )
```

or:

```
COUNT( [ ALL |  DISTINCT ] identification-variable )
```

or:

```
COUNT( * )
```

The DISTINCT option eliminates duplicate values before applying the function. ALL is the default option and does not eliminate duplicates. Null values are ignored in computing the aggregate function except in the cases of COUNT(*) and COUNT(identification-variable), which return a count of all the elements in the set.

If your datastore is Informix, you must limit the expression argument to a single valued path expression when using the COUNT function or the DISTINCT forms of the functions SUM, AVG, MIN, and MAX.

Defining return type

For a select method using an aggregation function, you can define the return type as a primitive type or a wrapper type. The return type must be compatible with the return type from the datastore. The MAX and MIN functions can apply to any numeric, string or datetime datatype and return the corresponding datatype. The SUM and AVG functions take a numeric type as input, and return the same numeric type that is used in the datastore. The COUNT function can take any datatype, and returns an integer.

When applied to an empty set, the SUM, AVG, MAX, and MIN functions can return a null value. The COUNT function returns zero (0) when it is applied to an empty set. Use wrapper types if the return value might be NULL; otherwise, the container displays an ObjectNotFound exception.

Using GROUP BY and HAVING

The set of values that is used for the aggregate function is determined by the collection that results from the FROM and WHERE clause of the query. You can divide the set into groups and apply the aggregation function to each group. To perform this action, use a GROUP BY clause in the query. The GROUP BY clause defines grouping members, which comprise a list of path expressions. Each path expression specifies a field that is a primitive type of byte, short, int, long, float, double, boolean, char, or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

The following example illustrates the use of the GROUP BY clause in a query that computes the average salary for each department:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e GROUP BY e.dept.deptno
```

In division of a set into groups, a NULL value is considered equal to another NULL value.

Just as the WHERE clause filters tuples (that is, records of the return collection values) from the FROM clause, the groups can be filtered using a HAVING clause that tests group properties involving aggregate functions or grouping members:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e
GROUP BY e.dept.deptno
HAVING  COUNT(*) > 3  AND  e.dept.deptno > 5
```

This query returns the average salary for departments that have more than three employees and the department number is greater than five.

It is possible to use a HAVING clause without a GROUP BY clause, in which case the entire set is treated as a single group, to which the HAVING clause is applied.

SELECT clause: For finder and select queries, the syntax of the SELECT clause is illustrated in the following example:

```
SELECT  [  ALL | DISTINCT  ]
 { single-valued-path-expression  |  aggregation expression  |  OBJECT ( identification-variable )  }
```

The SELECT clause consists of either a single identification variable that is defined in the FROM clause, or a single valued path expression that evaluates to a object reference or CMP value. You can use the DISTINCT keyword to eliminate duplicate references.

For a query that defines a finder method, the query must return an object type consistent with the home that is associated with the finder method. For example, a finder method for a department home can not return employee objects.

Example: SELECT clause

Find all employees that earn more than John:

```
SELECT OBJECT(e) FROM EmpBean ej, EmpBean e
WHERE  ej.name = 'John'  and e.salary > ej.salary
```

Find all departments that have one or more employees who earn less than 20000:

```
SELECT DISTINCT  e.dept  FROM EmpBean e where e.salary < 20000
```

A select method query can have a path expression that evaluates to an arbitrary value:

```
SELECT  e.dept.name  FROM EmpBean e where e.salary < 2000
```

The previous query returns a collection of name values for those departments having employees earning less than 20000.

A select method query can return an aggregate value:

```
SELECT  avg(e.salary)  FROM EmpBean e
```

Example: Valid dynamic queries

For dynamic queries the syntax is as follows:

```
SELECT { ALL | DISTINCT }  [ selection , ]*  selection
selection  ::= { expression   |  scalar-subselect [[AS] id ] }
```

A scalar-subselect is a subselect that returns a single value.

The following are examples of dynamic queries:

```
SELECT e.name, e.salary+e.bonus as total_pay from EmpBean e
```

```
SELECT  SUM( e.salary+e.bonus) from EmpBean e where e.dept.deptno = ?1
```

ORDER BY clause: The ORDER BY clause specifies an ordering of the objects in the result collection:

```
ORDER BY  [ order_element ,]* order_element
order_element ::= { path-expression | integer } [ ASC | DESC ]
```

The path expression must specify a single valued field that is a primitive type of byte, short, int, long, float, double, char or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp.

ASC specifies ascending order and is the default. DESC specifies descending order.

Integer refers to a selection expression in the SELECT clause.

Example: ORDER BY clause

Return department objects in decreasing deptno order:

```
SELECT  OBJECT(d) FROM  DeptBean d ORDER BY  d.deptno DESC
```

Return employee objects sorted by department number and name:

```
SELECT  OBJECT(e) FROM EmpBean e ORDER BY e.dept.deptno ASC,  e.name DESC
```

UNION operation: The UNION clause specifies a combination of the output of two subqueries. The two queries must return the same number of elements and compatible types. For the purposes of UNION, all EJB types in the same inheritance hierarchy are considered compatible. UNION requires that equality be defined for the element types.

```
query_expression := query_term [UNION [ALL] query_term]*

query_term := {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }
```

You cannot use dependent value objects with UNION.

UNION ALL combines all results together in a single collection.

UNION combines results but eliminates duplicates.

If ORDER BY is used together with UNION, the ORDER BY must refer to selection expression using integer numbers.

Examples: UNION operation

This example returns a collection of all employee objects of type EmpBean and all manager objects of type ManagerBean where ManagerBean is a subtype of EmpBean.

```
 select e from EmpBean e union all select m from DeptBean d, in(d.mgr) m
```

This example shows a query that is not valid, because EmpBean and DeptBean are not compatible.

```
 select e from EmpBean e union all select d from DeptBean d
```

Subqueries: A subquery can be used in quantified predicates, EXISTS predicate or IN predicate. A subquery should only specify a single element in the SELECT clause. When a path expression appears in a subquery, the identification variable of the path expression must be defined either in the subquery, in one of the containing subqueries, or in the outer query. A scalar subquery is a subquery that returns one value. A scalar subquery can be used in a basic predicate and in the SELECT clause of a dynamic query.

Example: Subqueries
```
SELECT  OBJECT(e) FROM  EmpBean e
WHERE e.salary > ( SELECT  AVG(e1.salary) FROM  EmpBean e1)
```

The above query returns employees who earn more than average salary of all employees.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE  e.salary >
( SELECT AVG(e1.salary) FROM  IN  (e.dept.emps) e1  )
```

The above query returns employees who earn more than average salary of their department.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE e.salary =
( SELECT MAX(e1.salary) FROM IN (e.dept.emps) e1  )
```

The above query returns employees who earn the most in their department.

```
 SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > ( SELECT AVG(e.salary) FROM EmpBean e1
WHERE YEAR(e1.hireDate) =  YEAR(e.hireDate)  )
```

The above query returns employees who earn more than the average of employees hired in same year.

EJB query language limitations and restrictions: This topic outlines current known limitations and restrictions.

- EJB query language (QL) queries involving enterprise beans with keys made up of relationships to other enterprise beans appear as not valid and cause errors at deployment time. This is a known problem.
- The IBM EJB QL support extends the EJB 2.0 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB QL queries strictly according to Chapter 11 in the EJB 2.0 specification.

- Pre-loading across m:n relationships results in the generation of inaccurate structured query language (SQL). This is a known limitation that may be addressed in the future.
- Pre-loading across self referencing relationships causes inaccurate SQL to be generated.
- Avoid relationships between parent and children enterprise beans within the same inheritance hierarchy that are not well-defined.
- EJB Query Language validation for EJB 2.0 JAR files currently runs as a part of the EJB-RDB Mapping validation. If a mapping document (Map.mapxmi file) does not exist in the project, the EJB queries are not validated.

EJB query compatibility issues with SQL: Because an Enterprise JavaBeans query is compiled into SQL, you must be aware of compatibility issues between the Java language and SQL. The two languages differ along the following points that can be critical to correct EJB query formulation:

- The comparison semantics of SQL strings do not exactly match those of the Java language. For example: 'A' (the letter A) and 'A ' (the letter A plus a blank space) are considered equal in SQL, but not in the Java language.
- Comparisons and collating order depend on the underlying database. For example, if you are using DB2 with an EBCDIC code page, the collating order is not the same as doing the sort in a Java program. Some databases sort the NULL value low while others sort the NULL value high.
- An arithmetic overflow causes an exception in SQL, but not in the Java language.
- SQL databases have differing minimum and maximum ranges for floating point values, which can differ from floating point value ranges in the Java language. Values near the range limits of Java Double may fail to translate into SQL.
- Java methods do not translate into SQL; therefore standard EJB queries cannot include Java methods.

    Note: Only with the dynamic EJB query service can you use functions that do not translate into SQL. Such functions include Java methods and converters or composers that are used in mapping enterprise beans to relational databases (RDBs). A standard finder or select query that uses any of these functions fails at deployment time with the message ″Cannot push down query″. (You can resolve this problem by changing either the query or the mapping.) The dynamic query run time, however, processes the query by performing the operation involving the function in the application server.

Database restrictions for EJB query: **General database restriction**

All of the enterprise beans involved in a given query must map to the same data source. The EJB query does not support cross-data source join operations.

Specific database restrictions

Different database products place different restrictions on elements that can be included in EJB query statements. Following is a list of those restrictions; check with your database administrator to see if any apply in your environment:

- Certain functions are used in queries that run against DB2 only, because these functions are not supported by other databases. These functions include date and time arithmetic expressions, certain scalar functions (those *not* listed as portable across vendors), and implied scalar functions when used for mapping certain CMP fields. For example, consider mapping an int numeric type to a decimal (5,2) type field. When deployed against a database other than DB2, a finder or select query that contains a CMP field with this particular mapping fails, producing a `Cannot push down query` error message.
- A CMP of type String, when mapped to a character large object (CLOB) in the database, cannot be used in comparison operations because the database does not support CLOB comparisons.

- Databases can impose limits on the length of string values that are used either as literals or input parameters with comparison operators. These limits can hinder query performance. For example: For DB2 on the z/OS platform, the search ″name = ?1″ can fail if the value of ?1 at run time is greater than 255 in length.
- Mapping a numeric CMP type to a column that contains a dissimilar type can cause unexpected results. For example, consider the case of mapping the int numeric type to a column of type decimal (5,2). This scenario does not preserve an exact decimal value (for example, the value 12.25) over the course of transfer from the database to the enterprise bean CMP field, and back again to the database. This mapping causes replacement of the initial value with a whole number (in this case, 12). Consequently, you want to avoid using the CMP field in comparison operations when the CMP field uses a mapping of this nature.
- Some databases do not support a datatype that corresponds to the semantics of java.sql.Time. For example: If a CMP field of type java.sql.Time is mapped to an Oracle DATE column, comparisons on time might not produce the expected result because the year-month-day portion of the column value is truncated in the mapping.
- Some databases treat a zero length string value ('') as a null value; this approach can affect the query results. For the sake of portability, avoid the use of zero length string values.
- Some databases perform division between two integer values using integer arithmetic rules, while others use non-integer rules. This discrepancy might not be desirable in environments that use both kinds of databases. For the sake of portability, avoid the division of integer values in an EJB query.
- Current releases of UDB DB2 for i5/OS only support a TIMESTAMP value of the format 'yyyy-mm-dd-hh.mm.ss.nnnnnn'. This is not compatible with the standard format supported by the java.sql.Timestamp class, which is 'yyyy-mm-dd-hh mm.ss.nnnnnn'. The TIMESTAMP scalar function should be used to convert a string representation of a java.sql.Timestamp object to a value that can be recognized by DB2 UDB for i5/OS.

Rules for data type manipulation in EJB query: **Rules on CMP field type**

You can use a CMP field of any type in a SELECT clause. You must, however, use fields of only the following types in search conditions and in grouping or ordering operations:
- Primitive types: byte, short, int, long, float, double, boolean, char
- Object types: Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date
- JDBC types: java.sql.Date, java.sql.Time, java.sql.Timestamp
- Binary string: byte[]

Converters and basic types

If ALL of the following conditions occur:
- a CMP field of one of the basic types listed previously is mapped to an SQL column using a converter
- the CMP field appears in the left hand side of a basic predicate
- the right hand side of the predicate is a literal or input parameter

then the toData() method of the converter is used to compute the SQL search value.

For example, given a converter that maps the integer value 10 to the string value ″Ten,″ the following EJB query:

```
e.cmp = 10
```

is translated into the following SQL query:

```
column = 'Ten'
```

If you include a more complicated predicate, such as in the following example:

```
e.cmp * 10 > e.salary
```

in a finder or select query, you receive the `Cannot push down query` error message. Use the dynamic EJB query service for such multi-function queries; the dynamic query run time processes the predicate in the application server.

Overall, converters preserve equality, collating sequence, and NULL values. If a converter does not meet these requirements, avoid using it for CMP field comparison operations.

User types, converters, and composers

A user type cannot be used in a comparison operation or expression. You can, however, use subfields of the user type in a path expression. For example, consider the CMP addr field with the type `com.exam.Address`, and street, city, and state subfields. The following syntax for a query on this CMP field is not valid:

`e.addr =  ?1`

However, a query that designates one of the subfields is valid:

`e.addr.street = ?1`

A CMP field can be mapped to an SQL column using Java serialization. Using the CMP field in predicates or expressions for deployment queries usually results in the `Cannot push down query` error message. The dynamic query run time processes the expression by reading and deserializing all instances of the user type in the application server.

However, this expensive process sacrifices performance. You can maintain performance by using a composer in a deployment EJB query. In the previous example, if you want to map the addr field to a binary type, you use a composer to map each subfield to a binary column in the database.

EJB query: Reserved words:

The following words are reserved in WebSphere EJB query:

all, as, distinct, empty, false, from, group, having, in, is, like, select, true, union, where

Avoid using identifiers that start with underscore (for example, _integer) as these are also reserved.

EJB query: BNF syntax:

```
EJB QL ::= [select_clause] from_clause [where_clause] [order_by_clause]

DYNAMIC EJB QL := query_expression  [order_by_clause]

query_expression := query_term [UNION [ALL] query_term]*

query_term :=  {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }  [order_by_clause]

from_clause::=FROM identification_variable_declaration
               [, {identification_variable_declaration | collection_member_declaration } ]*

identification_variable_declaration::=collection_member_declaration |
       range_variable_declaration [join]*

xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
           [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

Comparison of EJB 2.1 specification and WebSphere query language: WebSphere Application Server Version supports the following extensions to the Enterprise JavaBeans Query Language.

Item		
Delimited identifiers		
Dependent Value object attributes used in path expressions		
EJB Inheritance		
EXISTS predicate		
Java methods: EJB bean methods or value object methods	dynamic query only	
Multiple element select clauses	dynamic query only	
SQL Date/time expressions		
Subqueries, group by, and having clauses		

Using the dynamic query service

Following are common reasons for using the dynamic query service rather than the regular EJB query service (which can be referred to as *deployment query*):

- You need to programmatically define a query at application run time, rather than at deployment.
- You need to return multiple CMP or CMR fields from a query. (Deployment queries allow only a single element to be specified in the SELECT clause.) For more information, see the Example: EJB queries article.
- You want to return a computed expression in the query.
- You want to use value object methods or bean methods in the query statement. For more information, see Path expressions.
- You want to interactively test an EJB query during development, but do not want to repeatedly deploy your application each time you update a finder or select query.

The dynamic query API is a stateless session bean; using it is similar to using any other J2EE EJB application bean. You can consult the API specifications in "Reference: Generated API documentation" on page 26 (the section for package com.ibm.websphere.ejbquery).

The dynamic query bean has both a remote and a local interface. If you want to return remote EJB references from the query, or if the query statement contains remote methods, you must use the query remote interface:

```
remote interface = com.ibm.websphere.ejbquery.Query
remote home interface = com.ibm.websphere.ejbquery.QueryHome
```

If you want to return local EJB references from the query, or if the query statement contains local methods, you must use the query local interface:

```
local interface = com.ibm.websphere.ejbquery.QueryLocal
local home interface = com.ibm.websphere.ejbquery.QueryLocalHome
```

Because it uses less application server memory, the local interface ensures better overall EJB performance than the remote.

1. Verify that the query.ear application file is installed on the application server on which your application is to run, if that server is different from the default application server created during installation of the product.

The `query.ear` file is located in the *app_server_root* directory, where <WAS_HOME> is the location of the WebSphere Application Server. The product installation program installs the `query.ear` file on the default application server using a JNDI name of

```
com/ibm/websphere/ejbquery/Query
```

(You or the system administrator can change this name.)

2. Set up authorization for the methods executeQuery(), prepareQuery(), and executePlan() in the remote and local dynamic query interfaces to control access to sensitive data. (This step is necessary only if your application requires security.)

   Because you cannot control which ASN names, CMP fields, or CMR fields can be used in a dynamic EJB query, you or your system administrator must place restrictions on use of the methods. If, for example, a user is permitted to run the executeQuery method, he or she can run any valid dynamic query. In a production environment, you certainly want to restrict access to the remote query interface methods.

3. Write the dynamic query as part of your application client code. You can consult the following examples as query models; they illustrate which import statements to use, and so on:

   - Remote interface dynamic query example
   - Local interface dynamic query example

4. If the CMP you want to query is on a different module, you should:

   a. do a remote lookup on query.ear

   b. map the query.ear file to the server that the queried CMP bean is installed on.

5. Compile and run your client program with the file **qryclient.jar** in the classpath.

Example: Dynamic query remote interface:

When you run a dynamic EJB query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the executeQuery method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic =  new InitialContext();

Object obj =  ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome  qh =
 ( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the QueryIterator object. (See *Class QueryIterator* in "Reference: Generated API documentation" on page 26 for more details.) This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of IQueryTuple objects, which are records of the return collection values. (See *Class IQueryTuple* in "Reference: Generated API documentation" on page 26 for more details.) Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
 System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

Handling large result collections for the remote interface query

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the skipRow and maxRow parameters on the remote executeQuery method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
 it = qb.executeQuery(query, null, null ,skipRow, maxRow );
 while (it.hasNext() ) {
 // display result
 skipRow = skipRow + maxRow;
}
} while ( ! it.isComplete() ) ;
```

Example: Dynamic query local interface:

When you run a dynamic EJB query using the local interface, you are calling the executeQuery method on the QueryLocal interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

Note: To establish a transaction context, the following example calls the begin() and commit() methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";
```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, `ejb/query` is used as a local EJB reference pointing to the dynamic query JNDI name (`com/ibm/websphere/ejbquery/Query`):

```
InitialContext ic =  new InitialContext();
    QueryLocalHome  qh =  ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();
```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. (See *Class QueryIterator* in "Reference: Generated API documentation" on page 26 for more details.) Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 EmpLocal e = ( EmpLocal ) tuple.getObject(2);
 System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();
```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

Dynamic query performance considerations: **General performance considerations**

Use of the following elements in your dynamic query can diminish application performance somewhat:

- Datatype converters and Java methods

  Why: In general, query operations and predicates are translated into SQL so that the database server can perform them. If your query includes datatype converters (for EJB to RDB mapping, for example) or Java methods, however, the associated predicates and operations of your query must be performed in the memory of the application server.

- EJB methods and criteria that call for the return of EJB references

Why: Queries that incorporate these elements trigger full activation of EJBs in the memory of the application server. (Returning a list of CMP fields from a query does not cause an EJB to be activated.)

When assessing application performance, you should also be aware that dynamic queries share connections with the persistence manager. Consequently, an application that includes a mixture of finder methods, CMR navigation, and dynamic queries relies on a single shared connection between the persistence manager and the dynamic query service to perform these tasks.

Limiting the return collection size

- **Remote interface queries**: The QueryIterator class of the remote interface mandates that all of your query results materialize in application server memory over the course of one method call. The SQL cursor(s) used to run the EJB query are closed upon completion of that call. Because this requirement poses a high risk for creating bottlenecks within the database server, you need to limit the size of any potentially large result collections.

- **Local interface queries**: In most situations, the QueryLocalIterator object behaves as a wrapper around an SQL cursor. It is *demand-driven*; it causes data to be returned incrementally. For each record retrieval from the database, the next() method must be called on the iterator.

  Use of certain operations in local interface queries, however, overrides the demand-driven behavior. In these cases, the query results fully materialize in memory just as do the result collections of remote interface queries. An example of such a case is:

  ```
  select  e.myBusinessMethod( ) from EmpBean e
   where e.salary < 50000 order by 1 desc
  ```

  This query requires performance of an EJB method to produce the final result collection. Consequently, the full dataset from the database must be returned in one collection to application server memory, where the EJB method can be run on the dataset in its entirety. For that reason, local interface query operations that invoke EJB methods are generally not demand-driven. You cannot control the return collection size for such queries.

  Because they *are* demand-driven, all other local interface queries allow you to control the size of return collections. You can use a call of the close() method on the QueryLocalIterator object to close the query loop after the desired number of return values has been fetched from the datastore. Otherwise, the SQL cursor(s) used to run the EJB query are not closed until the full result set accumulates in memory, or the transaction ends.

Access intent implications for dynamic query: WebSphere Application Server gives you the option to set access intent policies for your entity enterprise beans as a way of managing their transfer of data with the underlying datastore. An access intent policy controls the isolation level used on the data source connection, as well as the database locks used during data retrieval. By manipulating these elements, you can maximize the efficiency of your application's data flow. To learn more, begin with the topics "Access intent policies" on page 181 and "Concurrency control" on page 182.

When formulating dynamic queries, keep in mind the following considerations concerning their interaction with access intent policies:

- A dynamic query uses the first ASN name in the FROM clause to determine access intent.
- The collection increment attribute of an access intent policy is not used in processing a dynamic query.
- When performed on entity beans that have a pessimistic-Update access intent policy, your dynamic queries must return updateable collections. Therefore you need to formulate your query statements to return only collections of entity beans, *not* collections of CMP fields. For example, the statement `select object(c) from Customer` is valid for a dynamic query performed under the constraint of a pessimistic-Update policy. The statement `select c.name from Customer c`, however, is not a valid dynamic query under this constraint.
- Using pessimistic-Update policy places restrictions on the types of query expressions. The restrictions depend on the back end database type and release. Refer to the topic "Access intent -- isolation levels and update locks" on page 705 for details.

Dynamic query API: prepareQuery() and executePlan() methods:

Use these methods to more efficiently allocate the overhead associated with dynamic query. They are equivalent in function to the prepareStatement() and executeQuery() methods of the JDBC API.

To perform a dynamic EJB query, the application server must parse the query string into SQL at run time. You can, of course, eliminate run-time overhead by choosing to perform a standard EJB query instead of a dynamic query. Sometimes referred to as *deployment queries*, standard queries are parsed and built at deployment, then performed by a finder or select method.

Another option is to write code that redistributes dynamic query overhead for better application performance. Begin by calling the prepareQuery() method in place of the executeQuery() method. The prepareQuery() method parses and translates your query, and returns a string called a *query plan*. The plan contains the SQL statement produced by parsing and translation, as well as other information needed by the dynamic query API. Save this string in your application and call the executePlan() method with the string to run your query. (You also might want to use the prepareQuery() method simply to see the SQL translation product; just call the method and display the return value.)

Pass the parameters of your query as an array of type Object on the prepareQuery() and the executePlan() method calls. Ensure that you pass appropriate data types, because the application server validates your query according to parameter type (rather than actual values) when it processes the prepareQuery() method call.

Example code

Note: In the example code that follows, the first executePlan() method call substitutes `parms[0]` for ?1. Hence the first query performed is functionally equivalent to the following query statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000
```

The second call runs a query that is functionally equivalent to this statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 60000
```

The example:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < ?1";
QueryIterator it = null;
Integer[] parms = new Integer[1];
parms[0] = new Integer(0);
```

In the call to `prepareQuery()`, pass any Integer value. Doing so defines ?1 as an Integer type, as in the following:

```
String queryPlan= qb.prepareQuery(query, parms, null );

   parms[0] = new Integer(50000);
```

Next you run the query with a real value of `Integer(50000)` for ?1:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000it =
 qb.executePlan( queryPlan, parms, 0, 99);

parms[0] = new Integer(60000);
```

Run the query again with a different value of `Integer(60000)` for ?1:

```
it = qb.executePlan( queryPlan, parms, 0, 99);
```

Comparison of the dynamic and deployment EJB query services:

You can use the dynamic query service to build and execute queries against entity beans constructed dynamically at run time, rather than defining them at deployment time. By using dynamic query you gain the flexibility of queries defined at run time and utilize the power of EJB-Query Language (QL). Apart from supporting all of the capabilities of an EJB-QL query, dynamic query adds functionality not available to standard static query. Two examples are the ability to select multiple data fields directly from the bean itself (static queries currently only allow one) and executing business methods directly in the query.

You can effectively create more efficient and less resource intensive applications with dynamic query. For example, two data fields are required from the results of a query. Because a standard EJB-QL query can only select one data field, it is necessary to select the entire EJB object and extract the needed data from the returned results through data access methods, possibly traversing Container Managed Relationships (CMR) boundaries in the process. However, when using dynamic query, you can get both pieces of data directly from the query without additional CMR traversal or accessor methods. This principle is the key to evaluating whether or not dynamic query can be used for performance gain. You should review the amount of data that must be retrieved, in addition to the amount of business logic needed to retrieve it, for example, CMR traversal or accessor methods.

Using parameters in the query rather than literal values is another performance consideration. Under most circumstances, it is better to define conditional values as parameters in the query and then pass those parameters through the appropriate mechanisms. By using this method, you have a greater chance of matching a cached query plan, and you eliminate the need to parse and build the plan from scratch. For example, ″SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE foo″, is more appropriately expressed as ″SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE ?1″ with the value *foo* passed as a parameter to the executeQuery method. The result is that any subsequent execution of a dynamic query structure that is the same, except for different string literal conditions, is registered as a plan cache hit (which delivers better ″observed″ performance).

When used as a direct replacement for an equivalent static query, dynamic query is approximately 25% slower than the static variation. This slowdown is due to the need for parsing and building a plan for the query, in addition to executing it. In the static variation, these costs are paid at deploy time. Despite this, the added functionality gained through the use of dynamic query, specifically the ability to select multiple data fields in a single query even across CMRs, creates opportunities to utilize dynamic query for the sake of performance improvement.

Internationalization

Task overview: Globalizing applications
An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component to use regional conventions) and *localization* (implementing a specific regional convention). This product supports globalization through the use of its localizable-text API and internationalization service.

- Make sure the server runtime environment is properly configured.

  For more information about supported locales and character encodings, see Working with locales and character encodings.

- Implement message catalogs in your application by using the localizable-text API.

  This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

  For more information about the localizable-text API, see "Task overview: Internationalizing interface strings (localizable-text API)" on page 1239.

- Implement more extensive locale support by using the internationalization service.

  With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to perform localizations within Java 2 Platform, Enterprise Edition (J2EE) application components. Supported application components also include Web service client environments and Web service-enabled enterprise beans.

  For more information about the internationalization service, see "Task overview: Internationalizing application components (internationalization service)" on page 1248.

Globalization:

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component to use regional conventions) and *localization* (implementing a specific regional convention).

Historically, the creation of globalized applications has been restricted to large corporations writing complex systems. However, given the rise in distributed computing and in the use of the World Wide Web, application developers are pressured to globalize a much wider variety of applications. This trend requires making globalization techniques much more accessible to application developers.

Internationalization of an application is driven by two variables, the time zone and the locale. The *time zone* indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The *locale* is a collection of information about language, currency, and the conventions for presenting information like dates. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

A first step: Localization of interface strings

In an application that is not globalized, the user interface is unalterably written into the application code. Internationalizing a user interface adds a layer of abstraction into the design of an application. The additional layer of abstraction enables you to localize the application for each locale that must be supported by the application.

In a localized application, the locale determines the message catalog from which the application retrieves message strings. Instead of printing an error message, the application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, the application looks up the key in a *message catalog*. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages that are supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints the string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application needs no further modification.

The localizable-text package is a set of Java classes and interfaces that can be used to localize the strings in distributed applications easily. Language-specific string catalogs can be stored centrally so that they can be maintained efficiently.

Globalization challenges in distributed applications

With the advent of Internet-based business computational models, applications increasingly consist of clients and servers that operate in different geographical regions. These differences introduce the following challenges to the task of designing a solid client-server infrastructure:

Clients and servers can run on computers that have different endian architectures or code sets

Clients and servers can reside in computers that have different endian architectures: A client can reside in a little-endian CPU, while the server code runs in a big-endian one. A client might want to call a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code-set tracking and conversion rules. The Java platform has nearly eliminated these problems in a unique way by relying on its Java virtual machine (JVM), which encodes all of the string data in UCS-2 format and externalizes everything in big-endian format. The JVM uses a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

Clients and servers can run on computers with different locale settings

Client and server processes can use different locale settings. For example, a Spanish client might call a business method upon an object that resides on an American English server. Some business methods are locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the English collating sequence of the server. Because data retrieval and sorting procedures run on the server, the locale of the client must be available to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, that are formatted according to the cultural expectations of the client.

Clients and servers can reside in different time zones

Client and server processes can run in different time zones. To date, all internationalization literature and resources concentrate mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that orders received before 2:00 PM are processed by 5:00 PM the same day. The times given, of course, are in the time zone of the server that is processing the order. It is important to know the time zone of the client to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time further complicates the time zone issue.

Java 2 Platform, Enterprise Edition (J2EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The conventional method for solving locale and time zone mismatches across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in Enterprise JavaBeans (EJB) applications:
- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not support modification, such as legacy applications.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets. For more information, see "Task overview: Internationalizing application components (internationalization service)" on page 1248.

Language versions offered by this product:

This product is offered in several languages, as enabled by the operating platform on which the product is installed.

The following language versions are available:
- Brazilian Portuguese
- Chinese (Simplified)
- Chinese (Traditional)
- English
- French
- German
- Italian
- Japanese
- Korean
- Spanish

Globalization: Resources for learning:

Task overview: Internationalizing interface strings (localizable-text API)

This topic summarizes the steps involved in implementing message catalogs through the localizable-text API.

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

1. Identify localizable text in your application.
2. Create the message catalogs that are necessary for the locales to be supported by your application.
3. In your application code, compose the language-specific strings for output.
4. Using an assembly tool, assemble your application code as one or more application components.
5. Prepare the localizable-text package for deployment with your localized application. In this step, you create a deployment Java archive (JAR) file.
6. Assemble the application modules and the deployment JAR file into a Java 2 Platform, Enterprise Edition (J2EE) application.
7. Deploy and manage the application.

Your application is deployed with localized text.

Identifying localizable text

The first step in localizing strings in an application component is identifying the best candidates for translation.

1. Determine which elements of the application need translating. Good candidates for localization include the following:
   - Graphical user interfaces: window titles, menus and menu items, buttons, on-screen instructions
   - Prompts in command-line interfaces
   - Application output: messages and logs
2. Assign a unique key to each element for use in message catalogs for the application. The key provides a language-neutral link between the application and language-specific strings in the message catalogs. Establishing a naming convention for keys before creating the catalogs can make writing code with these keys much more intuitive for interface programmers.

Suppose you are localizing the GUI for a banking system, and the first window contains a pull-down list to use for selecting a type of account.

The labels for the list and the account types in the list are good choices for localization. Three elements require keys: the list and two items in the list.

Create message catalogs for the language-specific strings.

Creating message catalogs

Perform this task to begin the localization of strings in an application component.

Identify strings that need to be localized.

You can create a catalog as either a java.util.ResourceBundle subclass or a Java properties file. The properties-file approach is more common, because properties files can be prepared by people without programming experience and swapped without modifying the application code.

1. For each string that is identified for localization, add a line to the message catalog that lists the string key and value in the current language. In a properties file, each line has the following structure:

   ```
   key = string associated with the key
   ```

2. Save the catalog, giving it a locale-specific name. To enable resolution to a specific properties file, the Java API specifies naming conventions for the properties files in a resource bundle as *bundleName_localeID*.properties. Give the set of message catalogs a collective name, for example, BankingResources. For information about locale IDs that are recognized by the Java APIs, see "Resources for learning."

The following English catalog (BankingResources_en.properties) supports the labels for the list and its two list items:

```
accountString = Accounts
savingsString = Savings
checkingString = Checking
```

Do not create compound strings by concatenation (for example, combining the values of savingsString and accountString to form `Savings Accounts` in English. Success depends upon the grammar of the original language (in this case, English) and is not likely to extend to other languages.

The corresponding German catalog (BankingResources_de.properties) supports the labels as follows:

```
accountString = Konten
savingsString = Sparkonto
checkingString = Girokonto
```

Write code to compose the language-specific strings.

Composing language-specific strings

Perform this task to complete the localization of strings in an application component.

Create message catalogs for the language-specific strings.

1. In application code, create a LocalizableTextFormatter instance, passing in required localization values.
2. Set other localization values as needed for more complex situations.
3. Generate a properly formatted, language-specific string.

When the application is finished, deploy your application. For more information, see "Preparing the localizable-text package for deployment" on page 1247.

Localization API support:

The com.ibm.websphere.i18n.localizabletext package contains classes and interfaces for localizing text.

This package makes extensive use of the internationalization features of the standard Java APIs from Sun Microsystems, including the following classes:
- java.util.Locale
- java.util.TimeZone
- java.util.ResourceBundle
- java.text.MessageFormat

For more information about the standard Java APIs, see "Globalization: Resources for learning" on page 1238.

The localizable-text package wraps the Java support and extends it for efficient and simple use in a distributed environment. The primary class used by application programmers is LocalizableTextFormatter. Instances of this class are usually created in server programs, but client programs can also create them. Formatter instances are created for specific resource-bundle names and keys. Client programs that receive a LocalizableTextFormatter instance call its format method. This method uses the locale of the client application to retrieve the appropriate resource bundle and compose a locale-specific message based on the key.

For example, suppose that a distributed application supports both French and English locales; the server is using an English locale and the client, a French locale. The server creates two resource bundles, one each for English and French. When the client makes a request that triggers a message, the server creates a LocalizableTextFormatter instance that contains the name of the resource bundle and the key for the message and passes the instance back to the client.

When the client receives the LocalizableTextFormatter instance, it calls the format method of the object. By using the locale and name of the resource bundle, the format method determines the name of the resource bundle that supports the French locale and retrieves the message that corresponds to the key from the French resource bundle. Formatting of the message is transparent to the client.

In this simple example, the resource bundles reside centrally with the server. They do not have to exist with the client. Part of what the localizable-text package provides is the infrastructure to support centralized catalogs. This implementation uses an enterprise bean (a stateless session bean provided with the localizable-text package) to access the message catalogs. When the client calls the format method on the LocalizableTextFormatter instance, the following events occur:

1. The client application sets the time-zone and locale values in the LocalizableTextFormatter instance, either by passing them explicitly or through default values.
2. A LocalizableTextFormatterEJBFinder call is made to retrieve a reference to the formatter bean.
3. Information from the LocalizableTextFormatter instance, including the time zone and locale of the client, is sent to the formatting bean.
4. The formatting bean uses the name of the resource bundle, the message key, the time zone, and the locale to compose a language-specific message.
5. The formatter bean returns the formatted message to the client.
6. The formatted message is inserted into the LocalizableTextFormatter instance and returned by the format method.

A call to the format method requires at most one remote call, to contact the formatter bean. As an alternative, the LocalizableTextFormatter instance can cache formatted messages, eliminating the remote call for subsequent uses. In addition, you can set a fallback string so that the application can return a readable string even if it cannot access the appropriate message catalog.

The resource bundles can be stored locally. The localizable-text package provides a static variable that indicates whether the bundles are stored locally (LocalizableConfiguration.LOCAL) or remotely (LocalizableConfiguration.REMOTE). However, the setting of this variable applies to all applications running within the same Java virtual machine.

LocalizableTextFormatter class:

The LocalizableTextFormatter class, found in the com.ibm.websphere.i18n.localizabletext package, is the primary programming interface for using the localizable-text package. Instances of this class contain the information needed to create language-specific strings from keys and resource bundles.

The LocalizableTextFormatter class extends the java.lang.Object class and implements the following interfaces:
- java.io.Serializable
- com.ibm.websphere.i18n.localizabletext.LocalizableText
- com.ibm.websphere.i18n.localizabletext.LocalizableTextL
- com.ibm.websphere.i18n.localizabletext.LocalizableTextTZ
- com.ibm.websphere.i18n.localizabletext.LocalizableTextLTZ

Creation and initialization of class instances

The LocalizableTextFormatter class supports the following constructors:
- LocalizableTextFormatter()
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName)
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName, Object[] args)

The LocalizableTextFormatter instance must have certain values, such as a resource-bundle name, a key, and the name of the formatting application. If you do not pass these values in by using the second constructor listed previously, you can set them separately by making the following calls:
- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)

You can use a fourth method, setArguments(Object[] args), to set optional localization values after construction. See "Processing of application-specific values" on page 1243 at the end of this topic. For a usage example, see "Composing complex strings" on page 1245.

API for formatting text

The formatting methods in the LocalizableTextFormatter class generate a string from a set of message keys and resource bundles, based on some combination of locale and time-zone values. Each method corresponds to one of the four localizable-text interfaces implemented. The following list indicates the interface in which each formatting method is defined:
- LocalizableText.format()
- LocalizableTextL.format(java.util.Locale locale)
- LocalizableTextTZ.format(java.util.TimeZone timeZone)
- LocalizableTextLTZ.format(java.util.Locale locale, java.util.TimeZone timeZone)

The format method with no arguments uses the locale and time-zone values set as defaults for the Java virtual machine. All four methods issue LocalizableException objects as needed.

Location of message catalogs and the appName value

Applications written with the localizable-text package can access message catalogs locally or remotely. In a distributed environment, the use of remote, centrally located message catalogs is appropriate. All clients can use the same catalogs, and maintenance of the catalogs is simplified. Local formatting is useful in test situations and appropriate under some circumstances. To support either local or remote formatting, a LocalizableTextFormatter instance must indicate the name of the formatting application.

For example, when an application formats a message by using remote catalogs, the message is actually formatted by an enterprise bean on the server. Although the localizable-text package contains the code to automate the lookup of the formatter bean and to issue a call to it, the application needs to know the name of the formatter bean. Several methods in the LocalizableTextFormatter class use a value described as *appName*, which refers to the name of the formatting application. It is not necessarily the name of the application in which the value is set.

Caching of messages

LocalizableTextFormatter instances can optionally cache formatted messages so that they do not require reformatting when needed again. By default, caching is not enabled, but you can use a `LocalizableTextFormatter.setCacheSetting(true)` call to enable caching. When caching is enabled and the format method is called, the method determines whether the message is already formatted. If so, the cached message is returned. If the message is not found in the cache, the message is formatted and returned to the caller, and a copy of the message is cached for future use.

If caching is disabled after messages are cached, those messages remain in the cache until the cache is cleared by a call to the LocalizableTextformatter.clearCache method. You can clear the cache at any time; the cache is automatically cleared when any of the following methods is called:
- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)
- setArguments(Object[] args)

API for providing fallback information

Under some circumstances, it can be impossible to format a message. The localizable-text package implements a fallback strategy, making it possible to get some information even if a message cannot be formatted correctly into the requested language. The LocalizableTextFormatter instance can optionally store fallback values for a message string, the time zone, and the locale. These values can be ignored unless the LocalizableTextFormatter instance issues an exception. To set fallback values, call the following methods as appropriate:
- setFallBackString(String message)
- setFallBackLocale(Locale locale)
- setFallBackTimeZone(TimeZone timeZone)

For a usage example, see "Generating localized text" on page 1246.

Processing of application-specific values

The localizable-text package provides native support for localization based on time zone and locale, but you can construct messages on the basis of other values as well. If you need to consider variables other than locale and time zone in formatting localized text, write your own formatter class.

Your formatter class can extend the LocalizableTextFormatter class or independently implement some or all of the same localizable-text interfaces. As a minimum, your class must implement the java.io.Serializable interface and at least one of the localizable-text interfaces and its corresponding format method. If your class implements more than one localizable-text interface and format method, the order of evaluation of the interfaces is as follows:
1. LocalizableTextLTZ
2. LocalizableTextL
3. LocalizableTextTZ
4. LocalizableText

As an example, the localizable-text package provides a class that reports the time and date (LocalizableTextDateTimeArgument). In that class, date and time formatting is localized in accordance with three values: locale, time zone, and style.

Creating a formatter instance:

Perform this task to set localization values for strings in an application component.

Server programs typically create LocalizableTextFormatter instances that are sent to clients as the result of some operation; clients format the objects at the appropriate time. Less typically, client programs create LocalizableTextFormatter objects locally.

1. If needed for your application, write your own formatter class. For more information about implementation, see "LocalizableTextFormatter class" on page 1241.

2. In application code, call the appropriate constructor for the formatter class and set required localization values. Some localization values, such as resource bundle name, key and formatting application, must be set, either through a constructor or soon after construction. Other localization values can be set only as needed. For more information about the API, see the related reference.

The following code creates a LocalizableTextFormatter instance by using the default constructor and then sets the required localization values:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType) {
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ltf.setPatternKey("accountNumber");
   ltf.setResourceBundleName("BankingSample.BankingResources");
   ltf.setApplicationName("BankingSample");
   ...
}
```

The line of code in boldface exploits default behavior of the Java platform. By default, the Java platform looks first for a subclass of java.util.ResourceBundle called BankingResources. When none is found, the Java platform looks for a valid properties file of the same name. In this continuing example, a properties file is found.

The application that is requesting a localized message can specify the locale and time zone for message formatting, or the application can use the default values set for the Java virtual machine.

For example, a GUI can enable users to select the language in which to display the interface. A default value must be set initially so that the GUI can be created properly when the application first starts, but users can then change the locale for the GUI to suit their needs. The following code shows how to change the locale used by an application based on the selection of a menu item:

```
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
...
import java.util.Locale;

public void actionPerformed(ActionEvent event) {
   String action = event.getActionCommand();
   ...
   if (action.equals("en_us")) {
      applicationLocale = new Locale("en", "US");
      ...
   }
   if (action.equals("de_de")) {
      applicationLocale = new Locale("de", "DE");
      ...
   }
   if (action.equals("fr_fr")) {
      applicationLocale = new Locale("fr", "FR");
      ...
   }
   ...
}
```

For more information, see ″Generating localized text.″

Set optional localization values.

Setting optional localization values:

In addition to setting localization values that are required by the LocalizableTextFormatter interface, you can set a number of optional values in application code, either through the constructor or by calling any of several methods for that purpose.

With optional values, you can do the following actions:
* Compose complex strings from variable substrings
* Customize the formatting of strings, considering variables other than time zone and locale

1. In application code, add the optional values into an array of type Object.

   ```
   Object[] arg = {new String(getAccountNumber())};
   ```

2. Pass the array into a LocalizableTextFormatter instance. You can pass the array through the appropriate constructor or call the setArguments(Object[]) method. For a usage example, see "Composing complex strings."

   Because the array is passed by value rather than by reference, any updates to the array variable after this point are not reflected in the LocalizableTextFormatter instance unless it is reset by calling the setArguments(Object[]) method.

Write code to generate the localized text.

Composing complex strings:

Perform this task to insert variable substrings into a localized string.

Identify strings that need to be localized.

The localized-text package supports the substitution of variable substrings into a localized string that is retrieved from the message catalog by key.

1. In the message catalog, specify the location of the substitution in the string to be retrieved. Variable components are designated by braces (for example, {0}).

2. In application code, create a LocalizableTextFormatter instance, passing in an array that contains the variable value. If the variable substring must be localized, you can create a nested LocalizableTextFormatter instance and pass the instance in instead of a value.

3. Generate a localized string. When a format method is called on a formatter instance, the formatter takes each element of the array passed in the previous step and substitutes it for the placeholder with the matching index in the string that is retrieved from the message catalog. For example, the value at index 0 in the array replaces the {0} variable in the retrieved string.

The following line from an English message catalog shows a string with a single substitution:

```
successfulTransaction = The operation on account {0} was successful.
```

The same key in message catalogs for other languages has a translation of this string with the variable at the appropriate location for each language.

The following code shows the creation of a single-element argument array and the creation and use of a LocalizableTextFormatter instance:

```
public void updateAccount(String transactionType) {
   ...
   Object[] arg = {new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
```

```
             new LocalizableTextFormatter ("BankingResources",
                                           "successfulTransaction",
                                           "BankingSample",
                                           arg);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Nesting formatter instances for localized substrings:

The ability to substitute variable substrings into the strings retrieved from message catalogs adds a level of flexibility to the localizable-text package, but this capability is of limited use unless the variable value can be localized. You can localize this value by nesting LocalizableTextFormatter instances.

Identify strings that need to be localized.
1. In the message catalog, add entries that correspond to potential values for the variable substring.
2. In application code, create a LocalizableTextFormatter instance for the variable substring, setting required localization values.
3. Create a LocalizableTextFormatter instance for the primary string, passing in an array that contains the formatter instance for the variable substring.

The following line from an English message catalog shows a string entry with two substitutions and entries to support the localizable variable at index 0 (the second variable in the string, the account number, does not need to be localized):

```
successfulTransaction = The {0} operation on account {1} was successful.
depositOpString = deposit
withdrawOpString = withdrawal
```

The following code shows the creation of the nested formatter instance and its insertion (with the account number variable) into the primary formatter instance:

```
public void updateAccount(String transactionType) {
   ...
   // Successful deposit
   LocalizableTextFormatter opLTF =
      new LocalizableTextFormatter("BankingResources",
                                   "depositOpString",
                "BankingSample");
   Object[] args = {opLTF, new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
      new LocalizableTextFormatter ("BankingResources",
                                    "successfulTransaction",
                                    "BankingSample",
                                    args);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Generating localized text:

Perform this task to specify the runtime formatting of localized text in an application component.

Create a formatter instance and set the localization values as needed.
1. If needed, customize the formatting behavior.
2. In application code, call the appropriate format method.

You can provide fallback behavior for use if the appropriate message catalog is not available at formatting time.

The following code generates a localized string. If the formatting fails, the application retrieves and uses a fallback string instead of the localized string:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType){
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ...
   ltf.setFallBackString("Enter account number: ");
   try {
      msg = new Label(ltf.format(this.applicationLocale), Label.CENTER);
   }
   catch (LocalizableException le) {
      msg = new Label(ltf.getFallBackString(), Label.CENTER);
   }
   ...
}
```

When the application is finished, deploy your application. For more information, see "Preparing the localizable-text package for deployment."

Customizing the behavior of a formatting method:

Perform this task to change the runtime formatting of localized strings in an application component.

You can customize formatting behavior by passing your own formatter classes into a LocalizableTextFormatter instance through an array of optional values. This action enables you to consider variables other than locale and time zone when formatting localized text.

1. Write your own formatter class. For more information about implementation, see "LocalizableTextFormatter class."

2. In application code, create an instance of your formatter class as appropriate and pass it with any other optional localization values into an instance of LocalizableTextFormatter. When the LocalizableTextFormatter instance reads the instance that has been passed in, it attempts to call the format() method on the passed-in instance. The string returned is then processed with any other elements in the array.

The localizable-text package provides an example of a user-defined class, called LocalizableTextDateTimeArgument. This class enables date and time information to be selectively formatted according to the style values defined in the java.text.DateFormat interface as well as the constants that are defined within the LocalizableTextDateTimeArgument class.

Preparing the localizable-text package for deployment

The LocalizableTextEJBDeploy tool is used to create a deployment Java Archive (JAR) file for the localizable text service. You must deploy the enterprise bean in each enterprise application that requires support for localized text.

Write code to compose the language-specific strings.

1. Make sure that the LocalizableTextEJBDeploy tool is included in the class path.

   transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/lib/ltext.jar. It now resides in the file *app_server_root*/plugins/ com.ibm.ws.runtime_1.0.0.jar.

2. Set up a working directory for the LocalizableTextEJBDeploy tool to use. You need to pass this location to the tool through a command-line interface.

3. Run the LocalizableTextEJBDeploy tool. You might be asked if you want to regenerate deployment code for the LocalizableText bean. Do not redeploy the bean; if you do, an incorrect Java Naming and Directory Interface (JNDI) name will be generated.

   To deploy the bean on multiple hosts and servers, run the tool for each host and server combination. This action generates a unique JNDI name for each deployment. After the tool is run, a deployment JAR file is located in the working directory that you specified.

Using an assembly tool, assemble the deployment JAR file in an enterprise application with other application components.

As part of preparing for deployment, perform the following:
• Add the resource bundles for your application to the Enterprise Archive (EAR) file as files.
• Add the location of the EAR file to the server class path for the server so that the resource bundles can be located on the virtual host and server.

The same deployment JAR file can be included in several enterprise applications.

LocalizableTextEJBDeploy command:

This topic describes the command-line syntax for the LocalizableTextEJBDeploy tool.

transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/lib/ltext.jar. It now resides in the file *app_server_root*/plugins/com.ibm.ws.runtime_1.0.0.jar.

```
LocalizableTextEJBDeploy
   -a applicationName
   -h virtualHostName
   -i installationDirectory
   -s serverName
   -w workingDirectory
```

Parameters

The required parameters, which can be specified in any order, follow:

applicationName
   The name of the formatting session bean. This name is used in LocalizableTextFormatter instances to specify where the actual formatting occurs. If the name cannot be resolved at run time, the format method issues an exception.

virtualHostName
   The name of the virtual host on which the formatting session bean is deployed. This value is case-sensitive on all operating platforms.

installationDirectory
   The location at which the application server product is installed.

serverName
   The name of the application server. If this argument is not specified, the default server name for the product is used.

workingDirectory
   A location for the tool to use temporarily.

Task overview: Internationalizing application components (internationalization service)
This topic summarizes the steps involved in using the internationalization service.

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to perform localizations within Java 2 Platform, Enterprise Edition (J2EE) application components. Supported application components also include Web service client environments and Web service-enabled enterprise beans.

1. Use the internationalization context API within application components to obtain or manage internationalization context.

   Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. Enterprise JavaBeans (EJB) client applications, and server components that are configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

   You use the internationalization context API within Web service-enabled J2EE client programs and stateless session beans in the same manner that you would use conventional J2EE components, with one exception. Internationalization context propagated over Web service requests contains a time zone ID, whereas conventional Remote Method Invocation/ Internet Inter-ORB Protocol (RMI/IIOP) requests propagate complete time zone information, including the raw offset, Daylight Savings Time information, and so on.

2. Assemble internationalized applications.

   The internationalization type specifies the internationalization policy that applies to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting J2EE container manages internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container scopes to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application deployment descriptor, the distribution and management of context throughout an application.

   As you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

   You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.

3. Manage the internationalization service.

   Use the administrative console to enable the service on all application servers.

   By default, the service is enabled within J2EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your servlets and enterprise beans to use internationalization context.

4. Troubleshoot the internationalization service as needed.

   Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

   The trace strings for the internationalization service follow; use both:

   ```
   com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
   ```

Internationalization service:

In a distributed client-server environment, application processes can run on different machines, configured for different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. The internationalization service can help manage your application in a globally distributed environment.

For an understanding of how differences in locale impact application development, read "Globalization" on page 1236.

Java 2 Platform, Enterprise Edition (J2EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every service request within an application. When a client-side component calls a business method, the internationalization service interposes by obtaining the internationalization context associated with the current client-side process and by attaching that context to the outgoing request. On the server side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the server-side process on which the business method will run, effectively scoping the context to the business method. For HTTP requests, the caller context is constructed from the HTTP attributes and default values. The service propagates internationalization context on subsequent business method invocations in the same manner, which distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by *internationalization context management policies*. Internationalization policies specify whether an application component or its hosting J2EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container scopes to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At run time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then call the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java 2 SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

Assembling internationalized applications

Perform this task to configure application components for deployment with the internationalization service.

Use an assembly tool to configure internationalization in the deployment descriptors for servlets and enterprise beans.

1. Set the **internationalization type**.

   All servlets and enterprise beans have an internationalization type setting that specifies whether internationalization context is managed by the application component or by its hosting Java 2 Platform, Enterprise Edition (J2EE) container during invocations of their respective life cycle and business methods. The internationalization type can be configured for all server application components except entity beans, which are container-managed only.

   By default, all server components use container-managed internationalization (CMI). The default setting suffices in most cases; when it does not, modify the internationalization type setting by completing the steps that are described in one of the following topics:
   - "Setting the internationalization type for servlets" on page 1251
   - "Setting the internationalization type for enterprise beans" on page 1252

2. Set the **container internationalization attribute**.

   You can associate CMI servlets, and business methods of CMI enterprise beans, with a container internationalization attribute. That attribute specifies which of three internationalization contexts (**Caller**, **Server**, or **Specified**) the container is to scope to an invocation. When running as specified, the container internationalization attribute also specifies the custom internationalization context elements.

Named container internationalization attributes can be associated with sets of servlets or with sets of Enterprise JavaBeans (EJB) business methods. Initially, CMI servlets and business methods implicitly run as caller and do not associate with a container internationalization attribute. When the implicit behavior or an associated attribute setting is unsuitable, configure an attribute by completing the steps that are described in one of the following topics:

- "Configuring container internationalization for servlets"
- "Configuring container internationalization for enterprise beans" on page 1253

Setting the internationalization type for servlets:

This task sets the internationalization type for a servlet within a Web module.

This topic assumes that you have an assembly tool such as Application Server Toolkit (AST) or Rational Application Developer.

For information about assembly, refer to the online documentation or information center for your assembly tool. This topic points you to AST documentation. The AST information center accompanies the WebSphere Application Server information center.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java 2 Platform, Enterprise Edition (J2EE) modules, and created or imported a dynamic Web project. Refer to the following topics in AST documentation:

- Starting WebSphere Application Server Toolkit
- Configuring WebSphere Application Server Toolkit
- Creating a dynamic Web project
- Importing Web archive (WAR) files

1. In the J2EE perspective, open the Web project for which you want to set the internationalization type.

    a. Double-click **Dynamic Web Projects**.

    b. Double-click the name of the Web project to see its contents.

    c. Double-click the deployment descriptor object.

    The Web Deployment Descriptor panel is displayed.

2. In the Web Deployment Descriptor panel, click the Servlets tab.

3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.

4. From the **Servlets and JSPs** list of the Servlets panel, select the servlet for which you want to set the internationalization type.

5. Under **Internationalization**, select a value from the **Internationalization type** list. Valid values are `Application` or `Container`.

6. From the menu bar, click **File > Save**.

The internationalization type setting is assigned to the servlet.

If you selected container-managed internationalization, you can then set container-managed internationalization attributes for methods within the servlet. For more information, see "Configuring container internationalization for servlets."

Configuring container internationalization for servlets:

This task configures container internationalization for a servlet within a Web module.

This topic assumes that you have an assembly tool such as Application Server Toolkit (AST) or Rational Application Developer.

For information about assembly, refer to the online documentation or information center for your assembly tool. This topic points you to AST documentation. The AST information center accompanies the WebSphere Application Server information center.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java 2 Platform, Enterprise Edition (J2EE) modules, and created or imported a dynamic Web project. Refer to the following topics in AST documentation:
- Starting WebSphere Application Server Toolkit
- Configuring WebSphere Application Server Toolkit
- Creating a dynamic Web project
- Importing Web archive (WAR) files

You must also have set the internationalization type of one or more servlets in a Web project to `Container`.

This procedure relates one or more servlets to a container-managed internationalization attribute.
1. In the J2EE perspective, open the Web project for which you want to configure container internationalization.
   a. Double-click **Dynamic Web Projects**.
   b. Double-click the name of the Web project to see its contents.
   c. Double-click the deployment descriptor object.

   The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. Following **Container-managed Internationalization Attribute**, set the **Run As** field by selecting `Caller`, `Server`, or `Specified`.
5. If the servlet is to be run as Specified, select an internationalization policy from the **Specified** list or define a new policy.
   a. To define an internationalization policy, click **New**. The New Specified Initialization wizard is displayed.
   b. In the **Description** field, give the policy a name.
   c. If needed, set a time zone ID and add a time zone description. If you do not find the appropriate time zone in the ID list, click **Customize** to define one relative to Greenwich Mean Time (GMT).
   d. Create at least one locale for the policy. To create a locale, click **Add**; select a language and (optional) geographic region; specify a variant as needed. Add a locale description and click **OK** to finish. The new locale is added to the **Locales** list.
   e. If more than one locale is defined for the policy, select a locale from the **Locales** list and click **Finish**. Otherwise, just click **Finish**
6. From the menu bar, click **File > Save**.

Selected servlets are now configured to run under the associated internationalization settings.

Setting the internationalization type for enterprise beans:

This task sets the internationalization type for an enterprise bean within an Enterprise JavaBeans (EJB) module.

This topic assumes that you have an assembly tool such as Application Server Toolkit (AST) or Rational Application Developer.

For information about assembly, refer to the online documentation or information center for your assembly tool. This topic points you to AST documentation. The AST information center accompanies the WebSphere Application Server information center.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java 2 Platform, Enterprise Edition (J2EE) modules, and created or imported an EJB project. Refer to the following topics in AST documentation:
- Starting WebSphere Application Server Toolkit
- Configuring WebSphere Application Server Toolkit
- Creating EJB projects
- Importing EJB JAR files

Container-managed internationalization (CMI) is the default type; entity beans cannot be set to application-managed internationalization (AMI). Use CMI also for stateless session beans that are enabled for Web services.

1. In the J2EE perspective, open the EJB project for which you want to set the internationalization type.
   a. Double-click **EJB Projects**.
   b. Double-click the name of the EJB project to see its contents.
   c. Double-click the deployment descriptor object.

   The EJB Deployment Descriptor panel is displayed.
2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any enterprise beans that are already configured for AMI are displayed in the **Internationalization type** list.
3. To set the internationalization type for any other enterprise beans to AMI, click **Add** following the **Internationalization type** list. The Internationalization Type wizard opens. Only message-driven or session beans can be selected.
4. Select the beans that you want to set and click **Finish** to exit the wizard.
5. From the menu bar, click **File > Save**.

The internationalization type is assigned to the bean.

For beans that use container-managed internationalization, you can then set container-managed internationalization attributes. For more information, see ″Configuring container internationalization for enterprise beans.″

Configuring container internationalization for enterprise beans:

This task configures container internationalization for enterprise bean business methods.

This topic assumes that you have an assembly tool such as Application Server Toolkit (AST) or Rational Application Developer.

For information about assembly, refer to the online documentation or information center for your assembly tool. This topic points you to AST documentation. The AST information center accompanies the WebSphere Application Server information center.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java 2 Platform, Enterprise Edition (J2EE) modules, and created or imported an EJB project. Refer to the following topics in AST documentation:
- Starting WebSphere Application Server Toolkit
- Configuring WebSphere Application Server Toolkit
- Creating EJB projects
- Importing EJB JAR files

You must also have one or more enterprise beans set to container-managed internationalization (CMI) by default.

This procedure relates one or more business methods to one or more container-managed internationalization (CMI) attributes. Use this procedure also for stateless session beans that are enabled for Web services.

1. In the J2EE perspective, open the EJB project for which you want to configure container internationalization.

    a. Double-click **EJB Projects**.

    b. Double-click the name of the EJB project to see its contents.

    c. Double-click the deployment descriptor object.

    The EJB Deployment Descriptor panel is displayed.

2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any business methods that are already configured are displayed in the **Internationalization attributes** list.

3. To configure a CMI business method, click **Add** following the **Internationalization attributes** list. The Internationalization Attributes wizard opens.

4. Set the **Run As** field by selecting `Caller`, `Server`, or `Specified`. Add a meaningful description. As a group, the CMI attribute settings comprise an internationalization policy.
    • The description appears as `Internationalization description (runAsSetting)` in the **Internationalization attributes** list when you are finished.
    • If you do not provide a description, the policy name appears as `Internationalization (runAsSetting)`.

    If the bean is to be run as Specified, complete the following steps to specify the context elements that the container scopes to bean method invocations.

    a. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Custom** to define one relative to Greenwich Mean Time (GMT).

    b. Set a locale. Select a language and (optional) geographic region; specify a variant as needed. Add a locale description as needed and click **OK** to finish.

5. Click **Next**.

6. Select the beans for which you want to configure method-level internationalization attributes and click **Next**.

7. Select the methods that you want to configure and click **Next**. A check box is displayed next to each method name that you select.
    • Click **Apply to All** to place a check box next to the displayed bean name.
    • Click **Select Beans** to select more beans with CMI.

8. Click **Finish** to exit the wizard.

9. From the menu bar, click **File > Save**.

The bean methods are now configured to run under the associated internationalization settings.

Using the internationalization context API

Enterprise JavaBeans (EJB) client applications, servlets, and enterprise beans can programmatically obtain and manage internationalization context using the internationalization context API. For Web service client applications, you use the API to obtain and manage internationalization context in the same manner as for EJB clients.

The java.util and com.ibm.websphere.i18n.context packages contain all of the classes necessary to use the internationalization service within an EJB application.

1. Gain access to the internationalization context API.

    Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.

2. Access caller locales and time zones.

   Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

3. Access invocation locales and time zones.

   Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

The resulting components are said to use *application-managed internationalization* (AMI). For more information about AMI, see "Internationalization context: Management policies" on page 1269.

Each supported application component uses the internationalization context API differently. Three code examples are provided that illustrate how to use the API within each component type. Differences in API usage, as well as other coding tips, are noted in comments that precede the relevant statement blocks.

Gaining access to the internationalization context API:

Perform this task to access the internationalization service by resolving a reference to the internationalization context API.

Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.

1. Resolve a reference to the UserInternationalization interface by performing a lookup on the Java Naming and Directory Interface (JNDI) name `java:comp/websphere/UserInternationalization`. For example:

```
//------------------------------------------------------------------
// Internationalization context imports.
//------------------------------------------------------------------
import com.ibm.websphere.i18n.context.*;
import javax.naming.*;
...

public class MyApplication {
  ...

  //------------------------------------------------------------------
  // Resolve a reference to the UserInternationalization interface.
  //------------------------------------------------------------------
  InitialContext initCtx = null;
  UserInternationalization userI18n = null;
  final String UserI18nUrl = "java:comp/websphere/UserInternationalization";
  try {
    initCtx = new InitialContext();
    userI18n = (UserInternationalization)initCtx.lookup(UserI18nUrl);
  }
  catch (NamingException ne) {
    // UserInternationalization URL is unavailable.
  }
```

If the UserInternationalization object is unavailable because of an anomaly or a restriction, the JNDI lookup invocation issues a javax.naming.NameNotFoundException exception that contains the java.lang.IllegalStateException instance.

2. Use the UserInternationalization reference to create references to the CallerInternationalization or InvocationInternationalization objects, which provide access to elements of the Caller or Invocation internationalization contexts, respectively. The CallerInternationalization reference can be bound to the Internationalization interface only; the InvocationInternationalization reference can be bound to either the Internationalization or the InvocationInternationalization interfaces, depending on whether the application requires read-only or read-write access to the invocation context. For example:

```
...
//--------------------------------------------------------------
// Resolve references to the Internationalization and
// InvocationInternationalization interfaces.
//--------------------------------------------------------------
Internationalization callerI18n = null;
InvocationInternationalization invocationI18n = null;
try {
  callerI18n = userI18n.getCallerInternationalization();
  invocationI18n = userI18n.getInvocationInternationalization();
}
catch (IllegalStateException ise) {
  // An Internationalization interface(s) is unavailable.
}
```

Accessing caller locales and time zones:

Perform this task to access elements of the caller internationalization context.

An application component must first resolve a reference to the CallerInternationalization object and then bind it to the Internationalization interface.

Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

1. Obtain the desired caller context elements.

```
java.util.Locale [] myLocales  = null;
try {
  myLocales  = callerI18n.getLocales();
}
catch (IllegalStateException ise) {
  // The Caller context is unavailable;
  // is the service started and enabled?
}
...
```

The Internationalization interface contains the following methods to get caller internationalization context elements:
- **Locale [] getLocales()** Returns the list of caller locales that are associated with the current thread.
- **Locale getLocale()** Returns the first in the list of caller locales that are associated with the current thread.
- **TimeZone getTimeZone()** Returns the SimpleTimeZone caller that is associated with the current thread.

The Internationalization interface supports read-only access to internationalization context within application components. Methods of the Internationalization interface are available to all EJB application components and are used in the same manner for each, but the method semantics vary according to the component type. For instance, when obtaining the caller locale within an EJB client application, the interface returns the default locale of the host Java virtual machine (JVM); in contrast, when obtaining caller context within a servlet service method (for example, doPost or doGet methods),

the interface returns the first locale (accept-language) propagated within the corresponding HTML request. See Internationalization context for a discussion of how the service propagates internationalization context throughout an application.

2. Use the caller context elements to localize computations under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...
```

Accessing invocation locales and time zones:

Perform this task to access elements of the invocation internationalization context.

An application component must first resolve a reference to the InvocationInternationalization object and then bind it to the InvocationInternationalization interface of the internationalization context API.

Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

1. Obtain the desired invocation context elements.

```
java.util.Locale myLocale;
try {
  myLocale = invocationI18n.getLocale();
}
catch (IllegalStateException ise) {
  // The invocation context is unavailable;
  // is the service started and enabled?
}
...
```

The InvocationInternationalization interface contains the following methods to both get and set invocation internationalization context elements:
- **Locale [] getLocales()**. Returns the list of invocation locales that is associated with the current thread.
- **Locale getLocale()**. Returns the first in the list of invocation locales that is associated with the current thread.
- **TimeZone getTimeZone()**. Returns the SimpleTimeZone invocation that is associated with the current thread.
- **setLocales(Locale [])**. Sets the list of invocation locales that are associated with the current thread to the supplied list.
- **setLocale(Locale)**. Sets the list of invocation locales that are associated with the current thread to a list that contains the supplied locale.
- **setTimeZone(TimeZone)**. Sets the invocation time zone that is associated with the current thread to the supplied SimpleTimeZone.
- **setTimeZone(String)**. Sets the invocation time zone that is associated with the current thread to a SimpleTimeZone that has the supplied ID.

The InvocationInternationalization interface supports read and write access to invocation internationalization context within application components. However, according to internationalization context management policies, only components configured to manage internationalization context (application-managed internationalization, or AMI, components) have write access to invocation internationalization context elements. Calls to set invocation context elements within container-managed internationalization (CMI) application components result in a java.lang.IllegalStateException exception. Any differences in how application components can use InvocationInternationalization methods are explained in Internationalization context.

2. Use the invocation context elements to localize a computation under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
  String localizedDate = df.getDateInstance().format(aDateInstance);
    ...
```

In the following code example, locale (en,GB) and simple time zone (GMT) transparently propagate on the call to the myBusinessMethod method. Server-side application components, such as `myEjb`, can use the InvocationInternationalization interface to obtain these context elements.

```
...
//-------------------------------------------------------------------
// Set the invocation context under which the business method or
// servlet will run and propagate on subsequent remote business
// method invocations.
//-------------------------------------------------------------------
try {
  invocationI18n.setLocale(new Locale("en", "GB"));
  invocationI18n.setTimeZone(SimpleTimeZone.getTimeZone("GMT"));
}
catch (IllegalStateException ise) {
  // Is the component CMI; is the service started and enabled?
}
myEjb.myBusinessMethod();
```

Within CMI application components, the Internationalization and InvocationInternationalization interfaces are semantically equivalent. You can use either of these interfaces to obtain the context associated with the thread on which that component is running. For instance, both interfaces can be used to obtain the list of locales propagated to the servlet doPost service method.

Example: Internationalization context in an EJB client program:

Enterprise JavaBeans (EJB) client applications, Web service client applications, and enterprise beans programmatically obtain and manage internationalization context by using the internationalization context API (com.ibm.websphere.i18n.context).

The following code example illustrates how to use the internationalization context API within a contained EJB client program or Web service client program.

```
//----------------------------------------
// Basic Example: J2EE EJB client.
//----------------------------------------
package examples.basic;

//----------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//----------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;
import java.util.SimpleTimeZone;

public class EjbClient {

  public static void main(String args[]) {

    //-------------------------------------------------
    // INTERNATIONALIZATION SERVICE: API references.
    //-------------------------------------------------
```

```
UserInternationalization userI18n = null;
Internationalization callerI18n = null;
InvocationInternationalization invocationI18n = null;

//--------------------------------------------------
// INTERNATIONALIZATION SERVICE: JNDI name.
//--------------------------------------------------
final String UserI18NUrl =
    "java:comp/websphere/UserInternationalization";

//--------------------------------------------------
// INTERNATIONALIZATION SERVICE: Resolve the API.
//--------------------------------------------------
try {
 Context initialContext = new InitialContext();
 userI18n = (UserInternationalization)initialContext.lookup(
     UserI18NUrl);
 callerI18n = userI18n.getCallerInternationalization();
 invI18n = userI18n.getInvocationInternationalization ();
} catch (NamingException ne) {
  log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
} catch (IllegalStateException ise) {
  log("Error: UserInternationalization is not available: " + ise);
}
...

//----------------------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Set invocation context.
//
// Under Application-managed Internationalization (AMI), contained EJB
// client programs may set invocation context elements. The following
// statements associate the supplied invocation locale and time zone
// with the current thread. Subsequent remote bean method calls will
// propagate these context elements.
//----------------------------------------------------------------------
try {
  invocationI18n.setLocale(new Locale("fr", "FR", ""));
  invocationI18n.setTimeZone("ECT");
} catch (IllegalStateException ise) {
  log("An anomaly occurred accessing Invocation context: " + ise );
}
...

//----------------------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Get locale and time zone.
//
// Under AMI, contained EJB client programs can get caller and
// invocation context elements associated with the current thread.
// The next four statements return the invocation locale and time zone
// associated above, and the caller locale and time zone associated
// internally by the service. Getting a caller context element within
// a contained client results in the default element of the JVM.
//----------------------------------------------------------------------
Locale invocationLocale = null;
SimpleTimeZone invocationTimeZone = null;
Locale callerLocale = null;
SimpleTimeZone callerTimeZone = null;
try {
  invocationLocale = invocationI18n.getLocale();
  invocationTimeZone =
      (SimpleTimeZone)invocationI18n.getTimeZone();
  callerLocale = callerI18n.getLocale();
  callerTimeZone = SimpleTimeZone)callerI18n.getTimeZone();
} catch (IllegalStateException ise) {
  log("An anomaly occurred accessing I18n context: " + ise );
}
```

```
    ...
  } // main

  ...
  void log(String s) {
    System.out.println (((s == null) ? "null" : s));
  }
} // EjbClient
```

Example: Internationalization context in a servlet:

Servlets programmatically obtain and manage internationalization context by using the internationalization context API (com.ibm.websphere.i18n.context).

The following code example illustrates how to use the internationalization context API within a servlet. Note comments in the init and doPost methods.

```
...
//------------------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//------------------------------------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

public class J2eeServlet extends HttpServlet {

  ...
  //----------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: API references.
  //----------------------------------------------------------------
  protected UserInternationalization userI18n = null;
  protected Internationalization i18n = null;
  protected InvocationInternationalization invI18n = null;

  //------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: JNDI name.
  //------------------------------------------------------------
  public static final String UserI18NUrl =
      "java:comp/websphere/UserInternationalization";

  protected Locale callerLocale = null;
  protected Locale invocationLocale = null;

  /**
   * Initialize this servlet.
   * Resolve references to the JNDI initial context and the
   * internationalization context API.
   */
  public void init() throws ServletException {

    //----------------------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Resolve API.
    //
    // Under Container-managed Internationalization (CMI), servlets have
    // read-only access to invocation context elements. Attempts to set these
    // elements result in an IllegalStateException.
    //
    // Suggestion: cache all internationalization context API references
    // once, during initialization, and use them throughout the servlet
    // lifecycle.
```

1260 Developing and deploying applications

```
      //-------------------------------------------------------------------
      try {
        Context initialContext = new InitialContext();
        userI18n = (UserInternationalization)initialContext.lookup(UserI18nUrl);
        callerI18n = userI18n.getCallerInternationalization();
        invI18n = userI18n.getInvocationInternationalization();
      } catch (NamingException ne) {
        throw new ServletException("Cannot resolve UserInternationalization" + ne);
      } catch (IllegalStateException ise) {
        throw new ServletException ("Error: UserInternationalization is not
            available: " + ise);
      }
      ...
} // init

/**
 * Process incoming HTTP GET requests.
 * @param request Object that encapsulates the request to the servlet
 * @param response Object that encapsulates the response from the
 *     Servlet.
 */
public void doGet(
    HttpServletRequest  request,
    HttpServletResponse response)
  throws ServletException, IOException {
  doPost(request, response);
} // doGet

/**
 * Process incoming HTTP POST requests
 * @param request Object that encapsulates the request to
 *     the Servlet.
 * @param response Object that encapsulates the response from
 *     the Servlet.
 */
public void doPost(
    HttpServletRequest  request,
    HttpServletResponse response)
  throws ServletException, IOException {

  ...
  //-------------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: Get caller context.
  //
  // The internationalization service extracts the accept-languages
  // propagated in the HTTP request and associates them with the
  // current thread as a list of locales within the caller context.
  // These locales are accessible within HTTP Servlet service methods
  // using the caller internationalization object.
  //
  // If the incoming HTTP request does not contain accept languages,
  // the service associates the server's default locale. The service
  // always associates the GMT time zone.
  //
  //-------------------------------------------------------------------
  try {
    callerLocale = callerI18n.getLocale();   // caller locale
    // the following code enables you to get invocation locale,
    // which depends on the Internationalization policies.
    invocationLocale = invI18n.getLocale();  // invocation locale
  } catch (IllegalStateException ise) {
    log("An anomaly occurred accessing Invocation context: " + ise);
  }
  // NOTE: Browsers may propagate accept-languages that contain a
  // language code, but lack a country code, like "fr" to indicate
  // "French as spoken in France."  The following code supplies a
  // default country code in such cases.
```

```
      if (callerLocale.getCountry().equals(""))
        callerLocale = AccInfoJBean.getCompleteLocale(callerLocale);

      // Use iLocale in JDK locale-sensitive operations, etc.
      ...
    } // doPost

    ...
    void log(String s) {
      System.out.println (((s == null) ? "null" : s));
    }
} // CLASS J2eeServlet
```

Example: Internationalization context in a session bean:

This code example illustrates how to perform a localized operation using the internationalization service within a session bean or Web service-enabled session bean.

```
...
//-----------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//-----------------------------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

/**
 * This is a stateless Session Bean Class
 */
public class J2EESessionBean implements SessionBean {

  //-----------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: API references.
  //-----------------------------------------------------------
  protected UserInternationalization        userI18n = null;
  protected InvocationInternationalization  invI18n  = null;

  //-----------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: JNDI name.
  //-----------------------------------------------------------
  public static final String UserI18NUrl =
      "java:comp/websphere/UserInternationalization";
  ...

  /**
   * Obtain the appropriate internationalization interface
   * reference in this method.
   * @param ctx javax.ejb.SessionContext
   */
  public void setSessionContext(javax.ejb.SessionContext ctx) {

    //-----------------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Resolve the API.
    //-----------------------------------------------------------
    try {
      Context initialContext = new InitialContext();
      userI18n = (UserInternationalization)initialContext.lookup(
          UserI18NUrl);
      invI18n = userI18n.getInvocationInternationalization();
    } catch (NamingException ne) {
      log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
```

```
      } catch (IllegalStateException ise) {
        log("Error: UserInternationalization is not available: " + ise);
      }
    } // setSessionContext

  /**
   * Set up resource bundle using I18n Service
   */
  public void setResourceBundle()
  {
    Locale invLocale   = null;

    //-----------------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Get invocation context.
    //-----------------------------------------------------------
    try {
      invLocale = invI18n.getLocale();
    } catch (IllegalStateException ise) {
      log ("An anomaly occurred while accessing Invocation context: " + ise );
    }
    try {
      Resources.setResourceBundle(invLocale);
      // Class Resources provides support for retrieving messages from
      // the resource bundle(s). See Currency Exchange sample source code.
    } catch (Exception e) {
      log("Error: Exception occurred while setting resource bundle: " + e);
    }
  } // setResourceBundle

  /**
   * Pass message keys to get the localized texts
   * @return java.lang.String []
   * @param key java.lang.String []
   */
  public String[] getMsgs(String[] key) {
    setResourceBundle();
    return Resources.getMsgs(key);
  }

  ...
  void log(String s) {
    System.out.println(((s == null) ? ";null" : s));
  }
} // CLASS J2EESessionBean
```

Internationalization context API: Programming reference:

Application components programmatically manage internationalization context through the UserInternationalization, Internationalization, and InvocationInternationalization interfaces in the com.ibm.websphere.i18n.context package.

The following code example introduces the internationalization context API:

```
public interface UserInternationalization {
  public Internationalization getCallerInternationalization();
  public InvocationInternationalization
  getInvocationInternationalization();
}

public interface Internationalization {
  public java.util.Locale[] getLocales();
  public java.util.Locale getLocale();
  public java.util.TimeZone getTimeZone();
}

public interface InvocationInternationalization
```

```
    extends Internationalization {
  public void setLocales(java.util.Locale[] locales);
  public void setLocale(java.util.Locale jmLocale);
  public void setTimeZone(java.util.TimeZonetimeZone);
  public void setTimeZone(String timeZoneId);
}
```

UserInternationalization interface

The UserInternationalization interface provides factory methods for obtaining references to the CallerInternationalization and InvocationInternationalization context objects. Use these references to access elements of the caller and invocation contexts correlated to the current thread.

Methods of the UserInternationalization interface:
Internationalization getCallerInternationalization()
> Returns a reference implementing the Internationalization interface that supports access to elements of the caller internationalization context correlated to the current thread. If the service is disabled, this method issues an IllegalStateException exception.

InvocationInternationalization getInvocationInternationalization()
> Returns a reference implementing the InvocationInternationalization interface. If the service is disabled, this method issues an IllegalStateException exception.

Internationalization interface

The Internationalization interface declares methods that provide read-only access to internationalization context. Given a caller or invocation internationalization context object created with the UserInternationalization interface, bind the object to the Internationalization interface to get elements of that context type. Observe that caller internationalization context can be accessed only through this interface.

Methods of the Internationalization interface:
Locale[] getLocales()
> Returns the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns a chain of length(1) containing the default locale of the Java virtual machine (JVM).

Locale getLocale()
> Returns the first in the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns the default locale of the JVM.

TimeZone getTimeZone()
> Returns the caller time zone (that is, the SimpleTimeZone instance) that is associated with the current thread, provided the time zone is non-null; otherwise this method returns the process time zone.

InvocationInternationalization interface

The InvocationInternationalization interface declares methods that provide read and write access to InvocationInternationalization context. Given an invocation internationalization context object created with the UserInternationalization interface, bind the object to the InvocationInternationalization interface to get and set elements of the invocation context.

According to the container-managed internationalization (CMI) policy, all set methods, setXxx(), issue an IllegalStateException exception when called within a CMI servlet or enterprise bean.

Methods of the InvocationInternationalization interface:
void setLocales(java.util.Locale[] locales)
> Sets the chain of locales to the supplied chain, *locales*, within the invocation internationalization

context. The supplied chain can be null or have length(>= 0). When the supplied chain is null or has length(0), the service sets the chain of invocation locales to an array of length(1) containing the default locale of the JVM. Null entries can exist within the supplied locale list, for which the service substitutes the default locale of the JVM on remote invocations.

void setLocale(java.util.Locale locale)

Sets the chain of locales within the invocation internationalization context to an array of length(1) containing the supplied locale, *locale*. The supplied locale can be null, in which case the service instead sets the chain to an array of length(1) containing the default locale of the JVM.

void setTimeZone(java.util.TimeZone timeZone)

Sets the time zone within the invocation internationalization context to the supplied time zone, *time zone*. If the supplied time zone is not an exact instance of java.util.SimpleTimeZone or is null, the service sets the invocation time zone to the default time zone of the JVM instead.

void setTimeZone(String timeZoneId)

Sets the time zone within the invocation internationalization context to the java.util.SimpleTimeZone having the supplied ID, *timeZoneId*. If the supplied time zone ID is null or invalid (that is, the ID is not displayed in the list of IDs returned by the java.util.TimeZone.getAvailableIds method) the service sets the invocation time zone to the simple time zone having an ID of GMT, an offset of 00:00, and otherwise invalid fields.

Internationalization context:

An *internationalization context* is a distributable collection of internationalization information containing an ordered list, or chain, of locales and a single time zone, where the locales and time zone are instances of the java.util.Locale and java.util.TimeZone Java SDK types, respectively. A locale chain is ordered according to the user's preference.

The internationalization service manages and makes available two varieties of internationalization context: the *caller context*, which represents the caller's localization environment, and the *invocation context*, which represents the localization environment under which a business method runs. Server application components use elements of the caller and invocation internationalization contexts to appropriately tailor locale-sensitive and time zone-sensitive computations.

The internationalization service does not support time zone types other than the java.util.SimpleTimeZone type that is found in the Java SDK. Unsupported time zone types silently map to the default time zone of the JVM when supplied to internationalization context API methods. For a complete description of the java.util.Locale, java.util.TimeZone and java.util.SimpleTimeZone types, refer the Java SDK API documentation.

Caller context

Caller internationalization context contains the locale chain and time zone received on incoming EJB business method and servlet service method invocations; it is the internationalization context propagated from the calling process. Use caller context elements within server application components to localize computations to the calling component. Caller context is read-only and can be accessed by all application components by using the Internationalization interface of the internationalization context API.

Caller context is computed in the following manner: On an EJB business method or servlet service method invocation, the internationalization service extracts the internationalization context from the incoming request and scopes this context to the method as the caller context. For any missing or null context element, the service inserts the corresponding default element of the JVM (for example, java.util.Locale.getDefault() or java.util.TimeZone.getDefault().) The service performs a similar insertion whenever missing or null Caller context elements are encountered on invocations of stateless session beans that are enabled for Web services.

Formally, caller context is the invocation context of the calling business method or application component.

Invocation context

Invocation internationalization context contains the locale chain and time zone under which EJB business methods and servlet service methods run. It is managed by either the hosting container or the application component, depending on the applicable internationalization policy. On outgoing business method requests, it is the context that propagates to the target process. Use invocation context elements to localize computations under the specified settings of the current application component.

Invocation context is computed in the following manner: On an incoming business method or servlet service method invocation, the internationalization service queries the associated context management policy. If the policy is container-managed internationalization (CMI), the container scopes the context designated by the policy to the invocation; otherwise the policy is application-managed internationalization (AMI), and the container scopes an empty context to the invocation that can be altered by the method implementation.

Application components can access invocation context elements through both the Internationalization and InvocationInternationalization interfaces of the internationalization context API. Invocation context elements can be set (overwritten) under the application-managed internationalization policy only.

On an outgoing business method request, the service obtains the currently scoped invocation context and attaches it to the request. This outgoing exported context becomes the caller context of the target invocation. When supplying invocation context elements, either for export on outgoing requests or through the API, the internationalization service always provides the most recent element set using the API; the service also supplies the corresponding default element of the JVM for any null invocation context element.

Because the internationalization context that is propagated over Web services (SOAP) requests contains a time zone ID rather than the entire state of a java.lang.SimpleTimeZone object, time zone information might be lost when a Web service-enabled client program or session bean becomes involved in remote business computation.

Internationalization context: Propagation and scope:

The scope of internationalization context is implicit. Every Enterprise JavaBeans (EJB) client application, servlet service method, and EJB business method call has two internationalization contexts under which it runs.

For each application component call, the container enters the caller context and the call context, as indicated by the pertinent internationalization policy, into scope before the container delegates to the actual implementation. When the implementation returns, the service removes these contexts from scope. The internationalization service supplies no programmatic mechanism for components to explicitly manage the scope of internationalization context.

The service scopes internationalization context differently with respect to application component type:

Internationalization context observes by-value semantics over remote method requests. Changes to internationalization context elements that are scoped to a call do not affect the corresponding elements of the internationalization context that is scoped to the remote calling process. Also, modifications to context elements obtained using the internationalization context API do not affect the corresponding elements that are scoped to the invocation.

EJB client programs (contained)

Before it calls the main method of a client program, the J2EE client container introduces into scope invocation and caller internationalization some contexts that contain null elements. These contexts remain in scope throughout the life of the program. EJB client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a caller context element yields the corresponding default element of the client JVM. On outgoing EJB business method requests, the internationalization service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the JVM when exported by the internationalization context API or by outgoing requests.

Tip:

> To propagate values other than the JVM defaults to remote business methods, EJB client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. To learn how to set invocation context elements, see "Accessing invocation locales and time zones" on page 1257.

Servlets

On every servlet service method (doGet or doPost) invocation, the J2EE Web container introduces caller and invocation internationalization contexts into scope before delegating to the service method implementation. The caller context contains the accept-languages propagated in the HTTP servlet request, typically from a Web browser. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the servlet. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

Enterprise beans

On every EJB business method invocation, the J2EE EJB container introduces caller and invocation internationalization contexts into scope before delegating to the business method implementation. The caller context contains the internationalization context elements imported from the incoming IIOP request; if the incoming request lacks a particular internationalization context element, the container scopes a null element. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, when the container removes them from scope.

Consider a simple EJB application with a Java client that calls the remote myBeanMethod bean method. On the client side, the application can use the Internationalization Service API to set invocation context elements. When the client calls myBeanMethod(), the service exports the client invocation context to the outgoing request. On the server side, the service detaches the imported context from the incoming request and scopes it to the method as its caller context; the service also scopes the invocation context to the method as indicated by the associated internationalization context management policy. The EJB container then calls the myBeanMethod method, which can use the internationalization context API to access elements of either the caller or invocation contexts. When the myBeanMethod method returns, the EJB container removes these contexts from scope.

Web service client programs (contained)

Before it calls the main method of a Web service client program, the J2EE client container introduces into scope both invocation and caller internationalization contexts that contain null elements. These contexts remain in scope throughout the duration of the program. Web service client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a Caller context element yields the corresponding default element of the client virtual machine.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context that is associated with the current thread; the SOAP representation of invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests. Also, because the header contains only a time zone ID, the additional state of the time zone object (java.lang.SimpleTimeZone) of the invocation context might be lost, because it does not get propagated through the request.

Tip:

> To propagate values other than the JVM defaults to remote business methods, Web service client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. For more information, see "Accessing invocation locales and time zones" on page 1257.

Stateless session beans that are enabled for Web services

On every method invocation of a Web service-enabled bean, the EJB container introduces caller and invocation internationalization contexts into scope before delegating control to the business method implementation. The caller context contains the internationalization context elements that are imported from the SOAP header block of the incoming request. If the incoming request lacks a particular internationalization context element, the container introduces a null element into scope. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after control returns from the business method implementation, at which time the container removes them from scope.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context associated with the current thread. The SOAP representation of the invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests.

Thread association considerations

The Web and EJB containers scope internationalization contexts to a method by associating the method with the thread that run the method implementation. Similarly, methods of the internationalization context API either associate context with, or obtain context associated with, the thread on which these methods run.

In cases where new threads are spawned within an application component (for instance, a user-generated thread inside the service method of a servlet, or a system-generated event handling thread in an AWT client) the internationalization contexts associated with the parent thread does not automatically transfer to the newly-spawned thread. In such instances, the service exports the default locale and time zone of the JVM on any remote business method request and on any API calls that run on the new thread.

If the default context is inappropriate, the desired invocation context elements must be explicitly associated to the new thread by using the setXxx methods of the InvocationInternationalization interface. Currently, internationalization context management policies enable invocation context to be set within EJB client programs, as well as within servlets, session beans, and message-driven beans that use application-managed internationalization.

Example: Internationalization context in a SOAP header:

This code example illustrates how internationalization context is represented within the SOAP header of a Web service request.

```
<InternationalizationContext>
   <Locales>
      <Locale>
         <LanguageCode>ja</LanguageCode>
         <CountryCode>JP</CountryCode>
         <VariantCode>Nihonbushi</VariantCode>
      </Locale>
      <Locale>
         <LanguageCode>fr</LanguageCode>
         <CountryCode>FR</CountryCode>
      </Locale>
      <Locale>
         <LanguageCode>en</LanguageCode>
         <CountryCode>US</CountryCode>
      </Locale>
   </Locales>
   <TimeZoneID>JST</TimeZoneID>
</InternationalizationContext>
```

Internationalization context: Management policies:

Internationalization policies prescribe how J2EE application components or their hosting containers manage internationalization context on component invocations.

Two internationalization context management policies apply to all component types:
- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

These policies are represented in two parts:
- Internationalization type
- Container internationalization attribute

The service defines a default, or implicit, internationalization policy for every application component type. At development time, assemblers can override the default policy for server component types by explicitly configuring their internationalization type, and optional container internationalization attributes. Policies configured during assembly are preserved in the deployment descriptor for the application.

All components have an internationalization type that indicates whether it is AMI or CMI; that is, whether a component is to deploy under the application-managed or the container-managed internationalization policy. Application assemblers can set the internationalization type for servlets, session beans, and message-driven beans. Entity beans are implicitly CMI and EJB clients are implicitly AMI; neither can be configured otherwise.

For CMI servlets and enterprise beans, optional container internationalization attributes can be specified to indicate which invocation internationalization context the container is to scope to service or business methods. A CMI service or business method invocation can run under the context of the caller's process, under the default context of the server JVM, or under a custom context specified in the attribute. Assemblers can specify one container internationalization attribute per disjoint set of CMI servlets within a

Web module, or one Attribute per disjoint set of business methods of CMI beans within an EJB module. A container internationalization attribute can be associated with more than one method, but a method cannot be associated with more than one attribute.

When a WebSphere Application Server launches an application, the internationalization service collects policy information from the deployment descriptor, then uses this information to construct and associate an internationalization policy to every component invocation. A policy is denoted as:

`[<Internationalization Type>,<Container Internationalization Attribute>]`

Several cases exist in which the deployment descriptor seems to lack policy information, for example: EJB client applications have no configurable internationalization policy settings; AMI components do not have container internationalization attributes; and you are not required to specify container internationalization attributes for CMI components. When the service cannot obtain the explicit internationalization type and container attribute settings from a well-formed deployment descriptor, it implicitly inserts the appropriate setting into the policy.

The service observes the following conventions when applying policies to invocations:
- Servlets (service) and EJB business methods lacking all internationalization policy information in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- CMI servlets and business methods lacking a container internationalization attribute in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- AMI servlets and business methods always lack container internationalization attributes in the deployment descriptor, but implicitly run under the logical policy `[AMI,RunAsServer]`.
- EJB clients always lack internationalization policy information in the deployment descriptor. By definition, EJB clients are implicitly AMI types and run under the invocation context of the JVM; they run under the logical policy `[AMI,RunAsServer]`.

For conditions other than these cited examples, such as a malformed deployment descriptor, refer to Internationalization service errors.

Internationalization policies for EJB clients and HTTP clients cannot be configured; HTTP clients do, however, run under the language priority settings of the hosting Web browser. These settings are configurable under the options dialog of most Web browsers. Refer to your Web browser documentation for details.

Internationalization type:

Every server application component has an *internationalization type* setting that indicates whether the invocation internationalization context is managed by the component or by the hosting J2EE container.

Server application components can be deployed to use one of two types of internationalization context management:
- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

A server component can be deployed as AMI or CMI, but not both; CMI is the default. The setting applies to the entire component on every invocation. Entity beans use CMI only. Enterprise JavaBeans (EJB) client applications do not have an internationalization type setting; they implicitly use AMI.

Application-managed internationalization

Under the AMI deployment policy, component developers assume complete control over the invocation internationalization context. AMI components can use the internationalization context API to programmatically set invocation context elements.

AMI components are expected to manage invocation context. Invocations of AMI components implicitly run under the default locale and time zone of the hosting JVM. Invocation context elements not set using the API default to the corresponding elements of the JVM when accessed through the API or when exported on business methods. To export context elements other than the JVM defaults, AMI servlets, AMI enterprise beans, and EJB client applications must set (overwrite) invocation elements using the internationalization context API. Moreover, the container logically suspends the caller context that is imported on the AMI servlet lifecycle method and AMI EJB business method invocations. To continue propagating the context of the calling process, AMI servlets and enterprise beans must use the API to transfer caller context elements to the invocation context.

Specify AMI for server components that have internationalization context management requirements that are not supported by container-managed internationalization (CMI).

Container-managed internationalization

CMI is the preferred internationalization context management policy for server application components; it is also the default policy. Under CMI, the internationalization service collaborates with the Web and EJB containers to set the invocation internationalization context for servlets and enterprise beans. The service sets invocation context according to the container internationalization attribute of the policy that is associated with a servlet (service method) or an EJB business method.

A CMI policy has a container internationalization attribute that indicates which internationalization context the container is to scope to an invocation. For details, see Container internationalization attributes. By default, invocations of CMI components run under the caller's internationalization context; or rather, they adhere to the implicit policy [CMI,RunasCaller] whenever the servlet or business is not associated with an attribute in the deployment descriptor. For complete details, see Internationalization context: Management policies.

Methods within CMI components can obtain elements of the invocation context using the internationalization context API, but cannot set them. Any attempt to set invocation context elements within CMI components results in a java.lang.IllegalStateException exception.

Specify container-managed internationalization for server application components that require standard internationalization context management. Then specify the container internationalization attributes for CMI servlets and for business methods of CMI enterprise beans that you do not want to run under the caller's internationalization context.

Container internationalization attributes:

The internationalization policy of every CMI servlet and EJB business method has a *container internationalization attribute* that specifies which internationalization context the container is to scope to its invocation.

The container internationalization attribute has three main fields:
• Run as
• Locales
• Time zone ID

As a convenience, you can create named container internationalization attributes and associate them to the following subsets:
• CMI servlets within a Web module
• Business methods of CMI enterprise beans within an Enterprise JavaBeans (EJB) module
• Business methods of Web service-enabled session beans. In the following descriptions, the term *supported enterprise bean* refers to both CMI enterprise beans and Web service-enabled session beans.

Run-as field

The **Run-as** field specifies one of three types of invocation context that a container can scope to a method. For servlet service and EJB business methods, the container constructs the invocation internationalization context according to the **Run as** field setting and associates this context to the current thread before delegating to the method implementation.

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the **Run as** field of a policy attribute specifies otherwise. EJB client applications and AMI server components always run as server (`RunAsServer`).

You can specify the following invocation context types with the **Run as** field are:

Caller The container calls the method under the internationalization context of the calling process. For any missing context element, the container supplies the corresponding default context element of the Java virtual machine (JVM). Select run as caller when you want the invocation to run under the invocation context of the calling process.

Server
The container calls the method under the default locale and time zone of the JVM. Select run as server when you want the invocation to run under the invocation context of the JVM.

Specified
The container calls the method under the internationalization context specified in the attribute. Select run as specified when you want the invocation to run under the custom invocation context that is specified in the policy; then provide the custom context elements by completing the Locales and Time zone ID fields.

Remember: Java Message Service (JMS) messages do not contain internationalization context. Although container-managed message-driven beans can be configured to run as caller, the container associates the default elements of the server process when calling the onMessage method of any message-driven bean that is configured as [`CMI, RunAsCaller`]. You can also configure the **Run as** field for Web service business methods.

Locales field

The **Locales** field specifies an ordered list of locales that the container scopes to an invocation. A locale represents a specific geographical, cultural, or political region and contains three fields:

- **Language code**. Ideally, language code is one of the lower-case, two-character codes that are defined by the ISO 639 standard; however, language code is not restricted to ISO codes and is not a required field. A valid locale must specify a language code if it does not specify a country code.
- **Country code**. Ideally, country code is one of the upper-case, two-character codes that are defined by the ISO 3166 standard; however, country code is not restricted to ISO codes and is not a required field. A valid locale must specify a country code if it does not specify a language code.
- **Variant**. Variant is a vendor-specific code. Variant is not a required field and serves only to supplement the language and country code fields according to application- or platform-specific requirements.

A valid locale must specify at least a language code or a country code; the variant is always optional. The first locale of the list is returned when accessing invocation context using the getLocale method of the internationalization context API.

Time zone ID field

The **Time zone ID** field specifies an abbreviated identifier for a time zone that the container scopes to an invocation. You can also configure the **Time zone ID** field for Web service business methods.

A time zone represents a temporal offset and computes daylight savings information. A valid ID indicates any time zone supported by the java.util.TimeZone type. Specifically, a valid ID is any of the IDs that appear in the list of time zone IDs returned by method java.util.TimeZone.getAvailableIds(), or a custom ID

having the form `GMT[+|-]hh[[:]mm]`; for example, `America/Los_Angeles`, `GMT-08:00` are valid time zone IDs.

Object pools

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
   Scope The scope of the configured resource. This value indicates the location for the configuration file.
   Name The name of the object pool manager. This name can be up to 30 ASCII characters long.
   JNDI Name
   　　　The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
{
 arrayListPool = opm.getPool(ArrayList.class);
 vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
 // problem creating pool
}
catch(IllegalAccessException e)
{
 // problem creating pool
}
```

When the application has the pools, the application can use them as in the following example:

```
ArrayList list = null;
try
{
 list = (ArrayList)arrayListPool.getObject();
 list.clear(); // just in case
 for(int i = 0; i < 10; ++i)
 {
  list.add("" + i);
 }
 // do what ever we need with the ArrayList
}
finally
{
 if(list != null) arrayListPool.returnObject(list);
}
```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers:

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:
```
public interface ObjectPoolManager
{
 ObjectPool getPool(Class aClass)
  throws InstantiationException, IllegalAccessException;
 ObjectPool createFastPool(Class aClass)
  throws InstantiationException, IllegalAccessException;

}

public interface ObjectPool
{
 Object getObject();
 void returnObject(Object o);

}
```

Each object pool manager can be used to pool any Java object with the following characteristics:
- The object must be a public class with a public default constructor.
- If the object implements the java.util.Collection interface, it must support the optional clear() method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the ObjectPoolManager.getPool() method or the ObjectPoolManager.createFastPool() method. The difference between these methods is that the getPool() method returns a pool that can be shared across multiple threads. The createFastPool() method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the getPool() method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the createFastPool() method is called. Basically, the getPool() method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool. Consider the following interface:

```
public interface PoolableObject
{
 void init();
 void returned();
}
```

If the objects placed in the pool implement this interface and the ObjectPool.getObject() method is called, the object that the pool distributes has the init() method called on it. When the ObjectPool.returnObject() method is called, the PoolableObject.returned() method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement PoolableObject. For example, an application might want to pool ArrayList objects. The ArrayList object needs clearing each time the application reuses it. The application might extend the ArrayList object and have the ArrayList object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
 public PooledArrayList()
 {
 }

 public void init() {
 }

 public void returned()
 {
  clear();
 }
}
```

If the application uses this object, in place of a true ArrayList object, the ArrayList object is cleared automatically when it is returned to the pool.

Clearing an ArrayList object simply marks it as empty and the array backing the ArrayList object is not freed. Therefore, as the application reuses the ArrayList, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name:

Specifies the name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies the description of the object pool manager.

Data type	String

Category:

Specifies the category name used to classify or group this object pool manager.

Data type	String

Object pool managers settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name*

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

| **Data type** | String |
| **Range** | 1 through 30 ASCII characters |

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

| **Data type** | String |

Description:

A description of the object pool manager.

| **Data type** | String |

Category:

A category name used to classify or to group this object pool manager.

| **Data type** | String |

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:
- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

| **Data type** | String |

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Data type   String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools >** *objectpool_name*.

Use custom object pools to insert additional logic around the following mechanisms:
* Constructing an object pool (A list of properties can be set)
* Flushing the object pool
* Getting objects from the pool
* Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Data type   String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Data type   String

Object pool service settings:

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Application Servers >** *server_name* **>** Container services > **Object Pool Service**.

Enable service at server startup:

Specifies whether the server attempts to start the object pool service.

Default   Cleared

Range

Selected

When the application server starts, it attempts to start the object pool service automatically.

Cleared

The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

Object pools: Resources for learning:

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions
- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name. For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:             My ObjectPool
object pool manager JNDI name:        op/MyObjectPool
pooled class name:                    java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

```
ObjectPoolManager_My ObjectPool
```

and the legacy object pool MBean name will be:

```
ObjectPool_My ObjectPool_java.util.ArrayList
```

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

```
ObjectPoolManager_op/MyObjectPool
```

and the JNDI name-based object pool MBean name is:

```
ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f
```

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Scheduler

Using schedulers

Schedulers enable J2EE application tasks to run at a requested time. Schedulers also enable application developers to create their own stateless session EJB components to receive event notifications during a task life cycle, allowing the plugging-in of custom logging utilities or workflow applications.

You can schedule the following types of tasks:
* Invoke a session bean method
* Send a Java Message Service (JMS) message to a queue or topic

Stateless session EJB components are also used to provide generic calendaring. Developers can either use the supplied calendar bean or create their own for their existing business calendars. For example, one of your business processes might involve invoicing for services. With the scheduler's use of stateless EJB components, you can schedule when periodic email distributions are to be sent to your customers who have received invoices. The scheduler service performs these tasks, repeating as necessary, according to the metadata for that task.

A scheduler is the mechanism by which the timer service for Enterprise Java Beans 2.1 runs. You can configure the EJB timer service to use many of the features that schedulers provide. See the timer service for Enterprise Java Beans 2.1 documentation for more details.

Use the following table to determine which persistent timer service is best for you:

Schedulers	EJB timers
Run stateless session EJB components and sends JMS messages	Run all EJB types except for stateful session beans
Persistent, transactional and highly available.	Persistent, transactional and highly available.
Tasks guaranteed to run only once	Timers guaranteed to run only once, if the timer EJB uses a container-managed global transaction
Run repeating tasks using any calculation rules	Run repeating tasks using a repeating interval defined in milliseconds

Uses a modified fixed-delay time calculation to determine repeating intervals (next run time based on the start-time of the previous task)	Uses a fixed-rate time calculation to determine repeating intervals (time of the next task is based on the original scheduled time).
Programmatic task monitoring capability with the use of the NotificationSink stateless session EJB	No programmatic timer monitoring
Abort late or time-sensitive tasks from running	Abort late or time-sensitive tasks from running (achieved through manual detection within the javax.ejb.TimedObject implementation).
Manage any task lifecycle (find, suspend, resume, cancel and purge tasks programmatically and through Java Management Extensions (JMX)).	Find and cancel its timers programmatically. Administrators find and cancel timers using a command-line utility.
Store a limited amount of text with the data, like a **Name** (arbitrary data stored externally.)	Store arbitrary data with a timer

This task demonstrates how to manage, develop and interoperate with schedulers and subsequent tasks.

1. Manage the scheduler service. This article includes instructions for creating and configuring schedulers, creating and configuring a database for schedulers and administering schedulers.

2. Develop and schedule tasks. This article includes instructions for developing various types of tasks, receiving notifications from a task, submitting tasks to a scheduler, and managing tasks.

   Note: Creating and manipulating scheduled tasks through the Scheduler API interface is only supported from within the Enterprise Java Beans (EJB) container or Web container (JavaServer Pages or servlets). Looking up and using a configured scheduler from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

3. Interoperate with schedulers. This article explains how to manage scheduler in a clustered environment with mixed WebSphere Application Server product versions and mixed platforms.

Scheduler daemon:

A scheduler daemon is a background thread that searches for tasks to run in the database.

A scheduler daemon is started for each scheduler defined on each server. If `Scheduler 1` is configured on `server1`, then only one scheduler daemon runs on `server1` unless it is cloned. If `Scheduler 1` is defined at the node scope level, then the scheduler will run on each server within that node.

The poll interval determines the frequency at which the persistent store is queried. By default, this value is set to 30 seconds. When a task is found that is scheduled to run within the current poll interval, an asynchronous beans alarm is set. The task then runs as close to this time as possible using an alarm thread from the scheduler's associated work manager. Thus, the number of alarm threads configured on the work manager determines how many concurrent tasks are executed. No tasks are lost. If we reach this limit, then new tasks are simply queued to be executed when an alarm thread becomes available. The actual firing time is dictated by server load and availability of free threads in the alarm thread pool of the associated work manager.

Scheduler daemons in a cluster

When multiple schedulers are configured to use the same tables (as is the case in a clustered environment), any of the daemons can find a task and set the alarm in its Java virtual machine (JVM). The task is executed in the virtual machine where the scheduler daemon first runs, until the daemon is stopped and another daemon starts. If an application on `server1` schedules a task to run and `server2` was started before `server1`, then the task runs on `server2`.

Example: Stopping and starting scheduler daemons using Java Management Extensions API:

Use the wsadmin scripting tool to invoke a `Jacl` script and stop and start a scheduler daemon.

This example JACL script can be invoked using the wsadmin scripting tool. It will attempt to stop and start a scheduler daemon.

```
# Example JACL Script to restart a Scheduler Daemon

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Invoke the stopDaemon operation.
puts "Stopping the daemon..."
$AdminControl invoke $sched stopDaemon
puts "The daemon has stopped."

# Invoke the startDaemon operation.
puts "Starting the daemon..."
$AdminControl invoke $sched startDaemon 0
puts "The daemon has started."
```

Example: Dynamically changing scheduler daemon poll intervals using Java Management Extensions API:

Use the wsadmin scripting tool to invoke a `Jacl` script and dynamically change scheduler daemon poll intervals.

To dynamically change scheduler daemon poll intervals, use the wsadmin scripting tool to invoke this example JACL script. Invoking this example sets the poll interval of the scheduler daemon to 60 seconds.

```
# Example JACL Script to set the Scheduler daemon's poll interval

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Set the poll interval to 60 seconds (60000 ms)
$AdminControl setAttribute $sched pollInterval 60000
puts "Poll interval set."
```

Interoperating with schedulers:

Schedulers support forward compatibility. Tasks created in previous versions of WebSphere Application Server Enterprise Edition 5.0 or WebSphere Business Integration Server Foundation 5.1 continue to run in WebSphere Application Server, Version 6.x schedulers. Tasks that you create using Version 6.x are not compatible with product schedulers from Version 5.x. Version 5.x schedulers do not run any Version 6.x tasks.

Schedulers and versions

All schedulers that are configured to use the same database and tables are considered a clustered scheduler. To guarantee that your tasks run correctly, all servers in a scheduler cluster must be at the same version. If the servers are at different versions, tasks created with a Version 6.x scheduler might not run. If a mixed-Version environment is required for a short period of time, then all scheduler poll daemons

should be stopped on all Version 5.x servers to allow a Version 6.x server to run all tasks. This action allows the Version 6.x schedulers to obtain leases and run tasks that have been created with a Version 6.x scheduler.

Running tasks created with schedulers prior to Version 5.0.2 is not supported. See the topic, "Interoperating with the Scheduler service," in the WebSphere Application Server Enterprise Edition Version 5.0.2 information center for details on how to migrate these tasks to a more recent version. See the Information Center Library to access the Version 5.0.2 information center.

Scheduler calendars:

The scheduler provides stateless session bean interfaces which allow creating common calendars which can be used by the scheduler and any J2EE application.

The `SchedulerCalendars.ear` application is available and provides a default UserCalendar EJB implementation which allows using the SIMPLE and CRON calendars. Although this application is not required when using the scheduler, it is available to use from any J2EE application.

For details on how the SIMPLE and CRON calendars behave, see the API documentation for the com.ibm.websphere.scheduler.UserCalendar interface.

Specifying a UserCalendar with the scheduler

A UserCalendar is specified using the setUserCalendar() method of the TaskInfo interface of the scheduler. This interface allows you to select the JNDI name of the home interface of a UserCalendar bean. Because some UserCalendar bean implementations might handle multiple types of calendars, the interface also allows you to optionally select which type of calendar to use. A list of valid calendar types can be retrieved by invoking the getCalendarNames() method of the UserCalendar interface.

If the setUserCalendar() method is not invoked, or if a value of null or empty-string is specified for the home JNDI name parameter, then the default UserCalendar is used internally by the scheduler. When the default UserCalendar is accessed internally, it is not necessary that the `SchedulerCalendars.ear` system application be installed.

You might want to use the default UserCalendar directly in your other J2EE applications, apart from the scheduler. In this case, you may use the UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME value to look up the default UserCalendar from your applications. You may also supply this value to the setUserCalendar() method of the TaskInfo interface. You will need to ensure the `SchedulerCalendars.ear` system application was either automatically installed or that you have installed it manually.

Scheduler service settings:

Use this page to enable or disable the scheduler service. The scheduler service manages scheduler resources used by the server. The administrative console page used to configure the scheduler service is not available for version 6 (and above) servers. It is only available for version 5.*x* servers.

To view this administrative console page, click **Servers > Application Servers >** *server_name* **> Scheduler Service**.

Startup:

Specifies whether the server attempts to start the scheduler service.

Default   Selected

Range

                                     Selected

                                           When the application server starts, it attempts to start the scheduler service automatically.

                                     Cleared

                                           The server does not try to start the scheduler service. If scheduler resources are to be used on this server, the system administrator must start the scheduler service manually or select this property, then restart the server.

Developing and scheduling tasks

To develop and schedule tasks, use a configured scheduler.

1. Look up a configured scheduler. Each configured scheduler is available from two different programming models:
   - A J2EE server application, such as a servlet or EJB component can use the Scheduler API. Schedulers are accessed by looking them up using a JNDI name or resource reference.
   - Java Management Extensions (JMX) applications, such as wsadmin scripts, can use the Scheduler API using WASScheduler MBeans.

2. Develop the task.

   The Scheduler API supports different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. Refer to one of the following topics for details:
   - Developing a task that calls a session bean.
   - Develop a task that sends a Java Message Service (JMS) message. This task object can send a JMS message to either a queue or a topic.

   Note: Creating and manipulating scheduled tasks through the Scheduler interface is only supported from within the EJB container or Web container (Enterprise beans or servlets). Looking up and using a configured scheduler from a J2EE application client container is not supported.

3. Receive scheduler notifications. A notification sink is set on a task in order to receive the notification events that are generated by a scheduler when it performs an operation on the task.

4. Use custom calendars. You can assign aUserCalendar session bean to a task that allows schedulers to use custom and predefined date algorithms to determine when a task should run. See the UserCalendar interface for details.

5. Submit tasks to a scheduler. After a TaskInfo object has been created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.

6. Manage tasks with a scheduler.

7. Secure tasks with a scheduler.

Accessing schedulers:

Each configured scheduler is available using the Scheduler API from a J2EE server application, such as a servlet or EJB module. Use a JNDI name or resource reference to access schedulers. Each scheduler is also available using the JMX API, using its associated WASScheduler MBean.

Scheduler and WASScheduler interfaces are the starting point for all scheduler activities. Each scheduler is independent and allows task life cycle operations, such as creating new tasks.

1. Locate schedulers using the javax.naming.Context.lookup() method from a J2EE server application, such as a servlet or EJB module like the following example:

```
//lookup the scheduler to be used
import com.ibm.websphere.scheduler.Scheduler;
import javax.naming.InitialContext;
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/sched/MyScheduler");
```

2. Use wsadmin to locate a WASScheduler MBean using JACL scripting:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name.  The mbean name is
# formed by replacing the / in the JNDI namewith . and prepending
# Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched
```

The scheduler is now available to use from a J2EE server application or from a JMX API client. To create a task see the topics, Developing a task that calls a session bean or Developing a task that sends a JMS message.

Developing a task that calls a session bean:

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task to call a method on a TaskHandler session bean.

To create a task to call a method on a TaskHandler session bean, use these steps.

1. Create a new enterprise application with an EJB module. This application hosts the TaskHandler EJB module.
2. Create a stateless session bean in the EJB Module that implements the process() method in the com.ibm.websphere.scheduler.TaskHandler remote interface. Place the business logic you want created in the process() method. The process() method is called when the task runs. The Home and Remote interfaces must be set as follows in the deployment descriptor bean:
   * com.ibm.websphere.scheduler.TaskHandlerHome
   * com.ibm.websphere.scheduler.TaskHandler
3. Create an instance of the BeanTaskInfo interface by using the following example factory method. Using a JavaServer Pages (JSP) file, servlet or EJB component, create the instance as shown in the following code example. This code should coexist in the same application as the previously created TaskHandler EJB module:

   ```
   // Assume that a scheduler has already been looked-up in JNDI.
   BeanTaskInfo taskInfo = (BeanTaskInfo) scheduler.createTaskInfo(BeanTaskInfo.class)
   ```

   You can also use the wsadmin tool to create the instance as shown in the following JACL scripting example:

   ```
   set taskHandlerHomeJNDIName ejb/MyTaskHandler

   # Map the JNDI name to the mbean name.  The mbean name is formed by replacing the / in the jndi name
   # with . and prepending Scheduler_
   regsub -all {/} $jndiName "." jndiName
   set mbeanName Scheduler_$jndiName

   puts "Looking-up Scheduler MBean $mbeanName"
   set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
   puts $sched

   # Get the ObjectName format of the Scheduler MBean
   set schedO [$AdminControl makeObjectName $sched]

   # Create a BeanTaskInfo object using invoke_jmx
   puts "Creating BeanTaskInfo"
   set params [java::new {java.lang.Object[]} 1]
   $params set 0 [java::field com.ibm.websphere.scheduler.BeanTaskInfo class]

   set sigs [java::new {java.lang.String[]} 1]
   ```

```
$sigs set 0 java.lang.Class

set ti [$AdminControl invoke_jmx $schedO createTaskInfo $params $sigs]
set bti [java::cast com.ibm.websphere.scheduler.BeanTaskInfo  $ti]
puts "Created the BeanTaskInfo object: $bti"
```

> **Note:** Creating a BeanTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the topic Submitting tasks to schedulers.

4. Set parameters on the BeanTaskInfo object. These parameters define which session bean is called and when. The TaskInfo interface contains various set() methods that you can use to control execution of the task, including when the task runs and what work the task does when it runs.

   The BeanTaskInfo interface requires that the TaskHandler JNDI name or TaskHandlerHome is set using the setTaskHandler method. If using the WASScheduler MBean API to set the task handler, then the JNDI name must be the fully-qualified global JNDI name.

   The TaskInfo interface specifies additional control points, as documented in the API documentation.Set parameters using the TaskInfo interface API method as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//find the session bean to be called when the task executes
Object o = new InitialContext().lookup("java:comp/env/ejb/MyTaskHandlerHome");
TaskHandlerHome home = (TaskHandlerHome)javax.rmi.PortableRemoteObject.narrow(o,TaskHandlerHome.class);

//now set the start time and task handler to be called in the task info
taskInfo.setTaskHandler(home);
taskInfo.setStartTime(startDate);
```

   You can also set parameters using the following JACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$bti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$bti setStartTimeInterval 30seconds

# Set JNDI name of the EJB which will get called when the task runs.  Since there is no
# application J2EE Context when the task is created by the MBean, this must be a
# global JNDI name.
$bti setTaskHandler $taskHandlerHomeJNDIName

# Do not purge the task when it's complete
$bti setAutoPurge false

# Set the name of the task.  This can be any string value.
$bti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $bti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

A BeanTaskInfo object has been created that contains all of the relevant data to call an EJB method.

Submit the task to a scheduler for creation, as described in the topic Submitting a task to a scheduler.

Developing a task that sends a Java Message Service message:

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task that sends a Java Message Service (JMS) message to a queue or topic.

To create a task that sends a Java Message Service (JMS) message to a queue or topic, use these steps.

1. Create an instance of the MessageTaskInfo interface using the Scheduler.createTaskInfo() factory method. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//lookup the scheduler to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");

MessageTaskInfo taskInfo = (MessageTaskInfo) scheduler.createTaskInfo(MessageTaskInfo.class);
```

You can also use the wsadmin tool, create the instance as shown in the following JACL scripting example:

```
# Sample create a task using MessageTaskInfo task type
# Call this mbean with the following parameters:
#    <scheduler jndiName>    = JNDI name of the scheduler resource,
#                                for example scheduler/myScheduler
#    <JNDI name of the QCF>  = The global JNDI name of the Queue Connection Factory.
#    <JNDI name of the Queue> = The global JNDI name of the Queue destination

set jndiName [lindex $argv 0]
set jndiName_QCF [lindex $argv 1]
set jndiName_Q [lindex $argv 2]

# Map the JNDI name to the mbean name.  The mbean name is formed by replacing the / in the jndi name
# with . and prepending Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a MessageTaskInfo object using invoke_jmx
puts "Creating MessageTaskInfo"
set params [java::new {java.lang.Object[]} 1]
$params set 0 [java::field com.ibm.websphere.scheduler.MessageTaskInfo class]

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.Class

set ti [$AdminControl invoke_jmx $schedO createTaskInfo $params $sigs]
set mti [java::cast com.ibm.websphere.scheduler.MessageTaskInfo  $ti]
puts "Created the MessageTaskInfo object: $mti"
```

Note: Creating a MessageTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the topic Submitting a task to a scheduler.

2. Set parameters on the MessageTaskInfo object. The TaskInfo interface contains various set() methods that can be used to control execution of the task, including when the task runs and what work the task does when it starts.

The TaskInfo interface specifies additional behavior settings, as documented in the API documentation. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//now set the start time and the JNDI names for the queue connection factory and the queue
taskInfo.setConnectionFactoryJndiName("jms/MyQueueConnectionFactory");
taskInfo.setDestination("jms/MyQueue");
taskInfo.setStartTime(startDate);
```

You can also use the wsadmin tool, to create the instance as shown in the following JACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$mti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$mti setStartTimeInterval 30seconds

# Set the global JNDI name of the QCF & Queue to send the message to.
$mti setConnectionFactoryJndiName $jndiName_QCF
$mti setDestinationJndiName $jndiName_Q

# Set the message
$mti setMessageData "Test Message"

# Do not purge the task when it's complete
$mti setAutoPurge false

# Set the name of the task.  This can be any string value.
$mti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $mti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

A MessageTaskInfo object has been created that contains all of the relevant data for a task that sends a JMS message.

Submit the task to a scheduler for creation, as described in the topic Submitting a task to a scheduler.

Scheduling long-running tasks:

The default behavior of the scheduler is designed to run business logic that runs for a short period of time. In version 6.0.2 and later, two API methods on the com.ibm.websphere.scheduler.TaskInfo interface help avoid some of the problems that can occur when running tasks for an extended time.

The TaskInfo.setQOS method supports tasks with both a transactional and non-transactional quality of service. When running tasks that run for long periods, you can use the TaskInfo.QOS_ATLEASTONCE quality of service to run the task without a global transaction. This process prevents various timeout issues that can occur when resources are held by a long-running transaction. See Transactions and schedulers for details on the TaskInfo.setQOS method and how it can be used.

Using the TaskInfo.setExpectedDuration method, the scheduler can to adjust timeout values, as appropriate, for a given task for all qualities of service. The application server attempts to adjust various run-time parameters to accommodate the estimated run time of the task.

1. When you assemble the TaskInfo object with the Scheduler API or the WASScheduler MBean, use the following methods on the TaskInfo interface:
   a. Set the quality of service.

> 1) If the task must be transactional, use the setQOS method with the QOS_ONLYONCE constant, which is the default, if not set.
>
> 2) If the task does not need to be transactional, use the setQOS method with the QOS_ATLEASTONCE constant.

  b. Set the expected duration.

> 1) Use the setExpectedDuration method to set the expected duration of the task in seconds.

2. Schedule the task using the Scheduler.create method.

Access schedulers.

Receiving scheduler notifications:

Various notification events are generated by a scheduler when it performs an operation on a task. These notifications events are described in this topic.

The notification events generated by a scheduler when it performs a task include:

Scheduled
> A task has been scheduled.

Purged
> A task has been permanently deleted from the persistent store.

Suspended
> A task was suspended.

Resumed
> A task was resumed.

Complete
> A task has run completely. If it was a repeating task, all repeats have been performed.

Cancelled
> A task has been cancelled. It will not run again.

Firing A task is prepared to run.

Fired A task completed successfully.

Fire failed
> A task could not run successfully.

To receive notification events, call the setNotificationSink() method on the TaskInfo interface before creating the task. The setNotificationSink() method enables you to specify the session bean that is to act as the callback, and a mask that restricts which events are generated.

1. Create a NotificationSink session bean. Create a stateless session bean that implements the handleEvent() method in the com.ibm.websphere.scheduler.NotificationSink remote interface. The handleEvent() method is called when the notification is fired. The Home and Remote interfaces can be set as follows in the bean's deployment descriptor:

   ```
   com.ibm.websphere.scheduler.NotificationSinkHome
   com.ibm.websphere.scheduler.NotificationSink
   ```

   The NotificationSink interface defines the following method:

   ```
   public void handleEvent(TaskNotificationInfo task) throws java.rmi.RemoteException;
   ```

2. Specify the notification sink session bean prior to submitting the task to the Scheduler using the TaskInfo interface API setNotificationSink() method.

   If using the WASScheduler MBean API to set the notification sink, then the JNDI name must be the fully-qualified global JNDI name. Using a JavaServer Pages (JSP) file, servlet or EJB component, look up and set the notification sink on a task as shown in the following code example:

   ```
   TaskInfo taskInfo = ...
   Object o = new InitialContext().lookup("java:comp/env/ejb/NotificationSink");
   NotificationSinkHome home = (NotificationSinkHome )javax.rmi.PortableRemoteObject.narrow
   (o,NotificationSinkHome.class);
   taskInfo.setNotificationSink(home,TaskNotificationInfo.ALL_EVENTS);
   ```

You can also use the wsadmin tool to set the notification sink callback session bean as shown in the following JACL scripting example:

```
# Use the NotificationSinkHome's Global JNDI name
# Assume that a TaskInfo was already created...
$taskInfo setNotificationSink "ejb/MyNotificationSink"
```

3. Specify the event mask. The event mask is specified as an integer bitmap. You can either use an individual mask such as TaskNotificationInfo.CREATED to receive specific events, TaskNotificationInfo.ALL_EVENTS to receive all events or a combination of specific events. If you use Java, your script might look like the following example:

```
int eventMask = TaskNotificationInfo.FIRED | TaskNotificationInfo.COMPLETE;
taskInfo.setNotificationSink(home,eventMask);
```

If you use JACL, your script might look like the following example:

```
# Set the event mask based on two event constants.
set eventmask [expr [java::field com.ibm.websphere.scheduler.TaskNotificationInfo FIRED] +
 [java::field com.ibm.websphere.scheduler.TaskNotificationInfo COMPLETE]]

# Set our Notification Sink based on our global JNDI name AND event mask.
# Note:  We need to use the full method signature here since the
# method resolver can't always detect the right method.
$taskInfo {setNotificationSink String int} "ejb/MyNotificationSink" $eventmask
```

A notification sink bean is now set on a TaskInfo object and can now be submitted to a scheduler using the create method.

Submitting a task to a scheduler:

This topic describes the process of submitting a task to a configured scheduler.

This task assumes that you have already configured a scheduler and created and configured a TaskInfo object that calls a session bean or sends a JMS message.

Once you have developed a TaskInfo object that contains all relevant data for a task, submit the task to a scheduler for creation. When the task is created, the scheduler runs it.

Create the task. After you configure TaskInfo, submit it to the appropriate scheduler, using the Scheduler API create method.

```
// Create the TaskInfo using the Scheduler that you already looked up and print out the Task ID
TaskStatus ts = scheduler.create(taskInfo);
System.out.println("Task created with id: " + ts.getTaskId()"
```

You can also create the task using the wsadmin tool as shown in the following JACL scripting example:

```
# Create the TaskInfo using the WASScheduler MBean that you previously located and print out the Task ID
puts "Creating the task..."

set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 create $params $sigs]]

puts "Task Created.  TaskID= [$taskStatus getTaskId]"

puts $taskStatus
```

When the call to the create() method is complete, the task exists in the persistent store and is run at the time specified in the TaskInfo object. If a global transactional context is present on the thread, and the create() transaction rolls back or is aborted, the task does not run.

The TaskStatus object, which has been returned by the call to the create() method, contains information about the state of the task, as well as the task ID. The task ID is the unique identifier for this task, and is required if the task is to be suspended, resumed, cancelled, and so on, at a later time.

Note: The TaskStatus object is only a snapshot of the current state of the task. Use the Scheduler.getStatus() method to receive the current state when needed.

Managing tasks with a scheduler:

The scheduler provides several task management methods.

When a task is created by calling the create() method on a scheduler, a TaskStatus object is returned to the caller. The TaskStatus object contains the task ID, which is a unique identifier. The Scheduler API and WASScheduler MBean define several additional methods that pertain to the management of tasks, each of which accepts the task ID as a parameter. The following task management methods are defined:

suspend()
> Suspends a task. The task does not run until it has been resumed.

resume()
> Resumes a previously suspended task.

cancel()
> Cancels a task. The task is not run and cannot be resumed.

purge()
> Permanently deletes a cancelled task from the persistent store.

getStatus()
> Returns the current status of the task.

Use the following API example to create and cancel a task:

```
//Create the task.
TaskInfo taskInfo = ...
TaskStatus status = scheduler.create(taskInfo);

//Get the task ID
String taskId = status.getTaskId();

//Cancel the task. Specify the purgeAlso flag so that the task does not remain in the persistent store
scheduler.cancel(taskId,true);
```

Use the following example JACL script operations in the wsadmin tool to create and cancel a task:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name.  The mbean name is
# formed by replacing the / in the jndi name with . and prepending
# Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a TaskInfo object...
# (Some code excluded...)
set params [java::new {java.lang.Object[]} 1]
```

```
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 create $params $sigs]]

set taskID [$taskStatus getTaskId]
puts "Task Created.  TaskID= $taskID"

# Cancel the task using the Task ID from the TaskStatus object returned during create.
set params [java::new {java.lang.Object[]} 1]
$params set 0 false

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.boolean

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 cancel $params $sigs]]
```

Transactionality. All methods of the Scheduler API are transactional. If a global transactional context is present, it is used to perform the operation. If an unexpected exception is thrown, the transaction is marked to roll back, and the caller must handle it appropriately. If an expected or declared exception is thrown, the transaction remains intact and the caller must choose to roll back or to commit the transaction. If the transaction is rolled back at some point, all scheduler operations performed within the transaction are also rolled back.

If a local transactional context is present, it is suspended and a new global transactional context begins. Likewise, if no transactional context is active, a global transactional context begins. In both cases, if an unexpected exception is thrown, the transaction rolls back. If a declared exception is thrown, the transaction is committed.

If another thread is concurrently modifying the task in question, a TaskPending exception is thrown. This is because schedulers lock the database optimistically. The calling application can then retry the operation.

Task management functions may block if the task is currently running. Because the scheduler guarantees that each task will run only once, the task must be locked for the duration of a running task. Likewise, if a task is changed using one of the management functions but the global transaction is not committed, any other management functions issued from another transaction for that task will be blocked.

A stateless session bean task's TaskHandler.process() method can change it's own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the Required or Mandatory container managed transaction types. If the Requires New transaction type is specified on the process() method, all management functions will deadlock.

All methods defined by the Scheduler API are described in API documentation.

Identifying tasks that are currently running:

When a task runs, the task database record is locked until the task completes. This topic describes how to determine whether or not a task is running.

Prior to version 6.0.2, all tasks ran in a single global transaction. This process not only prevented the task from running more than once successfully, but it also blocked all attempts at reading the state of the task, since each task used read-committed transaction isolation.

There are two methods for determining whether a task is running:

1. **NotificationSink**

A NotificationSink EJB can be set on the task using the setNotificationSink method on the TaskInfo object. The NotificationSink bean can then log the life cycle of the task to a separate database record in a custom table. This would result in a history log of the task that can be queried independently from the scheduler. This solution works for all versions of the scheduler service. See Receiving Scheduler Notifications for details.

2. **Delayed Execution and Uncommitted Read**

   In Version 6.0.2 and later, two behaviors enable the scheduler find and retrieve API methods, such as getTask, getTaskStatus or findTasksByName, to see the current state of the task without blocking. To see the current state of the task, including its uncommitted running state, complete the following steps:

1. Enable read-uncommitted transaction isolation for the scheduler read methods to prevent these methods from blocking while a task is running. To set the default transaction isolation for read methods, see Configuring scheduler default transaction isolation for read operation details.

   Note: If the scheduler database does not support uncommitted reads, such as Oracle, it might not be possible to determine if a task is running unless you use the QOS_ATLEASTONCE quality of service.

2. Use the TaskInfo.EXECUTION_DELAYEDUPDATE option on the TaskInfo.setTaskExecutionOptions method to force the scheduler to write the TaskStatus.RUNNING state to the task when that task starts running.

Stopping tasks that are failing:

The scheduler runs tasks in a global transactional context, by default. If a task is failing due to a configuration problem or application error, the scheduler attempts to retry the task until the scheduler failure threshold is reached. This topic describes how to stop the tasks that are failing.

When the task reaches the failure threshold, the scheduler stops running the task until the scheduler daemon is restarted using the WASScheduler MBean, the scheduler fails over to another server, or until the scheduler is resumed using the resume method on the Scheduler API or WASScheduler MBean.

1. Cancel or suspend a transactional (QOS_ONLYONCE) task that is continually failing. This action can be difficult if the scheduler has not yet reached the failure threshold. The cancel and suspend Scheduler API methods or WASScheduler MBean operations block until the task fails or the method times out, while waiting for a database lock and throws a TaskPending exception. If this is occurs, then the application can retry the cancel or suspend operation until it completes.

2. Alternatively, stop the scheduler daemon using the stopDaemon operation on the WASScheduler MBean to avoid running the task multiple times, and run the cancel or suspend operation while it is stopped. While the daemon is stopped, the scheduler does not run tasks. However, all MBean operations and API methods are still available.

Scheduler tasks and J2EE context:

When a task is created using the Scheduler API create() method, the Java 2 Enterprise Edition (J2EE) thread context of the creator is stored with the scheduled task. When the task runs, the original J2EE thread context is reapplied to the thread before calling the customer TaskInfo instance.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate J2EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See Using asynchronous beans for details on how to configure the Application Server to propagate these service contexts.

Transactions and schedulers:

The scheduler runs a task in a single global transaction, by default. You can use the QOS_ONLYONCE or QOS_ATLEASTONCE quality of service to specify whether the task runs as a single unit of work once or as independent transactions.

Transaction behavior when running a task

Because the scheduler runs a task in a single global transaction, by default, the transaction is open until the task completes or fails. The resources involved in that transaction are subject to various timeouts and the thread of the task could be identified as hung if the task runs for a long period of time that can span many minutes or hours.

The TaskInfo.setQOS method allows reducing the quality of service for the task to run at-least-once. When you set the task to TaskInfo.QOS_ATLEASTONCE, the task does not keep a transaction open for the duration of the running task. Because this quality of service is no longer transactional, the task may fire more than one time if the scheduler fails to update the result of the task. This quality of service is ideal for batch jobs. Use QOS_ATLEASTONCE with check points in the business logic, so if the task needs to recover, the business logic can continue at the next check point. See the com.ibm.websphere.scheduler.TaskInfo API documentation for more details.

QOS_ONLYONCE

Scheduled tasks execute only one time successfully when using the QOS_ONLYONCE quality of service. This action is accomplished by grouping all of the work done in the task as a single unit of work. When each task fires, the following events occur in a single global transactional context:
1. The context of the application that created the task is applied to the thread.
2. A global transactional context is started.
3. The next fire time and start-by time are calculated using the UserCalendar bean or the DefaultUserCalendar.

    Note: If using the TaskInfo.setTaskExcecutionOptions method with the TaskInfo.EXECUTION_DELAYEDUPDATE option, this step will occur after the record is updated.
4. The task database task record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true.
5. The task database record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true. If the EXECUTION_DELAYEDUPDATE option is used, the database will not reflect the next state of the task, but the current state with the TaskStatus.RUNNING state set.
6. If the NotificationSink bean is set, a FIRING notification is fired.
7. The BeanTaskInfo or MessageTaskInfo object starts.
8. If the task fails and the NotificationSink bean is set, a FIRE_FAILED notification is fired on a separate transaction.
9. If the task's NotificationSink bean is set, then the various notifications are fired as required.
10. If the EXECUTION_DELAYEDUPDATE option is used for the task, the database will be updated a second time with the next state of the task.
11. The global transaction is committed.

Because all events belonging to a task are executed in a single global transactional context, consider the following points in order to avoid transaction-related errors:
- Each resource participating in the task transaction must be two-phase XA capable.

  This includes the JDBC datasource configured for the scheduler, any JMS services used by the MessageTaskInfo objects, and any resources used within any of the UserCalendar, TaskHandler, or NotificationSink beans that have a transaction setting of "Required".

- One resource can be single-phase, if last participant support is enabled for the application that created the transaction. Enable last participant support using an assembly tool. You can also enable last participant support through the administrative console. See the article, "Last participant support extension settings" for details.

All unexpected exceptions are logged to the activity log and all events participating in the task's global transaction are rolled back. This includes changes to the task's database record, which force the task to be executed again when the scheduler daemon polls the database during the next poll cycle. The UserCalendar, TaskHandler, and NotificationSink beans can choose not to participate in the global transaction by configuring the bean transaction setting to "Requires new".

QOS_ATLEASTONCE

Scheduled tasks that use the QOS_ATLEASTONCE quality of service do not have a single transactional context. In this case, each calendar calculation, event notification and database update occurs in an independent transaction:

1. The context of the application that created the task is applied to the thread.
2. The task's database record is updated with the RUNNING state of the task.
3. UserCalendar, NotificationSink beans are called.
4. The BeanTaskInfo or MessageTaskInfo is started.
5. Result notifications are sent.
6. The database is updated with the next state of the task, if the task has not been changed since the RUNNING state was written.

If a failure happens after the RUNNING state is written to the database and before the result is written, then the task may run more than one time.

When using QOS_ATLEASTONCE, all NotificationSink, UserCalendar and TaskHandler beans must not mandate a transaction (TX_MANDATORY), since there is no global transaction available when the task runs. The EJB components use "Required" or "Requires new" container managed transaction or a bean managed transaction.

Transaction behavior when using the Scheduler API methods or WASScheduler MBean operations

All Scheduler interface methods participate in a single global transactional context. If a global transactional context is already present on the thread when the create(), suspend(), resume(), cancel(), and purge() methods are executed, then the existing global transaction is used. Otherwise, a new global transaction begins.

If the method participates in the global transaction of the caller and an unexpected error occurs, then the transaction is marked to roll back. If the exception is a declared exception, then the exception is resubmitted to the caller, and the transaction is left alone for the caller to commit or roll back.

If the method starts its own global transaction and any exception occurs, then the transaction is rolled back, and the exception is resubmitted to the caller.

Scheduler task user authorization:

The scheduler service uses the asynchronous beans deferred start mechanism to propagate J2EE service context information to a task when it runs. If you plan to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread.

Tasks run with specified security credentials using the following methods:

- Using the Java Authentication and Authorization Service (JAAS) security context on the thread at the time the task was created. See the topic, Deferred start and security in the Asynchronous beans section of the information center.
- Using the setAuthenticationAlias method on the TaskInfo object.
- Using a specified security identity on a BeanTaskInfo task TaskHandler EJB method.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate J2EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See Using asynchronous beans for details on how to configure the Application Server to propagate these service contexts.

Java Authentication and Authorization Service Security context

If you intend to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread. Once each task has the correct credentials, you can disable and re-enable administrative security without causing any security problems. If you do not set the security context when the scheduler task is created and you later enable security in the target application, a security exception or error message might display, such as SECJ0053E. You might also see this error if two or more schedulers on different servers are accessing the same tables (a clustered or redundant scheduler) and the security settings are different.

The JAAS security context is not set if any of the follow conditions are true:
- administrative security is disabled.
- Security context policies are disabled on the configured WorkManager for the associated scheduler configuration.
- A credential is not set on the thread. For example, the enterprise bean or servlet that is used to create the scheduled task is not secured, or the task was created with a WASScheduler MBean.

If any of the previously mentioned conditions are true when you create your task and you need to enable security on your application server or application, you must complete the following steps for each task:
1. Find the task using the Scheduler API find or get methods.
2. Cancel the task using the Scheduler.cancel() API.
3. Recreate the task using the Scheduler.create() method with security enabled. Submitting a task that was retrieved from the scheduler using the find or get methods will automatically generate a new task ID.

Security order of precedence

As previously noted, there are three ways of verifying that a task will run with the correct user credentials. In addition, each TaskInfo implementation may have its own way of supplying user information, which may override the standard mechanisms. If multiple methods are used, refer to the following lists to determine which security mechanism is going to be employed.

BeanTaskInfo
1. TaskHandler security identity set on the process() method of the EJB
2. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
3. JAAS security context

MessageTaskInfo
1. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface

2. The setUsername and setPassword methods on the MessageTaskInfo interface. See the Deprecated features list for more information.

Securing scheduler tasks:

Scheduled tasks are protected using application isolation and administrative roles. This topic describes how to secure scheduler tasks.

If a task is created using a Java 2 Platform, Enterprise Edition (J2EE) server application, only applications with the same name can access those tasks. Tasks created with a WASScheduler MBean using the AdminClient interface or scripting are not part of a J2EE application and have access to all tasks regardless of the application with which they were created. Tasks created with a WASScheduler MBean are only accessible from the WASScheduler MBean API and are not accessible from the Scheduler API.

If the Use Administration Roles attribute is enabled on a scheduler and administrative security is enabled on the Application Server, all Scheduler API methods and WASScheduler MBean API operations enforce access based on the WebSphere Administration Roles. If either of these attributes are disabled, then all API methods are fully accessible by all users.

1. Enable security for all application servers.
2. Manage schedulers.

Scheduler configuration or topology:

The scheduler uses a database to persist information concerning which tasks to run and when. Errors might occur when changing the application server topology or when changing the application or server configuration. When you change the configuration or topology, carefully consider how this action affects the scheduler.

Restricting security

If you created tasks with an application server while security is disabled, and you later decide to enable security, then the scheduler might have difficulty running tasks. When you create a task, the security context of the application thread is automatically stored with the task. If security is not stored with the task (see Scheduler task user authorization), and you later enable security on the server or application where the task is to run, then the following errors might be logged:

```
SECJ0053E: Authorization failed for /UNAUTHENTICATED while invoking (Home)com/ibm/websphere/scheduler
/TaskHandler create:2 securityName: /UNAUTHENTICATED;accessID: UNAUTHENTICATED is not granted any of
the required roles: MySecurityRole
```

Before you enable security on the server or application, determine if any tasks might be adversely affected. If so, use the Scheduler API or WASScheduler MBean to cancel the tasks and recreate them after you configure security.

Application server topology changes

The scheduler stores javax.ejb.HomeHandle objects for TaskHandler, NotificationSink and UserCalendar *homes* when the task is created. When you run the task later, these home handles are reinflated and used to access the EJB component home. When the home handle references an EJB on a single-server environment, the home handles have affinity to that server. When the home handle references an EJB component on a cluster, then the home handles have affinity to the cluster.

If the application server or the Workload Managed (WLM) cluster that a home handle is referencing is not available, then the scheduler fails to run the task, and the following error is logged:

```
SCHD0063E: A task with ID 123 failed to run on Scheduler MyScheduler (sched/MyScheduler) because of
an exception: {cause of failure}
```

If you upgrade the application server to a cluster, or if the Object Request Broker (ORB) ORB_LISTENER_ADDRESS is not set to a fixed port number (see Configuring Inbound Transports), then the task might also fail, since the information stored within the home handle does not have the appropriate information to find the desired server.

Upgrading to a scheduler cluster

A scheduler cluster (not to be confused with a WLM cluster) is a collection of scheduler configurations on different application servers that share the same JNDI name, JDBC data source and table prefix. If you upgrade a stand-alone scheduler to a clustered scheduler, then the application and any associated resources that the application requires must be available. If this is not the case, the scheduled task fails to run and error messages might be logged:

```
SCHD0103W: The Scheduler MyScheduler (sched/MyScheduler) was unable to run task 123 because the
application or module is unavailable: MyTaskHandlerEJB
```

To avoid issues with application availability and achieve optimal results, use the same servers in a scheduler cluster as those used in a WLM cluster.

Reusing scheduler tables

When changing any topology, moving from development to production environments, or making any configuration changes that make the environment more restrictive, you might get optimal results if you use a different set of scheduler tables. Reusing scheduler tables that have scheduled tasks from previous releases without careful planning might cause problems:

- EJB components running on unexpected application servers.
- Tasks failing to run due to invalid or missing security credentials.
- Tasks failing to run due to invalid or missing J2EE context information.

Diagnosing such problems is challenging and requires analyzing logs on all servers that have a scheduler installed and configured. When the problem tasks are located, the tasks can be cancelled using the Scheduler APIs, or the tables can be dropped and recreated.

Scheduler interface:

Use the `com.ibm.websphere.scheduler.Scheduler` Java object (in the JNDI namespace for the scheduler configuration) to find a reference to a scheduler and work with tasks.

A `com.ibm.websphere.scheduler.Scheduler` Java object exists in the JNDI namespace for each scheduler configuration. A reference to a scheduler can be obtained by performing a lookup on the JNDI name; however, the lookup is valid only from the server process where the scheduler instance exists. Once a reference has been obtained, tasks can be created, suspended, cancelled, and so on, if the caller has access to the scheduler instance.

For details, see Interface Scheduler in the API documentation.

Task creation

The task is created in the persistent store using the global transactional context of the caller, if present. See the topic, "Transactions and schedulers" on page 1293, for more details. Since this is a transactional operation, the task cannot be run or modified from another thread until the current transaction commits.

Task modification

Tasks that have been created can be modified with the suspend(), resume(), cancel(), and purge() methods. These methods take a Task Identifier string as a parameter, which is generated by the create() method and can be found in the TaskStatus object. If a task is currently running or being

modified by another thread, an operation that attempts to modify the state of the task might block on the attempt. Tasks can only be modified by the same application (EAR file) that was used to create the task.

Task execution

Tasks are run in the thread pool specified by the configuration's work manager. If multiple schedulers are configured to share the same database tables, the scheduler is clustered and the tasks found in the table can be run on any of the schedulers, whether or not they are in the same server, node, or cell.

Task lookup

Tasks can be located using the Name property that was assigned at creation time. This is useful when you need to modify a group of tasks and tracking individual task ID's is not convenient.

TaskInfo interface:

TaskInfo objects contain the information that can be used to create a task. Several implementations of this class exist, one for each type of task that can be run.

Available TaskInfo implementations include:

BeanTaskInfo

Calls a stateless session bean.

MessageTaskInfo

Sends a JMS message to a queue or publishes a message to a topic. For details, see the Interface TaskInfo in the API documentation.

After a TaskInfo object is created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.

For details about the TaskInfo interface, see the API documentation .

TaskHandler interface:

A task handler is a user-defined stateless session bean that is called by tasks created using a BeanTaskInfo object.

A task handler bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as the Application Server Toolkit (AST) or Rational Application Developer:

```
com.ibm.websphere.scheduler.TaskHandlerHome
com.ibm.websphere.scheduler.TaskHandler
```

The bean itself needs to implement the process() method defined in the remote interface. For details, see the Interface TaskHandler in the API documentation.

Once an EJB is created and available within an enterprise application, it can be called by a BeanTaskInfo task when it runs. See the Developing a task that calls a session bean topic for details.

When a task is created using a BeanTaskInfo object, the process() method on the TaskHandler session bean is called whenever the task runs. Because the TaskStatus object for the task is passed as a parameter to the process() method, the task handler determines different types of information about the task, such as when it will fire next, the number of repeats remaining, its name and its ID.

The process() method can also change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the **Required** or **Mandatory** container managed transaction types. If the **Requires New** transaction type is specified on the process()method, all management functions deadlock.

NotificationSink interface:

A notification sink is a user-defined stateless session bean that is called when the task changes state.

A notification sink bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as the Application Server Toolkit (AST) or Rational Application Developer:

```
com.ibm.websphere.scheduler.NotificationSinkHome
com.ibm.websphere.scheduler.NotificationSink
```

The bean itself needs to implement the handleEvent() method defined in the remote interface. For details, see the Interface NotificationSink section of the API documentation and the Receiving scheduler notifications topic.

A NotificationSink provides an event notification callback on a task-by-task basis. A notification sink is set on the TaskInfo interface, using the setNotificationSink() method. If a notification sink is not specified on a task, all notifications are lost; however, the status of a task can be determined by calling the getStatus() method from the Scheduler interface. A notification callback is made for each of the following events:
- Scheduled
- Suspended
- Resumed
- Fired
- Firing
- Fire Failed
- Complete
- Purged

UserCalendar interface:

A user calendar is a user-defined stateless session bean that is called by tasks when they need to calculate date-related values.

A user calendar bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as the Application Server Toolkit (AST) or Rational Application Developer:

```
com.ibm.websphere.scheduler.UserCalendarHome
com.ibm.websphere.scheduler.UserCalendar
```

The bean itself needs to implement the applyDelta(), validate(), and getCalendarNames() methods defined in the remote interface. For details, see the Interface UserCalendar in the API documentation.

User calendars are used to calculate time intervals, such as the time between task runs. A user calendar takes a java.util.Date object, applies the interval string and returns the resulting java.util.Date.

User calendars are set with the setUserCalendar() method on the TaskInfo interface and called by the scheduler run-time code when a delta calculation is necessary.

The following methods on the TaskInfo interface specify delta strings that use the user calendar for calculation:
- setStartTimeInterval
- setStartByInterval
- setRepeatInterval

Default user calendar

> If a user calendar has not been specified using the TaskInfo.setUserCalendar() method, a default user calendar is used. The default calendar allows for simple delta specifications, such as seconds, minutes, hours, days, and months. See the API documentation for details on the default calendar. The Default user calendar also provides a CRON-like syntax for calculating absolute times versus time deltas.

Calendar identifiers

A single user calendar can contain logic for multiple calendars. A calendar specifier string determines which calendar is used. For example, a calendar bean might be implemented to recognize the interval *day*. However, the identifier also recognizes two calendar implementations: *standard* (for a standard calendar day) and *business* (for a business day).

Internationalization and time zones

Scheduler makes use of the java.util.Date class when storing and processing dates. Internally, this class saves the time as milliseconds since the Epoch, Greenwich Mean Time. Since the Date is not converted to local time until converted to a string, the scheduler respects the time zone where the date was created.

Writing user calendars

Because the user calendar is a stateless session bean, the same Java 2 Platform Enterprise Edition (J2EE) programming model available to other session beans is available to the user calendar as well.

Startup beans

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available.

1. For Application startup beans, use the home interface, com.ibm.websphere.startupservice.AppStartUpHome, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, com.ibm.websphere.startupservice.ModStartUpHome, to designate a bean as a Module startup bean.

2. For Application startup beans, use the remote interface, com.ibm.websphere.startupservice.AppStartUp, to define start() and stop() methods on the bean. For Module startup beans, use the remote interface, com.ibm.websphere.startupservice.ModStartUp, to define start() and stop() methods on the bean.

   The startup bean start() method is called when the module or application starts and contains business logic to be run at module or application start time.

   The start() method returns a boolean value. **True** indicates that the business logic within the start() method ran successfully. Conversely, **False** indicates that the business logic within the start() method failed to run completely. A return value of False also indicates to the Application server that application startup is aborted.

   The startup bean stop() methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a stop() method is logged only. No other action is taken.

   The start() and stop() methods must never use the TX_MANDATORY transaction attribute. A global transaction does not exist on the thread when the start() or stop() methods are invoked. Any other TX_* attribute can be used. If TX_MANDATORY is used, an exception is logged, and the application start is aborted.

   The start() and stop() methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal

has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.

4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module

5. To control who can invoke startup bean methods via WebSphere Security do the following:

   a. Define the method permissions for the Start() and Stop() methods as you would for any EJB. (See "Defining method permissions for EJB modules.")

   b. Ensure that the User that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the "Server user ID" within the User Registry.

View the startup beans service settings.

Startup beans service settings:

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

To view this administrative console page, click **Servers** > **Application servers** >*server_name* > **Container services** > **Startup beans service**.

Enable service at server startup:

Specifies whether the server attempts to initiate the startup beans service.

Default	Cleared
Range	**Selected**
	When the application server starts, it attempts to initiate the startup bean service automatically.
	Cleared
	The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Work area

Task overview: Implementing shared work areas

The work area service enables application developers to implicitly propagate information beyond the information passed in remote calls. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of each method. The methods on the server side can use or ignore the information in the work area as appropriate.

Before proceeding with the steps to implement work areas, as described below, review the topic Work area service: Overview.

1. Developing applications that use work areas. Applications interact with the work area service by implementing the UserWorkArea interface.

2. Managing work areas. The work area service is managed using the administrative console.

Overview of work area service: One of the foundations of distributed computing is the ability to pass information, typically in the form of arguments to remote methods, from one process to another. When application-level software is written over middleware services, many of the services rely on information beyond that passed in the application's remote calls. Such services often make use of the implicit propagation of private information in addition to the arguments passed in remote requests; two typical users of such a feature are security and transaction services. Security certificates or transaction contexts are passed without the knowledge or intervention of the user or application developer. The implicit propagation of such information means that application developers do not have to manually pass the information in method invocations, which makes development less error-prone, and the services requiring the information do not have to expose it to application developers. Information such as security credentials can remain secret.

The work area service gives application developers a similar facility. Applications can create a work area, insert information into it, and make remote invocations. The work area is propagated with each remote method invocation, eliminating the need to explicitly include an appropriate argument in the definition of every method. The methods on the server side can use or ignore the information in the work area as appropriate. If methods in a server receive a work area from a client and subsequently invoke other remote methods, the work area is transparently propagated with the remote requests. When the creating application is done with the work area, it terminates it.

There are two prime considerations in deciding whether to pass information explicitly as an argument or implicitly by using a work area. These considerations are:
* Pervasiveness: Is the information used in a majority of the methods in an application?
* Size: Is it reasonable to send the information even when it is not used?

When information is sufficiently pervasive that it is easiest and most efficient to make it available everywhere, application programmers can use the work area service to simplify programming and maintenance of code. The argument does not need to go onto every argument list. It is much easier to put the value into a work area and propagate it automatically. This is especially true for methods that simply pass the value on but do nothing with it. Methods that make no use of the propagated information simply ignore it.

Work areas can hold any kind of information, and they can hold an arbitrary number of individual pieces of data, each stored as a property.

Work area property modes: The information in a work area consists of a set of properties; a property consists of a key-value-mode triple. The key-value pair represents the information contained in the property; the key is a name by which the associated value is retrieved. The mode determines whether the property can be removed or modified.

Property modes

There are four possible mode values for properties, as shown in the following code example:

Code example: The PropertyModeType definition

```
public final class PropertyModeType {
    public static final PropertyModeType normal;
    public static final PropertyModeType read_only;
    public static final PropertyModeType fixed_normal;
    public static final PropertyModeType fixed_readonly;
};
```

A property's mode determines three things:
- Whether the value associated with the key can be modified
- Whether the property can be deleted
- Whether the mode associated with the key-value pair can be modified

The two read-only modes forbid changes to the information in the property; the two fixed modes forbid deletion of the property.

The work area service does not provide methods specifically for the purpose of modifying the value of a key or the mode associated with a property. To change information in a property, applications simply rewrite the information in the property; this has the same effect as updating the information in the property. The mode of a property governs the changes that can be made. Modifying key-value pairs describes the restrictions each mode places on modifying the value and deleting the property. Changing modes describes the restrictions on changing the mode.

Changing modes

The mode associated with a property can be changed only according to the restrictions of the original mode. The read-only and fixed read-only properties do not permit modification of the value or the mode. The fixed normal and fixed read-only modes do not allow the property to be deleted. This set of restrictions leads to the following permissible ways to change the mode of a property within the lifetime of a work area:
- If the current mode is normal, it can be changed to any of the other three modes: fixed normal, read-only, fixed read-only.
- If the current mode is fixed normal, it can be changed only to fixed read-only.
- If the current mode is read-only, it can be changed only by deleting the property and re-creating it with the desired mode.
- If the current mode is fixed read-only, it cannot be changed.
- If the current mode is not normal, it cannot be changed to normal. If a property is set as fixed normal and then reset as normal, the value is updated but the mode remains fixed normal. If a property is set as fixed normal and then reset as either read-only or fixed read-only, the value is updated and the mode is changed to fixed read-only.

Note: The key, value, and mode of any property can be effectively changed by terminating (completing) the work area in which the property was created and creating a new work area. Applications can then insert new properties into the work area. This is not precisely the same as changing the value in the original work area, but some applications can use it as an equivalent mechanism.

Nested work areas: Applications can nest work areas. When an application creates a work area, a work area context is associated with the creating thread. If the application thread creates another work area, the new work area is nested within the existing work area and becomes the current work area. Nested work areas allow applications to define and scope properties for specific tasks without having to make them available to all parts of the application. All properties defined in the original, enclosing work area are visible to the nested work area. The application can set additional properties within the nested work area that are not part of the enclosing work area.

An application working with a nested work area does not actually see the nesting of enclosing work areas. The current work area appears as a flat set of properties that includes those from enclosing work areas. In the figure below, the enclosing work area holds several properties and the nested work area holds additional properties. From the outermost work area, the properties set in the nested work area are not visible. From the nested work area, the properties in both work areas are visible.

Figure 22. Defining new properties in nested work areas

Nesting can also affect the apparent settings of the properties. Properties can be deleted from or directly modified only within the work areas in which they were set, but nested work areas can also be used to temporarily override information in the property without having to modify the property. Depending on the modes associated with the properties in the enclosing work area, the modes and the values of keys in the enclosing work area can be overridden within the nested work area.

The mode associated with a property when it is created determines whether nested work areas can override the property. From the perspective of a nested work area, the property modes used in enclosing work areas can be grouped as follows:
- Modes that permit a nested work area to override the mode or the value of a key locally. The modes that permit overriding are:
  - Normal
  - Fixed normal
- Modes that do not permit a nested work area to override the mode or the value of a key locally. The modes that do not permit overriding are:
  - Read-only
  - Fixed read-only

If an enclosing work area defines a property with one of the modes that can be overridden, a nested work area can specify a new value for the key or a new mode for the property. The new value or mode becomes the value or mode seen by subsequently nested work areas. Changes to the mode are governed by the restrictions described in Changing modes. If an enclosing work area defines a property with one of the modes that cannot be overridden, no nested work area can specify a new value for the key.

A nested work area can delete properties from enclosing work areas, but the changes persist only for the duration of the nested work area. When the nested work area is completed, any properties that were added in the nested area vanish and any properties that were deleted from the nested area are restored.

The following figure illustrates the overriding of properties from an enclosing work area. The nested work area redefines two of the properties set in the enclosing work area. The other two cannot be overridden. The nested work area also defines two new properties. From the outermost work area, the properties set or redefined in the nested work are not visible. From the nested work area, the properties in both work areas are visible, but the values seen for the redefined properties are those set in the nested work area.

Work Area 2		
key	**value**	**mode**
key1	A	normal
key2	B	fixed normal
key3	C	read-only
key4	D	fixed read-only

Visible to Work Area 2
key1 = A
key2 = B
key3 = C
key4 = D

Work Area 2.1		
key	**value**	**mode**
key1	X	normal
key2	Y	fixed normal
key5	E	normal
key6	F	fixed

Visible to Work Area 2.1
key1 = X (overridden in 2.1)
key2 = Y (overridden in 2.1)
key3 = C
key4 = D
key5 = E
key6 = F

Figure 23. Redefining existing properties in nested work areas

Distributed work areas: The propagation of work area context operates differently depending on whether a work area partition is defined as bidirectional or not. In either case all work area context propagates to a target object on a remote invocation. However, whether the context propagates from a target object back to the originator depends on whether a partition is defined as bidirectional.

Non-bidirectional work area partitions (UserWorkArea partition)

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information is propagated to any remote objects it invokes. However, no changes made to a nested work area on a target object are propagated back to the calling object. The caller's work area is unaffected by changes made in the remote method.

Bidirectional work area partitions

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work

area and all its ancestors is propagated to the target. The target application can locally modify the information, as allowed by the property modes, this information is propagated to any remote objects it invokes. In a partition that is not defined as bidirectional, a target application must begin a nested work area before making changes to the imported work area. However, if a partition is defined as bidirectional, a target application need not begin a nested work area before operating on an imported work area. By not beginning a nested work area, any new context set into the work area, or any context changes made by the target application, is not only propagated on future remote invocations but is also propagated back to the originating application (that is, the one who initiated the remote invocation) thus allowing bidirectional propagation of work area context. If the target application does not want new or changed context to propagate back to the originating application, then the target application must begin a nested work area to scope the context to its process. However, the new or changed context in the nested work area propagates on any future remote invocation the target application may make.

WorkArea service: Special considerations: Developers who use work areas should consider the following issues that could potentially cause problems: interoperability between the EJB and CORBA programming models; and the use of work areas with Java's Abstract Windowing Toolkit.

EJB and CORBA interoperability

Although the work area service can be used across the EJB and CORBA programming models, many composed data types cannot be successfully used across those boundaries. For example, if a SimpleSampleCompany instance is passed from the WebSphere environment into a CORBA environment, the CORBA application can retrieve the SimpleSampleCompany object encapsulated within a CORBA Any object from the work area, but it cannot extract the value from it. Likewise, an IDL-defined struct defined within a CORBA application and set into a work area is not readable by an application using the UserWorkArea class.

best-practices: Applications can avoid this incompatibility by directly setting only primitive types, like integers and strings, as values in work areas, or by implementing complex values with structures designed to be compatible, like CORBA valuetypes.

Also, CORBA Anys that contains either the tk_null or tk_void typecode can be set into the work area by using the CORBA interface. However, the work area specification cannot allow the Java 2 Platform, Enterprise Edition (J2EE) implementation to return null on a lookup that retrieves these CORBA-set properties without incorrectly implying that there is no value set for the corresponding key. For example, when a user attempts to retrieve a nonexistent key from a work area, the work area service returns null to indicate that the specified key does not contain a value, implying that the key itself is not in use or does not exist. In the case where CORBA Anys contains either tk_null or tk_void, when a user requests the key associated with one of these values, the work area service returns null as expected. In this case, the key may actually exist and the work area service was simply returning the key's value of null. Therefore, when working with CORBA Anys, a user must not make any implications when a null is returned from a work area because it could mean that either there isn't a property associated with the given key, or that there is a property associated with the given key and it contains a tk_null or tk_void, for example, a null in the J2EE environment. If a J2EE application tries to retrieve CORBA-set properties that are non-serializable, or contain CORBA nulls or void references, the com.ibm.websphere.workarea.IncompatibleValue exception is raised.

Using work areas with Java's Abstract Windowing Toolkit (AWT)

Work areas must be used cautiously in applications that use Java's Abstract Windowing Toolkit (AWT). The AWT implementation is multithreaded, and work areas begun on one thread are not available on another. For example, if a program begins a work area in response to an AWT event, such as pressing a button, the work area might not be available to any other part of the application after the execution of the event completes.

Work area service performance considerations: The work area service is designed to address complex data passing patterns that can quickly grow beyond convenient maintenance. A *work area* is a note pad that is accessible to any client that is capable of looking up Java Naming Directory Interface (JNDI). After a work area is established, data can be placed there for future use in any subsequent method calls to both remote and local resources.

You can utilize a work area when a large number of methods require common information or if information is only needed by a method that is significantly further down the call graph. The former avoids the need for complex parameter passing models where the number of arguments passed becomes excessive and hard to maintain. You can improve application function by placing the information in a work area and subsequently accessing it independently in each method, eliminating the need to pass these parameters from method to method. The latter case also avoids unnecessary parameter passing and helps to improve performance by reducing the cost of marshalling and de-marshalling these parameters over the Object Request Broker (ORB) when they are only needed occasionally throughout the call graph.

When attempting to maximize performance by using a work area, cache the UserWorkArea partition that is retrieved from JNDI wherever it is accessed. You can reduce the time spent looking up information in JNDI by retrieving it once and keeping a reference for the future. JNDI lookup takes time and can be costly.

Additional caching mechanisms available to a user-defined partition are defined by the configuration property, ″Deferred Attribute Serialization″. This mechanism attempts to minimize the number of serialization and deserialization calls. See Work area partition service for further explanation of this configuration attribute.

The maxSendSize and maxReceiveSize configuration parameters can affect the performance of the work area. Setting these two values to 0 (zero) effectively turns off the policing of the size of context that can be sent in a work area. This action can enhance performance, depending on the number of nested work areas an application uses. In applications that use only one work area, the performance enhancement might be negligible. In applications that have a large number of nested work areas, there might be a performance enhancement. However, a user must note that by turning off this policing it is possible that an extremely large amount of data might be sent to a server.

Performance is degraded if you use a work area as a direct replacement to passing a single parameter over a single method call. The reason is that you incur more overhead than just passing that parameter between method calls. Although the degradation is usually within acceptable tolerances and scales similarly to passing parameters with regard to object size, consider degradation a potential problem before utilizing the service. As with most functional services, intelligent use of the work areas yields the best results.

The work area service is a tool to simplify the job of passing information from resource to resource, and in some cases can improve performance by reducing the overhead that is associated with a parameter passing when the information is only sparsely accessed within the call graph. Caching the instance retrieved from JNDI is important to effectively maximize performance during runtime.

Developing applications that use work areas

Applications interact with the work area service by using the UserWorkArea interface and its implementation. This interface defines all of the methods used to create, manipulate, and complete work areas:

1. Access a partition by either:
   - "Accessing the UserWorkArea partition" on page 1310, to access the UserWorkArea partition.
   - Accessing a user defined work area partition, to access a user defined work area.

   The following steps use the UserWorkArea partition as an example, however a user defined partition can be used in the same way.
2. Beginning a work area.

3. Setting properties in a work area.
4. Using a work area to manage local work.
5. Completing a work area.

An example application, the Work area SimpleSample application, is used throughout this documentation to illustrate these tasks.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

UserWorkArea interface: Applications interact with the work area service by implementing the UserWorkArea interface. This interface, shown below, defines all of the methods used to create, manipulate, and terminate work areas:

```
package com.ibm.websphere.workarea;

public interface UserWorkArea {
   void begin(String name);
   void complete() throws NoWorkArea, NotOriginator;

   String getName();
   String[] retrieveAllKeys();
   void set(String key, java.io.Serializable value)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   void set(String key, java.io.Serializable value, PropertyModeType mode)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   java.io.Serializable get(String key);
   PropertyModeType getMode(String key);
   void remove(String key)
      throws NoWorkArea, NotOriginator, PropertyFixed;
}
```

Note: Enterprise JavaBeans (EJB) applications can use the UserWorkArea interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

Exceptions

The work area service defines the following exceptions for use with the UserWorkArea interface:
NoWorkArea
      Raised when a request requires an associated work area but none is present.
NotOriginator
      Raised when a request attempts to manipulate the contents of an imported work area.
PropertyReadOnly
      Raised when a request attempts to modify a read-only or fixed read-only property.
PropertyFixed
      Raised by the remove method when the designated property has one of the fixed modes.

Example: WorkArea SimpleSample application: In this example, the client creates a work area and inserts two properties into the work area: a site identifier and a priority. The site-identifier is set as a read-only property; the client does not allow recipients of the work area to override the site identifier. This property consists of the key company and a static instance of a SimpleSampleCompany object. The priority property consists of the key priority and a static instance of a SimpleSamplePriority object. The object types are defined as shown in the following code example

```
public static final class SimpleSampleCompany {
    public static final SimpleSampleCompany Main;
    public static final SimpleSampleCompany NewYork_Sales;
    public static final SimpleSampleCompany NewYork_Development;
    public static final SimpleSampleCompany London_Sales;
    public static final SimpleSampleCompany London_Development;
}

public static final class SimpleSamplePriority {
    public static final SimpleSamplePriority Platinum;
    public static final SimpleSamplePriority Gold;
    public static final SimpleSamplePriority Silver;
    public static final SimpleSamplePriority Bronze;
    public static final SimpleSamplePriority Tin;
}
```

The client then makes an invocation on a remote object. The work area is automatically propagated; none of the methods on the remote object take a work area argument. On the remote side, the request is first handled by the SimpleSampleBean; the bean first reads the site identifier and priority properties from the work area. The bean then intentionally attempts, and fails, both to write directly into the imported work area and to override the read-only site-identifier property.

The SimpleSampleBean successfully begins a nested work area, in which it overrides the client's priority, then calls another bean, the SimpleSampleBackendBean. The SimpleSampleBackendBean reads the properties from the work area, which contains the site identifier set in the client and priority set in the SimpleSampleBean. Finally, the SimpleSampleBean completes its nested work area, writes out a message based on the site-identifier property, and returns.

The implementation of this application is discussed in the topic, Developing applications that use work areas.

Accessing the UserWorkArea partition:

The work area service provides a JNDI binding to an implementation of the UserWorkArea interface under the name java:comp/websphere/UserWorkArea. This is the default work area partition, namly the "UserWorkArea" partition. It is created and bound into JNDI naming automatically, as long as it is enabled as defined in Enabling the work area service (UserWorkArea partition). Applications that need to access UserWorkArea partition can perform a lookup on that JNDI name, as shown in the following code example:

```
import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
  ...

  InitialContext jndi = null;
  UserWorkArea userWorkArea = null;
  try {
     jndi = new InitialContext();
     userWorkArea = (UserWorkArea)jndi.lookup(
        "java:comp/websphere/UserWorkArea");
  }
  catch (NamingException e) { ... }
}
```

Rather than using this default work area partition, a user has the option to create their own work area partition using the Work area partition service.

The next step is to use the begin method to create a new work area and associate it with the calling thread, as described in the topic, Beginning a new work area.

Beginning a new work area:

Be sure that your client has a reference to the UserWorkArea interface, as described in the topic Accessing the work area service or a reference to a user defined partition as defined in Accessing a user defined work area partition. The following steps use the UserWorkArea partition as an illustration. However a user defined partition can be used in the exact same way.

Use the begin method to create a new work area and associate it with the calling thread. A work area is scoped to the thread that began the work area and is not accessible by multiple threads. The begin method takes a string as an argument; the string is used to name the work area. The argument must not be null, which causes the java.lang.NullPointer exception to be raised. In the following code example, the application begins a new work area with the name SimpleSampleServlet:

```
public class SimpleSampleServlet {
...
   try {
      ...
      userWorkArea = (UserWorkArea)jndi.lookup(
         "java:comp/websphere/UserWorkArea");
   }
   ...

   userWorkArea.begin("SimpleSampleServlet");
   ...
}
```

The begin method is also used to create nested work areas; if a work area is associated with a thread when the begin method is called, the method creates a new work area nested within the existing work area.

The work area service makes no use of the names associated with work areas; You can name work areas in any way that you choose. Names are not required to be unique, but the usefulness of the names for debugging is enhanced if the names are distinct and meaningful within the application. Applications can use the getName method to return the name associated with a work area by the begin method.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Using a work area

Setting properties in a work area:

An application with a current work area can insert properties into the work area and retrieve the properties from the work area. The UserWorkArea interface provides two set methods for setting properties and a get method for retrieving properties. The two-argument set method inserts the property with the property mode of normal. The three-argument set method takes a property mode as the third argument. (See ″Setting property modes″, later in this topic.)

Both set methods take the key and the value as arguments. The key is a String; the value is an object of the type java.io.Serializable. None of the arguments can be null, which causes the java.lang.NullPointer exception to be raised.

The "Example: WorkArea SimpleSample application" on page 1309 uses objects of two classes, the SimpleSampleCompany class and the SimpleSampleProperty class, as values for properties. The SimpleSampleCompany class is used for the site identifier, and the SimpleSamplePriority class is used for the priority. These classes are shown in following code example:

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");
```

```
    try {
        // Set the site-identifier (default is Main).
        userWorkArea.set("company",
            SimpleSampleCompany.Main, PropertyModeType.read_only);

        // Set the priority.
        userWorkArea.set("priority", SimpleSamplePriority.Silver);
    }

    catch (PropertyReadOnly e) {
        // The company was previously set with the read-only or
        // fixed read-only mode.
        ...
    }

     catch (NotOriginator e) {
        // The work area originated in another process,
        // so it can't be modified here.
        ...
    }

    catch (NoWorkArea e) {
        // There is no work area begun on this thread.
        ...
    }

    // Do application work.
    ...
}
```

The get method takes the key as an argument and returns a Java Serializable object as the value
associated with the key. For example, to retrieve the value of the company key from the work area, the
code example above uses the get method on the work area to retrieve the value.

Setting property modes. The two-argument set method on the UserWorkArea interface takes a key and
a value as arguments and inserts the property with the default property mode of normal. To set a property
with a different mode, applications must use the three-argument set method, which takes a property mode
as the third argument. The values used to request the property modes are as follows:
• **Normal**: PropertyModeType.normal
• **Fixed normal**: PropertyModeType.fixed_normal
• **Read-only**: PropertyModeType.read_only
• **Fixed read-only**: PropertyModeType.fixed_readonly

For additional information about work area, see the com.ibm.websphere.workarea package in the API
documentation. The generated API documentation is available in the information center table of contents
from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Using a work area to manage local work:
Be sure that your client has a reference to the UserWorkArea interface, as described in the topic
"Accessing the UserWorkArea partition" on page 1310 or a reference to a user defined partition as defined
in Accessing a user defined work area partition. The following steps use the UserWorkArea partition as an
illustration. However a user defined partition can be used in the exact same way.

In a business application that uses work areas, server objects typically retrieve the work area properties
and use them to guide local work.

1. Retrieving the name of the active work area This step determines whether the calling thread is
   associated with a work area.

2. Overriding work area properties. Server objects can override client work area properties by creating
   their own, nested work area.

3. Retrieving properties from a work area

4. "retrieveAllKeys method" on page 1315
5. Querying the mode of a work area property
6. Deleting a work area property
7. Completing a work area

The server side of the "Example: WorkArea SimpleSample application" on page 1309 accepts remote invocations from clients. With each remote call, the server also gets a work area from the client if the client has created one. The work area is propagated transparently. None of the remote methods includes the work area on its argument list.

In the example application, the server objects use the work area interface for demonstration purposes only. For example, the SimpleSampleBean intentionally attempts to write directly to an imported work area, which creates the NotOriginator exception. Likewise, the bean intentionally attempts to mask the read only SimpleSampleCompany, which triggers the PropertyReadOnly exception. The SimpleSampleBean also nests a work area and successfully overrides the priority property before invoking the SimpleSampleBackendBean. A true business application would extract the work area properties and use them to guide the local work. The SimpleSampleBean mimics this by writing a message that function is denied when a request emanates from a sales environment.

Retrieving the name of the active work area:
Applications use the getName method on the UserWorkArea interface to retrieve the name of the current work area. This is the recommended method for determining whether the thread is associated with a work area; if the thread is not associated with a work area, the getName method returns null. In the following code example, the name of the work area corresponds to the name of the class in which the work area was begun.

```
public class SimpleSampleBeanImpl implements SessionBean {

    ...

    public String [] test() {
        // Get the work-area reference from JNDI.
        ...

        // Retrieve the name of the work area. In this example,
        // the name is used to identify the class in which the
        // work area was begun.
        String invoker = userWorkArea.getName();
        ...
    }
}
```

For additional information about work area, see the package, com.ibm.websphere.workarea, in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Overriding work area properties:

Work areas are inherently associated with the process that creates them. In the sample application, the client begins a work area and sets into it the site-identifier and priority properties. This work area is propagated to the server when the client makes a remote invocation.

Applications nest work areas in order to temporarily override properties imported from a client process. The nesting mechanism is automatic; invoking begin on the UserWorkArea interface from within the scope of an existing work area creates a nested work area that inherits the properties from the enclosing work area. Properties set into the nested work area are strictly associated with the process in which the work area was begun; the nested work area must be completed within the process that created them. If a work area is not completed by the creating process, the work-area facility terminates the work area when the

process exits. After a nested work area is completed, the original view of the enclosing work area is restored. However, the view of the complete set of work areas associated with a thread cannot be decomposed by downstream processes.

Applications set properties into a work area using property modes in ensure that a particular property is fixed (not removable) or read-only (not overrideable) within the scope of the given work area.

In the following code example, the server-side sample bean attempts to write directly to the imported work area; because the UserWorkArea partition is not defined to be bidirectional, this action is not permitted, and the NotOriginator exception is thrown. When the UserWorkArea partition is not defined as bidirectional, the sample bean must begin its own work area in order to override any imported properties, as shown in the second code example. If a work area in a user defined partition is used and is defined as bidirectional, this bean can set context into the work area before beginning another work area. This context set in the bidirectional case propagates back to the caller. See Bidirectional propagationfor additional information.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...
      String invoker = userWorkArea.getName();

      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }
      ...
    }
}
```

The following code example demonstrates beginning a nested work area, using the name of the creating class to identify the nested work area.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...
      String invoker = userWorkArea.getName();
      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }

      // Begin a nested work area. By using the name of the creating
      // class as the name of the work area, we can avoid having
      // to explicitly set the name of the creating class in
      // the work area.
      userWorkArea.begin("SimpleSampleBean");

      ...
    }
}
```

In the example application, the client sets the site-identifier property as read-only; that guarantees that the request is always associated with the client's company identity. A server cannot override that value in a nested work area. In the following code example, the SimpleSampleBean attempts to change the value of the site-identifier property in the nested work area it created.

```
public class SimpleSampleBeanImpl implements SessionBean {

  public String [] test() {
    ...
```

```
        String invoker = userWorkArea.getName();
        try {
          userWorkArea.set("key", "value");
        }
        catch (NotOriginator e) {
        }

        // Begin a nested work area.
        userWorkArea.begin("SimpleSampleBean");

        try {
          userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
        }
        catch (NotOriginator e) {
        }
        ...
  }
}
```

Retrieving work area properties:

Properties can be retrieved from a work area by using the get method. This method is intentionally lightweight; there are no declared exceptions to handle. If there is no active work area, or if there is no such property set in the current work area, the get method returns null.

Note: The get method can raise a NotSerializableError in the relatively rare scenario in which CORBA clients set composed data types and invoke enterprise-bean interfaces.

The following example shows the retrieval of the site-identifier and priority properties by the SimpleSampleBean. Notice that one property was set into an outer work area by the client, and the other property was set into the nested work area by the server-side bean; the nesting is transparent to the retrieval of the properties.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");
      try {
        userWorkArea.set("company",
                       SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }

      SimpleSampleCompany company =
          (SimpleSampleCompany) userWorkArea.get("company");
      SimpleSamplePriority priority =
          (SimpleSamplePriority) userWorkArea.get("priority");
       ...
  }
}
```

For additional information about work areas, see the package, com.ibm.websphere.workarea, in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

retrieveAllKeys method:

The UserWorkArea interface provides the retrieveAllKeys method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. The retrieveAllKeys method returns null if there is no work area associated with the thread. If there is an associated work area that does not contain any properties, the method returns an array of size 0.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Querying the mode of a work area property:
The UserWorkArea interface provides the getMode method for determining the mode of a specific property. This method takes the property's key as an argument and returns the mode as a PropertyModeType object. (See Setting property modes for more information on names of mode types.) If the specified key does not exist in the work area, the method returns PropertyModeType.normal, indicating that the property can be set and removed without error.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Deleting a work area property:

The UserWorkArea interface provides the remove method for deleting a property from the current scope of a work area. If the property was initially set in the current scope, removing it deletes the property. If the property was initially set in an enclosing work area, removing it deletes the property until the current scope is completed. When the current work area is completed, the deleted property is restored.

The remove method takes the property's key as an argument. Only properties with the modes normal and read-only can be removed. Attempting to remove a fixed property creates the PropertyFixed exception. Attempting to remove properties in work areas that originated in other processes creates the NotOriginator exception.

For additional information about work area, see the package, com.ibm.websphere.workarea, in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **Developer** > **API documentation** > **Application programming interfaces**.

Completing a work area:

After an application has finished using a work area, it must complete the work area by calling the complete method on the UserWorkArea interface. This terminates the association with the calling thread and destroys the work area. If the complete method is called on a nested work area, the nested work area is terminated and the parent work area becomes the current work area. If there is no work area associated with the calling thread, a NoWorkArea exception is created.

Every work area must be completed, and work areas can be completed only by the originating process. For example, if a server attempts to call the complete method on a work area that originated in a client, a NotOriginator exception is created. Work areas created in a server process are never propagated back to an invoking client process.

Note: The work area service claims full local-remote transparency. Even if two beans happen to be deployed in the same server, and therefore the same JVM and process, a work area begun on an invocation from another is completed and the bean in which the request originated is always in the same state after any remote call.

The following code example shows the completion of the work area created in the client application.

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");
   userWorkArea.set("company",
        SimpleSampleCompany.Main, PropertyModeType.read_only);
   userWorkArea.set("priority", SimpleSamplePriority.Silver);
   ...

   // Do application work.
   ...

   // Terminate the work area.
   try {
      userWorkArea.complete();
   }

   catch (NoWorkArea e) {
      // There is no work area associated with this thread.
      ...
   }

   catch (NotOriginator e) {
      // The work area was imported into this process.
      ...
   }
  ...
}
```

The following code example shows the sample application completing the nested work area it created
earlier in the remote invocation.

```
public class SimpleSampleBeanImpl implements SessionBean {

   public String [] test() {
      ...

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");
      try {
        userWorkArea.set("company",
                      SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }

      SimpleSampleCompany company =
         (SimpleSampleCompany) userWorkArea.get("company");
      SimpleSamplePriority priority =
         (SimpleSamplePriority) userWorkArea.get("priority");

      // Complete all nested work areas before returning.
      try {
        userWorkArea.complete();
      }
      catch (NoWorkArea e) {
      }
      catch (NotOriginator e) {
      }
   }
}
```

Chapter 5. Rapid deployment of J2EE applications

The rapid deployment tools extends the mechanism for generating deployment artifacts, packaging the application and preparing the application to run only on WebSphere Application Server v6.x.

You can use rapid deployment tools to:

1. Create a new J2EE application quickly without the overhead of using an integrated development environment (IDE).
2. Package J2EE artifacts quickly into an EAR file.
3. Test and deploy J2EE artifacts quickly on a server.

For example, you can place fully composed enterprise applications (EAR files), application modules (WAR files, EJB JAR files), or application artifacts (Java source files, Java class files, images, XML, or HTML) into a configurable location on your file system, referred to as the *monitored* directory. The rapid deployment tool automatically detects added or changed parts of these J2EE artifacts and performs the necessary steps to produce a running application on the server.

There are two ways to configure the monitored directory, each performing separate and distinct tasks. You can either specify the monitored directory as a free-form project or as an automatic installation project.

Free-form project

The rapid deployment tools free you from understanding J2EE application structure, as well as having to update and modify basic deployment descriptor information, such as new servlet or EJB entries. With the free-form approach you can place in a single project directory the individual parts of your application, such as Java source files that represent servlets or enterprise beans, static resources, XML files and other supported application artifacts. The rapid deployment tools then use your artifacts dropped in this free-form project directory to automatically place them in the appropriate J2EE project structure, generate any additional required artifacts to construct a J2EE compliant application and deploy that application on a target server.

Example

Assume that you want to set up a simple Web application on a server using the free-form approach. You have created the Java source files that implement a group of servlets. In addition, you have created the JSP files, images, and static HTML files to define the application. Using the free-form approach, you simply place all of these files together, or one at a time, in the free-form project directory. As J2EE artifacts are placed inside this free-form project, the rapid deployment tools dynamically generate the necessary J2EE project structure and deployment descriptors. For example, the deployment descriptor includes Web deployment descriptor (web.xml). The J2EE project structure includes an enterprise application project, a Web module project, an EJB module project, an EJB client JAR project, and a utility Java project.

The rapid deployment tools detect additions or changes to J2EE artifacts in the free-form project and run a build. As you drop files into the free-form project, the necessary J2EE projects are created, if these projects do not already exist. For example, if you drop a servlet source file, a Web project and an Application project is created if these projects do not exist in your workspace. Then the rapid deployment tool maps the artifacts to their correct location in the appropriate project. In this case, the servlet source file is compiled and its compiled class files are copied to *MyProject*Web\WebContent\WEB-INF\classes. The rapid deployment tools then generate or update any additional required deployment artifacts. In this case, the web.xml for the Web project is updated to include a servlet and servlet mapping entry.

The rapid deployment publishes the updated application on the server. If you choose to use the optional **earExportPath** option that specifies the directory location of the output EAR file, an EAR file is created. If the target server is remote, it will generate an EAR file and transfers the EAR to the remote server.

Benefits

The benefits of using the free-form approach is that you can focus on the structure of your application independent of the requirements of J2EE or other standards. One of the complexities of J2EE development is that it defines the location of artifacts in an application relative to one another. For example, in a Web application, class files must be placed in WEB-INF/classes and JSP files must be placed outside of the WEB-INF folder. This structural requirement must be understood and followed during development in order for the application to operate correctly. The rapid deployment tools removes this structural requirement, allowing the source project to follow your development defined structure and freeing you from having to understand the J2EE defined structures.

Automatic installation project

The rapid deployment tools simplify the process of installing, modifying, and uninstalling applications on a server. Automatic installation relies on a single project directory that listens for J2EE compliant applications (EAR files) or modules (WAR, JAR, or RAR files). The rapid deployment tools then deploy the artifacts to the target server.

If you place EAR files in the automatic installation project, the EAR file is automatically deployed to the server. If you delete EAR files from project, the application is uninstalled from the server. If you place a new copy of the same EAR file in the automatic installation project, then the application is reinstalled. If you place WAR or EJB JAR files in the automatic application installation project, the rapid deployment tool generates the necessary EAR wrapper and then publishes that EAR file on the server. For RAR files, a wrapper is not created. The standalone RAR files are published to the server.

Benefits

The benefit of using the automatic installation project is that it frees you from the complexity of administering your application. For example, using **wsadmin** scripting program or the administrative console to install the application through a multiple-step wizard.

Remember: If you want to go into any of the generated projects, for example, to modify the deployment descriptor, you should not do it here. First switch to a tool designed for such advanced tasks, such as the WebSphere Application Server Toolkit or one of the IBM Rational Software Development Platform.

Constructing a J2EE application from artifacts

The *free-form* configuration allows you to create or drop your J2EE artifacts or module files into a free-form project directory. J2EE artifacts can include the source, annotated-source, or class files of servlets, JavaServer Pages (JSP) files, static Web content, Web filters, Web listeners, enterprise beans, and other generic files. The rapid deployment tools automatically place your artifacts in the appropriate J2EE project structure, generate any additional required artifacts to construct a J2EE compliant application, and deploy that application on a target server.

Steps

To construct a J2EE application from artifacts:

Setting up a rapid deployment environment

You can run the rapid deployment batch tools from a command line to create, configure, and launch rapid deployment projects using the IBM WebSphere v6.x runtime environment. The rapid deployment tools run in a non-graphical command line interface.

Prerequisites

- WebSphere Application Server v6.x installed
- The rapid deployment launch tool is in the *x:*/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:
  - ▶ Windows   wrd.bat
  - ▶ UNIX   wrd.sh
- The rapid deployment configuration tool is in the *x:*/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:
  - ▶ Windows   wrd-config.bat
  - ▶ UNIX   wrd-config.sh

To set up a rapid deployment workspace:

1. Open a command prompt.
2. Specify the location on your file system that will host the rapid deployment activities. This location serves as your workspace root, and all your rapid deployment projects reside here. Define an environment variable called WORKSPACE:

   - ▶ Windows   `set WORKSPACE=<workspace root>`

   - ▶ UNIX   `export WORKSPACE=<workspace root>`

   Configure a rapid deployment workspace for each rapid deployment project, rather than configuring multiple rapid deployment projects inside a single rapid deployment workspace.

   Tip: To list all your environment variables and their values, run the command:

   - ▶ Windows   `set "`

   - ▶ Linux   `export -n`

   - ▶ AIX   ▶ Solaris   ▶ HP-UX   `export`

After the WORKSPACE environment variable is defined, you can continue to configure and launch your rapid deployment workspace.

Creating a free-form project in your workspace

The *free-form* project allows the creation of a J2EE application using a single project directory for development. Free-form development releases you from having to maintain multiple projects as well as having to understand the J2EE application structure.

Prerequisite

- Learn how to work with free-form projects
- Set up a rapid deployment environment.

Steps for this task

1. From the command prompt, change to the *x:*/profiles/*<profileName>*/bin directory, where *x* is the directory WebSphere Application Server is installed.
2. Use one of the following options to configure a new free-form project:
   - To configure a new free-form project, you can complete this by typing the following at the prompt:
     - ▶ Windows   `wrd-config.bat -project "project_name" -style "freeform"`
     - ▶ UNIX   `wrd-config.sh -project "project_name" -style "freeform"`
   - If you want to specify a particular runtime environment to compile your application against, use the optional `runtime` and `runtimePath` parameters. Targeting your runtime will configure which JRE

library to use, based on the runtime location, and configure the project's classpath to contain the WebSphere runtime libraries. You can complete this by typing the following at the prompt:

– `Windows` `wrd-config.bat -project "project_name" -style "freeform" -runtime "was60"` `-runtimePath "x:\WebSphere\AppServer"`

– `UNIX` `wrd-config.sh -project "project_name" -style "freeform" -runtime "was60"` `-runtimePath "x:\WebSphere\AppServer"`

where *x:\WebSphere\AppServer* is the directory WebSphere Application Server is installed.

> **Tip:** The `runtimePath` is not used for targeting the server to publish against but rather specifying the WebSphere libraries you want your application to compile against. If the `runtime` and `runtimePath` are not specified, the default runtime environment used is WebSphere Application Server v6.1.

3. The **Parameter Configuration Settings** dialog box opens. Specify the value for one or more of the following settings:

Option	Description
earExportPath	This is an optional field to specify the directory location of the output EAR file that is created by rapid deployment tools and contains the generated classes required for deployment. For example: c:\temp\export. **Note:** • When you specify the directory for the output EAR file and then run the **wrd-config** command, any existing output EAR file of the same name will be overwritten without warning. In addition, the EAR file gets overwritten as additional J2EE artifacts are added to the free-form project to reflect the new changes.
serverName	The name of the server process you want to publish your application. For example, server1. For WebSphere Application Server Network Deployment, the server name is in the form *<cell name>/<node name>/<server name>*. To publish to a cluster, the server name is in the form *<cell name>/<cluster name>*.
username	(Optional) If security is enabled, specify the user name for current active authentication settings defined in the server configuration.
password	(Optional) If security is enabled, specify the password for current active authentication settings defined in the server configuration.
serverJMXHost	The host name of the machine containing the server you want to make a connection to. For example, localhost. For WebSphere Application Server Network Deployment, type the host name of the Network Deployment Manager.
serverJMXPort	The server administrative port number, also known as the Simple Object Access Protocol (SOAP) connector port. This port is used for making JMX connections with the server. For example, 8880. For WebSphere Application Server Network Deployment, type the SOAP port number of the Network Deployment Manager, default is 8879.

A *projectName*_headless.xml file is generated at the root of your rapid deployment workspace. You can use this file later to configure a free-form project with the same configuration without having to be prompted again for these parameters. Use the optional **configData** parameter to complete this task.

Results

You can see that the initial configuration of the free-form project creates only the free-form project. As artifacts are introduced and modified in the free-form project, rapid deployment tools will dynamically generate the necessary J2EE project structures inside the workspace directory. The following table lists the naming convention of the project folder with its associated project type:

Naming Convention of the Project Folder	Project Type
project_name	The free-form project
*project_name*App	A single enterprise application project
*project_name*EJB	A single EJB module project
*project_name*EJBClient	A single EJB client jar project
*project_name*Utility	A single utility Java project
*project_name*Web	A single Web module project

where *project_name* is the string value provided for the **-project** parameter.

After you have configured the workspace to contain a free-form project and the supporting J2EE projects, you will then launch a rapid deployment session. Launching a rapid deployment session indicates that you want the free-form project to start listening for your J2EE artifacts.

Starting a rapid deployment session

You can launch a rapid deployment session to start listening for application artifacts that are dropped into the folder you configured for either the free-form or automatic installation approach. Use the **wrd** command to launch a rapid deployment session. If you want to monitor rapid deployment activities, you can specify console output.

Prerequisites
- Set up a rapid deployment environment.
- Configure the behavior of the monitored directory as free-form or automatic installation.

Steps
1. From the command prompt, change to the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server is installed.
2. Verify that the server on which you want to deploy your application is running.

   Tip: If there is no server connection, you get the following console output:
   ```
   [06:52:28 PM] Publishing MyProjectApp to server_510658053
   [06:52:28 PM] Failed to make connection to Websphere Application Server.
   ```
3. At the command prompt, type the appropriate command:
   - (Recommended) To monitor rapid deployment activities:
     - ▶ Windows
     - ▶ UNIX `wrd.sh -monitor`
   - To launch a rapid deployment session:
     - ▶ Windows `wrd.bat`
     - ▶ UNIX `wrd.sh`
   - To use batch mode to run a full build of the workspace and then shut down the process:
     - ▶ Windows `wrd.bat -project "project_name" -batch`
     - ▶ UNIX `wrd.sh -project "project_name" -batch`

After you launch the rapid deployment tools, you can create or drop your J2EE artifacts into the monitored directory. The application generated is deployed and updated on the target server.

Dropping J2EE artifacts into a free-form project

You can place application artifacts in a free-form project and let the rapid deployment tools automatically place them in the appropriate J2EE project structure, generate any additional required artifacts to construct a J2EE compliant application, and deploy that application on a target server.

Prerequisites

- Learn how to work with free-form projects
- Set up a rapid deployment environment.
- Create a free-form project in your workspace.

Steps

1. Verify the server you want to deploy your application is running.

   Tip: If there is no server connection, you get the following console output:

   ```
   [06:52:28 PM] Publishing MyProjectApp to server_510658053
   [06:52:28 PM] Failed to make connection to Websphere Application Server.
   ```

2. Launch a rapid deployment session by using the **wrd** command.

3. Use your file management system to place your application artifacts properly into a free-form project. The directory name of the free-form project has the same string value you provided for the **-project** parameter when you created the free-form project.

   Note: When you create or drop in your J2EE artifacts into the free-form project, these resources will automatically be placed in the appropriate location in the J2EE project structure. You might experience approximately five seconds delay for the changes in the files system to be picked up, as these changes are being polled from the workspace.

Tip:

The rapid deployment tools preserve the folder structures created and dropped into a free-form project. When dropping Java source files, place these files in the correct package structure to avoid compilation errors. For example, suppose a Java package statement, package java.src;, is defined in a Java source file, HelloWorld.java. Simply dropping the Java source file, HelloWorld.java, in the file path, *workspace*/MyFreeForm/HelloWorld.java, where *workspace* is the directory where your rapid deployment project resides, results in the following compilation error, displayed in the console output:

```
[06:32:19 PM] [/MyFreeForm/HelloWorld.java] Added
[06:32:20 PM] [/MyFreeForm/bin/HelloWorld.class] copied to project [MyFreeFormUtility]
[06:32:20 PM] 'The declared package does not match the expected package ' in resource 'HelloWorld.java'
```

To correct the compilation error, place the HelloWorld.java source file in the following file path *workspace*/MyFreeForm/java/src/HelloWorld.java

The following topics show how to handle supported artifacts in free-form projects:

Free-form projects

The initial configuration of the free-form project in your workspace creates a free-form project.

Within the free-form project, you can drop or create J2EE artifacts or fully-composed J2EE modules. As artifacts are introduced or modified in the free-form project, the necessary J2EE project structures are dynamically generated in the workspace directory. The J2EE project structures at most contain a Web module project, an EJB module project, an EJB client jar project and a utility Java project; all belonging to

a single enterprise application project. From a J2EE development perspective, the free-form project supports a single J2EE application that contains two modules: a web module and an EJB jar module.

The following table lists the naming convention for dynamically generated project folder with its associate project type in a workspace:

Naming conventions for the project folder	Project type
project_name	The free-form project
*project_name*App	A single enterprise application project
*project_name*EJB	A single EJB module project
*project_name*EJBClient	A single EJB client jar project
*project_name*Utility	A single utility Java project
*project_name*Web	A single Web module project

where *project_name* is the string value provided for the **-project** parameter.

The rapid deployment tools will configure and update the manifest files and project references to maintain the following default settings:
- The EJB module project will have reference and visibility to the EJB client jar project.
- The Web module project will have reference and visibility to the EJB client jar project.
- The Web module project, EJB module project, and EJB client jar project will have reference and visibility to the Utility Project.
- The enterprise application project will contain the Web module project, EJB module project, and EJB client jar project.
- The utility Java project is added as a utility Jar inside the enterprise application project.
- Each of the projects, excluding the enterprise application project, contains an imported_classes directory. The imported_classes folder is set as an exported entry on the classpath of its containing project. As a result, the directory and any contents within it is visible to any projects referencing that project.

The initial configuration of the free-form project creates subdirectories:
- The gen folder is a repository of non-Java artifacts that get generated by the rapid deployment tools.
- The src folder is a subdirectory of the gen folder and is a repository of Java artifacts generated by rapid deployment tools. For example, if you drop an annotated session bean, the remote, home and local interfaces are generated in src directory.
- The bin directory contains the class files that were compiled for any Java source files dropped into the free-form project.

When Java source files are dropped into a free-form project, they are compiled into this project and the generated class files are copied into the target J2EE project's imported_classes folder. The source files are not copied into any of the J2EE project structures. The deployed application contains only class files.

If a classification of a resource changes from one artifact type to another that results in changes to its target J2EE module project, the old mapped locations are purged. For example, if A.java implemented a servlet, its class files map to the Web module project. If the content of A.java changes to implement an enterprise bean, its class files now map to the EJB module project. The dangling class in the Web project is removed.

Any resources that cannot be classified by rapid deployment tools are mapped to the utility Java project, and their folder structure is preserved as created and dropped into the free-form project. For example, if the following resource exists in the free-form project, /MyFreeForm/data/myproperties.props. This file is

mapped to /MyFreeFormUtility/data/myproperties.props, preserving the data folder. In addition, if the class files cannot be classified by rapid deployment as other than a class file, the tool maps these files to the imported classes folder in the utility Java project.

When removing artifacts from the free-form project, the rapid deployment tools remove the artifact from its mapped J2EE project structure location and if applicable, remove the deployment descriptor entries. However, the rapid deployment tools keep any project folders created.

If the free-form project is configured to a local server (on the same machine running the rapid deployment session), the application synchronizes with the server after every change. If the free-form project is configured to a remote server, to limit file transfers over the network for every change, changes are batched together in one minute intervals. A publish is triggered every minute, only when a change occurs.

Adding and deleting Web artifacts from a free-form project

You can add various artifacts to or delete various artifacts from a free-form project. The artifacts can be source code, annotation source files or compiled classes.

Adding and deleting servlets to a free-form project:

You can add or delete servlet source code, annotated source or compiled class files to or from a free-form project.

Prerequisites

The servlet class must be an implementation of the following types:

```
javax.servlet.Servlet
javax.servlet.GenericServlet
javax.servlet.http.HttpServlet
```

Steps

1. To add servlets to a free-form project, use your file management system to properly place your servlet artifacts into the free-form project. The directory name of the free-form project has the same string value you provided for the **-project** parameter used in the wrd-config command.

2. The following activities occur when you drop a servlet into a free-form project:

   a. If necessary, the servlet class is generated and mapped to the imported_classes directory of the Web module project. The rapid deployment tools will then copy the class files to its appropriate J2EE location which is WebContent/WEB-INF/classes folder of the Web module project. The console output can look like this example when adding a servlet Java source file (called *HelloServlet.java*) to a free-form project (called *MyProject*):

   ```
   [06:52:23 PM] [/MyProject/servlet/HelloServlet.java] Added
   [06:52:26 PM] [/MyProject/bin/servlet/HelloServlet.class] copied to project [MyProjectWeb]
   [06:52:27 PM] Servlet added to web.xml: HelloServlet
   [06:52:27 PM] Servlet mapping added.  URL is: [MyProjectWeb/HelloServlet]
   ```

   Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

   - ▶ Windows ◀ `wrd.bat -monitor`

   - ▶ UNIX ◀ `wrd.sh -monitor`

   b. A new servlet entry and servlet mapping entry is created in the Web deployment descriptor (found in the WebContent\WEB-INF\web.xml file in the Web module project). The following is an example of the entries in web.xml:

   ```
   <servlet>
    <servlet-name>HelloServlet</servlet-name>
    <servlet-class>servlet.HelloServlet</servlet-class>
   </servlet>
   ```

```
<servlet-mapping>
 <servlet-name>HelloServlet</servlet-name>
 <url-pattern>/HelloServlet</url-pattern>
</servlet-mapping>
```

    c. The application is synchronized with the server.

3. You can test the servlet running on the server, use the URL displayed in the console. In this example, the console output provided the following URL mapping information to the deployed servlet:

```
[06:52:27 PM] Servlet mapping added.  URL is: [MyProjectWeb/HelloServlet]
```

Type http://*<machine_name>*:*<port>*/MyProjectWeb/HelloServlet in the address bar and press **Enter**. Where *<machine_name>* is the host machine where WebSphere Application Server runs. By default, WebSphere Application Server runs on port 9080.

4. To delete servlets from a free-form project, use your file management system to properly remove your servlet artifacts from the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

5. The following activities occur when you remove a servlet from the free-form project:

    a. The console output can look like this example when removing a servlet Java source file (called *HelloServlet.java*) from a free-form project (called *MyProject*):

```
[07:03:42 PM] [/MyProject/bin/servlet/HelloServlet.class] Deleted
[07:03:42 PM] [/MyProject/servlet/HelloServlet.java] Deleted
[07:03:42 PM] Servlet Mapping removed from web.xml /HelloServlet
[07:03:42 PM] Servlet removed from web.xml: HelloServlet
```

    b. The application is synchronized with the server.

Adding and deleting Web filters to a free-form project:

You can add or delete Web filter source code, annotated source or compiled class files for various J2EE filter types, such as authentication filters, encryption filters, and data compression filters to or from a free-form project.

Prerequisites

The filter class must be an implementation of the following type:

```
javax.servlet.Filter
```

Steps

1. To add Web filters into a free-form project, use your file management system to properly place your filter artifacts into the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

2. The following activities occurs when you drop a filter into the free-form project:

    a. If necessary, the filter class is generated and mapped to the imported_classes directory of the Web module project. The rapid deployment tools will then copy the class files to its appropriate J2EE location which is WebContent/WEB-INF/classes folder of the Web module project. The console output can look like this example when adding a filter Java source file (called *MyFilter.java*) to a free-form project (called *MyProject*):

```
[07:47:17 PM] [/MyProject/MyFilter.java] Added
[07:47:20 PM] [/MyProject/bin/MyFilter.class] copied to project [MyProjectWeb]
[07:47:20 PM] Web Filter added to web.xml MyFilter
[07:47:20 PM] Filter Mapping added to web.xml /MyFilter
```

    Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

        • ▶ Windows wrd.bat -monitor

        • ▶ UNIX wrd.sh -monitor

b. A new filter entry along with its display name, and any initialization parameters, URL mappings, and servlet mappings is created in the web deployment descriptor (found in the WebContent\WEB-INF\web.xml file in the Web module project). The following is an example of the entries in web.xml:

```
<filter>
 <filter-name>MyFilter</filter-name>
 <filter-class>MyFilter</filter-class>
</filter>
<filter-mapping>
 <filter-name>MyFilter</filter-name>
 <url-pattern>MyFilter</url-pattern>
</filter-mapping>
```

c. The application is synchronized with the server.

3. To delete Web filters from a free-form project, use your file management system to properly remove your filter artifacts from the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

4. The following activities occurs when you remove a filter from the free-form project:

a. The console output can look like this example when removing a filter Java source file (called *MyFilter.java*) from a free-form project (called *MyProject*):

```
[07:56:10 PM] [/MyProject/MyFilter.java] Deleted
[07:56:10 PM] [/MyProject/bin/MyFilter.class] Deleted
[07:56:10 PM] Web Filter removed from web.xml MyFilter
[07:56:10 PM] Filter Mapping removed from web.xml /MyFilter
```

b. The application is synchronized with the server.

Adding and deleting listeners to a free-form project:

You can add or delete servlet listener source code, annotated source or compiled class files for various J2EE listener types related to servlet context and session events and attributes to or from a free-form project.

Prerequisites

The listener class must be an implementation of the following types:

```
javax.servlet.ServletContextListener
javax.servlet.ServletContextAttributesListener
javax.servlet.http.HttpSessionListener
javax.servlet.http.HttpSessionAttributesListener
```

Steps

1. To add listeners to a free-form project, use your file management system to properly place your listener artifacts into the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

2. The following activities occur when you drop a listener into the free-form project:

a. If necessary, the listener class is generated and mapped to the imported_classes directory of the Web module project. The rapid deployment tools will then copy the class files to its appropriate J2EE location which is WebContent/WEB-INF/classes folder of the Web module project. The console output can look like this example when adding a listener Java source file (called *MyListener.java*) to a free-form project (called *MyProject*):

```
[07:58:31 PM] [/MyProject/MyListener.java] Added
[07:58:31 PM] [/MyProject/bin/MyListener.class] copied to project [MyProjectWeb]
[07:58:31 PM] Listener added to web.xml: MyListener
```

Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

- • ▶ `Windows` `wrd.bat -monitor`

- • ▶ `UNIX` `wrd.sh -monitor`

   b. A new listener entry is created in the Web deployment descriptor (found in the WebContent\WEB-INF\web.xml file in the Web module project). The following is an example of the entries in web.xml:

```
<listener>
 <display-name>MyListener</display-name>
 <listener-class>MyListener</listener-class>
</listener>
```

   c. The application is synchronized with the server.

3. To delete listeners from a free-form project, use your file management system to properly remove your listener artifacts from the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

4. The following activities occur when you remove a listener from the free-form project:

   a. The console output can look like this example when removing a listener Java source file (called *MyListener.java*) from a free-form project (called *MyProject*):

```
[08:00:23 PM] [/MyProject/MyListener.java] Deleted
[08:00:23 PM] [/MyProject/bin/MyListener.class] Deleted
[08:00:23 PM] Listener removed from web.xml: MyListener
```

   b. The application is synchronized with the server.

Adding and deleting JavaServer Pages to a free-form project:

You can add or delete JavaServer Pages (JSP) to or from a free-form project.

Steps

1. To add a JSP file to a free-form project, use your file management system to properly place your JSP artifacts into the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

2. The following activities occur when you drop a JSP into the free-form project:

   a. The JSP is mapped to the Web Content folder in the Web module project. The console output can look like this example when adding a JSP source file (called *MyJSP.jsp*) to a free-form project (called *MyProject*):

```
[08:15:23 PM] [/MyProject/MyJSP.jsp] Added
[08:15:23 PM] [/MyProject/MyJSP.jsp] coppied to project [MyProject]
[08:15:23 PM] JSP entry added to web.xml: MyJSP
[08:15:23 PM] Servlet mapping added.  URL is: [MyProjectWeb/MyJSP]
```

   Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

   - • ▶ `Windows` `wrd.bat -monitor`

   - • ▶ `UNIX` `wrd.sh -monitor`

   b. A new servlet entry and servlet mapping entry is created in the Web deployment descriptor (found in the WebContent\WEB-INF\web.xml file in the Web module project). The following is an example of the entries in web.xml:

```
<servlet>
 <servlet-name>MyJSP</servlet-name>
 <jsp-file>MyJSP.jsp</jsp-file>
</servlet>
<servlet-mapping>
 <servlet-name>MyJSP</servlet-name>
 <url-pattern>/MyJSP</url-pattern>
</servlet-mapping>
```

c. The application is synchronized with the server.

3. You can test the JSP running on the server, use the URL displayed in the console. In this example, the console output provided the following URL mapping information to the deployed JSP:

    ```
    [08:15:23 PM] Servlet mapping added.  URL is: [MyProjectWeb/MyJSP]
    ```

    Type `http://<machine_name>:<port>/MyProjectWeb/MyJSP` in the address bar and press **Enter**. Where *<machine_name>* is the host machine where WebSphere Application Server runs. By default, WebSphere Application Server runs on port 9080.

4. To delete JSP files from a free-form project, use your file management system to properly remove your JSP artifacts from the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

5. The following activities occur when you remove a JSP from the free-form project:

    a. The console output can look like this example when removing a JSP source file (called *MyJSP.jsp*) from a free-form project (called *MyProject*):

    ```
    [08:19:40 PM] [/MyProject/MyJSP.jsp] Deleted
    [08:19:40 PM] Servlet Mapping removed from web.xml /MyJSP
    [08:19:40 PM] JSP entry removed from web.xml MyJSP
    ```

    b. The application is synchronized with the server.

Adding and deleting static Web content to a free-form project:

You can add or delete static Web content to or from a free-form project.

Static content will maintain its directory structure. For example if /page1/index.html is placed in the free-form project, /page1/index.html will be copied into the Web module project, as a result, preserving the page1 folder in the Web module project.

Steps

1. To add static Web contents to a free-form project, use your file management system to properly place your static Web content artifacts into the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

2. The following activities occur when you drop a static Web content to a free-form project:

    a. The static Web content is mapped to the Web Content folder of the Web module project. The console output can look like this example when adding a static Web content file (called *MyStatic.html*) to a free-form project (called *MyProject*):

    ```
    [08:15:23 PM] [/MyProject/MyStatic.html] Added
    [08:15:23 PM] [/MyProject/MyStatic.html] copied to project [MyProjectWeb]
    ```

    Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

    - ▶ Windows `wrd.bat -monitor`

    - ▶ UNIX `wrd.sh -monitor`

    b. The application is synchronized with the server.

3. To delete static Web contents from a free-form project, use your file management system to properly remove your static Web content artifacts from the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

4. The following activities occurs when you remove a static Web content from a free-form project:

    a. The console output can look like this example when removing a static Web content (called *MyStatic.html*) from a free-form project (called *MyProject*):

    ```
    [08:19:40 PM] [/MyProject/MyStatic.html] Deleted
    ```

b. The application is synchronized with the server.

Adding and deleting enterprise beans to a free-form project

You can drop enterprise bean (EJB) artifacts or module files (ejb.jar) into a free-form project. The EJB artifacts can be annotated or non-annotated; they can contain source or compiled classes. The EJB artifacts include the EJB classes or the EJB interfaces (remote, local, home, and primary key class for entity beans).

Prerequisites

- Prior to dropping EJB module files (ejb.jar) into a free-form project, you need to generate the deployment code. The ejbDeploy tools do not automatically run on these already packaged ejb.jar files.

- If you drop an entity bean, by default the rapid deployment tools will generate a bean-managed persistence (BMP) entry in the deployment descriptor. If you want a container-managed persistence (CMP) bean, this needs to be specified using annotated source file.

- A naming convention must be followed for the Java source, compiled class, or annotated source files for each enterprise bean. For example, if an enterprise bean implementation class is named *MySession*Bean.java, follow this convention for any bean interfaces that are defined:

  – The home interface class must be named *MySession*Home.java

  – The remote interface class must be named *MySession*.java

  – The local interface class must be named *MySession*Local.java

  – The local home interface class must be named *MySession*LocalHome.java

  – The primary key class for entity beans can be named anything because the rapid deployment tools logically locates the correct class name by introspecting either the home or local home interface.

  These rules do not imply that both remote and local view types must be created; these are just naming conventions when creating source for a set of bean interfaces.

  A new EJB entry to the deployment descriptor is only added when a minimum set of resources are available in the free-form project. For example, if the bean class is placed in the free-form project, its compiled class maps to the EJB project but no deployment descriptor entry is created until the rapid deployment tools locate either a set of remote view type classes or local view type classes. For entity beans, a primary key class is also required. If the minimum resources are removed, the bean descriptor entry is removed. The examples section of this topic provides a concrete example of these rules.

Steps

1. Use your file management system to place your EJB artifacts properly into the free-form project. The directory name of the free-form project has the same string value you provided for the **-project** parameter used in the wrd-config command.

2. The following activities occur when you drop EJB artifacts into a free-form project:

   - The EJB interface classes are mapped into the imported classes folder of the EJB client JAR project.

   - The EJB classes are mapped into the imported classes folder of the EJB module project.

   - A new enterprise bean entry is created in the deployment descriptor (found in the ejbModule\META-INF\ejb-jar.xml file in the EJB module project).

   - A new enterprise bean binding is created in the bindings with a default JNDI name.

   - The application is synchronized with the server.

3. (Optional) Use the Universal Test Client to test your enterprise beans.

Example

This example shows the activities of the bean entry in the deployment descriptor when EJB resources are added and removed from the free-form project.

Tip: If you want to monitor rapid deployment activities, run your rapid deployment session with console output. Run the rapid deployment launch tool as follows:

- **Windows** `wrd.bat -monitor`

- **UNIX** `wrd.sh -monitor`

1. The console output can look like this when adding an enterprise bean Java source file (called *MyEJBBean.java*), remote interface Java source file (called *MyEJB.java*), and home interface (called *MyEJBHome.java*) to a free-form project (called *MyProject*):

```
[08:47:25 PM] [/MyProject/ejbs/MyEJB.java] Added
[08:47:25 PM] [/MyProject/ejbs/MyEJBBean.java] Added
[08:47:25 PM] [/MyProject/ejbs/MyEJBHome.java] Added
[08:47:30 PM] [/MyProject/bin/ejbs/MyEJB.class] copied to project [MyProjectEJBClient]
[08:47:30 PM] [/MyProject/bin/ejbs/MyEJBBean.class] copied to project [MyProjectEJB]
[08:47:30 PM] [/MyProject/bin/ejbs/MyEJBHome.class] copied to project [MyProjectEJBClient]
[08:47:32 PM] Enterprise bean added to ejb-jar.xml: MyEJB
[08:47:32 PM] Enterprise bean binding for [MyEJB] added to ejb-jar-bnd.xmi.  JNDI Name is: [ejb/MyEJBBean]
```

A new enterprise bean entry is created in the deployment descriptor (found in the ejbModule\META-INF\ejb-jar.xml file in the EJB module project):

```
<session id="Session_1092185252700">
 <ejb-name>MyEJB</ejb-name>
 <home>ejbs.MyEJBHome</home>
 <remote>ejbs.MyEJB</remote>
 <ejb-class>ejbs.MyEJBBean</ejb-class>
 <session-type>Stateless</session-type>
 <transaction-type>Container</transaction-type>
</session>
```

A new enterprise bean binding is created in the bindings with a default JNDI name. The ibm-ejb-bnd.xmi file might contain the following entries:

```
<ejbBindings xmi:id="EnterpriseBeanBinding_1092185252700" jndiName="ejb/MyEJBBean">
 <enterpriseBean xmi:type="ejb:Session" href="META-INF/ejb-jar.xml#Session_1092185252700"/>
</ejbBindings>
```

2. The console output can look like this example when adding a local interface (called *MyEJBLocal.java*) and local home interface (called *MyEJBLocalHome.java*) for the same bean in the same free-form project:

```
[08:52:59 PM] [/MyProject/ejbs/MyEJBLocal.java] Added
[08:52:59 PM] [/MyProject/ejbs/MyEJBLocalHome.java] Added
[08:52:59 PM] [/MyProject/bin/ejbs/MyEJBLocal.class] copied to project [MyProjectEJBClient]
[08:52:59 PM] [/MyProject/bin/ejbs/MyEJBLocalHome.class] copied to project [MyProjectEJBClient]
[08:53:01 PM] Local view type added for ejb: MyEJB
```

An update is made to the existing deployment descriptor (found in the ejbModule\META-INF\ejb-jar.xml file in the EJB module project):

```
<session id="Session_1092185252700">
 <ejb-name>MyEJB</ejb-name>
 <home>ejbs.MyEJBHome</home>
 <remote>ejbs.MyEJB</remote>
 <local-home>ejbs.MyEJBLocalHome</local-home>
 <local>ejbs.MyEJBLocal</local>
 <ejb-class>ejbs.MyEJBBean</ejb-class>
 <session-type>Stateless</session-type>
 <transaction-type>Container</transaction-type>
</session>
```

3. The console output can look like this example when the local interface (called *MyEJBLocal.java*) is removed from the same free-form project:

```
[08:56:27 PM] [/MyProject/bin/ejbs/MyEJBLocal.class] Deleted
[08:56:27 PM] [/MyProject/ejbs/MyEJBLocal.java] Deleted
[08:56:28 PM] Local view type removed ejb: MyEJB
```

Since the local interface was removed from the free-form project and the existing local home interface is not sufficient to define a local view type the bean deployment descriptor (found in the ejbModule\META-INF\ejb-jar.xml file in the EJB module project) is updated to reflect the removal of the local view type:

```
<session id="Session_1092185252700">
 <ejb-name>MyEJB</ejb-name>
 <home>ejbs.MyEJBHome</home>
 <remote>ejbs.MyEJB</remote>
 <ejb-class>ejbs.MyEJBBean</ejb-class>
 <session-type>Stateless</session-type>
 <transaction-type>Container</transaction-type>
</session>
```

4. The console output can look like this example when the remote interface (called *MyEJB.java*) is removed from the same free-form project:

```
[09:00:04 PM] [/MyProject/bin/ejbs/MyEJB.class] Deleted
[09:00:04 PM] [/MyProject/ejbs/MyEJB.java] Deleted
[09:00:09 PM] Enterprise bean removed from ejb-jar.xml: MyEJB
```

Since the remote interface has been removed from the free-form project, the existing home interface is not sufficient to define a remote view type. Both the remote and local view type are not defined, so the bean is removed from the deployment descriptor as well as its bindings.

Deploying Web services using a free-form project

You can add Java beans containing Web service annotation tags to a free-form project. This will generate a WSDL file and Web service deployment descriptors, and deploy the Web service.

Prerequisites: Before you can add the Java bean to the free-form project, the bean must contain the Web service annotation tags that define how the Web service will be deployed. The minimum required tag is `@WebSphere.WebService`, which tells the rapid deployment tools that you want to deploy a Web service. If you want to deploy a stateless session EJB Web service, the Java bean that you add to the free-form project must contain `@ejb.session` with `type=Stateless`. For more information on the available tags and how to add them to your beans, refer to the IBM WebSphere Application Server Toolkit online help.

To deploy a Web service from a Java bean using a free-form project:

1. Create a directory structure within your free-form project that maps exactly to the package name for the bean from which you are deploying the Web service. Note: If your project supports J2EE 1.3 (as compared to J2EE 1.4), the bean and its package structure must be contained in the `gen/src` folder or the free-form project. If it is located somewhere else the tools will create an SEI with the same name as the bean which in turn will result in a conflict.

2. Use your file management system to properly place your Java bean into the free-form project. The directory name of the free-form project has the same string value you had provided for the **-project** parameter used in the wrd-config command.

3. The following activities occur when you drop a bean containing the `@WebSphere.WebService` tag to a free-form project:

   a. The bean searched for annotation tags and is then compiled.

   b. The bean is analyzed and a Java2WSDL model is created. If any invalid or malformed tags are encountered the deployment process will abort at this point.

   c. The Service Endpoint Interface (SEI) code is generated and compiled.

   d. If you are deploying a stateless session EJB Web service, at this point a Web project is created or selected to act as the router project.

   e. Java2WSDL creates the WSDL file for the Web service.

   f. The Web service deployment descriptors, JAX-RPC mapping file, serializers, deserializers, helper and holder code are created. These files are then compiled.

g. If you are deploying a stateless session EJB Web service, at this point the EJB is deployed and the deployment files are compiled.

The Web service endpoint can be accessed with the following URL: `http://<hostname>:<WC_defaulthost>/<free-form project name>Web/services/<port-component-name>`, and the `<port-component-name>` element can be found in the generated `webservices.xml` in the Web project.

For example, if your free-form project is called `MyProject`, the port-component-name is `MyService`. If you have published the application to `myhost` using the default ports, then the endpoint URL will be: `http://myhost:9080/MyProjectWeb/services/MyService`

Tip: If you want to monitor the rapid deployment activity, run your rapid deployment session with console output. You can complete this by running the rapid deployment launch tool as follows:

- ▶ `Windows` `wrd.bat -monitor`
- ▶ `UNIX` `wrd.sh -monitor`

Restriction: There is no support for deleting Web services deployed by a free-form project at this time.

Automatically installing applications on WebSphere Application Server v6.x

The *automatic installation* configuration creates a single monitored directory that listens for fully composed EAR files or application module such as WAR, EJB JAR files, or standalone resource adapter archive (RAR) files.

If you place EAR files inside this monitored directory, the EAR file is automatically deployed to the server. If you delete the EAR file from the monitored directory, that application is uninstalled from the server. If you place WAR or EJB jar files in the monitored directory, the rapid deployment tool generates the necessary EAR wrapper and then publishes that EAR file on the server. For RAR files, a wrapper is not created; the standalone RAR files are published to the server.

Restrictions
- The rapid deployment tools do not automatically configure server-specific functions for an application. You need to create and manage the server-specific configurations through the WebSphere administrative console. Examples of server-specific configurations include setting up ports, security role mappings or data sources.
- If you did not generate deployment code for the enterprise beans or enterprise application containing enterprise beans, the rapid deployment tool generates the deployment code with the default backend option set to DB2UDB_V82. If you want to set a different backend option, run the EJB deployment tools (ejbdeploy.bat) on the EAR file before dropping it into the automatic installation project.

To automate the installation of applications on WebSphere Application Server v6.x:

Setting up a rapid deployment environment

You can run the rapid deployment batch tools from a command line to create, configure, and launch rapid deployment projects using the IBM WebSphere v6.x runtime environment. The rapid deployment tools run in a non-graphical command line interface.

Prerequisites
- WebSphere Application Server v6.x installed
- The rapid deployment launch tool is in the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:

- – | Windows | wrd.bat
- – | UNIX | wrd.sh
- The rapid deployment configuration tool is in the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:
  - – | Windows | wrd-config.bat
  - – | UNIX | wrd-config.sh

To set up a rapid deployment workspace:

1. Open a command prompt.
2. Specify the location on your file system that will host the rapid deployment activities. This location serves as your workspace root, and all your rapid deployment projects reside here. Define an environment variable called WORKSPACE:

   - | Windows | `set WORKSPACE=<workspace root>`
   - | UNIX | `export WORKSPACE=<workspace root>`

   Configure a rapid deployment workspace for each rapid deployment project, rather than configuring multiple rapid deployment projects inside a single rapid deployment workspace.

   Tip: To list all your environment variables and their values, run the command:

   - | Windows | `set "`
   - | Linux | `export -n`
   - | AIX | | Solaris | | HP-UX | `export`

After the WORKSPACE environment variable is defined, you can continue to configure and launch your rapid deployment workspace.

Creating an automatic installation project in your workspace

The *automatic installation* project automates the installation, modification, and uninstallation of J2EE compliant applications (EAR files) or modules (WAR, JAR, or RAR files) on a server. Automatic application installation releases you from the complexity of administrating your application on a server.

The initial configuration of the automatic installation project in your workspace creates an automatic installation project. After you have configured the workspace to contain an automatic installation project, you can launch a rapid deployment session. Launching a rapid deployment session indicates that you want the project to start listening for your EAR or module files. If you place an EAR file in the automatic application installation project, the EAR file is automatically deployed to the server. If you delete EAR files from the project, the application is uninstalled from the server. If you place a new copy of the same EAR file in the automatic application installation project, the application is either reinstalled or the server restarts to pick up the modifications. If you place module files in the project, a supporting EAR wrapper is generated, and then that EAR file is deployed to the server.

Prerequisite

- Set up a rapid deployment environment.

To configure a new automatic installation workspace:

1. From the command prompt, change to the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server is installed.
2. Type the following at the prompt:

   - | Windows | `WRD-config.bat -project "project_name" -style "autoappinstall"`

- > UNIX WRD-config.sh -project *"project_name"* -style *"autoappinstall"*

3. In the **Parameter Configuration Settings** dialog box, specify the value for one or more of the following settings:

Option	Description
serverName	The name of the server process you want to publish your application. For example, server1. For WebSphere Application Server Network Deployment, the server name is in the form *<cell name>/<node name>/<server name>*. To publish to a cluster, the server name is in the form *<cell name>/<cluster name>*
username	(Optional) If security is enabled, specify the user name for current active authentication settings defined in the server configuration.
password	(Optional) If security is enabled, specify the password for current active authentication settings defined in the server configuration.
serverJMXHost	The host name of the machine containing the server you want to make a connection to. For example, localhost. For WebSphere Application Server Network Deployment, type the host name of the Network Deployment Manager.
serverJMXPort	The server administrative port number, also known as the Simple Object Access Protocal (SOAP) connector port. This port is used for making JMX connections with the server. For example, 8880. For WebSphere Application Server Network Deployment, type the SOAP port number of the Network Deployment Manager, default is 8879.

The automatic installation project is created with the naming convention *project_name*, where *project_name* is the string value provided for the **-project** parameter.

Starting a rapid deployment session

You can launch a rapid deployment session to start listening for application artifacts that are dropped into the folder you configured for either the free-form or automatic installation approach. Use the **wrd** command to launch a rapid deployment session. If you want to monitor rapid deployment activities, you can specify console output.

Prerequisites
- Set up a rapid deployment environment.
- Configure the behavior of the monitored directory as free-form or automatic installation.

Steps
1. From the command prompt, change to the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server is installed.
2. Verify that the server on which you want to deploy your application is running.

   Tip: If there is no server connection, you get the following console output:

   ```
   [06:52:28 PM] Publishing MyProjectApp to server_510658053
   [06:52:28 PM] Failed to make connection to Websphere Application Server.
   ```
3. At the command prompt, type the appropriate command:
   - (Recommended) To monitor rapid deployment activities:
     - > Windows

- – `UNIX` `wrd.sh -monitor`
- To launch a rapid deployment session:
  - – `Windows` `wrd.bat`
  - – `UNIX` `wrd.sh`
- To use batch mode to run a full build of the workspace and then shut down the process:
  - – `Windows` `wrd.bat -project "project_name" -batch`
  - – `UNIX` `wrd.sh -project "project_name" -batch`

After you launch the rapid deployment tools, you can create or drop your J2EE artifacts into the monitored directory. The application generated is deployed and updated on the target server.

Managing EAR or module files in the automatic installation project

You can place J2EE compliant applications (EAR files) or application modules such as WAR files, EJB JAR files, or standalone RAR files in an automatic application installation project and let rapid deployment tools deploy that application on to a target server.

From a J2EE development perspective, the automatic application installation project supports a single J2EE application and at most one of each of the application modules (WAR, EJB jars, or stand-alone RAR file).

Prerequisites

- Set up a rapid deployment environment.
- Created an automatic application installation project in your workspace.
- Verify that the server where you want to deploy your application is running.
- Launch a rapid deployment session by using the wrd command.

Use your file management system to place your EAR or module files properly in the automatic installation project. The directory name of the automatic installation project has the same string value you provided for the **-project** parameter used in the wrd-config command.

The following actions are supported when using the automatic installation projects:

Dropping EAR files

You can place EAR files in the automatic application installation project. The EAR file is automatically deployed to the server by expanding into the installedApps folder of the local WebSphere Application Server.

Restriction: If you did not generate deployment code for the enterprise beans contained in the enterprise application, the rapid deployment tool generates the deployment code with the default backend option set to DB2UDB_V82 during the installation of your application on the server. If you want to set a different backend option, run the EJB deployment tools (ejbdeploy.bat) on the EAR file before dropping it into the automatic installation project.

Deleting EAR files

When you delete EAR files from the automatic installation project, the application is uninstalled from the server.

Modifying EAR files

You can place a modified version of the same EAR file in the automatic installation project and the application is reinstalled.

Dropping module files

You can place WAR or EJB jar files in the automatic installation project. A supporting EAR wrapper is generated in the **gen** subdirectory, and then that EAR file is deployed to the server by expanding into the **installedApps** folder of the local WebSphere Application Server. For RAR files, a wrapper is not created. The standalone RAR files are published to the server.

Restriction: If you did not generate deployment code for the enterprise beans, the rapid deployment tool will generate the deployment code with the default backend option set to DB2UDB_V82. If you want to set a different backend option, run the EJB deployment tools (ejbdeploy.bat) on the EAR file prior to dropping it into the automatic installation project.

Deleting module files

When you delete module files from the automatic application installation project, the application is uninstalled from the server. In addition, any supporting EAR wrapper that was generated in the **gen** subdirectory is removed.

Modifying module files

You can place a modified version of the same module file in an automatic application installation project, then the application is reinstalled. In addition, any supporting EAR wrapper that was generated in the **gen** subdirectory is modified.

References

The rapid deployment configuration tool reference

You can use the rapid deployment configuration tool (wrd-config.bat or wrd-config.sh) from a command line to configure rapid deployment projects, such as free-form or automatic installation projects. The **wrd-config** command is run in a non-graphical command line interface.

Requirements

- WebSphere Application Server v6.x installed. The **wrd-config** command supports only WebSphere Application Server v6.x as the target server.
- The rapid deployment launch tool, is in the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:

  - Windows   wrd.bat

  - UNIX   wrd.sh

- The rapid deployment configuration tool, is in the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:

  - Windows   wrd-config.bat

  - UNIX   wrd-config.sh

.

Before using the wrd-config command you need to set up a workspace environment variable. For more information, see the related task about setting up a rapid deployment environment. After you have set up your command line, you can use the following syntax and arguments to run the tool.

Syntax

`Windows`   `wrd-config.bat -project <"project_name"> -style <"freeform"|"autoappinstall">` `[<optional parameters>]`

`UNIX`   `wrd-config.sh -project <"project_name"> -style <"freeform"|"autoappinstall">` `[<optional parameters>]`

Mandatory parameters:

-project <"*project_name*">
> The name of the rapid deployment project that you want to create. The project name needs to be unique in your workspace.

-style <"`freeform`"|"`autoappinstall`">
> The deployment approach - either the free-form or automatic application installation project is used as the deployment style.
>
> The free-form project ("`freeform`") allows you to create or drop in your J2EE artifacts (such as servlet source, JSP, static Web content, EJB classes or source files, Java class files, and all other generic files) into the free-form project. These resources are automatically placed in the appropriate location in the J2EE project structure.
>
> The automatic installation project ("`autoappinstall`") creates a single project that listens for fully composed EAR or module files. If EAR files are placed inside this project, the EAR file is automatically deployed to the server. If the EAR file is deleted, then that application is uninstalled from the server. If you place WAR or EJB jar files in a automatic installation project, the rapid deployment tool generates the necessary EAR wrapper and then publishes that EAR file on the server. For RAR files, a wrapper is not created. The standalone RAR files are published to the server.

Optional parameters:

-workspace
> Specifies the location on your file system that will host the rapid deployment activities.

-rebuild
> Cleans and rebuilds the contents of the rapid deployment project.

-configure
> Opens an interactive console session to modify any available parameters.

-runtime <"`was51`"|"`was60`" | "`was61`">
> Targeting your runtime will configure which JRE library to use, based on the runtime location, and configure the project's classpath to contain the WebSphere runtime libraries. Specify as an identifier if either WebSphere Application Server v5.1 ("`was51`"), WebSphere Application Server v6.0 ("`was60`"), or WebSphere Application Server v6.1 ("`was61`") is used as the target runtime environment for rapid deployment processing. If this parameter is not specified, the default setting is WebSphere Application Server v6.1. This parameter is only used with **-runtimePath** parameter.

-runtimePath <"*x:\WebSphere\AppServer*">
> Where *x:\WebSphere\AppServer* is the directory where WebSphere Application Server is installed. This runtimePath parameter specify the directory path to where the target runtime is installed and is used in conjunction with **-runtime** parameter.

-j2eeVersion <"`1.3`"|"`1.4`">
> Specifies either J2EE version 1.3 or 1.4 is used for development and deployment.

-configPath "*x:\filename.xml*"
> The destination file path for the configuration file, where *x* is the temporary directory. This file

persists the configuration data to an XML file, which can later be used to drive other rapid deployment configuration sessions. If this path is not specified, the default location is in the root of the rapid deployment workspace.

-configData *"x:\filename.xml"*

The path of an existing XML configuration file that is used to drive the configuration session. If this path is not specified, the default location of the XML configuration file is in the root of the rapid deployment workspace with the naming convention *projectName_*headlessconfig.xml, where *projectName* is the value specified in the **-project** parameter.

-listStyles

The available deployment styles and their descriptions.

-listServers

The available runtime server targets.

-properties

Lists the properties for a given deployment project. This parameter is only used with **-project**.

-buildMode

Specify to disable all console outputs. You find this useful for silent builds.

-usage

Displays the optional and required parameters for this command.

Examples of running the WRD-config command

To create a new free-form project:

```
WRD-config.bat -project "MyProject" -style "freeform" -runtime "was61" -runtimePath "c:\WebSphere\AppServer"
```

To create a new automatic application installation project:

```
WRD-config.bat -project "MyProject" -style "autoappinstall"
```

To persist configuration data to an XML file:WRD-config.bat -project *"MyProject"* -style *"freeform"* -runtime *"was61"* -runtimePath *"c:\WebSphere\AppServer"* -configPath *"c:\configData\myHeadlessConfig.xml"*

To create a new rapid deployment project using an existing XML configuration file:

```
WRD-config.bat -configData "c:\configData\myHeadlessConfig.xml"
```

To clean and rebuild an existing rapid deployment project:

```
WRD-config.bat -project "MyProject" -rebuild
```

To modify available deployment parameters:

```
WRD-config.bat -project "MyProject" -configure
```

To query properties of an existing rapid deployment project:

```
WRD-config.bat -project "MyProject" -properties
```

To query available rapid deployment styles and runtime targets:

```
WRD-config.bat -listStyles -listServers
```

The rapid deployment launch tool reference

You can use the rapid deployment launch tool (wrd.bat or wrd.sh) to specify that you want the tool to start listening for application artifacts that are dropped into the monitored project. The **wrd** command is run in a non-graphical command line interface.

Requirements

- WebSphere Application Server v6.x installed. The **wrd** command support only WebSphere Application Server v6.x as the target server.
- The rapid deployment launch tool is in the *x*:/profiles/*<profileName>*/bin directory, where *x* is the directory where WebSphere Application Server v6.x is installed:

    – ▶ Windows wrd.bat

    – ▶ UNIX wrd.sh

- The rapid deployment configuration tool is in the *x*:/profiles/*<profileName>*/bin directory where *x* is the directory where WebSphere Application Server v6.x is installed:

    – ▶ Windows wrd-config.bat

    – ▶ UNIX wrd-config.sh

Before using the **wrd-config** command you need to set up a workspace environment variable. For more information, see the related task about setting up a rapid deployment environment. After you have set up your command line, you can use the following syntax and arguments to run the tool.

Syntax

▶ Windows `wrd.bat [<optional parameters>]`

▶ UNIX `wrd.sh [<optional parameters>]`

Optional parameters

-workspace
> Specifies the location on your file system that will host the rapid deployment activities.

-monitor
> Enables console feedback from the rapid deployment tool.

-project <*"project_name"*>
> The name of the rapid deployment project that you want to target to run in batch mode. This **-project** parameter is only used in conjunction with **-batch** parameter.

-batch Batch mode runs a full build on the projects generated in the rapid deployment workspace and then shutdowns the process. A project, specified by the **-project**, is required when using the batch mode parameter to generate the rapid deployment projects that will be compiled during the full build.

-usage
> Displays the optional parameters for this command.

Chapter 6. Debugging applications

To debug your application, you must use a development environment like Application Server Toolkit or Rational Application Developer to create a Java project. You must then import the program that you want to debug into the project. By following the steps below, you can import the WebSphere Application Server examples into a Java project.

Two debugging styles are available:
- **Step-by-step** debugging mode prompts you whenever the server calls a method on a Web object. A dialog lets you step into the method or skip it. In the dialog, you can turn off step-by-step mode when you are finished using it.
- **Breakpoints** debugging mode lets you debug specific parts of programs. Add breakpoints to the part of the code that you must debug and run the program until one of the breakpoints is encountered.

Breakpoints actually work with both styles of debugging. Step-by-step mode just lets you see which Web objects are being called without having to set up breakpoints ahead of time.

You do not need to import an entire program into your project. However, if you do not import all of your program into the project, some of the source might not compile. You can still debug the project. Most features of the debugger work, including breakpoints, stepping, and viewing and modifying variables. You must import any source that you want to set breakpoints in.

The inspect and display features in the source view do not work if the source has build errors. These features let you select an expression in the source view and evaluate it.

1. Create a Java Project by opening the New Project dialog.
2. Select **Java** from the left side of the dialog and **Java Project** in the right side of the dialog.
3. Click **Next** and specify a name for the project, for example, WASExamples.
4. Click **Finish** to create the project.
5. Select the new project, choose **File > Import > File System**, then **Next** to open the import file system dialog.
6. Browse the directory for files.

   Go to the following directory: *app_server_root*/installedApps/*node_name*/DefaultApplication.ear/ DefaultWebApplication.war.
7. Select DefaultWebApplication.war in the left side of the Import dialog and then click **Finish**. This imports the JavaServer Pages files and Java source for the examples into your project.
8. Add any JAR files needed to build to the Java Build Path.

   Select **Properties** from the right-click menu. Choose the Java Build Path node and then select the Libraries tab. Click **Add External JARs** to add the following JAR files:
   - *app_server_root*/installedApps/*node_name*/DefaultApplication.ear/Increment.jar.

     When you have added this JAR file, select it and use the **Attach Source** function to attach the Increment.jar file because it contains both the source and class files.
   - *app_server_root*/lib/j2ee.jar
   - *app_server_root*/lib/pagelist.jar
   - *app_server_root*/lib/webcontainer.jar

   Click **OK** when you have added all of the JARs.
9. You can set some breakpoints in the source at this time if you like, however, it is not necessary as step-by-step mode will prompt you whenever the server calls a method on a Web object.
   Step-by-step mode is explained in more detail below.
10. To start debugging, you need to start the WebSphere Application Server in debug mode and make note of the JVM debug port. The default value of the JVM debug port is 7777.

11. When the server is started, switch to the debug perspective by selecting **Window > Open Perspective > Debug**. You can also enable the debug launch in the Java Perspective by choosing **Window > Customize Perspective** and selecting the **Debug** and **Launch** checkboxes in the **Other** category.

12. Select the workbench toolbar **Debug** pushbutton and then select **WebSphere Application Server Debug** from the list of launch configurations. Click the **New** pushbutton to create a new configuration.

13. Give your configuration a name and select the project to debug (your new WASExamples project). Change the port number if you did not start the server on the default port (7777).

14. Click **Debug** to start debugging.

15. Load one of the examples in your browser. For example: `http://your.server.name:9080/hitcount`

To learn more about debugging, launch the Application Server Toolkit, select **Help > Help Contents** and choose the **Debugger Guide bookshelf** entry. To learn about known limitations and problems that are associated with the Application Server Toolkit, see the Application Server Toolkit release notes. For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the Must gather documents page for information to gather to send to IBM Support.

Debugging components in the Application Server Toolkit

The Application Server Toolkit, included with the WebSphere Application Server on a separately-installable CD, includes debugging functionality that is built on the Eclipse workbench. Documentation for the Application Server Toolkit is provided with that product. To learn more about the debug components, launch the Application Server Toolkit, select **Help > Help Contents** and choose the **Debugger Guide bookshelf** entry.

The Application Server Toolkit includes the following:

The WebSphere Application Server debug adapter
which allows you to debug Web objects that are running on WebSphere Application Server and that you have launched in a browser. These objects include enterprise beans, JavaServer Pages files, and servlets.

The JavaScript debug adapter
which enables server-side JavaScript debugging.

The Compiled language debugger
which allows you to detect and diagnose errors in compiled-language applications.

The Java development tools (JDT) debugger
which allows you to debug Java code.

All of the debug components in the Application Server Toolkit can be used for debugging locally and for remote debugging. To learn more about the debug components, launch the Application Server Toolkit, select **Help > Help Contents** and choose the **Debugger Guide bookshelf** entry.

To learn more about Log and Trace Analyzer, launch the Application Server Toolkit, and select **Help > Help Contents**. To learn about known limitations and problems that are associated with the Application Server Toolkit, see the Application Server Toolkit release notes.

Chapter 7. Assembling applications

Application assembly consists of creating Java 2 Platform, Enterprise Edition (J2EE) modules that can be deployed onto application servers. The modules are created from code artifacts such as Web application archives (WAR files), resource adapter archives (RAR files), enterprise bean (EJB) JAR files, and application client archives (JAR files). This packaging and configuring of code artifacts into enterprise application modules (EAR files) or standalone Web modules is necessary for deploying the modules onto an application server.

This topic assumes that you have developed code artifacts that you want to deploy onto an application server and have unit tested the code artifacts in your favorite integrated development environment. Code artifacts that you might assemble into deployable J2EE modules include the following:
- Enterprise beans
- Servlets, JavaServer Pages (JSP) files and other Web components
- Resource adapter (*connector*) implementations
- Application clients
- Session Initiation Protocol (SIP) modules (SAR files)
- Other supporting classes and files

Before you can assemble your code artifacts into deployable J2EE modules, you must install or get access to a supported assembly tool. WebSphere Application Server supports two tools that you can use to develop, assemble, and deploy J2EE modules:
- Application Server Toolkit (AST)
- Rational Application Developer

You assemble code artifacts into J2EE modules in order to deploy the code artifacts onto an application server. When you assemble code artifacts, you package and configure the code artifacts into deployable J2EE applications and modules, edit deployment descriptors, and map databases as needed. Unless you assemble your code artifacts into J2EE modules, you cannot run them successfully on an application server.

This topic describes how to assemble J2EE code artifacts into deployable modules using an assembly tool. Alternatively, you can use a WebSphere rapid deployment tool to quickly assemble and deploy J2EE code artifacts. Refer to Rapid deployment of J2EE applications for details.

1. Start an assembly tool.
2. **Optional:** Read the online documentation for the assembly tool.
   - Click **Help > Help Contents >** *product_name* **information**, for example **Help > Help Contents > Application Server Toolkit information**. The displayed documentation provides extensive information on assembling modules.
   - Click **Help > Cheat Sheets >** *tutorial_name* **> OK**. The displayed tutorial provides steps with illustrations.
   - Press **F1** to access information specific to an AST or Rational Application Developer view or window.
   - Visit the **Application Server Toolkit** information center that accompanies this WebSphere Application Server information center. Also, refer to articles on **Rapid deployment of J2EE applications** in this information center.
   - See the topic "Assembling applications: Resources for learning" on page 1348 for additional sources.
3. Configure the assembly tool for work on J2EE modules.
4. Migrate J2EE projects or code artifacts created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool.

   To migrate files, use the J2EE Migration wizard or import the files to AST or Rational Application Developer.

5. Create an enterprise application project to which you can add archive files. You can create an enterprise application project separately or when you create archive files such as the following:

   - Create a Web project.
   - Create an enterprise bean (EJB) project.
   - Create an application client.
   - Create a resource adapter (connector) project.

6. Edit the deployment descriptors as needed. You can edit deployment descriptors for enterprise application, Web, application client, and enterprise bean (EJB) modules.

   Topics on deployment descriptor editors such as Application Deployment Descriptor editor in AST documentation provide extensive information on editing deployment descriptors.

7. **Optional:** Generate enterprise bean (EJB) to relational database (RDB) mappings for EJB modules.

8. Verify the archive files.

9. Generate code for deployment for Web services-enabled modules or for enterprise applications that use Web service modules.

After assembling your applications, use a systems management tool to deploy the EAR or WAR files onto the application server. "Ways to install applications or modules" on page 1366 lists systems management tools available for deploying J2EE modules on an application server. The systems management tool follows the security and deployment instructions defined in the deployment descriptor, and enables you to modify bindings specified within an assembly tool. The tool locates the required external resources that the application uses, such as enterprise beans and databases.

To deploy EJB projects to a target server, right-click the EJB project in the Project Explorer view and click **Deploy**.

Package your application so that the `.ear` file contains necessary modules only. Modules can include metadata for the modules such as information on deployment descriptors, bindings, and IBM extensions.

Use the administrative console at installation to complete the security instructions defined in the deployment descriptor and to locate required external resources, such as enterprise beans and databases. You can add configuration properties and redefine binding properties defined in an assembly tool.

After installation, you can view module deployment descriptors using the console.

Application assembly and J2EE applications

Application assembly is the process of creating an enterprise archive (EAR) file containing all files related to an application, as well as an XML deployment descriptor for the application. This configuration and packaging prepares the application for deployment onto an application server.

EAR files are comprised of the following archives:
- Enterprise bean JAR files (known as EJB modules)
- Web archive (WAR) files (known as Web modules)
- Application client JAR files (known as client modules)
- Resource adapter archive (RAR) files (known as resource adapter modules)
- SAR files (known as Session Initiation Protocol (SIP) modules)

Ensure that modules are contained in an EAR file so that they can be deployed onto the server. The exceptions are WAR modules, which you can deploy individually. Although WAR modules can contain regular JAR files, they cannot contain the other module types described previously.

The assembly process includes the following actions:
- Selecting all of the files to include in the module.

- Creating a deployment descriptor containing instructions for module deployment on the application server.

  As you configure properties using an assembly tool, the tool generates the deployment descriptor for you. While the Application Server Toolkit (AST) or Rational Application Developer graphical interface is recommended, you can also edit descriptors directly in your favorite XML editor.
- Packaging modules into a single EAR file, which contains one or more files in a compressed format.

As part of the assembly process, you might also set environment-specific binding information. These bindings are defaults for an administrator to use when installing the application through the administrative console. Further, you might define IBM extensions to the J2EE specification, such as to allow servlets to be served by class name. To ensure portability to other application servers, these extensions are saved in an XML file that is separate from the standard J2EE deployment descriptor.

Assembly tools

WebSphere Application Server supports two tools that you can use to develop, assemble, and deploy J2EE modules: Application Server Toolkit (AST) and Rational Application Developer. These tools are referred to in this information center as the *assembly tools*.

The AST is available in your WebSphere Application Server CD-ROM package. Rational Application Developer is available only on a trial basis in the WebSphere Application Server CD-ROM package.

The assembly feature of the AST and Rational Application Developer products runs on Windows and Linux Intel platforms. Users of WebSphere Application Server on other platforms must assemble their modules using an assembly tool installed on Windows or Linux Intel platforms. To install an assembly tool, follow instructions available with the tool.

Although this information center refers to the AST and Rational Application Developer products as the *assembly tools*, you can use the products to do more than assemble modules. Rational Application Developer is an integrated development environment that provides development, testing, assembly and deployment capabilities. However, topics on application assembly in this information center focus on assembling J2EE modules using the J2EE Perspective of the assembly tools. Each assembly tool provides extensive online documentation; the topics on application assembly in this information center supplement that documentation. The **Application Server Toolkit** information center is available with this information center.

Generating code for Web service deployment

Before deploying Web services-enabled modules or any enterprise application archive (EAR) files that contain Web services-enabled module onto an application server, you must generate deployment code for the application.

This article assumes you have assembled a module enabled with Web services, added it to an application, saved the application, and verified the application. It also assumes that you have started and configured an assembly tool.

You can use an assembly tool to generate deployment code for the Web services-enabled module or for the EAR file that contains the Web services-enabled module.

1. If you have turned automatic validation off, manually validate any modules that use Web services with the JSR109 Web services validator before generating deployment code for them. If validating your module results in compilation errors or validation errors, fix the errors before generating deployment code. However, if validating your module results in warning or information messages, you can generate deployment code.

2. In the Project Explorer view of the assembly tool, right-click on the Web services-enabled module (WAR, enterprise bean JAR, or application client JAR file) for which you want to generate code for deployment.

3. Click **Deploy**. Alternatively, you can generate deployment code for Web services-enabled modules using the deployment tool for Web services (`wsdeploy`) from a command prompt.

4. If messages indicate that automatic file overwriting is not enabled, click **Yes to All** so the generated files are added to the module.

5. If errors such as *Unbound classpath variable: WAS_50_PLUGINDIR* appear in the Tasks list, change the Java build path libraries properties to define that variable to be the WebSphere Application Server installation directory.

Code is generated into the folder where your Web services-enable module is located. Problems with the generation of code result in a window that displays error messages.

Install the Java 2 Platform, Enterprise Edition (J2EE) application on your server machine. You can install the application onto a server using the administrative console. Before installing the application, you might need to set class paths.

Assembling applications: Resources for learning

Additional information and guidance on assembling applications is available on various Internet sites.

Use the following links to find relevant supplemental information about the application assembly and using an assembly tool. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to "Web resources for learning" on page 15 for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

Chapter 8. Class loading

Class loaders are part of the Java virtual machine (JVM) code and are responsible for finding and loading class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications. Class loaders affect the packaging of applications and the runtime behavior of packaged applications of deployed applications.

This topic describes how to configure class loaders for application files or modules that are installed on an application server.

To better understand class loaders in WebSphere Application Server, read "Class loaders." The topic "Class loading: Resources for learning" on page 1360 refers to additional sources.

Configure class loaders for application files or modules that are installed on an application server using the administrative console. You configure class loaders to ensure that deployed application files and modules can access the classes and resources that they need to run successfully.

1. If an installed application module uses a resource, create a resource provider that specifies the directory name of the resource drivers.

   Do not specify the resource Java archive (JAR) file names. All JAR files in the specified directory are added into the class path of the WebSphere Application Server extensions class loader. If a resource driver requires a native library (`.dll` or `.so` file), specify the name of the directory that contains the library in the native path of the resource configuration.

2. Specify class-loader values for an application server.

3. Specify class-loader values for an installed enterprise application.

4. Specify the class-loader mode for an installed Web module.

5. If your deployed application uses shared library files, associate the shared library files with your application. Use a library reference to associate a shared library file with your application.

   a. If you have not done so already, define a shared library instance for each library file that your applications need.

   b. Define a library reference instance for each shared library that your application uses.

After configuring class loaders, ensure that your application performs as desired. To diagnose and fix problems with class loaders, refer to Troubleshooting class loaders.

Class loaders

Class loaders find and load class files. Class loaders enable applications that are deployed on servers to access repositories of available classes and resources. Application developers and deployers must consider the location of class and resource files, and the class loaders used to access those files, to make the files available to deployed applications.

This topic provides the following information about class loaders in WebSphere Application Server:
- "Class loaders used and the order of use"
- "Class-loader isolation policies" on page 1353
- "Class-loader modes" on page 1355

Class loaders used and the order of use

The runtime environment of WebSphere Application Server uses the following class loaders to find and load new classes for an application in the following order:

1351

1. The bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine

   The bootstrap class loader uses the boot class path (typically classes in `jre/lib`) to find and load classes. The extensions class loader uses the system property java.ext.dirs (typically `jre/lib/ext`) to find and load classes. The CLASSPATH class loader uses the CLASSPATH environment variable to find and load classes.

   The CLASSPATH class loader loads the Java 2 Platform, Enterprise Edition (J2EE) application programming interfaces (APIs) provided by the WebSphere Application Server product in the `j2ee.jar` file. Because this class loader loads the J2EE APIs, you can add libraries that depend on the J2EE APIs to the class path system property to extend a server class path. However, a preferred method of extending a server class path is to add a shared library.

2. A WebSphere extensions class loader

   The WebSphere extensions class loader loads the WebSphere Application Server classes that are required at run time. The extensions class loader uses a ws.ext.dirs system property to determine the path that is used to load classes. Each directory in the `ws.ext.dirs` class path and every Java archive (JAR) file or ZIP file in these directories is added to the class path used by this class loader.

   The WebSphere extensions class loader also loads resource provider classes into a server if an application module installed on the server refers to a resource that is associated with the provider and if the provider specifies the directory name of the resource drivers.

3. One or more application module class loaders that load elements of enterprise applications running in the server

   The application elements can be Web modules, enterprise bean (EJB) modules, resource adapter archives (RAR files), and dependency JAR files. Application class loaders follow J2EE class-loading rules to load classes and JAR files from an enterprise application. WebSphere Application Server enables you to associate shared libraries with an application.

4. Zero or more Web module class loaders

   By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. Web module class loaders are children of application class loaders. You can specify that an application class loader load the contents of a Web module rather than the Web module class loader.

Each class loader is a child of the previous class loader. That is, the application module class loaders are children of the WebSphere extensions class loader, which is a child of the CLASSPATH Java class loader. Whenever a class needs to be loaded, the class loader usually delegates the request to its parent class loader. If none of the parent class loaders can find the class, the original class loader attempts to load the class. Requests can only go to a parent class loader; they cannot go to a child class loader. If the WebSphere extensions class loader is requested to find a class in a J2EE module, it cannot go to the application module class loader to find that class and a ClassNotFoundException error occurs. After a class is loaded by a class loader, any new classes that it tries to load reuse the same class loader or go up the precedence list until the class is found.

Class-loader isolation policies

The number and function of the application module class loaders depend on the class-loader policies that are specified in the server configuration. Class loaders provide multiple options for isolating applications and modules to enable different application packaging schemes to run on an application server.

Two class-loader policies control the isolation of applications and modules:

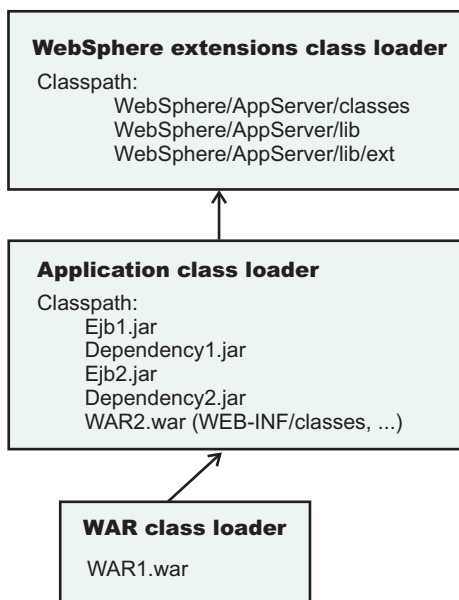
Class-loader policy	Description
Application	Application class loaders load EJB modules, dependency JAR files, embedded resource adapters, and application-scoped shared libraries. Depending on the application class-loader policy, an application class loader can be shared by multiple applications (Single) or unique for each application (Multiple). The application class-loader policy controls the isolation of applications that are running in the system. When set to `Single`, applications are not isolated. When set to `Multiple`, applications are isolated from each other.
WAR	By default, Web module class loaders load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The application class loader is the parent of the Web module class loader. You can change the default behavior by changing the Web application archive (WAR) class-loader policy of the application. The WAR class-loader policy controls the isolation of Web modules. If this policy is set to `Application`, then the Web module contents also are loaded by the application class loader (in addition to the EJB files, RAR files, dependency JAR files, and shared libraries). If the policy is set to `Module`, then each Web module receives its own class loader whose parent is the application class loader. **Tip:** The console and the underlying `deployment.xml` file use different names for WAR class-loader policy values. In the console, the WAR class-loader policy values are `Application` or `Module`. However, in the underlying `deployment.xml` file where the policy is set, the WAR class-loader policy values are `Single` instead of `Application`, or `Multiple` instead of `Module`. `Application` is the same as `Single`, and `Module` is the same as `Multiple`.

Note: WebSphere Application Server class loaders never load application client modules.

For each application server in the system, you can set the application class-loader policy to `Single` or `Multiple`. When the application class-loader policy is set to `Single`, then a single application class loader loads all EJB modules, dependency JAR files, and shared libraries in the system. When the application class-loader policy is set to `Multiple`, then each application receives its own class loader that is used for loading the EJB modules, dependency JAR files, and shared libraries for that application.

An application class loader loads classes from Web modules if the application's WAR class-loader policy is set to `Application`. If the application's WAR class-loader policy is set to `Module`, then each WAR module receives its own class loader.

The following example shows that when the application class-loader policy is set to `Single`, a single application class loader loads all of the EJB modules, dependency JAR files, and shared libraries of all applications on the server. The single application class loader can also load Web modules if an application has its WAR class-loader policy set to `Application`. Applications that have a WAR class-loader policy set to `Module` use a separate class loader for Web modules.

```
Server's application class-loader policy: Single
Application's WAR class-loader policy: Module


Application 1
 Module:  EJB1.jar
 Module: WAR1.war
   MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
```

```
Application 2
 Module:   EJB2.jar
  MANIFEST Class-Path: Dependency2.jar
 Module: WAR2.war
  WAR Classloader Policy = Application
```

WebSphere extensions class loader

Classpath:
        WebSphere/AppServer/classes
        WebSphere/AppServer/lib
        WebSphere/AppServer/lib/ext

Application class loader

Classpath:
    Ejb1.jar
    Dependency1.jar
    Ejb2.jar
    Dependency2.jar
    WAR2.war (WEB-INF/classes, ...)

WAR class loader

  WAR1.war

The following example shows that when the application class-loader policy of an application server is set
to `Multiple`, each application on the server has its own class loader. An application class loader also loads
its Web modules if the application WAR class-loader policy is set to `Application`. If the policy is set to
`Module`, then a Web module uses its own class loader.

```
Server's application class-loader policy: Multiple
Application's WAR class-loader policy: Module
Application 1
 Module:   EJB1.jar
 Module: WAR1.war
  MANIFEST Class-Path: Dependency1.jar
  WAR Classloader Policy = Module
Application 2
 Module:   EJB2.jar
  MANIFEST Class-Path: Dependency2.jar
 Module: WAR2.war
  WAR Classloader Policy = Application
```

Class-loader modes

The class-loader delegation mode, also known as the *class loader order*, determines whether a class loader delegates the loading of classes to the parent class loader. The following values for class-loader mode are supported:

Class-loader mode	Description
Parent first Also known as **Classes loaded with parent class loader first**.	The `Parent first` or `Classes loaded with parent class loader first` class-loader mode causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.
Parent last Also known as **Classes loaded with application class loader first**.	The `Parent last` or `Classes loaded with application class loader first` class-loader mode causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

The following settings determine the mode of a class loader:
- If the application class-loader policy of an application server is `Single`, the server-level mode value defines the mode for an application class loader.
- If the application class-loader policy of an application server is `Multiple`, the application-level mode value defines the mode for an application class loader.
- If the WAR class-loader policy of an application is `Module`, the module-level mode value defines the mode for a WAR class loader.

Configuring class loaders of a server

You can configure the application class loaders for an application server. Class loaders enable applications that are deployed on the application server to access repositories of available classes and resources.

This topic assumes that an administrator created an application server on a WebSphere Application Server product.

Configure the class loaders of an application server to set class-loader policy and mode values which affect all applications that are deployed on the server. Use the administrative console to configure the class loaders.

1. Click **Servers > Application Servers >** *server_name* to access the settings page for an application server.

2. Specify the application class-loader policy for the application server. The application class-loader policy controls the isolation of applications that run in the system (on the server). An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets. The application class-loader policy controls whether an application class loader can be shared by multiple applications or is unique for each application. Use the settings page for the application server to specify the application class-loader policy for the server:

Option	Description
Single	Applications are not isolated from each other. Uses a single application class loader to load all of the EJB modules, shared libraries, and dependency JAR files in the system.
Multiple	Applications are isolated from each other. Gives each application its own class loader to load the EJB modules, shared libraries, and dependency JAR files of that application.

3. Specify the application class-loader mode for the application server. The application class loading mode specifies the class-loader mode when the application class-loader policy is `Single`. On the settings page for the application server, select either of the following values:

Option	Description
Parent first	Causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. `Parent first` is the default value for class loading mode.
Parent last	Causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

4. Specify the class-loader mode for the class loader.
   a. On the settings page for the application server, click **Java and Process Management > Class loader** to access the Class loader page.
   b. On the Class loader page, click **New** to access the settings page for a class loader.
   c. On the settings page for a class loader, specify the class loader order. The `Classes loaded with parent class loader first` value causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path. The `Classes loaded with application class loader first` value causes the class loader to attempt to load classes from its local class path before delegating the class loading to its parent.
   d. Click **OK**.

   An identifier is assigned to a class-loader instance. The instance is added to the collection of class loaders shown on the Class loader page.

Save the changes to the administrative configuration.

Class loader collection

Use this page to manage class-loader instances on an application server. A class loader determines whether an application class loader or a parent class loader finds and loads Java class files for an application.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Java and Process Management > Class loader**.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Class loader order

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and WebSphere Application Server class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

Class loader settings

Use this page to configure a class loader for applications that reside on an application server.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Java and Process Management > Class loader >** *class_loader_ID*.

Class loader ID

Provides a string that is unique to the server identifying the class-loader instance. The product assigns the identifier.

Data type   String

Class loader order

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and WebSphere Application Server class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Classes loaded with parent class loader first` and `Classes loaded with application class loader first`. The default is to search in the parent class loader before searching in the application class loader to load a class.

For your application to use the default configuration of Jakarta Commons Logging in WebSphere Application Server, set this application class loader order to `Classes loaded with parent class loader first`. For your application to override the default configuration of Jakarta Commons Logging in WebSphere Application Server, your application must provide the configuration in a form supported by Jakarta Commons Logging and this class loader order must be set to `Classes loaded with application class loader first`. Also, to override the default configuration, set the class loader order for each Web module in your application so that the correct logger factory loads.

Data type   String

Configuring application class loaders

You can set values that control the class-loading behavior of an installed enterprise application. Class loaders enable an application to access repositories of available classes and resources.

This topic assumes that you installed an application on an application server.

Configure the class loaders of an enterprise application to set class-loader policy and mode values for this application.

An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets.

An application class loader is the parent of a Web application archive (WAR) class loader. By default, a Web module has its own WAR class loader to load the contents of the Web module. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module.

Use the administrative console to configure the class loaders.

1. Click **Applications > Enterprise Applications >** *application_name* **> Class loading and update detection** to access the settings page for an application class loader.
2. Specify whether to reload application classes when the application or its files are updated.

   By default, class reloading is not enabled. Select **Reload classes when application files are updated** to choose to reload application classes. You might specify different values for EJB modules and for Web modules such as servlets and JavaServer Pages (JSP) files.
3. Specify the number of seconds to scan the application's file system for updated files.

   The value specified for **Polling interval for updated files** takes effect only if class reloading is enabled. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the enterprise application (EAR file). You might specify different values for EJB modules and for Web modules such as servlets and JSP files.

   To enable reloading, specify an integer value that is greater than zero (for example, 1 to 2147483647).

   To disable reloading, specify zero (0).
4. Specify the class loader order for the application.

   The application class loader order specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The default is to search in the parent class loader before searching in the application class loader to load a class.

   Select either of the following values for **Class loader order**:

Option	Description
Classes loaded with parent class loader first	Causes the class loader to search in the parent class loader first to load a class. This value is the standard for Development Kit class loaders and WebSphere Application Server class loaders.

Option	Description
Classes loaded with application class loader first	Causes the class loader to search in the application class loader first to load a class. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader. **Attention:** Specifying the `Classes loaded with application class loader first` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

5. Specify whether to use a single or multiple class loaders to load Web application archives (WAR files) of your application.

   By default, Web modules have their own WAR class loader to load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The default WAR class loader value is `Class loader for each WAR file in application`, which uses a separate class loader to load each WAR file. Setting the value to `Single class loader for application` causes the application class loader to load the Web module contents as well as the EJB modules, shared libraries, RAR files, and dependency JAR files associated to the application. The application class loader is the parent of the WAR class loader.

   Select either of the following values for **WAR class loader policy**:

Option	Description
Class loader for each WAR file in application	Uses a different class loader for each WAR file.
Single class loader for application	Uses a single class loader to load all of the WAR files in your application.

6. Click **OK**.

Save the changes to the administrative configuration.

Configuring Web module class loaders

You can set values that control the class-loading behavior of an installed Web module.

This topic assumes that you installed a Web module on an application server.

Configure the class loader order value of an installed Web module. By default, a Web module has its own Web application archive (WAR) class loader to load the contents of the Web module, which are in the `WEB-INF/classes` and `WEB-INF/lib` directories.

An application class loader is the parent of a WAR class loader. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module. The default WAR class loader policy value is `Class loader for each WAR file in application`. If the policy is set to `Class loader for each WAR file in application`, then each Web module receives its own class loader whose parent is the application class loader. If the policy is set to `Single class loader for application` on the settings page of an application class loader, then the application class loader loads the Web module contents as well as the enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Thus, the configuration of the parent application class loader affects the WAR class loader.

Use the administrative console to configure the application and WAR class loaders.

1. If you have not done so already, configure the application class loader.

Settings such as **Reload classes when application files are updated**, **Polling interval for updated files** and **WAR class loader policy** can affect Web module class loading.

If **WAR class loader policy** is set to `Class loader for each WAR file in application`, then the Web module receives its own class loader and the WAR class-loader policy of the Web module defines the mode for a WAR class loader. If the policy is set to `Single class loader for application`, then the application class loader loads the Web module contents.

2. Specify the class loader order for the installed Web module.

   The Web module class-loader mode specifies whether the class loader searches in the parent application class loader or in the WAR class loader first to load a class. The default is to search in the parent application class loader before searching in the WAR class loader to load a class.

   Select either of the following values for **Class loader order**:

Option	Description
Classes loaded with parent class loader first	Causes the class loader to search in the parent application class loader first to load a class. This is the standard for Development Kit class loaders and WebSphere Application Server class loaders. **Tip:** If classes and resources needed by the Web module cannot be accessed by the application class loader, but can be accessed by the WAR class loader, specify `Classes loaded with application class loader first`. If the application class loader cannot find a class, the class loader delegates the request to find the class to its parent, the WebSphere Application Server extensions class loader. If the WebSphere Application Server extensions class loader cannot find the class, the class loader delegates the request to its parent, the bootstrap, extensions, and CLASSPATH class loaders created by the Java virtual machine. Requests can only go to a parent class loader; they cannot go to a child class loader. Thus, if `Classes loaded with parent class loader first` is specified, the WAR class loader never receives a request to load a class.
Classes loaded with application class loader first	Causes the class loader to search in the WAR class loader first to load a class. By specifying `Classes loaded with application class loader first`, your WAR class loader can override classes contained in the parent application class loader. **Attention:** Specifying the `Classes loaded with application class loader first` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

3. Click **OK**.

Save the changes to the administrative configuration.

Class loading: Resources for learning

Additional information and guidance on class loading is available on various Internet sites.

Use the following links to find relevant supplemental information about class loaders. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to "Web resources for learning" on page 15 for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. IBM Support has documents that can save you time gathering information that is needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Chapter 9. Deploying and administering applications

Deploying an application file consists of installing the application file on a server configured to hold installable modules.

Before installing an enterprise application or other installable module on an application server, you must develop the module, assemble the module, and configure the target server or cluster. Before choosing a deployment target for the module, ensure that the target version is compatible with your module.

During installation, you can configure the module enough to enable it to run on the server. After installation, you can configure the module further, start or stop the application, and otherwise manage its activity.

The topics in this section describe how to deploy and administer applications or modules using the administrative console. You can also use scripting or administrative programs (JMX).
* Install application files on an application server.
* Edit the administrative configuration for an application.
* **Optional:** View the deployment descriptor for an application or module.
* Start and stop the application.
* Export applications.
* Export DDL files.
* Update an application or module.
* Uninstall applications.
* Remove a file from an application or module.

If a changed application or module is deployed on a cluster, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Use **Rollout Update** if the application is deployed on one or more clusters spread across multiple nodes. This action reduces the amount of time that any single cluster member is unavailable to serve requests to the smallest interval possible. Pending IIOP transactions will complete before a cluster member stops; in-flight HTTP and JMS transactions might be lost while the cluster member is stopping. For an application server without clusters, use **Update** and then save and synchronize the node instead. For a standalone application server, simply update and save.

After making changes to administrative configurations of your applications in the administrative console, ensure that you save the changes.

Enterprise (J2EE) applications

Enterprise applications (or J2EE applications) are applications that conform to the Java 2 Platform, Enterprise Edition, specification.

Enterprise applications can consist of the following:
* Zero or more EJB modules (packaged in JAR files)
* Zero or more Web modules (packaged in WAR files)
* Zero or more connector modules (packaged in RAR files)
* Zero or more Session Initiation Protocol (SIP) modules (packaged in SAR files)
* Zero or more application client modules
* Additional JAR files containing dependent classes or other components required by the application

- Any combination of the above

A J2EE application is represented by, and packaged in, an enterprise archive (EAR) file.

System applications

A *system application* is a J2EE enterprise application that is central to a WebSphere Application Server product.

Examples of system applications include *isclite*, *managementEJB* and *filetransfer*.

Because a system application is an important part of a WebSphere Application Server product, a system application is deployed when the product is installed and is updated only through a product fix or upgrade. For some system applications, such as *filetransfer*, users cannot change the metadata for the system application, unless the metadata assigns users and groups for security purposes. For these applications, non-security related metadata such as its J2EE bindings or J2EE extensions must be updated through a product fix or upgrade.

System applications are not shown in the list of installed applications on the console Enterprise Applications page, or through wsadmin and Java application programming interfaces, to prevent users from accidentally stopping, updating or removing the system applications.

Note that J2EE Samples are not system applications even though they are provided as part of a WebSphere Application Server product. Similarly, applications that support changes to their metadata are not system applications.

Installing application files

As part of deploying an application, you install application files on a server configured to hold installable modules.

Before you can install your application files on an application server, you must configure the target application server. As part of configuring the server, determine whether your application files can be installed to your deployment targets.

Also, before you install the files, assemble modules as needed.

Installable modules include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), Session Initiation Protocol (SIP) module (SAR), resource adapter (connector or RAR), and application client modules. Application client files can be installed in a WebSphere Application Server configuration but cannot be run on a server. Complete the following steps to install your files.

1. Determine which method to use to install your application files. WebSphere Application Server provides several ways to install modules.
2. Install the application files using
   - Administrative console
   - wsadmin scripts
   - Java administrative programs that use JMX APIs
   - Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)
3. Start the deployed application files using
   - Administrative console
   - wsadmin startApplication
   - Java programs that use ApplicationManager or AppManagement MBeans

- Java programs that define a J2EE DeploymentManager object in accordance with J2EE Deployment API Specification (JSR-88)

Save the changes to your administrative configuration.

When saving the configuration, synchronize the configuration with the nodes where the application is expected to run.

Next, test the application. For example, point a Web browser at the URL for a deployed application (typically http://*hostname*:9060/*Web_module_name*, where *hostname* is your valid Web server and 9060 is the default port number) and examine the performance of the application. If the application does not perform as desired, edit the application configuration, then save and test it again.

Installable module versions

The contents of a module affect whether you can install the module on a WebSphere Application Server Version 6.0 and later (6.x) deployment target, or if you must install the module on a Version 5.0 and later (5.x) deployment target.

Installable application modules

You can install an application, enterprise bean (EJB) module, Session Initiation Protocol (SIP) module (SAR), or Web module developed for a Version 5.x product on a 5.x or 6.x deployment target, provided the module:
- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x runtime application programming interfaces (APIs); and
- Does not use any 6.x product features.

If the module supports J2EE 1.4, then you must install the module on a 6.x deployment target. If the module calls a 6.1.x API or uses a 6.1.x feature, then you must install the module on a 6.1.x deployment target. Modules that call a 6.0.x API or use a 6.0.x feature can be installed on a 6.0.x or 6.1.x deployment target.

Selecting options such as **Precompile JavaServer Pages files**, **Use binary configuration**, **Deploy Web services** or **Deploy enterprise beans** during application installation indicates that the application uses 6.1.x product features. You cannot deploy such applications on a 5.x or 6.0.x deployment target. You must deploy such applications on a 6.1.x deployment target.

Similarly, you must deploy an application that uses J2EE 1.4 features such as Java Authorization Contract for Containers (JACC) provided by an application server on a 6.x deployment target.

Installable RAR files

You can install a standalone resource adapter (connector) module, or RAR file, developed for a Version 5.x product to a 5.x or 6.x deployment target, provided the module does not call any 6.x runtime APIs. If the module calls a 6.x API, then you must install the module on a 6.x deployment target.

Deployment targets

A *5.x deployment target* is a server or a cluster with at least one member on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server or cluster with all members on a WebSphere Application Server Version 6 product.

Table 49. Compatible deployment target versions for 5.x and 6.x modules

Module type	Module Java support	Module calls 6.x runtime APIs or uses 6.x features?	Client versions that can install module	Deployment target versions
Application, EJB, Web, or client	J2EE 1.3	No	5.x or 6.x	5.x or 6.x
Application, EJB, Web, or client	J2EE 1.3	Yes	6.x	6.x Modules that call 6.1.x runtime APIs or use 6.1.x features must be installed on a 6.1.x deployment target. Modules that call 6.0.x runtime APIs or use 6.0.x features can be installed on any 6.x deployment target.
Application, EJB, SAR, Web, or client	J2EE 1.4	Yes or No	6.x	6.x
Resource adapter	JCA 1.0	No	5.x or 6.x	5.x or 6.x
Resource adapter	JCA 1.0	Yes	6.x	6.x Modules that call 6.1.x runtime APIs must be installed on a 6.1.x deployment target. Modules that call 6.0.x runtime APIs can be installed on any 6.x deployment target.
Resource adapter	JCA 1.5	Yes or No	6.x	6.x Modules that call 6.1.x runtime APIs must be installed on a 6.1.x deployment target. Modules that call 6.0.x runtime APIs can be installed on any 6.x deployment target.

Ways to install applications or modules

The product provides several ways to install application files.

Installable files include enterprise archive (EAR), enterprise bean (EJB), Web archive (WAR), Session Initiation Protocol (SIP) module (SAR), resource adapter (connector or RAR), and application client modules. They can be installed on a server or cluster. Application client files can be installed in a WebSphere Application Server configuration but cannot be run on a server.

Table 50. Ways to install application files

Option	Method	Modules	Comments	Starting after install
Administrative console install wizard See "Installing application files with the console" on page 1368.	Click **Applications > Install New Application** in the console navigation tree and follow instructions in the wizard.	All EAR, EJB, WAR, SAR, RAR, and application client files	Provides one of the easier ways to install application files. See "Preparing for application installation settings" on page 1373 for guidance. For applications that do not require changes to the default bindings, select **Show me all installation options and parameters**, select **Generate default bindings**, click the Summary step, and then click **Finish**.	Click **Start** on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.
wsadmin scripts	Invoke AdminApp object *install* commands in a script or at a command prompt.	All EAR, EJB, WAR, SAR, RAR, and application client files	Getting started with scripting provides an overview of wsadmin.	• Invoke the AdminApp *startApplication* command. • Invoke the *startApplication* method on an ApplicationManager MBean using AdminControl.
Java application programming interfaces	Install programs by completing the steps in Installing an application through programming.	All EAR files	Use MBeans to install the application. Managing applications through programming provides an overview of Java MBean programming.	Start the application by calling the *startApplication* method on a proxy.
WebSphere rapid deployment Refer to articles under Rapid deployment of J2EE applications in this information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	All J2EE modules, including EAR files and standalone EJB, WAR, SAR, RAR, and application client files	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.

Table 50. Ways to install application files (continued)

Option	Method	Modules	Comments	Starting after install
Java programs	Code programs that use J2EE DeploymentManager (JSR-88) methods.	All J2EE modules, including EAR files and standalone EJB, WAR, SAR, RAR, and application client files	• Uses J2EE Application Deployment Specification (JSR-88). • Can customize modules using DConfigBeans.	Call the J2EE DeploymentManager (JSR-88) method *start* in a program to start the deployed modules when the module's running environment initializes.

Installing application files with the console

Installing application files consists of placing assembled enterprise application, Web, enterprise bean (EJB), or other installable modules on a server or cluster configured to hold the files. Installed files that start and run properly are considered *deployed*.

Before installing enterprise application files, ensure that you are installing your application files onto a compatible deployment target. If the deployment target is not compatible, select a different target.

To install new enterprise application files to a WebSphere Application Server configuration, you can use the administrative console, the wsadmin tool, Java MBean programs, or Java programs that call J2EE DeploymentManager (JSR-88) methods. This topic describes how to use the administrative console to install an application, EJB component, Session Initiation Protocol (SIP) module (SAR), or Web module.

Important: After you start performing the steps below, click **Cancel** to exit if you decide not to install the application. Do not simply move to another administrative console page without first clicking **Cancel** on an application installation page.

1. Click **Applications > Install New Application** in the console navigation tree.
2. On the first Preparing for application installation page:
   a. Specify the full path name of the source enterprise application file (`.ear` file otherwise known as an *EAR file*). The EAR file that you are installing can be either on the client machine (the machine that runs the Web browser) or on the server machine (the machine to which the client is connected). If you specify an EAR file on the client machine, then the administrative console uploads the EAR file to the machine on which the console is running and proceeds with application installation. You can also specify a standalone Web application archive (WAR), SAR or Java archive (JAR) file for installation.
   b. If you are installing a standalone WAR or SAR file, specify the context root.
   c. Select whether to view all installation options.
      Prompt me only when additional information is required
         Displays the module mapping step as well as any steps that require you to specify needed information to install the application successfully.
      Show me all installation options and parameters
         Displays all installation options. To use **Generate default bindings**, which supplies default values for incomplete bindings, select this option.
   d. Click **Next**.
3. If you selected **Show me all installation options and parameters**, for the second Preparing for application installation page:
   a. Select whether to generate default bindings. Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not altered. You can customize default values used in generating default bindings. For example, you can specify a Java Naming and Directory Interface (JNDI) prefix for EJB files in EJB modules, default data

source and connection factory settings for EJB modules, virtual host for Web modules, and so on. "Preparing for application installation settings" on page 1373 describes available customizations and provides sample bindings.

b. Click **Next**. If security warnings are displayed, click **Continue**. The Install New Application pages are displayed. If you chose to generate default bindings, you can proceed to the Summary step. "Example: Installing an EAR file using the default bindings" on page 1388 provides sample steps.

4. Specify values for installation options as needed.

You can click on a step number to move directly to that panel instead of clicking **Next**.

Panel	Description
Select installation options	On the **Select installation options** panel, provide values for the settings specific to WebSphere Application Server. Default values are used if you do not specify a value.
Map modules to servers	On the **Map modules to servers** panel, specify deployment targets where you want to install the modules contained in your application. Modules can be installed on the same deployment target or dispersed among several deployment targets. Each module must be mapped to a target server. A deployment target can be an application server, cluster of application servers or Web server.
Provide options to compile JSPs	If the **Precompile JavaServer Pages files** setting is enabled on the **Select installation options** panel and your application uses JavaServer Pages (JSP) files, then you can specify JSP compiler options on the **Provide options to compile JSPs** panel.
Provide JNDI names for beans	If your application uses EJB modules, on the **Provide JNDI names for beans** panel, specify a JNDI name for each enterprise bean in every EJB module. You must specify a JNDI name for every enterprise bean defined in the application. For example, for the EJB module `MyBean.jar`, specify `MyBean`.
Map default data sources for modules containing 1.x entity beans	If your application uses EJB modules that contain Container Managed Persistence (CMP) beans that are based on the EJB 1.x specification, for **Map default data sources for modules containing 1.x entity beans**, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
Map data sources for all 1.x CMP beans	If your application has CMP beans that are based on the EJB 1.x specification, for **Map data sources for all 1.x CMP beans**, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error displays after you click **Finish** and the installation is cancelled.
Map EJB references to beans	If your application defines EJB references, for Map EJB references to beans, specify JNDI names for enterprise beans that represent the logical names specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking **Finish** on the Summary panel.
Map resource references to resources	If your application defines resource references, for **Map resource references to resources**, specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in the application must be bound to a resource defined in your WebSphere Application Server configuration before clicking on **Finish** on the Summary panel.

Panel	Description
Map virtual hosts for Web modules	If your application uses Web modules, for **Map virtual hosts for Web modules**, select a virtual host from the list that should map to a Web module defined in the application. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. Each Web module must have a virtual host to which it maps. Not specifying all needed virtual hosts will result in a validation error displaying after you click **Finish** on the Summary panel.
Map security roles to users or groups	If the application has security roles defined in its deployment descriptor then, for **Map security roles to users or groups**, specify users and groups that are mapped to each of the security roles. Select **Role** to select all of the roles or select individual roles. For each role, you can specify whether predefined users such as **Everyone** or **All authenticated users** are mapped to it. To select specific users or groups from the user registry: 1. Select a role and click **Lookup users** or **Lookup groups**. 2. On the Lookup users or groups panel displayed, enter search criteria to extract a list of users or groups from the user registry. 3. Select individual users or groups from the results displayed. 4. Click **OK** to map the selected users or groups to the role selected on the **Map security roles to users or groups** panel.
Map RunAs roles to users	If the application has Run As roles defined in its deployment descriptor, for **Map RunAs roles to users**, specify the Run As user name and password for every Run As role. Run As roles are used by enterprise beans that must run as a particular role while interacting with another enterprise bean. Select **Role** to select all of the roles or select individual roles. After selecting a role, enter values for the user name, password, and verify password and click **Apply**.
Ensure all unprotected 1.x methods have the correct level of protection	If your application contains EJB 1.x CMP beans that do not have method permissions defined for some of the EJB methods, for **Ensure all unprotected 1.x methods have the correct level of protection**, specify if you want to leave such methods unprotected or assign protection with deny all access.
Bind listeners for message-driven beans	If your application contains message driven enterprise beans, for **Bind listeners for message-driven beans**, provide a listener port name or an activation specification JNDI name for every message driven bean.
Map default data sources for modules containing 2.x entity beans	If your application uses EJB modules that contain CMP beans that are based on the EJB 2.x specification, for **Map default data sources for modules containing 2.x entity beans**, specify a JNDI name for the default data source and the type of resource authorization to be used for the default data source for the EJB modules. You can optionally specify a login configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The default data source for EJB modules is optional if data sources are specified for individual CMP beans.
Map data sources for all 2.x CMP beans	If your application has CMP beans that are based on the EJB 2.x specification, on the **Map data sources for all 2.x CMP beans** panel, for each of the 2.x CMP beans specify a JNDI name and the type of resource authorization for data sources to be used. You can optionally specify a login configuration name and authentication properties for the data source. When creating authentication properties, you must click **OK** to save the values and return to the mapping step. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error is displayed after you click **Finish** and installation is cancelled.

Panel	Description
Ensure all unprotected 2.x methods have the correct level of protection	If your application contains EJB 2.x CMP beans that do not have method permissions defined in the deployment descriptors for some of the EJB methods, on the **Ensure all unprotected 2.x methods have the correct level of protection** panel, specify whether you want to assign a specific role to the unprotected methods, add the methods to the exclude list, or mark them as unchecked. Methods added to the exclude list are marked as uncallable. For methods marked unchecked no authorization check is performed prior to their invocation.
Provide options to perform the EJB Deploy	If the **Deploy enterprise beans** setting is enabled on the **Select installation options** panel, then you can specify options for the EJB deployment tool on the **Provide options to perform the EJB Deploy** panel. On this panel, you can specify extra class paths, RMIC options, database types, and database schema names to be used while running the EJB deployment tool.
Map shared libraries	On the **Shared library references** and **Shared library mapping** panels, specify shared library files for your application or Web modules to use. A defined shared library must exist to associate your application or module to the library file.
Provide JSP reloading options for Web modules	If your application uses Web modules, for **Provide JSP reloading options for Web modules**, configure the class reloading of JavaServer Pages (JSP) files.
Map context roots for Web modules	If your application uses Web modules, for **Map context roots for Web modules**, specify a context root for each Web module in the application.
Initialize parameters for servlets	If your application uses Web modules, for **Initialize parameters for servlets**, specify or override initial parameters that are passed to the init method of Web module servlet filters.
Map environment entries for Web modules	If your application uses Web modules, for **Map environment entries for Web modules**, configure the environment entries of Web modules such as servlets and JSP files.
Map resource environment entry references to resources	If your application contains resource environment references, for **Map resource environment entry references to resources**, specify JNDI names of resources that map to the logical names defined in resource environment references. If each resource environment reference does not have a resource associated with it, after you click **Finish** a validation error is displayed.
Correct use of system identity	If your application defines **Run-As Identity** as *System Identity*, for **Correct use of system identity**, you can optionally change it to *Run-As role* and specify a user name and password for the Run As role specified. Selecting *System Identity* implies that the invocation is done using the WebSphere Application Server security server ID and should be used with caution as this ID has more privileges.
Correct isolation levels for all resource references	If your application has resource references that map to resources that have an Oracle database doing backend processing, for **Correct isolation levels for all resource references**, specify or correct the isolation level to be used for such resources when used by the application. Oracle databases support ReadCommitted and Serializable isolation levels only.
Bind message destination references to administered objects	If your application uses message driven beans, for **Bind message destination references to administered objects**, specify the JNDI name of the J2C administered object to bind the message destination reference to the message driven beans. **Attention:** If multiple message destination references are linked to the same message destination, only one JNDI name is collected. When a message destination reference links to the same message destination as a message driven bean and the destination JNDI name has been collected already, the destination JNDI name for the message destination reference is not collected.
Provide JNDI names for JCA objects	If your application contains an embedded .rar file, for **Provide JNDI names for JCA objects**, specify the name and JNDI name of each J2C connection factory, J2C administered object and J2C activation specification.

Panel	Description
Bind J2C activationspecs to destination JNDI names	If your application contains an embedded `.rar` file, its activationSpec property has the value `Destination`, and its introspected type is `javax.jms.Destination`, for **Bind J2C activationspecs to destination JNDI names**, specify the jndiName value for each activation bound to it.
Select current backend ID	If your application has EJB modules for which deployment code has been generated for multiple backend databases using an assembly tool, for **Select current backend ID**, specify the backend ID representing the backend database to be used when the EJB module runs. For information on backend databases, refer to EJB deployment tool. This step is not shown if the **Deploy enterprise beans** setting is enabled on the **Select installation options** panel and if a database type other than `None` is specified on the **Provide options to perform the EJB Deploy** panel.
Provide options to perform the Web services deployment	If the **Deploy Web services** setting is enabled on the **Select installation options** panel and your application uses Web services, then you can specify `wsdeploy` command options on the **Provide options to perform the Web services deployment** panel. For information on this panel, refer to descriptions of the `wsdeploy -cp` and `-jardir` options.
Configure remote request dispatch properties	If you are using a remote request dispatcher, you need to first configure it for use. Remote Request Dispatcher (RRD) is a pluggable extension to the Web container that allows application frameworks, servlets and JavaServer Pages to include content from outside of the current executing resource's Java virtual machine (JVM) as part of the response sent to the client. Refer to "Remote request dispatch property settings" on page 90 for information on where to configure these properties in the administration console.

5. On the Summary panel, verify the cell, node, and server onto which the application modules will install:
   a. Beside **Cell/Node/Server**, click **Click here**.
   b. Verify the settings.
   c. Return to the Summary panel.
   d. Click **Finish**.

Several messages are displayed, indicating whether your application file is installing successfully.

If **Validate input off/warn/fail** on the **Select installation options** panel is set to **warn**, the default, several validation warnings might be displayed. If the setting is **fail**, the validation warnings might cause errors.

If you receive an OutOfMemory exception and the source application file does not install, your system might not have enough memory or your application might have too many modules in it to install successfully onto the server. If lack of system memory is not the cause of the exception, package your application again so the `.ear` file has fewer modules. If lack of system memory and the number of modules are not the cause of the exception, check the options you specified on the Java Virtual Machine page of the application server running the administrative console. Then, try installing the application file again.

▶ Windows ◀ During installation certain application files are extracted in the directory represented by the configuration session and, when the configuration is saved, these files are saved in the WebSphere Application Server configuration repository. On Windows machines, there is a limit of 256 characters for file paths. Therefore, the application installation might fail if the path for application files in the configuration session or in the configuration repository exceeds the limit of 256 characters. You might see FileNotFound exceptions with *path name too long* in the message. To overcome such problems, make application names and module URI names shorter in length, which helps reduce the file path length. Then, try installing the application file again.

After the application file installs successfully, do the following:

1. Save the changes to your configuration.

   The application is registered with the administrative configuration and application files are copied to the target directory, which is *app_server_root*/installedApps/*cell_name* by default or the directory that you designate.

   For a Network Deployment installation, files are copied to remote nodes when the configuration on the deployment manager synchronizes with the configuration on individual nodes.

2. Start the application.

3. Test the application. For example, point a Web browser at the URL for the deployed application and examine the performance of the application. If necessary, edit the application configuration.

Preparing for application installation settings

Use this page to install an application (EAR file) or module (JAR, SAR or WAR file).

To view this administrative console page, click **Applications > Install New Application**.

Follow the steps on this page to install an application or module. You must complete, at minimum, the first step; you must complete some or all of the later steps, depending on whether you are installing an application, EJB module, SIP module or Web module.

Path to the new application:

Specifies the fully qualified path to the .ear, .jar, .sar, or .war file for the enterprise application.

Use **Local file system** if the browser and application files are on the same machine (whether or not the server is on that machine, too).

Use **Remote file system** if the application file resides on any node in the current cell context.You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only .ear, .jar, .sar, or .war files are shown during the browsing.

During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select EAR, WAR, SAR or JAR modules to upload to the server machine.

In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value might be *profile_root*/installableApps/ test.ear. If you are installing a standalone WAR module, then specify the context root as well.

After the application file is transferred, the **Remote file system** value shows the path of the temporary location on the deployment manager or server machine.

Context root:

Specifies the context root of the Web application (WAR)or a Session Initiation Protocol (SIP) module (SAR).

This field is used only to install a standalone WAR or SAR file. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is /gettingstarted and the servlet mapping is MySession, then the URL is http://host:port/gettingstarted/MySession.

How do you want to install the application?:

Specifies whether to show only installation options that require you to supply information or to show all installation options.

The **Prompt me only when additional information is required** option enables you to install your application more easily because you do not need to examine all available installation options.

However, to use the **Generate default bindings** option, which might be the quickest and easiest option for installing your application, you must select the **Show me all installation options and parameters** and then select **Generate default bindings** on the next panel.

Generate default bindings:

Specifies whether to generate default bindings. If you place a check mark in the check box, then any incomplete bindings in the application are filled in with default values. Existing bindings are not altered.

By choosing this option, you can directly jump to the Summary step and install the application if none of the steps have a red asterisk (*) next to them. A red asterisk denotes that the step has incomplete data and requires a valid value. On the Summary panel, verify the cell, node and server on which the application is installed.

You must select **Show me all installation options and parameters** to view this option.

Bindings are generated as follows:
- EJB JNDI names are generated of the form *prefix*/*ejb-name*. The default prefix is `ejb`, but can be overridden. The *ejb-name* is as specified in the deployment descriptors `<ejb-name>` tag.
- EJB references are bound as follows: If an `<ejb-link>` is found, it is honored. Otherwise, if a unique enterprise bean is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.
- Resource reference bindings are derived from the `<res-ref-name>` tag. Note that this action assumes that the `java:comp/env` name is the same as the resource global JNDI name.
- Connection factory bindings (for EJB 2.0 JAR files) are generated based on the JNDI name and authorization information provided. This action results in default connection factory settings for each EJB 2.0 JAR file in the application being installed. No bean-level connection factory bindings are generated.
- Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source user name password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
- For EJB2.1 or EJB2.0 message-driven beans deployed as JCA 1.5-compliant resources, the JNDI names corresponding to activationSpec instances are generated in the form eis/*MDB_ejb-name*. Message Destination references are bound as follows: if a `<message-destination-link>` is found then the JNDI name is set to ejs/*message-destination-link*Name. Otherwise the JNDI name is set to eis/*message-destination-ref*Name.
- For EJB 2.0 message-driven beans deployed against a listener ports, the listener ports are derived from the MDB `<ejb-name>` tag with the string `Port` appended.
- For `.war` files, the virtual host is set as `default_host` unless otherwise specified.

The default strategy suffices for most applications or at least for most bindings in most applications. However, it does not work if:
- You want to explicitly control the global JNDI names of one or more EJB files.
- You need tighter control of data source bindings for container-managed persistence (CMP) beans. That is, you have multiple data sources and need more than one global data source.
- You must map resource references to global resource JNDI names that are different from the `java:comp/env` name.

In such cases, you can change the behavior with an XML document (a custom strategy). Use the **Specific bindings file** field to specify a custom strategy and see the field's help for examples.

Prefixes:

Specifies prefixes to use for generated JNDI names.

You must select **Show me all installation options and parameters** to view prefix options.

Prefixes is similar to the scripting option `-defaultbinding.ejbjndi.prefix`.

Override:

Specifies whether generated bindings are to override existing bindings.

If **Override existing bindings** is selected, the existing bindings are overridden by the generated ones.

You must select **Show me all installation options and parameters** to view override options.

Override is similar to the scripting option `-defaultbinding.force`.

EJB 1.1 CMP bindings:

Specifies the default data source JNDI name.

If the **Default bindings for EJB 1.1 CMPs** radio button is selected, specify the JNDI name for the default data source to be used with the container-managed persistence (CMP) 1.1 beans. Also specify the user ID and password for this default data source.

You must select **Show me all installation options and parameters** to view EJB CMP binding options.

Default bindings for EJB 1.1 CMPs is similar to the scripting option `-defaultbinding.datasource.jndi`.

Data source bindings for 2.0 CMP beans:

Specifies the default data source JNDI name for 2.0 CMP beans.

If **Default data source for 2.0 CMP beans** is selected, specify the JNDI name for the default data source to be used with the 2.0 CMP beans. Also specify the resource authorization.

You must select **Show me all installation options and parameters** to view data source binding options.

Default data source for 2.0 CMP beans is similar to the scripting option `-defaultbinding.cf.jndi`.

Virtual host:

Specifies the virtual host for the Web module.

You must select **Show me all installation options and parameters** to view virtual host options.

Virtual host is similar to the scripting option `-defaultbinding.virtual.host`.

Specific bindings file:

Specifies a bindings file that overrides the default binding.

You must select **Show me all installation options and parameters** to view this option.

Specific bindings file is similar to the scripting option `-defaultbinding.strategy.file`.

Change the behavior of the default binding with an XML document (a custom strategy). Custom strategies extend the default strategy so you only need to customize those areas where the default strategy is insufficient. Thus, you only need to describe how you want to change the bindings generated by the default strategy; you do not have to define bindings for the entire application.

Brief examples of how to override various aspects of the default bindings generator follow:

Controlling an EJB JNDI name

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>helloEjb.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
         <ejb-name>HelloEjb</ejb-name>
         <jndi-name>com/acme/ejb/HelloHome</jndi-name>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Note: Ensure that the setting for `<ejb-name>` matches the `ejb-name` entry in the EJB JAR deployment descriptor. Here the setting is `<ejb-name>HelloEjb</ejb-name>`.

Setting the connection factory binding for an EJB JAR file

```
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <connection-factory>
        <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
        <res-auth>Container</res-auth>
      </connection-factory>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Setting the connection factory binding for an EJB file

```
<?xml version="1.0">
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>yourEjb20.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourCmp20</ejb-name>
          <connection-factory>
           <jndi-name>eis/jdbc/YourData_CMP</jndi-name>
           <res-auth>PerConnFact</res-auth>
          </connection-factory>
        </ejb-binding>
```

```
        </ejb-bindings>
      </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Restriction: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourCmp20</ejb-name>`.

Setting the message destination reference JNDI for a specific enterprise bean

Example XML extract in a custom strategy file for setting message-destination-refs for a specific enterprise bean.

```
<?xml version="1.0">
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
 <dfltbndngs>
  <module-bindings>
   <ejb-jar-binding>
     <jar-name>yourEjb21.jar</jar-name>
     <ejb-bindings>
      <ejb-binding>
        <ejb-name>YourSession21</ejb-name>
        <message-destination-ref-bindings>
         <message-destination-ref-binding>
           <message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>
           <jndi-name>eis/somAO</jndi-name>
         </message-destination-ref-binding>
        </message-destination-ref-bindings>
      </ejb-binding>
     </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Restriction: Ensure that the setting for `<ejb-name>` matches the `ejb-name` tag in the deployment descriptor. Here the setting is `<ejb-name>YourSession21</ejb-name>`. Also ensure that the setting for `<message-destination-ref-name>` matches the `message-destination-ref-name` tag in the deployment descriptor. Here the setting is `<message-destination-ref-name>jdbc/MyDataSrc</message-destination-ref-name>`.

Overriding a resource reference binding from a WAR, EJB JAR file, or J2EE client JAR file

Example code for overriding a resource reference binding from a WAR file follows. Use similar code to override a resource reference binding from an enterprise bean (EJB) JAR file or a J2EE client JAR file.

```
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <war-binding>
      <jar-name>hello.war</jar-name>
      <resource-ref-bindings>
        <resource-ref-binding>
          <resource-ref-name>jdbc/MyDataSrc</resource-ref-name>
          <jndi-name>war/override/dataSource</jndi-name>
        </resource-ref-binding>
      </resource-ref-bindings>
    </war-binding>
  </module-bindings>
</dfltbndngs>
```

Restriction: Ensure that the setting for `<resource-ref-name>` matches the `resource-ref` tag in the deployment descriptor. Here the setting is `<resource-ref-name>jdbc/MyDataSrc</resource-ref-name>`.

Overriding the JNDI name for a message-driven bean deployed as a JCA 1.5-compliant resource

Example XML extract in a custom strategy file for overriding the JMS activationSpec JNDI name for an
EJB 2.1 or EJB 2.0 message-driven bean deployed as a JCA 1.5-compliant resource.

```xml
<?xml version="1.0"?>
 <!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
  <dfltbndngs>
  <module-bindings>
   <ejb-jar-binding>
     <jar-name>YourEjbJar.jar</jar-name>
     <ejb-bindings>
      <ejb-binding>
        <ejb-name>YourMDB</ejb-name>
        <activationspec-jndi-name>activationSpecJNDI</activationspec-jndi-name>
      </ejb-binding>
     </ejb-bindings>
   </ejb-jar-binding>
  </module-bindings>
 </dfltbndngs>
```

Overriding the JMS listener port name for an EJB 2.0 message-driven bean

Example XML extract in a custom strategy file for overriding the JMS listener port name for an EJB 2.0
message-driven bean deployed against a listener port.

```xml
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-bindings>
        <ejb-binding>
          <ejb-name>YourMDB</ejb-name>
          <listener-port>yourMdbListPort</listener-port>
        </ejb-binding>
      </ejb-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Overriding an EJB reference binding from an EJB JAR, WAR file, or EJB file

Example code for overriding an EJB reference binding from an EJB JAR file follows. Use similar code to
override an EJB reference binding from a WAR file or an EJB file.

```xml
<?xml version="1.0"?>
<!DOCTYPE dfltbndngs SYSTEM "dfltbndngs.dtd">
<dfltbndngs>
  <module-bindings>
    <ejb-jar-binding>
      <jar-name>YourEjbJar.jar</jar-name>
      <ejb-ref-bindings>
        <ejb-ref-binding>
          <ejb-ref-name>YourEjb</ejb-ref-name>
          <jndi-name>YourEjb/JNDI</jndi-name>
        </ejb-ref-binding>
      </ejb-ref-bindings>
    </ejb-jar-binding>
  </module-bindings>
</dfltbndngs>
```

Select installation options settings

Use this panel to specify options for the installation of an application onto a WebSphere Application Server deployment target. Default values for the options are used if you do not specify a value. After application installation, you can specify values for many of these options from an enterprise application settings page.

To view this administrative console panel, click **Applications > Install New Application** and then specify values as needed for your application on the Preparing for application installation pages. The Select installation options panel is the same for the application installation and update wizards.

Precompile JavaServer Pages files:

Specify whether to precompile JavaServer Pages (JSP) files as a part of installation. The default is not to precompile JSP files.

For this option, install only onto a 6.1 deployment target.

If you select **Precompile JavaServer Pages files** and try installing your application onto an earlier deployment target such as version 5.x, the installation is rejected. You can deploy applications to only those targets that have same WebSphere version as the deployment manager. If applications are targeted to servers that have an earlier version than the deployment manager, then you cannot deploy to those targets.

Data type	Boolean
Default	False

Directory to install application:

Specifies the directory to which the enterprise application (EAR) file will be installed.

The default value is the value of `APP_INSTALL_ROOT`/*cell_name*, where the `APP_INSTALL_ROOT` variable is *app_server_root*/`installedApps`; for example, *app_server_root*/`installedApps`/*cell_name*.

Important: If an installation directory is not specified when an application is installed on a single-server configuration, the application is installed in `APP_INSTALL_ROOT`/*cell_name*. When the server is made a part of a Network Deployment configuration (using the addNode utility), the cell name of the new configuration becomes the cell name of the deployment manager node. If the `-includeapps` option is used for the addNode utility, then the applications that are installed prior to the addNode operation still use the installation directory `APP_INSTALL_ROOT`/*cell_name*. However, an application that is installed after the server is added to the network configuration uses the default installation directory `APP_INSTALL_ROOT`/*network_cell_name*. To move the application to the `APP_INSTALL_ROOT`/*network_cell_name* location upon running the addNode operation, explicitly specify the installation directory as `${APP_INSTALL_ROOT}`/`${CELL)` during installation. In such a case, the application files can always be found under `APP_INSTALL_ROOT`/*current_cell_name*.

You can specify an absolute path or use a pathmap variable such as `${MY_APPS}`. You can use a pathmap variable in any installation.

A pathmap variable is particularly needed when installing an application on a cluster with members on heterogeneous nodes because, in such cases, there might not be a single way to specify an absolute path. A WebSphere Application Server variable `${CELL}` that denotes the current cell name can also be in the pathmap variable; for example, `${MY_APP}`/`${CELL}`. You can define WebSphere Application Server variables on the WebSphere Variables console page, accessed by clicking **Environment > WebSphere Variables**.

This **Directory to install application** field is the same as the **Location (full path)** setting on an Application binaries page.

Data type	String
Units	Full path name

Distribute application:

Specifies whether the product expands application binaries in the installation location during installation and deletes application binaries during uninstallation. The default is to enable application distribution. Application binaries for installed applications are expanded to the directory specified. The binaries are deleted when you uninstall and save changes to the configuration, and, on the Network Deployment product, synchronize changes.

If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

Important: If you disable this option and you do not copy and expand the application binaries to the nodes, a later saving of the configuration or manual synchronization does not move the application binaries to the nodes for you.

This **Distribute application** field is the same as the **Enable binary distribution, expansion and cleanup post uninstallation** setting on an Application binaries page.

Data type	Boolean
Default	true

Use binary configuration:

Specifies whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file (default), or those located in the enterprise application resource (EAR) file. Select this setting for applications installed on 6.x deployment targets only. This setting is not valid for applications installed on 5.x deployment targets.

This **Use binary configuration** field is the same as the **Use configuration information in binary** setting on an Application binaries page.

Data type	Boolean
Default	false

Deploy enterprise beans:

Specifies whether the EJBDeploy tool runs during application installation.

The tool generates code needed to run enterprise bean (EJB) files. You must enable this setting in the following situations:
* The EAR file was assembled using an assembly tool such as Rational Application Developer, Rational Web Developer or Application Server Toolkit (AST) and the EJBDeploy tool was not run during assembly.
* The EAR file was not assembled using an assembly tool such as Rational Application Developer, Rational Web Developer or AST.
* The EAR file was assembled using versions of the Application Assembly Tool (AAT) previous to Version 5.

For this option, install only onto a 6.1 deployment target.

If you select **Deploy enterprise beans** and try installing your application onto an earlier deployment target such as version 5.x, the installation is rejected. You can deploy applications to only those targets that have same WebSphere version as the deployment manager. If applications are targeted to servers that have an earlier version than the deployment manager, then you cannot deploy to those targets.

Also, if you select **Deploy enterprise beans** and specify a database type on the **Provide options to perform the EJB Deploy** panel, previously defined backend IDs for all of the EJB modules are overwritten by the chosen database type. To enable backend IDs for individual EJB modules, set the database type to ″″ (null) on the **Provide options to perform the EJB Deploy** panel.

The default database type is `DB2UDB_V81`.

Enabling this setting might cause the installation program to run for several minutes.

Data type   Boolean
Default   true

Application name:

Specifies a logical name for the application. An application name must be unique within a cell and cannot contain an unallowed character.

An application name cannot begin with a period (**.**), cannot contain leading or trailing spaces, and cannot contain any of the following characters:

Unallowed characters		
/ forward slash	**$** dollar sign	**'** single quote mark
**** backslash	**=** equal sign	**″** double quote mark
* asterisk	**%** percent sign	**|** vertical bar
, comma	**+** plus sign	**<** left angle bracket
: colon	**@** at sign	**>** right angle bracket
; semi-colon	**#** hash mark	**&** ampersand (and sign)
? question mark	**]]>** No specific name exists for this character combination	

This **Application name** field is the same as the **Name** setting on an Enterprise application settings page.

Data type   String

Create MBeans for resources:

Specifies whether to create MBeans for resources such as servlets or JSP files within an application when the application starts. The default is to create MBeans.

This field is the same as the **Create MBeans for resources** setting on a Startup behavior page.

Data type   Boolean
Default   true

Enable class reloading:

Specifies whether the WebSphere Application Server run time detects changes to application classes when the application is running. If this setting is enabled and if application classes are changed, then the application is stopped and restarted to reload updated classes.

The default is not to enable class reloading.

This **Enable class reloading** field is the same as the **Reload classes when application files are updated** setting on an Class loading and update detection page.

Data type	Boolean
Default	false

Reload interval in seconds:

Specifies the number of seconds to scan the application's file system for updated files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file.

The reloading interval attribute takes effect only if class reloading is enabled.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0). The range is from 0 to 2147483647.

This **Reload interval in seconds** field is the same as the **Polling interval for updated files** setting on an Class loading and update detection page.

Data type	Integer
Units	Seconds
Default	3

Deploy Web services:

Specifies whether the Web services deploy tool `wsdeploy` runs during application installation.

The tool generates code needed to run applications using Web services. The default is not to run the `wsdeploy` tool. You must enable this setting if the EAR file contains modules using Web services and has not previously had the `wsdeploy` tool run on it, either from the **Deploy** menu choice of an assembly tool or from a command line.

For this option, install only onto a 6.1 deployment target.

If you select **Deploy Web services** and try installing your application onto an earlier deployment target such as version 5.x, the installation is rejected. You can deploy applications to only those targets that have same WebSphere version as the deployment manager. If applications are targeted to servers that have an earlier version than the deployment manager, then you cannot deploy to those targets.

Data type	Boolean
Default	false

Validate input off/warn/fail:

Specifies whether WebSphere Application Server examines the application references specified during application installation or updating and, if validation is enabled, warns you of incorrect references or fails the operation.

An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application.

Select **off** for no resource validation, **warn** for warning messages about incorrect resource references, or **fail** to stop operations that fail as a result of incorrect resource references.

This **Validate input off/warn/fail** field is the same as the **Application reference validation** setting on an Enterprise Application settings page.

Data type   String
Default   warn

Process embedded configuration:

Specifies whether the embedded configuration should be processed. An embedded configuration consists of files such as `resource.xml` and `variables.xml`. When selected or `true`, the embedded configuration is loaded to the application scope from the `.ear` file. If the `.ear` file does not contain an embedded configuration, the default is `false`. If the `.ear` file contains an embedded configuration, the default is `true`.

Data type   Boolean
Default   false

File permission:

Specifies access permissions for application binaries for installed applications that are expanded to the directory specified.

The **Distribute application** option must be enabled to specify file permissions.

You can specify file permissions in the text field. You can also set some of the commonly used file permissions by selecting them from the drop-down list. Drop-down list selections overwrite file permissions set in the text field.

You can set one or more of the following file permission strings in the drop-down list. Selecting multiple options combines the file permission strings.

Drop-down list option	File permission string set
Allow all files to be read but not written to	`.*=755`
Allow executables to execute	`.*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755`
Allow HTML and image files to be read by everyone	`.*\.htm=755#.*\.html=755#.*\.gif=755#.*\.jpg=755`

Instead of using the drop-down list to specify file permissions, you can specify a file permission string in the text field. File permissions use a string that has the following format:

file_name_pattern=permission#file_name_pattern=permission

where *file_name_pattern* is a regular expression file name filter (for example, `.*\\.jsp` for all JSP files), *permission* provides the file access control lists (ACLs), and *#* is the separator between multiple entries of *file_name_pattern* and *permission*. If *#* is a character in a *file_name_pattern* string, use `\#` instead.

If multiple file name patterns and file permissions in the string match a uniform resource identifier (URI) within the application, then the product uses the most stringent applicable file permission for the file. For example, if the file permission string is `.*\\.jsp=775#a.*\\.jsp=754`, then the `abc.jsp` file has file permission 754.

Tip: Using regular expressions for file matching pattern compares an entire string URI against the specified file permission pattern. You must provide more precise matching patterns using regular expressions as defined by Java programming API. For example, suppose the following directory and file URIs are processed during a file permission operation:

1	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war
2	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp
3	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF/MANIFEST.MF
4	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/WEB-INF/classes/MyClass.class
5	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/mydir/MyClass2.class
6	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF

The file pattern matching results are:
- `MyWarModule.war` does not match any of the URIs
- `.*MyWarModule.war.*` matches all URIs
- `.*MyWarModule.war$` matches only URI 1
- `.*\\.jsp=755` matches only URI 2
- `.*META-INF.*` matches URIs 3 and 6
- `.*MyWarModule.war/.*/.*\.class` matches URIs 4 and 5

If you specify a directory name pattern for **File permissions**, then the directory permission is set based on the value specified. Otherwise, the **File permissions** value set on the directory is the same as its parent. For example, suppose you have the following file and directory structure:

`/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp`

and you specify the following file pattern string:

`.*MyApp.ear$=755#.*\.jsp=644`

The file pattern matching results are:
- Directory `MyApp.ear` is set to 755
- Directory `MyWarModule.war` is set to 755
- Directory `MyWarModule.war` is set to 755

Important: Regardless of the operation system, always use a forward slash (/) as a file path separator in file patterns.

▶ Windows ◀ You cannot unset read permission on a file on Windows platforms. With POSIX style permission bits, the bit for denoting `readable` on a file is 4, `writable` is 2, and `executable` is 1. Thus, permission of a file on a Windows platform is either 5 or 7. Also, in POSIX style there are `user`, `group` and `world` permissions. You can only set the `user` permission for a file on Windows platforms. The `group` and `world` permission bits are ignored.

Access permissions specified here are at the application level. You can also specify access permissions for application binaries in the node level configuration. The node level file permissions specify the

maximum (most lenient) permissions that can be given to application binaries. Access permissions specified here at application level can only be the same as or more restrictive than those specified at the node level.

This setting is the same as the **File permissions** field on the Application binaries page.

Data type	String

Application build identifier:

Specifies an uneditable string that identifies the build version of the application.

This **Application build identifier** field is the same as the **Application build level** field on the Application binaries page.

Data type	String

Allow dispatching includes to remote resources:

Specifies whether an application can dispatch includes to resources across Web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher mechanism.

This field is the same as the **Allow dispatching includes to remote resources** field on the Remote request dispatch properties page.

Data type	Boolean
Default	true

Allow servicing includes from remote resources:

Specifies whether an enterprise application can service an include request from an application.

This field is the same as the **Allow servicing includes from remote resources** field on the Remote request dispatch properties page.

Data type	Boolean
Default	true

Provide options to perform the EJB Deploy settings

Use this panel to specify options for the enterprise bean (EJB) deployment tool. The tool generates code needed to run enterprise bean files. You can specify extra class paths, Remote Method Invocation compiler (RMIC) options, database types, and database schema names to be used while running the EJB deployment tool.

This administrative console panel is a step in the application installation and update wizards. To view this panel, you must select **Deploy enterprise beans** on the **Select installation options** panel. Thus, to view this panel, click **Applications > Install New Application >** *application_path* **> Show me all installation options and parameters > Next > Next > Deploy enterprise beans > Next > Step: Provide options to perform the EJB Deploy**.

You can specify the EJB deployment tool options on this panel only when installing or updating an application that contains EJB modules.

The options that you specify set parameter values for the `ejbdeploy` command. The tool, and thus the `ejbdeploy` command, is run on the enterprise archive (EAR) file during installation after you click **Finish** on the **Summary** panel of the wizard.

Deploy EJB option - Class path:

Specifies the class path of one or more zipped or Java archive (JAR) files on which the Java archive (JAR) or EAR file being installed depends.

To specify the class paths of multiple zipped and JAR files, the zipped and JAR file names must be fully qualified, separated by semicolons, and enclosed in double quotation marks. For example:

`path\myJar1.jar;path\myJar2.jar;path\myJar3.jar`

Deploy EJB option - Class path is the same as the `ejbdeploy` command parameter `-cp class_path`.

Data type	String
Default	null

Deploy EJB option - RMIC:

Specifies whether the EJB deployment tool passes RMIC options to the Remote Method Invocation compiler. Refer to RMI Tools documentation for information on the options.

Separate options by a space and enclose them in double quotation marks. For example:

`"-nowarn -verbose"`

Deploy EJB option - RMIC is the same as the `ejbdeploy` command parameter `-rmic "options"`.

Data type	String
Default	null

Deploy EJB option - Database type:

Specifies the name of the database vendor, which is used to determine database column types, mapping information, `Table.sql`, and other information. Select a database type or the empty choice from the drop-down list. The list contains the names of valid database vendors. Selecting the empty choice sets the database type to ″″ (null).

If you specify a database type, previously defined backend IDs for all of the EJB modules are overwritten by the chosen database type. To enable backend IDs for individual EJB modules, select the empty choice to set the database type to null.

The backend IDs SQL92 (1992 SQL Standard) and SQL99 (1999 SQL Standard) are deprecated. Although the `SQL92` and `SQL99` backend IDs are available in the list, they are deprecated.

Deploy EJB option - Database type is the same as the `ejbdeploy` command parameter `-dbvendor name`.

Data type	String
Default	DB2UDB_V82

Deploy EJB option - Database schema:

Specifies the name of the schema that you want to create.

The EJB deployment tool saves database information in the schema document in the JAR or EAR file, which means that the options do not need to be specified again. It also means that when a JAR or EAR is generated, the correct database must be defined at that point because it cannot be changed later.

If the name of the schema contains any spaces, the entire name must be enclosed in double quotes. For example:

`"my schema"`

Deploy EJB option - Database schema is the same as the `ejbdeploy` command parameter `-dbschema` `"name"`.

Data type	String
Default	null

Bind listeners for message-driven beans settings

Use this panel to specify bindings for message-driven beans in your application or module.

To view this administrative console panel, click **Applications > Enterprise Applications >** *application_name* **> Message Driven Bean listener bindings**. This panel is the same as the **Bind listeners for message-driven beans** panel on the application installation and update wizards.

Each message-driven bean must be bound to a listener port name or to an activation specification Java Naming and Directory Interface (JNDI) name.

Provide a listener port name if your application uses any of the following Java Message Service (JMS) providers:
*   Version 5 default messaging
*   WebSphere MQ
*   Generic

Provide an activation specification JNDI name if your application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging.

Not providing valid listener port names or activation specification JNDI names results in the following errors:
*   If neither a listener port name or an activation specification JNDI name is specified for a message driven bean, then a validation error is displayed after you click **Finish** on the **Summary** panel.
*   If the module containing the message-driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.
*   If multiple message driven beans are linked to the same destination, specify the same destination JNDI name for each message driven bean. If you specify different destination JNDI names, a validation error is displayed and all JNDI specifications after the first one are ignored.

To apply binding changes to multiple mappings:
1. In the list of mappings, select the **Select** check box beside each EJB module that you want mapped to a particular binding.
2. Expand **Apply Multiple Mappings**.
3. Specify a listener port name or select a target resource JNDI name for an activation specification.
4. If you are defining a binding for an activation specification, optionally specify the following:
    Destination JNDI name
    > For resource adapters that support JMS, specify javax.jms.Destinations so the resource adapter can service messages from the JMS destination. A destination JNDI name set as part of application deployment take precedence over properties set on an activation specification administrative object.

ActivationSpec authentication alias

Specify an authentication alias that is used to access the user name and password that are set on the configured J2C activation specification. Authentication alias properties set as part of application deployment take precedence over properties set on an activation specification administrative object.

5. Click **Apply**.

6. Click **OK**.

EJB module:

Specifies the name of the module that contains the enterprise bean.

EJB:

Specifies name of an enterprise bean in the application.

URI:

Specifies the location of the module relative to the root of the application EAR file.

Messaging type:

Specifies the type of message-driven bean.

Bindings:

Specifies a listener port name or an activation specification JNDI name for the message-driven bean. When a message-driven enterprise bean is bound to an activation specification JNDI name you can also specify the destination JNDI name and the authentication alias.

Bindings specify JNDI names for the referenceable and referenced artifacts in an application. An example JNDI name for a listener port to be used by a `Store` application might be `StoreMdbListener`. The binding definition is stored in IBM bindings files such as `ibm-ejb-jar-bnd.xmi`.

Example: Installing an EAR file using the default bindings

If application bindings were not specified for all enterprise beans or resources in an application during application development or assembly, you can select to generate default bindings. After application installation, you can modify the bindings as needed using the administrative console.

An example of a simple `.ear` file installation using the default bindings follows:

1. Go to the Preparing for application install pages.

   Click **Applications > Install New Application** in the console navigation tree.

2. For **Path to the new application**, specify the full path name of the `.ear` file.

   For this example, the base file name is `my_appl.ear` and the file resides on a server at `C:\sample_apps`.
   a. Select **Remote file system** and click **Browse**.
   b. On the Browse Remote Filesystems page, select the node that runs on the server which holds `my_appl.ear` and the EAR file name.

      Click **C:**, **sample_apps**, **my_appl.ear**, and then **OK**.

3. For **How do you want to install the application**, select **Show me all installation options and parameters**.

4. Click **Next**.

5. On the second Preparing for application installation page, select **Generate default bindings** and click **Next**.

   Using the default bindings causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed. By choosing this option, you can skip many of the steps on the Install New Application page and go directly to the Summary step.

6. If application security warnings are displayed, read the warnings and click **Continue**.

7. On the Install New Application page, click step 2, **Manage modules**, and verify the cell, node, and server onto which the application files will install.

   a. On the **Manage modules** panel, select the server onto which the application files will install from the **Clusters and Servers** list, click **Module** to select all of the application modules, and click **Next**.

      On the **Manage modules** panel, you can map modules to other servers such as Web servers. If you want a Web server to serve the application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.

8. On the Install New Application page, click the step number beside **Summary**, the last step.

9. On the Summary panel, click **Finish**.

Examine the application installation progress messages. If the application installs successfully, save your administrative configuration. You can now see the name of your application in the list of deployed applications on the Enterprise Applications page accessed by clicking **Applications > Enterprise Applications** in the console navigation tree.

If the application does not install successfully, read the messages to identify why the installation failed. Correct problems with the application as needed and try installing the application again.

Installing J2EE modules with JSR-88

You can install Java 2 Platform, Enterprise Edition (J2EE) modules on an application server provided by a WebSphere Application Server product using the J2EE Deployment API Specification (JSR-88).

JSR-88 defines standard application programming interfaces (APIs) to enable deployment of J2EE applications and stand-alone modules to J2EE product platforms. The J2EE Deployment Specification Version 1.1 is available at http://java.sun.com/j2ee/tools/deployment/reference/docs/index.html as part of the J2EE 1.4 Application Server Developer Release.

Read about JSR-88 and APIs used to manage applications at http://java.sun.com/j2ee/tools/deployment/.

JSR-88 defines a contract between a tool provider and a platform that enables tools from multiple vendors to configure, deploy and manage applications on any J2EE product platform. The tool provider typically supplies software tools and an integrated development environment (IDE) for developing and assembly of J2EE application modules. The J2EE platform provides application management functions that deploy, undeploy, start, stop, and otherwise manage J2EE applications.

WebSphere Application Server is a J2EE 1.4 specification-compliant platform that implements the JSR-88 APIs. Complete the following steps to deploy (install) J2EE modules on an application server provided by the WebSphere Application Server platform.

1. Code a Java program that can access the JSR-88 DeploymentManager class for WebSphere Application Server.

   a. Write code that finds the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. Under JSR-88, your code finds the DeploymentFactory using the JAR manifest file key J2EE-DeploymentFactory-Implementation-Class. For WebSphere Application Server, the application management JAR file containing this key and providing support is *app_server_root*/lib/

wjmxapp.jar. After your code finds the DeploymentFactory, the deployment tool can create an instance of the WebSphere DeploymentFactory and register the instance with its DeploymentFactoryManager. For example:

```
import javax.enterprise.deploy.shared.factories.DeploymentFactoryManager;
import javax.enterprise.deploy.spi.DeploymentManager;
import javax.enterprise.deploy.spi.factories.DeploymentFactory;
import java.util.jar.JarFile;

// Get the DeploymentFactory implementation class from the MANIFEST.MF file.
JarFile wjmxappJar = new JarFile(new File(wasHome + "/lib/wjmxapp.jar"));
java.util.jar.Manifest manifestFile = wjmxappJar.getManifest();
Attributes attributes = manifestFile.getMainAttributes();
String key = "J2EE-DeploymentFactory-Implementation-Class";
String className = attributes.getValue(key);
// Get an instance of the DeploymentFactoryManager
DeploymentFactoryManager dfm = DeploymentFactoryManager.getInstance();

// Create an instance of the WebSphere Application Server DeploymentFactory.
Class deploymentFactory = Class.forName(className);
DeploymentFactory deploymentFactoryInstance =
    (DeploymentFactory) deploymentFactory.newInstance();

// Register the DeploymentFactory instance with the DeploymentFactoryManager.
dfm.registerDeploymentFactory(deploymentFactoryInstance);

// Provide WebSphere Application Server URL, user ID, and password.
// For more information, see the step that follows.
wsDM = dfm.getDeploymentManager(
    "deployer:WebSphere:myserver:8880", null, null);
```

   b. Write code that accesses the DeploymentManager instance for WebSphere Application Server. The WebSphere Application Server URL for deployment has the format

   `"deployer:WebSphere:host:port"`

   The example in the previous step, `"deployer:WebSphere:myserver:8880"`, tries to connect to host *myserver* at port *8880* using the SOAP connector, which is the default.

   The URL for deployment can have an optional parameter *connectorType*. For example, to use the RMI connector to access *myserver*, code the URL as follows:

   `"deployer:WebSphere:myserver:2809?connectorType=RMI"`

2. **Optional:** Code a Java program that can customize or deploy J2EE applications or modules using the JSR-88 support provided by WebSphere Application Server.

3. Start the deployed J2EE applications or standalone J2EE modules using the JSR-88 API used to start applications or modules.

Test the deployed applications or modules. For example, point a Web browser at the URL for a deployed application and examine the performance of the application. If necessary, update the application.

Customizing modules using DConfigBeans

You can configure J2EE applications or standalone modules during deployment using the DConfigBean class in the Java 2 Platform, Enterprise Edition (J2EE) Deployment API Specification (JSR-88).

This topic assumes that you are deploying (installing) J2EE modules on an application server provided by the WebSphere Application Server platform using the WebSphere Application Server support for JSR-88.

Read about the JSR-88 specification and using the DConfigBean class at http://java.sun.com/j2ee/tools/deployment/.

The DConfigBean class in JSR-88 provides JavaBeans-based support for platform-specific configuration of J2EE applications and modules during deployment. Your code can inspect DConfigBean instances to get

platform-specific configuration attributes. The DConfigBean instances provided by WebSphere Application Server contain a single attribute which has an array of java.util.Hashtable objects. The hashtable entries contain configuration attributes, for which your code can get and set values.

1. Write code that installs J2EE modules on an application server using JSR-88.
2. Write code that accesses DConfigBeans generated by WebSphere Application Server during JSR-88 deployment. You (or a deployer) can then customize the accessed DConfigBeans instances. The following pseudocode shows how a J2EE tool provider can get DConfigBean instance attributes generated by WebSphere Application Server during JSR-88 deployment and set values for the attributes:

```
import javax.enterprise.deploy.model.*;
import javax.enterprise.deploy.spi.*;
{
DeploymentConfiguration dConfig = ___; // Get from DeploymentManager
DDBeanRoot ddRoot = ___;                // Provided by J2EE tool

// Obtain root bean.
DConfigBeanRoot dcRoot = dConfig.getDConfigBeanRoot(dr);

// Configure DConfigBean.
configureDCBean (dcRoot);
}

// Get children from DConfigBeanRoot and configure each child.
method configureDCBean (DConfigBean dcBean)
{
   // Get DConfigBean attributes for a given archive.
   BeanInfo bInfo = Introspector.getBeanInfo(dcBean.getClass());
   IndexedPropertyDescriptor ipDesc =
      (IndexedPropertyDescriptor)bInfo.getPropertyDescriptors()[0];

   // Get the 0th table.
   int index = 0;
   Hashtable tbl = (Hashtable)
      ipDesc.getIndexedReadMethod().invoke
         (dcBean, new Object[]{new Integer(index)});

   while (tbl != null)
   {
      // Iterate over the hashtable and set values for attributes.

      // Set the table back into the DCBean.
      ipDesc.getIndexedWriteMethod().invoke
         (dcBean, new Object[]{new Integer(index), tbl});

      // Get the next entry in the indexed property
      tbl = (Hashtable)
         ipDesc.getIndexedReadMethod().invoke
            (dcBean, new Object[]{new Integer(++index)});
   }
}
```

Enterprise application collection

Use this page to view and manage enterprise applications.

This page lists installed enterprise applications. System applications, which are central to the product, are not shown in the list because users cannot edit them. Examples of system applications include *isclite*, *managementEJB* and *filetransfer*.

To view this administrative console page, click **Applications > Enterprise Applications**.

To view the values specified for an application's configuration, click the application name in the list. The displayed application settings page shows the values specified. On the settings page, you can change existing configuration values and link to additional console pages that assist you in configuring the application.

To manage an installed enterprise application, enable the **Select** check box beside the application name in the list and click a button:

Button	Resulting action
Start	Attempts to run the application. After the application starts up successfully, the state of the application changes to *Started* if the application starts up on all deployment targets, else the state changes to *Partial Start*.
Stop	Attempts to stop the processing of the application. After the application stops successfully, the state of the application changes to *Stopped* if the application stops on all deployment targets, else the state changes to *Partial Stop*.
Install	Opens a wizard that helps you deploy an application or a module such as a `.jar`, `.war` or `.rar` file onto a server or a cluster.
Uninstall	Deletes the application from the WebSphere Application Server configuration repository and deletes the application binaries from the file system of all nodes where the application modules are installed after the configuration is saved and synchronized with the nodes.
Update	Opens a wizard that helps you update application files deployed on a server. You can update the full application, a single module, a single file, or part of the application. If a new file or module has the same name as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.
Rollout Update	Sequentially updates an application installed on multiple cluster members across a cluster. After you update an application's files or configuration, click **Rollout Update** to install the application's updated files or configuration on all cluster members of a cluster on which the application is installed. **Rollout Update** does the following for each cluster member in sequence: 1. Saves the updated application configuration. 2. Stops all of the cluster members on one node. 3. Updates the application on the node by synchronizing the configuration. 4. Restarts the stopped cluster members. 5. Repeats steps 2 through 4 for all of the nodes that have cluster members. Use **Rollout Update** if the application is deployed on one or more clusters spread across multiple nodes. This action reduces the amount of time that any single cluster member is unavailable to serve requests to the smallest interval possible. Pending IIOP transactions will complete before a cluster member stops; in-flight HTTP and JMS transactions might be lost while the cluster member is stopping. For an application server without clusters, use **Update** and then save and synchronize the node instead. For a standalone application server, simply update and save.
Remove File	Deletes a file of the deployed application or module. **Remove File** deletes a file from the configuration repository and from the file system of all nodes where the file is installed. If the application or module is deployed on a cluster, after removing a file click **Rollout Update** to roll out the changes across the entire cluster.
Export	Accesses the Export Application EAR files page, which you use to export an enterprise application to an EAR file at a location of your choice. Use the **Export** action to back up a deployed application and to preserve its binding information.
Export DDL	Accesses the Export Application DDL files page, which you use to export DDL files (`Table.ddl`) in the EJB modules of an enterprise application to a location of your choice.

These buttons are not available when this page is accessed from an application server settings page. When this page is accessed from an application server settings page, it is entitled the Installed applications page.

Name

Specifies the name of the installed (or deployed) application. Application names must be unique within a cell and cannot contain an unallowed character.

Application Status

Indicates whether the application deployed on the application server is started, stopped, or unavailable.

	Started	Application is running.
	Started	Application is running.
	Partial Start	Application is in the process of changing from a *Stopped* state to a *Started* state. Application is starting to run but is not fully running yet. Or, it cannot fully start because a server mapped to one or more application modules is stopped.
	Stopped	Application is not running.
	Partial Stop	Application is in the process of changing from a *Started* state to a *Stopped* state. Application has not stopped running yet.
	Unavailable	Status cannot be determined.
	Not applicable	Application does not provide information as to whether it is running.

Startup order

Specifies the order in which applications are started when the server starts. The application with the lowest startup order is started first.

This table column is available only when this page is accessed from an application server settings page; thus when this page is entitled the Installed applications page.

Enterprise application settings

Use this page to configure an enterprise application.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name*.

Name

Specifies a logical name for the application. An application name must be unique within a cell and cannot contain an unallowed character.

An application name cannot begin with a period (**.**), cannot contain leading or trailing spaces, and cannot contain any of the following characters:

Unallowed characters					
/	forward slash	**$**	dollar sign	**'**	single quote mark
****	backslash	**=**	equal sign	**″**	double quote mark
*	asterisk	**%**	percent sign	**|**	vertical bar
,	comma	**+**	plus sign	**<**	left angle bracket
:	colon	**@**	at sign	**>**	right angle bracket
;	semi-colon	**#**	hash mark	**&**	ampersand (and sign)

Unallowed characters	
? question mark	**]]>** No specific name exists for this character combination

Data type   String

Application reference validation

Specifies whether the product examines the application references specified during application installation or updating and, if validation is enabled, warns you of incorrect references or fails the operation.

An application typically refers to resources using data sources for container managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the application is defined in the scope of the deployment target of that application.

The resource can be defined on the server, its node, cell or the cluster if the server belongs to a cluster. Select **Don't validate** for no resource validation, **Issue warnings** for warning messages about incorrect resource references, or **Stop installation if validation fails** to stop operations that fail as a result of incorrect resource references.

This **Application reference validation** setting is the same as the **Validate input off/warn/fail** field on the application installation and update wizards.

Data type   String
Default   Issue warnings

Configuring an application

You can change the configuration of an application or module deployed on a server.

You can change the contents of and deployment descriptors for an application or module before deployment, such as in an assembly tool. However, it is assumed that the module is already deployed on a server.

Changing an application or module configuration consists of one or more of the following:
* Changing the settings of the application or module.
* Removing a file from an application or module.
* Updating the application or its modules.

This topic describes how to change the settings of an application or module using the administrative console.
* View current settings of the application or module.

  Click **Applications > Enterprise Applications >** *application_name* to access the settings page for the enterprise application.

  Many application or module settings are available on other console pages that you can access by clicking links on the settings page for the enterprise application. For detailed information on the settings and allowed values, examine the online help for the console pages. When you installed the application or module, you specified most of the settings values.
* Map each module of your application to a target server.

  Specify the application servers, clusters of application servers, or Web servers onto which to install modules of your application.
* Change how quickly your application starts compared to other applications or to the server.
* Configure the use of binary files.

- Change how your application or Web modules use class loaders.
- Map a virtual host for each Web module of your application. Configuring virtual hosts provides information on virtual hosts.
- Change application bindings or other settings of the application or module.
  1. Click **Applications > Enterprise Applications >** *application_name* **>** *property_or_item_name* in the console navigation tree. From the application settings page, you can access console pages for further configuring of the application or module.
     - Target specific application status
     - Remote request dispatch properties
     - Security role to user/group mapping
     - View deployment descriptor
     - Last participant support extension
     - Application scope resources
     - Resource references
     - EJB references
     - Shared library references
     - Initial parameters for servlets
     - Session management
     - Context root for Web modules
     - JSP reloading options for Web modules
     - Environment entries for Web modules
     - Virtual hosts
     - Stateful session bean failover (applications)
     - Stateful session bean failover (EJB modules)
     - Application profiles
     - 2.x CMP bean data sources
     - 2.x entity bean data sources.
     - EJB JNDI names
     - Correct use of system identity
     - Provide JMS and EJB endpoint URL information
     - Publish WSDL files
     - Provide HTTP endpoint URL information
     - Web modules
     - EJB modules
  2. Change the values for settings as needed, and click **OK**.
- **Optional:** Configure the application so it does not start automatically when the server starts. By default, an installed application starts when the server on which the application resides starts. You can configure the target mapping for the application so the application does not start automatically when the server starts. To start the application, you must then start it manually.
- If the installed application or module uses a resource adapter archive (RAR file), ensure that the **Classpath** setting for the RAR file enables the RAR file to find the classes and resources that it needs. Examine the **Classpath** setting on the console Resource adapter settings page.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Application bindings

Before an application that is installed on an application server can start, all enterprise bean (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. The jndiName values specified for artifacts must be qualified lookup names. An example referenceable artifact is an EJB defined in an application. An example referenced artifact is an EJB or a resource reference used by the application. Binding definitions are stored in the `ibm-xxx-bnd.xmi` files of an application. The *xxx* can be `ejb-jar`, `web`, `application` or `application-client`.

This topic provides the following information about bindings:
- "Times when bindings can be defined"
- "Required bindings" on page 1397
- "Other bindings that might be needed" on page 1400

Times when bindings can be defined

You can define bindings at the following times:
- During application development

  An application developer can create binding definitions in `ibm-xxx-bnd.xmi` files using a tool such as an IBM Rational developer tool. The developer then gives an enterprise application (`.ear` file) complete with bindings to an application assembler or deployer. When assembling the application, the assembler does not modify the bindings. Similarly, when installing the application onto a server supported by WebSphere Application Server, the deployer does not modify or override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.

- During application assembly

  An application assembler can define bindings when modifying deployment descriptors of an application. Bindings are specified in the **WebSphere Bindings** section of a deployment descriptor editor. Modifying the deployment descriptors might change the binding definitions in the `ibm-xxx-bnd.xmi` files created when developing an application. After defining the bindings, the assembler gives the application to a deployer. When installing the application onto a server supported by WebSphere Application Server, the deployer does not modify or override the bindings or generate default bindings unless changes to the bindings are necessary for successful deployment of the application.

- During application installation

  An application deployer or server administrator can modify the bindings when installing the application onto a server supported by WebSphere Application Server using the administrative console. New binding definitions can be specified on the install wizard pages.

  If the deployer or administrator selects to override any existing bindings or to generate default bindings during application installation, default bindings are assigned to the application and new bindings might need to be specified using the console.

  Selecting **Generate Default Bindings** during application installation causes any incomplete bindings in the application to be filled in with default values. Existing bindings are not changed.

  Restriction: Bindings can be defined or overridden during application installation for all modules except application clients. For clients, you must define bindings for application client modules during assembly and store the bindings in the `ibm-application-client-bnd.xmi` file.

- During configuration of an installed application

  After an application is installed onto a server supported by WebSphere Application Server, an application deployer or server administrator can modify the bindings by changing values in administrative console pages such as those accessed from the settings page for the enterprise application.

Required bindings

Before an application can be successfully deployed, bindings must be defined for references to the following artifacts:

EJB JNDI names

For each enterprise bean (EJB), you must specify a JNDI name. The name is used to bind an entry in the global JNDI name space for the EJB home object. An example JNDI name for a *Product* EJB in a *Store* application might be `store/ejb/Product`. The binding definition is stored in the `META-INF/ibm-ejb-jar-bnd.xmi` file.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns EJB JNDI names having the form `prefix/EJB_name` to incomplete bindings. The default prefix is `ejb`, but can be overridden. The *EJB_name* is as specified in the deployment descriptor `<ejb-name>` tag.

During and after application installation, EJB JNDI names can be specified on the Provide JNDI names for beans panel. After installation, click **Applications > Enterprise Applications >** *application_name* **> EJB JNDI names** in the administrative console.

Data sources for entity beans

Entity beans such as container-managed persistence (CMP) beans store persistent data in data stores. With CMP beans, an EJB container manages the persistent state of the beans. You specify which data store a bean uses by binding an EJB module or an individual EJB to a data source. Binding an EJB module to a data source causes all entity beans in that module to use the same data source for persistence.

An example JNDI name for a *Store* data source in a *Store* application might be `store/jdbc/store`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. A deployer can also specify whether authentication is handled at the container or application level.

If a deployer chooses to generate default bindings when installing the application, the install wizard generates the following for incomplete bindings:
- For EJB 2.x `.jar` files, connection factory bindings based on the JNDI name and authorization information specified
- For EJB 1.1 `.jar` files, data source bindings based on the JNDI name, data source user name and password specified

The generated bindings provide default connection factory settings for each EJB 2.x `.jar` file and default data source settings for each EJB 1.1 `.jar` file in the application being installed. No bean-level connection factory bindings or data source bindings are generated unless they are specified in the custom strategy rule supplied during default binding generation.

During and after application installation, data sources can be mapped to 2.x entity beans on the 2.x CMP bean data sources panel and on the 2.x entity bean data sources panel. After installation, click **Applications > Enterprise Applications >** *application_name* in the administrative console, then select **2.x CMP bean data sources** or **2.x entity bean data sources**. Data sources can be mapped to 1.x entity beans on the Map data sources for all 1.x CMP beans panel and on the Provide default data source mapping for modules containing 1.x entity beans panel. After installation, access console pages similar to those for 2.x CMP beans, except click links for 1.x CMP beans.

Backend ID for EJB modules

If an EJB `.jar` file that defines CMP beans contains mappings for multiple backend databases, specify the appropriate backend ID that determines which persister classes are loaded at run time.

Specify the backend ID during application installation. You cannot select a backend ID after the application is installed onto a server.

To enable backend IDs for individual EJB modules:

1. During application installation, select **Deploy enterprise beans** on the Select installation options panel. Selecting **Deploy enterprise beans** enables you to access the **Provide options to perform the EJB Deploy** panel.

2. On the **Provide options to perform the EJB Deploy** panel, set the database type to *""* (null).

During application installation, if you select **Deploy enterprise beans** on the Select installation options panel and specify a database type for the EJB deployment tool on the **Provide options to perform the EJB Deploy** panel, previously defined backend IDs for all of the EJB modules are overwritten by the chosen database type.

The default database type is `DB2UDB_V81`.

For information on backend databases, refer to EJB deployment tool. For information on EJB Deploy options, refer to The ejbdeploy command.

EJB references

An enterprise bean (EJB) reference is a logical name used to locate the home interface of an enterprise bean. EJB references are specified during deployment. At run time, EJB references are bound to the physical location (global JNDI name) of the enterprise beans in the target operational environment. EJB references are made available in the `java:comp/env/ejb` Java naming subcontext.

For each EJB reference, you must specify a JNDI name. An example JNDI name for a *Supplier* EJB reference in a *Store* application might be `store/ejb/Supplier`. The binding definition is stored in IBM binding files such as `ibm-ejb-jar-bnd.xmi`. When the referenced EJB is also deployed in the same application server, you can specify a server-scoped JNDI name. But if the referenced EJB is deployed on a different application server or if `ejb-ref` is defined in an application client module, then you should specify the global cell-scoped JNDI name.

If a deployer chooses to generate default bindings when installing the application, the install wizard binds EJB references as follows: If an `<ejb-link>` is found, it is honored. If the `ejb-name` of an EJB defined in the application matches the `ejb-ref` name, then that EJB is chosen. Otherwise, if a unique EJB is found with a matching home (or local home) interface as the referenced bean, the reference is resolved automatically.

During and after application installation, EJB reference JNDI names can be specified on the Map EJB references to beans panel. After installation, click **Applications > Enterprise Applications >** *application_name* **> EJB references** in the administrative console.

For more information, refer to "EJB references" on page 198.

Resource references

A resource reference is a logical name used to locate an external resource for an application. Resource references are specified during deployment. At run time, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment. Resource references are made available as follows:

Resource reference type	Subcontext declared in
Java DataBase Connectivity (JDBC) data source	`java:comp/env/jdbc`
JMS connection factory	`java:comp/env/jms`
JavaMail connection factory	`java:comp/env/mail`

| Uniform Resource Locator (URL) connection factory | `java:comp/env/url` |

For each resource reference, you must specify a JNDI name. If a deployer chooses to generate default bindings when installing the application, the install wizard generates resource reference bindings derived from the `<res-ref-name>` tag, assuming that the `java:comp/env` name is the same as the resource global JNDI name.

During application installation, resource reference JNDI names can be specified on the Map resource references to references panel. Specify JNDI names for the resources that represent the logical names defined in resource references. You can optionally specify login configuration name and authentication properties for the resource. After specifying authentication properties, click **OK** to save the values and return to the mapping step. Each resource reference defined in an application must be bound to a resource defined in your WebSphere Application Server configuration. After installation, click **Applications > Enterprise Applications >** *application_name* **> Resource references** in the administrative console to access the Resource references panel.

Virtual host bindings for Web modules

You must bind each Web module to a specific virtual host. The binding informs a Web server plug-in that all requests that match the virtual host must be handled by the Web application. An example virtual host to be bound to a *Store* Web application might be `store_host`. The binding definition is stored in IBM binding files such as `WEB-INF/ibm-web-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard sets the virtual host to `default_host` for each `.war` file.

During and after application installation, you can map a virtual host to a Web module defined in your application. On the Map virtual hosts for Web modules panel, specify a virtual host. The port number specified in the virtual host definition is used in the URL that is used to access artifacts such as servlets and JSP files in the Web module. For example, an external URL for a Web artifact such as a JSP file is `http://host_name:virtual_host_port/context_root/jsp_path`. After installation, click **Applications > Enterprise Applications >** *application_name* **> Virtual hosts** in the administrative console.

Message-driven beans

For each message-driven bean, you must specify a queue or topic to which the bean will listen. A message-driven bean is invoked by a Java Messaging Service (JMS) listener when a message arrives on the input queue that the listener is monitoring. A deployer specifies a listener port or JNDI name of an activation specification as defined in a connector module (`.rar` file) under **WebSphere Bindings** on the **Beans** page of an assembly tool EJB deployment descriptor editor. An example JNDI name for a listener port to be used by a `Store` application might be `StoreMdbListener`. The binding definition is stored in IBM bindings files such as `ibm-ejb-jar-bnd.xmi`.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete bindings.
- For EJB 2.x message-driven beans deployed as JCA 1.5-compliant resources, the install wizard assigns JNDI names corresponding to activationSpec instances in the form `eis/MDB_ejb-name`.
- For EJB 2.x message-driven beans deployed against listener ports, the listener ports are derived from the message-driven bean `<ejb-name>` tag with the string `Port` appended.

During application installation using the administrative console, you can specify a listener port name or an activation specification JNDI name for every message-driven bean on the panel **Bind listeners for message-driven beans**. A listener port name must be provided when using the JMS providers: Version 5 default messaging, WebSphere MQ, or generic. An activation specification must be provided when the application's resources are configured using the default messaging provider or any generic J2C resource adapter that supports inbound messaging. If neither is specified, then a validation error is displayed after you click **Finish** on the Summary panel. Also, if

the module containing the message-driven bean is deployed on a 5.x deployment target and a listener port is not specified, then a validation error is displayed after you click **Next**.

After application installation, you can specify JNDI names and configure message-driven beans on console pages under **Resources > JMS Providers** or under **Resources > Resource Adapters**. For more information, refer to "Using asynchronous messaging" on page 804.

Message destination references

A message destination reference is a logical name used to locate an enterprise bean in an EJB module that acts as a message destination. Message destination references exist only in J2EE 1.4 artifacts such as--
- J2EE 1.4 application clients
- EJB 2.1 projects
- 2.4 Web applications

If multiple message destination references are associated with a single message destination link, then a single JNDI name for an enterprise bean that maps to the message destination link, and in turn to all of the linked message destination references, is collected during deployment. At run time, the message destination references are bound to the administered message destinations in the target operational environment.

If a message destination reference and a message-driven bean are linked by the same message destination, both the reference and the bean should have the same destination JNDI name. When both have the same name, only the destination JNDI name for the message-driven bean is collected and applied to the corresponding message destination reference.

If a deployer chooses to generate default bindings when installing the application, the install wizard assigns JNDI names to incomplete message destination references as follows: If a message destination reference has a `<message-destination-link>`, then the JNDI name is set to `ejs/message-destination-linkName`. Otherwise, the JNDI name is set to `eis/message-destination-refName`.

Other bindings that might be needed

Depending on the references in and artifacts used by your application, you might need to define bindings for references and artifacts not listed in this article.

Configuring application startup

You can configure the startup behavior of an application. The values set affect how quickly an application starts and what occurs when an application starts.

This topic assumes that your application or module is already deployed on a server.

This topic also assumes that your application or module is configured to start automatically when the server starts. By default, an installed application starts when the server on which the application resides starts.

This topic describes how to change the settings of an application or module using the administrative console.

1. Click **Applications > Enterprise Applications >** *application_name* **> Startup behavior** in the console navigation tree.
2. Specify the startup order for the application.

   If your application starts automatically when its server starts, the value for **Startup order** controls how quickly the application starts. **Startup order** specifies the order in which applications are started when the server starts. The application with the lowest startup order, or starting weight, is started first.
3. Specify whether the application must initialize fully before its server is considered started.

If your application starts automatically when its server starts, **Launch application before server completes startup** specifies whether the application must initialize fully before its server is considered started. Background applications can be initialized on an independent thread, thus allowing the server startup to complete without waiting for the application. This setting applies only if the application is run on a Version 6 (or later) application server.

4. Specify whether to create MBeans for resources such as servlets or JavaServer Pages (JSP) files within an application when the application starts.

   The default for **Create MBeans for resources** is to create MBeans.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save changes to your administrative configuration.

The application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Startup behavior settings

Use this page to configure when an application starts compared to other applications and to the server, and to configure whether MBeans for resources are created when an application starts.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name* **> Startup behavior**.

Startup order:

Specifies the order in which applications are started when the server starts. The startup order is like a starting weight. The application with the lowest starting weight is started first.

Data type	Integer
Default	1
Range	0 to 2147483647

Launch application before server completes startup:

Specifies whether the application must initialize fully before the server starts.

The default setting of `false` indicates that server startup will not complete until the application starts.

A setting of `true` informs the product that the application might start on a background thread and thus server startup might continue without waiting for the application to start. Thus, the application might not be ready for use when the application server starts.

This setting applies only if the application is run on a Version 6 application server.

Data type	Boolean
Default	false

Create MBeans for resources:

Specifies whether to create MBeans for various resources (such as servlets or JSP files) within an application when the application starts. The default is to create MBeans.

Data type   Boolean
Default   true

Configuring binary location and use

You can designate where binary files (binaries) used by your application reside, whether the product distributes binaries for you automatically, and otherwise configure the use of binaries.

This topic assumes that your application or module is already deployed on a server.

This topic describes how to change the settings of an application or module using the administrative console.

1. Click **Applications > Enterprise Applications >** *application_name* **> Application binaries** in the console navigation tree. The Application binaries page is displayed.
2. Specify the directory to hold the application binaries.

   The default is `APP_INSTALL_ROOT/`*cell_name*, where the `APP_INSTALL_ROOT` variable is *app_server_root*/`installedApps`. For example:

   `C:\WebSphere\AppServer\profiles\`*profile_name*`\installedApps\`*cell_name*

   Refer to "Application binary settings" on page 1403 for a detailed description of the **Location (full path)** setting.
3. Specify the bindings, extensions, and deployment descriptors that an application server uses.

   By default, an application server uses the bindings, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file.

   To specify that the application server use the bindings, extensions, and deployment descriptors located in the application archive (EAR) file, select **Use configuration information in binary**. Select this setting for applications installed on 6.x deployment targets only. This setting is not valid for applications installed on 5.x deployment targets.
4. Specify whether the product distributes application binaries automatically to other nodes on the cell.

   By default, **Enable binary distribution, expansion and cleanup post uninstallation** is selected and binaries are distributed automatically.

   If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

   Important: If you disable this option and you do not copy and expand the application binaries to the nodes, a later saving of the configuration or manual synchronization does not move the application binaries to the nodes for you.
5. Specify access permissions for binaries.
   a. Ensure that the **Enable binary distribution, expansion and cleanup post uninstallation** option is enabled. That option must be enabled to specify access permissions for binaries.
   b. For **File permissions**, specify a string that defines access permissions for binaries that are expanded in the named location.

      You can specify file permissions in the text field. You can also set some of the commonly used file permissions by selecting them from the drop-down list. Drop-down list selections overwrite file permissions set in the text field.

      For details on **File permissions**, refer to "Application binary settings" on page 1403.
6. Click **OK**.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Application binary settings

Use this page to configure the location and distribution of application binary files.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name* **> Application binaries**.

Location (full path):

Specifies the directory to which the application EAR file is installed. This **Location** setting is the same as the **Directory to install application** field on the application installation and update wizards.

The default value is the value of `APP_INSTALL_ROOT`/*cell_name*, where the `APP_INSTALL_ROOT` variable is *app_server_root*/`installedApps`; for example, *app_server_root*/`installedApps`/*cell_name*.

Important: If an installation directory is not specified when an application is installed on a single-server configuration, the application is installed in `APP_INSTALL_ROOT`/*cell_name*. When the server is made a part of a Network Deployment configuration (using the addNode utility), the cell name of the new configuration becomes the cell name of the deployment manager node. If the `-includeapps` option is used for the addNode utility, then the applications that are installed prior to the addNode operation still use the installation directory `APP_INSTALL_ROOT`/*cell_name*. However, an application that is installed after the server is added to the network configuration uses the default installation directory `APP_INSTALL_ROOT`/*network_cell_name*. To move the application to the `APP_INSTALL_ROOT`/*network_cell_name* location upon running the addNode operation, explicitly specify the installation directory as `${APP_INSTALL_ROOT}/${CELL}` during installation. In such a case, the application files can always be found under `APP_INSTALL_ROOT`/*current_cell_name*.

You can specify an absolute path or use a pathmap variable such as `${MY_APPS}`. You can use a pathmap variable in any installation.

A pathmap variable is particularly needed when installing an application on a cluster with members on heterogeneous nodes because, in such cases, there might not be a single way to specify an absolute path. A WebSphere Application Server variable `${CELL}` that denotes the current cell name can also be in the pathmap variable; for example, `${MY_APP}/${CELL}`. You can define WebSphere Application Server variables on the WebSphere Variables console page, accessed by clicking **Environment > WebSphere Variables**.

Data type	String
Units	Full path name

Use configuration information in binary:

Specifies whether the application server uses the binding, extensions, and deployment descriptors located with the application deployment document, the `deployment.xml` file (default), or those located in the enterprise application resource (EAR) file.

This **Use configuration information in binary** setting is the same as the **Use binary configuration** field on the application installation and update wizards. Select this setting for applications installed on 6.x deployment targets only. This setting is not valid for applications installed on 5.x deployment targets.

Data type   Boolean
Default   false

Enable binary distribution, expansion and cleanup post uninstallation:

Specifies whether the product expands application binaries in the installation location during installation and deletes application binaries during uninstallation. The default is to enable application distribution. Application binaries for installed applications are expanded to the directory specified. The binaries are deleted when you uninstall and save changes to the configuration, and, on the Network Deployment product, synchronize changes.

If you disable this option, then you must ensure that the application binaries are expanded appropriately in the destination directories of all nodes where the application runs.

Important: If you disable this option and you do not copy and expand the application binaries to the nodes, a later saving of the configuration or manual synchronization does not move the application binaries to the nodes for you.

This **Enable binary distribution, expansion and cleanup post uninstallation** setting is the same as the **Distribute application** field on the application installation and update wizards.

Data type   Boolean
Default   true

File permissions:

Specifies access permissions for application binaries for installed applications that are expanded to the directory specified.

The **Enable binary distribution, expansion and cleanup post uninstallation** option must be enabled to specify file permissions.

You can specify file permissions in the text field. You can also set some of the commonly used file permissions by selecting them from the drop-down list. Drop-down list selections overwrite file permissions set in the text field.

You can set one or more of the following file permission strings in the drop-down list. Selecting multiple options combines the file permission strings.

Drop-down list option	File permission string set
Allow all files to be read but not written to	.*=755
Allow executables to execute	.*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755
Allow HTML and image files to be read by everyone	.*\.htm=755#.*\.html=755#.*\.gif=755#.*\.jpg=755

Instead of using the drop-down list to specify file permissions, you can specify a file permission string in the text field. File permissions use a string that has the following format:

file_name_pattern=permission#file_name_pattern=permission

where *file_name_pattern* is a regular expression file name filter (for example, `.*\\.jsp` for all JSP files), *permission* provides the file access control lists (ACLs), and `#` is the separator between multiple entries of *file_name_pattern* and *permission*. If `#` is a character in a *file_name_pattern* string, use `\#` instead.

If multiple file name patterns and file permissions in the string match a uniform resource identifier (URI) within the application, then the product uses the most stringent applicable file permission for the file. For example, if the file permission string is `.*\\.jsp=775#a.*\\.jsp=754`, then the `abc.jsp` file has file permission 754.

Tip: Using regular expressions for file matching pattern compares an entire string URI against the specified file permission pattern. You must provide more precise matching patterns using regular expressions as defined by Java programming API. For example, suppose the following directory and file URIs are processed during a file permission operation:

1	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war
2	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp
3	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF/ MANIFEST.MF
4	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/WEB-INF/classes/ MyClass.class
5	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/mydir/ MyClass2.class
6	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF

The file pattern matching results are:
*   `MyWarModule.war` does not match any of the URIs
*   `.*MyWarModule.war.*` matches all URIs
*   `.*MyWarModule.war$` matches only URI 1
*   `.*\\.jsp=755` matches only URI 2
*   `.*META-INF.*` matches URIs 3 and 6
*   `.*MyWarModule.war/.*/.*\.class` matches URIs 4 and 5

If you specify a directory name pattern for **File permissions**, then the directory permission is set based on the value specified. Otherwise, the **File permissions** value set on the directory is the same as its parent. For example, suppose you have the following file and directory structure:

`/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp`

and you specify the following file pattern string:

`.*MyApp.ear$=755#.*\.jsp=644`

The file pattern matching results are:
*   Directory `MyApp.ear` is set to 755
*   Directory `MyWarModule.war` is set to 755
*   Directory `MyWarModule.war` is set to 755

Important: Regardless of the operation system, always use a forward slash (/) as a file path separator in file patterns.

Windows You cannot unset read permission on a file on Windows platforms. With POSIX style permission bits, the bit for denoting `readable` on a file is 4, `writable` is 2, and `executable` is 1. Thus, permission of a file on a Windows platform is either 5 or 7. Also, in POSIX style there are `user`, `group` and `world` permissions. You can only set the `user` permission for a file on Windows platforms. The `group` and `world` permission bits are ignored.

Access permissions specified here are at the application level. You can also specify access permissions for application binaries in the node level configuration. The node level file permissions specify the maximum (most lenient) permissions that can be given to application binaries. Access permissions specified here at application level can only be the same as or more restrictive than those specified at the node level.

This setting is the same as the **File permission** field on the application installation and update wizards.

Data type   String

Application build level:

Specifies an uneditable string that identifies the build version of the application.

Data type   String

Configuring the use of class loaders by an application

You can configure whether your application and Web modules use their own class loaders to load classes or use different class loaders, as well as configure the reloading of classes when application files are updated. Class loaders enable an application to access repositories of available classes and resources.

This topic assumes that your application or module is already deployed on a server.

Selection of class loaders to be used by an application and Web modules affects whether your application and its modules find the resources that they need to run effectively. You can select whether your application and Web modules use their own class loaders to load classes, or use a parent class loader. Detailed information on class loaders is available in "Class loaders" on page 1351, Chapter 8, "Class loading," on page 1351 and Troubleshooting class loaders.

An application class loader groups enterprise bean (EJB) modules, shared libraries, resource adapter archives (RAR files), and dependency Java archive (JAR) files associated to an application. Dependency JAR files are JAR files that contain code which can be used by both enterprise beans and servlets.

An application class loader is the parent of a Web application archive (WAR) class loader. By default, a Web module has its own WAR class loader to load the contents of the Web module. The WAR class-loader policy value of an application class loader determines whether the WAR class loader or the application class loader is used to load the contents of the Web module.

You can also select whether classes are reloaded when application files are updated. For enterprise bean (EJB) modules or any non-Web modules, enabling class reloading causes the application server run time to stop and start the application to reload application classes. For Web modules such as servlets and JavaServer Pages (JSP) files, a Web container reloads a Web module only when the IBM extension reloadingEnabled in the `ibm-web-ext.xmi` file is set to `true`.

To configure use of class loaders by your application and Web modules, use the Class loading and update detection page of the administrative console.

1. Click **Applications > Enterprise Applications >** *application_name* **> Class loading and update detection** to access the settings page for an application class loader.
2. Specify whether to reload application classes when the application or its files are updated.

   By default, class reloading is not enabled. Select **Reload classes when application files are updated** to choose to reload application classes. You might specify different values for EJB modules and for Web modules such as servlets and JavaServer Pages (JSP) files.
3. Specify the number of seconds to scan the application's file system for updated files.

The value specified for **Polling interval for updated files** takes effect only if class reloading is enabled. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the enterprise application (EAR file). You might specify different values for EJB modules and for Web modules such as servlets and JSP files.

To enable reloading, specify an integer value that is greater than zero (for example, 1 to 2147483647).

To disable reloading, specify zero (0).

4. Specify the class loader order for the application.

   The application class loader order specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The default is to search in the parent class loader before searching in the application class loader to load a class.

   Select either of the following values for **Class loader order**:

Option	Description
Classes loaded with parent class loader first	Causes the class loader to search in the parent class loader first to load a class. This value is the standard for Development Kit class loaders and WebSphere Application Server class loaders.
Classes loaded with application class loader first	Causes the class loader to search in the application class loader first to load a class. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader. **Attention:** Specifying the `Classes loaded with application class loader first` value might result in LinkageErrors or ClassCastException messages if you have mixed use of overridden classes and non-overridden classes.

5. Specify whether to use a single or multiple class loaders to load Web application archives (WAR files) of your application.

   By default, Web modules have their own WAR class loader to load the contents of the `WEB-INF/classes` and `WEB-INF/lib` directories. The default WAR class loader value is `Class loader for each WAR file in application`, which uses a separate class loader to load each WAR file. Setting the value to `Single class loader for application` causes the application class loader to load the Web module contents as well as the EJB modules, shared libraries, RAR files, and dependency JAR files associated to the application. The application class loader is the parent of the WAR class loader.

   Select either of the following values for **WAR class loader policy**:

Option	Description
Class loader for each WAR file in application	Uses a different class loader for each WAR file.
Single class loader for application	Uses a single class loader to load all of the WAR files in your application.

6. Click **OK**.

The application or module configuration is changed. The application or standalone Web module is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Class loading and update detection settings

Use this page to configure use of class loaders by an application.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name* **> Class loading and update detection**.

Reload classes when application files are updated:

Specifies whether to enable class reloading when application files are updated.

Select **Reload classes when application files are updated** to set reloadEnabled to `true` in the `deployment.xml` file for the application. If an application's class definition changes, the application server run time stops and starts the application to reload application classes.

For JavaServer Pages (JSP) files in a Web module, a Web container reloads JSP files only when the IBM extension jspReloadingEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`. You can enable JSP reloading during deployment on the JSP Reload Options panel.

Data type	Boolean
Default	false

Polling interval for updated files:

Specifies the number of seconds to scan the application's file system for updated files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file.

This **Polling interval for updated files** setting is the same as the **Reload interval in seconds** field on the application installation and update wizards.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Data type	Integer
Units	Seconds
Default	3

Class loader order:

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and WebSphere Application Server class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Classes loaded with parent class loader first` and `Classes loaded with application class loader first`. The default is to search in the parent class loader before searching in the application class loader to load a class.

For your application to use the default configuration of Jakarta Commons Logging in WebSphere Application Server, set this application class loader mode to `Classes loaded with parent class loader first`. For your application to override the default configuration of Jakarta Commons Logging in WebSphere Application Server, your application must provide the configuration in a form supported by Jakarta Commons Logging and this class loader mode must be set to `Classes loaded with application class loader first`. Also, to override the default configuration, set the class loader mode for each Web module in your application so that the correct logger factory loads.

Data type	String
Default	Classes loaded with parent class loader first

WAR class loader policy:

Specifies whether to use a single class loader to load all WAR files of the application or to use a different class loader for each WAR file.

The options are `Class loader for each WAR file in application` and `Single class loader for application`. The default is to use a separate class loader to load each WAR file.

Data type	String
Default	Class loader for each WAR file in application

Manage modules settings

Use this panel to specify deployment targets where you want to install the modules contained in your application. Modules can be installed on the same deployment target or dispersed among several deployment targets. A deployment target can be an application server, cluster of application servers or Web server.

To view this administrative console panel, click **Applications > Enterprise Applications > *application_name* > Manage modules**. This panel is the similar to the **Map modules to servers** panel on the application installation and update wizards.

On this panel, each **Module** must map to one or more desired targets, identified under **Server**. To change a mapping:

1. In the list of mappings, select the **Select** check box beside each module that you want mapped to the same target(s).
2. From the **Clusters and Servers** drop-down list, select one or more targets. Select only appropriate deployment targets for a module. Modules that use WebSphere Application Server Version 6.x features cannot be installed onto a Version 5.x target server.

   Use the Ctrl key to select multiple targets. For example, to have a Web server serve your application, press the Ctrl key and then select an application server or cluster and the Web server together. The plug-in configuration file `plugin-cfg.xml` for that Web server will be generated based on the applications which are routed through it.
3. Click **Apply**.

If this Manage modules panel was accessed from a console enterprise application page for an already installed application, you can also use this panel to view and manage modules in your application.

To view the values specified for a module configuration, click the module name in the list. The displayed module settings page shows the values specified. On the settings page, you can change existing configuration values and link to additional console pages that assist you in configuring the module.

To manage a module, enable the **Select** check box beside the module name in the list and click a button:

Button	Resulting action
Remove	Removes the selected module from the deployed application. The module is deleted from the application in the configuration repository and also from all of the nodes where the application is installed and running (or expected to run). If the application is running on a node when the module file is deleted from the node as a result of configuration synchronization then the application is stopped, the module file is deleted from the node's file system, and the application is restarted.
Update	Opens a wizard that helps you update module in an application. If a module has the same URI as a module already existing in the application, the new module replaces the existing module. If the new module does not exist in the application, it is added to the deployed application. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and the application is restarted. If the application is running on a node when the module file is added as a result of configuration synchronization then the newly added module is started without stopping and restarting the running application.
Remove File	Deletes a file from a module of a deployed application. The file is also deleted from all the nodes where the module is installed after configuration is synchronized with nodes. If the application is running on a node when the module file is updated on the node as a result of configuration synchronization then the application is stopped, the module file is updated on the node's file system, and the application is restarted.

Clusters and Servers

Lists the names of available target servers and clusters. This list is the same for every application that is installed in the cell.

From this list, select only appropriate deployment targets for a module. You can install an application, enterprise bean (EJB) module or Web module developed for a Version 5.x product on a 5.x or 6.x deployment target, provided the module--
* Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
* Does not call any 6.x runtime application programming interfaces (APIs); and
* Does not use any 6.x product features.

If the module supports J2EE 1.4, then you must install the module on a 6.x deployment target. If the module calls a 6.1.x API or uses a 6.1.x feature, then you must install the module on a 6.1.x deployment target. Modules that call a 6.0.x API or use a 6.0.x feature can be installed on a 6.0.x or 6.1.x deployment target.

Module

Specifies the name of a module in the installed (or deployed) application.

URI

Specifies the location of the module relative to the root of the application (EAR file).

Module type

Specifies the type of module, for example a Web module or EJB module.

This setting is shown on the Manage modules panel accessed from a console enterprise application page.

Server

Specifies the name of each server or cluster to which the module currently is mapped--that is, the deployment targets.

To change the deployment targets for a module, select one or more targets from the **Clusters and Servers** drop-down list and click **Apply**. The new mapping replaces the previous mapping.

Mapping modules to servers

Each module of a deployed application must be mapped to one or more target servers. The target server can be an application server, cluster of application servers or Web server.

You can map modules of an application or standalone Web module to one or more target servers during or after application installation using the console. This topic assumes that the module is already installed on a server and that you want to change the mappings.

Before you change a mapping, check the deployment targets. You must specify an appropriate deployment target for a module. Modules that use Version 6.x features cannot be installed onto a Version 5.x target server.

During application installation, different deployment targets might have been specified.

You use the Manage modules panel of the administrative console to view and change mappings. This panel is displayed during application installation using the console and, after the application is installed, can be accessed from the settings page for an enterprise application.

On the Manage modules panel, specify target servers where you want to install the modules contained in your application. Modules can be installed on the same application server or dispersed among several application servers. Also, specify the Web servers as targets that will serve as routers for requests to your application. The plug-in configuration file `plugin-cfg.xml` for each Web server is generated based on the applications which are routed through it.

1. Click **Applications > Enterprise Applications >** *application_name* **> Manage modules** in the console navigation tree. The Manage modules panel is displayed.
2. Examine the list of mappings. Ensure that each **Module** entry is mapped to the desired target(s), identified under **Server**.
3. Change a mapping as needed.
   a. Select each module that you want mapped to the same target(s). In the list of mappings, place a check mark in the **Select** check boxes beside the modules.
   b. From the **Clusters and Servers** drop-down list, select one or more targets. Use the **Ctrl** key to select multiple targets. For example, to have a Web server serve your application, use the **Ctrl** key to select an application server or cluster and the Web server together in order to have the plug-in configuration file `plugin-cfg.xml` for that Web server generated based on the applications which are routed through it.
   c. Click **Apply**.
4. Repeat steps 2 and 3 until each module maps to the desired target(s).
5. Click **OK**.

The application or module configurations are changed. The application or standalone Web module is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save changes to your administrative configuration.

In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Tip: If, at a future time, you intend to delete the server or cluster to which the modules are mapped, add a new server or cluster and then remap the modules to it before deleting the old server or cluster. If you do not remap the modules to a new server or cluster before deleting the old one, you must uninstall each application or module and then reinstall them on an existing server or cluster. After a server or cluster to which modules are mapped is deleted, the modules cannot be remapped to another existing server or cluster.

Mapping virtual hosts for Web modules

A virtual host must be mapped to each Web module of a deployed application. Web modules can be installed on the same virtual host or dispersed among several virtual hosts.

You can map a virtual host to a Web module during or after application installation using the console. This article assumes that the Web module is already installed on a server and that you want to change the mappings.

Before you change a mapping, check the virtual hosts definitions. You can install a Web module on any defined virtual host. To view information on previously defined virtual hosts, click **Environment > Virtual Hosts** in the administrative console. Virtual hosts enable you to associate a unique port with a module or application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Pages (JSP) files in a Web module. For example, the alias `myhost:8080` is the `host_name:port_number` portion of the URL `http://myhost:8080/servlet/snoop`.

During application installation, a virtual host other than the one you want mapped to your Web module might have been specified.

The default virtual host setting usually is `default_host`, which provides several port numbers through its aliases:

80   An internal, insecure port used when no port number is specified
9080 An internal port
9443 An external, secure port

Unless you want to isolate your Web module from other modules or resources on the same node (physical machine), `default_host` is a suitable virtual host for your Web module.

In addition to `default_host`, WebSphere Application Server provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043. Do not select `admin_host` unless the Web module relates to system administration.

Use the Virtual hosts page of the administrative console to view and change mappings. This page is displayed during application installation using the console and, after the application is installed, can be accessed from the settings page for an enterprise application.

On the Virtual hosts page, specify a virtual host for each Web module. Web modules of an application can be installed on the same virtual host or on different virtual hosts.

1. Click **Applications > Enterprise Applications >***application_name* **> Virtual hosts** in the console navigation tree. The Virtual hosts page is displayed.

2. Examine the list of mappings. Ensure that each **Web module** entry has the desired virtual host mapped to it, identified under **Virtual host**.

3. Change the mappings as needed.

a. Select each Web module that you want mapped to a particular virtual host. In the list of mappings, place a check mark in the **Select** check boxes beside the Web modules.

b. From the **Virtual host** drop-down list, select the desired virtual host. If you selected more than one virtual host in step 1:

   1) Expand **Apply Multiple Mappings**.
   2) Select the desired virtual host from the **Virtual host** drop-down list.
   3) Click **Apply**.

4. Repeat steps 2 and 3 until a desired virtual host is mapped to each Web module.

5. Click **OK**.

The application or Web module configurations are changed. The application or standalone Web module is restarted so the changes take effect.

After mapping virtual hosts, do the following:

1. If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

2. Regenerate the plug-in configuration file.
   a. Click **Servers > Web servers**.
   b. Select the Web server for which you want to generate a plug-in.
   c. Click **Generate Plug-in**.

3. Save changes to your administrative configuration.

   In the Network Deployment product, the application binaries are transferred to nodes when the configuration changes on the deployment manager synchronize with configurations for individual nodes on which the application will run.

Virtual hosts settings

Use this panel to specify virtual hosts for Web modules contained in your application. Web modules can be installed on the same virtual host or dispersed among several virtual hosts.

To view this administrative console panel, click **Applications > Enterprise Applications > **application_name** > Virtual hosts**. This panel is the same as the **Map virtual hosts for Web modules** panel on the application installation and update wizards.

On this panel, each Web module must map to a previously defined virtual host, identified under **Virtual host**. You can see information on previously defined virtual hosts by clicking **Environment > Virtual Hosts** in the administrative console. Virtual hosts enable you to associate a unique port with a module or application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Pages (JSP) files in a Web module. For example, the alias `myhost:8080` is the `host_name:port_number` portion of the URL `http://myhost:8080/servlet/snoop`.

The default virtual host setting usually is `default_host`, which provides several port numbers through its aliases:

80   An internal, insecure port used when no port number is specified
9080   An internal port
9443   An external, secure port

Unless you want to isolate your Web module from other modules or resources on the same node (physical machine), `default_host` is a suitable virtual host for your Web module.

In addition to `default_host`, the product provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043. Do not select `admin_host` unless the Web module relates to system administration.

To change a mapping:

1. In the list of mappings, select the **Select** check box beside each Web module that you want mapped to a particular virtual host.
2. From the **Virtual host** drop-down list, select the desired virtual host. If you selected more than one virtual host in step 1:
   a. Expand **Apply Multiple Mappings**.
   b. Select the desired virtual host from the **Virtual Host** drop-down list.
   c. Click **Apply**.
3. Click **OK**.

Web module:

Specifies the name of a Web module in the application that you are installing or that you are viewing after installation.

Virtual host:

Specifies the name of the virtual host to which the Web module is currently mapped.

Expanding the drop-down list displays a list of previously defined virtual hosts. To change a mapping, select a different virtual host from the list.

Do not specify the same virtual host for different Web modules that have the same context root and are deployed on targets belonging to the same node even if the Web modules are contained in different applications. Specifying the same virtual host causes a validation error.

Mapping properties for a custom login configuration

Use this page to view and manage the mapping properties for a custom login configuration.

To access the administrative console panel, complete the following steps:

1. Click **Applications > Enterprise applications >** *application_name*.
2. Under Enterprise Java Bean Properties, click **2.x entity bean data sources**.
3. For Container authorization, modify the authorization type by selecting you rEJB module and selecting **Container** from the Resource authorization menu.
4. Click **Apply**.
5. Under Specify authentication method, select **Use custom login configuration** and the name of the application login configuration.
6. Select the name of your EJB module.
7. Click **Apply**.
8. Click **Mapping properties** in the Resource authorization column. This property is not available until after you click apply in the previous step.

Name
Specifies the name for the mapping property.

Do not use the `MAPPING_ALIAS` property name because the name is reserved by the product.

Value
Specifies the value paired with the specified name.

Description

Provides additional information about the name and value pair.

Viewing deployment descriptors

A deployment descriptor is an extensible markup language (XML) file that specifies configuration and container options for an application or module.

This topic assumes that you have installed an application or module on a server and that you want to view its deployment descriptor.

When you create an application or module in an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer, the assembly tool creates deployment descriptor files for the application or module.

You can edit a deployment descriptor file manually. However, it is preferable to edit a deployment descriptor using an assembly tool deployment descriptor editor to ensure that the deployment descriptor has valid properties and that its references contain appropriate values.

After an application or module is installed on a server, you can view its deployment descriptor in the administrative console.

1. Access a deployment descriptor view.

   Click the navigational option stated in **Accessing a console view** to view the deployment descriptor for a given module:

Module	Deployment descriptor file	Accessing a console view
Enterprise application	`application.xml`	**Applications > Enterprise Applications >** *application_name* > **View deployment descriptor**
Web application	`WEB-INF/web.xml`	**Applications > Enterprise Applications >** *application_name* > **Manage Modules >** *module_name* > • **View deployment descriptor**
	`WEB-INF/portlet.xml`	**Applications > Enterprise Applications >** *application_name* > **Manage Modules >** *module_name* > • **View portlet deployment descriptor**
Enterprise bean	`ejb-jar.xml`	**Applications > Enterprise Applications >** *application_name* > **Manage Modules >** *module_name* > **View deployment descriptor**
Application client	`application-client.xml`	No console view
Web service	`webservices.xml`	**Applications > Enterprise Applications >** *application_name* > **Manage Modules >** *module_name* > • **View Web services client deployment descriptor extension** • **View Web services server deployment descriptor** • **View Web services server deployment descriptor extension** "Viewing Web services deployment descriptors in the administrative console" on page 450 describes the views.
Resource adapter	`ra.xml`	**Resource Adapters > Resource Adapters >** *module_name* > **View deployment descriptor**

2. Click **Expand All** to view the deployment descriptor contents.

A deployment descriptor such as the following for the product DefaultApplication is displayed:

```
<application id="Application_ID" >
  <display-name> DefaultApplication.ear</display-name>
  <description> This is the IBM WebSphere Application Server Default Application.</<description>
  <module id="WebModule_1" >
    <web>
      <web-uri> DefaultWebApplication.war</web-uri>
      <context-root> /</context-root>
    </web>
  </module>
  <module id="EjbModule_1" >
    <ejb> Increment.jar</ejb>
  </module>
  <security-role id="SecurityRole_1130344639273" >
    <description> All Authenticated users role.</description>
    <role-name> All Role</role-name>
  </security-role>
</application>
```

Verify the deployment descriptor contents, including any configurations that it has for bindings, security roles, references to other resources, or Java Naming and Directory Interface (JNDI) names.

Change a deployment descriptor as needed in an assembly tool or using the console.

Starting or stopping applications

You can start an application that is not running (has a status of *Stopped*) or stop an application that is running (has a status of *Started*).

This topic assumes that the application is installed on a server. By default, the application starts automatically when the server starts.

You can start and stop applications manually using the following:
* Administrative console
* wsadmin startApplication and stopApplication commands
* Java programs that use ApplicationManager or AppManagement MBeans

This topic describes how to use the administrative console to start or stop an application.
1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.
2. Select the check box for the application you want started or stopped.
3. Click a button:

Option	Description
Start	Runs the application and changes the state of the application to *Started*. The status is changed to *partially started* if not all servers on which the application is deployed are running.
Stop	Stops the processing of the application and changes the state of the application to *Stopped*.

To restart a running application, select the application you want to restart, click **Stop** and then click **Start**.

The status of the application changes and a message stating that the application started or stopped displays at the top the page.

You can configure an application so it does not start automatically when the server on which it resides starts. You then start the application manually using options described in this article.

If you want your application to start automatically when its server starts, you can adjust values that control how quickly the application or its server starts:

1. Go the settings page for your enterprise application. Click **Applications > Enterprise Applications >** *application_name* **> Startup behavior**.

2. Specify a different value for **Startup order**.

   This setting specifies the order in which applications are started when the server starts. The default value is 1 in a range from 0 to 2147483647. The application with the lowest starting weight is started first.

3. Specify a different value for **Launch application before server completes startup**.

   This setting specifies whether the application must initialize fully before its server starts. The default value of `false` prevents the server from starting completely until the application starts. To reduce the amount of time it takes to start the server, you can set the value to `true` and have the application start on a background thread, thus allowing server startup to continue without waiting for the application

4. If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

5. Save the changes to the application configuration.

Disabling automatic starting of applications

You can enable and disable the automatic starting of an application. By default, an installed application starts automatically when the server on which the application resides starts.

This topic assumes that the application is installed on an application server and that the application starts automatically when the server starts.

This topic also assumes that you mapped the installed application to a server or cluster.

You might want an application to run only after you start it manually and not to run every time after the server starts. The target mapping for an application controls whether an application starts automatically when the server starts or requires you to start the application manually.

1. Go to the Target specific application status page for your application.

   Click **Applications > Enterprise Applications >** *application_name* **> Target specific application status**.

2. Select the target server or cluster on which the application resides.

3. Click **Disable Auto Start**.

4. Save changes to the administrative configuration.

The application does not start when its server starts. You must start the application manually.

To enable automatic starting of the application, do the following:
1. On the Target specific application status page for the application, select the target on which the application resides.
2. Click **Enable Auto Start**.
3. Save changes to the configuration.

Target specific application status

Use this page to view mappings of deployed applications or modules to servers or clusters.

Also use this page to enable or disable the automatic starting of an application when the server on which the application resides starts.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name* **> Target specific application status**.

Target

States the name of the target server or cluster to which the application or module maps. You specify the target on the Manage modules page accessed from the settings for an application.

Node

Specifies the node name if the target is a server.

Version

Specifies the version level of the target. The target can be a 5.x deployment target or a 6.x deployment target.

A *5.x deployment target* is a server or a cluster with at least one member on a WebSphere Application Server Version 5 product.

A *6.x deployment target* is a server or cluster with all members on a WebSphere Application Server Version 6 product.

An application, enterprise bean (EJB) module Session Initiation Protocol (SIP) module (SAR), or Web module developed for a Version 5.x product can reside on a 5.x or 6.x deployment target, provided the module--
- Does not support Java 2 Platform, Enterprise Edition (J2EE) 1.4;
- Does not call any 6.x runtime application programming interfaces (APIs); and
- Does not use any 6.x product features.

Similarly, a resource adapter (connector) module, or RAR file, developed for a Version 5.x product can reside on a 5.x or 6.x node, provided the module does not support Java Cryptography Architecture (JCA) 1.5 and does not call any 6.x runtime application programming interfaces (APIs). If the module supports JCA 1.5 or calls a 6.x API, then the module must reside on a 6.x node.

If JavaServer Pages (JSP) precompilation, EJB deployment (`ejbdeploy`), or Web Services deployment (`wsdeploy`) are enabled, then you can deploy applications to only those targets that have same product version as the deployment manager. If applications are targeted to servers that have an earlier version than the deployment manager, then you cannot deploy to those targets. Thus, if JSP precompilation, `ejbdeploy`, or `wsdeploy` are enabled, then you can deploy applications to only a 6.1 target.

Auto Start

Specifies whether the application modules installed on the target server are started (or enabled) when the server starts. This setting specifies the initial state of application modules. A `Yes` value indicates that the corresponding modules are enabled and thus are accessible when the server starts. A `No` value indicates that the corresponding modules are not enabled and thus are not accessible when the server starts.

By default, Auto Start is enabled. Thus, by default an installed application starts automatically when the server on which the application resides starts.

You can enable and disable the automatic starting of the application. To disable the automatic starting of the application, enable the **Select** check box beside the target server or cluster and click **Disable Auto Start**. When automatic starting is disabled, the application does not start when its server starts. To enable the automatic starting of the application, select the target and click **Enable Auto Start**.

Application Status

Indicates whether the application deployed on the application server is started, stopped, or unavailable.

	Started	Application is running.

	Partial Start	Application is in the process of changing from a *Stopped* state to a *Started* state. Application is starting to run but is not fully running yet. The application might be in the Partial Start state because one of its application servers is not started.
	Stopped	Application is not running.
	Partial Stop	Application is in the process of changing from a *Started* state to a *Stopped* state. Application has not stopped running yet.
	Unavailable	Status cannot be determined.
	Not applicable	Application does not provide information as to whether it is running.

Exporting applications

You can export an enterprise application to a location of your choice.

Exporting applications enables you to back up your applications and preserve binding information for the applications. You might export your applications before updating installed applications or migrating to a later version of the WebSphere Application Server product.

1. Click **Applications > Enterprise Applications** in the console navigation tree to access the Enterprise Applications page.
2. Select the check box beside the application and click **Export**.
3. On the Export Application EAR Files page, click on the link to download the exported EAR file.
4. Use the browser dialogue to specify a location at which to save the exported EAR file.
5. Click **Back** to return to the Enterprise Applications page.

The file containing binding information is exported to the specified node and directory, and has the name *enterprise_application_name*.ear.

Exporting DDL files

You can export data definition language (DDL) files in the enterprise bean (EJB) modules of an application.

Exporting DDL (`Table.ddl`) files in the EJB modules of an application downloads the DDL files to a location of your choice.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.
2. Place a check mark in the check box beside the application and click **Export DDL**. If the application has no DDL files in any of its EJB modules, then the message *No DDL files were found* is displayed at the top of the page. If the application has DDL files in its EJB modules, then a page listing DDL files in the format *application_name.ear/_module*.jar_Table.ddl is displayed.
3. Click on a file in the list and specify the location to which to download the file.

   Tip: Mozilla browsers might display the contents of the `Table.ddl` file instead of saving the file to disk. To save the file, edit the **Helper Application** preference settings of the Mozilla browser by adding a new type for DDL and specifying that you want to save DDL files to disk. That is, set `MIME type` = `ddl` and `Extension` = `ddl`.

The DDL file is downloaded to the specified location.

Updating applications

You can update application files deployed on a server.

Update your application or modules and reassemble them using an assembly tool. Typical tasks include adding or editing assembly properties, adding or importing modules into an application, and adding enterprise beans, Web components, and files.

Also, determine whether the updated files can be installed to your deployment targets. WebSphere Application Server Version 6.x supports Java 2 Platform, Enterprise Edition (J2EE) 1.4 enterprise applications and modules. If you are deploying J2EE 1.4 modules, ensure that the target server and its node support Version 6.x. The administrative console Server collection pages show the versions for servers and cluster members. You can deploy J2EE 1.4 modules to Version 6.x servers or to clusters that contain Version 6.x cluster members only. You cannot deploy J2EE 1.4 modules to servers on Version 5.x nodes or to clusters that contain Version 5.x cluster members. See "Installable module versions" on page 1365 for details.

Updating consists of adding a new file or module to an installed application, or replacing or removing an installed application, file or module. After replacement of a full application, the old application is uninstalled. After replacement of a module, file or partial application, the old installed module, file or partial application is removed from the installed application.

1. Determine which method to use to update your application files. WebSphere Application Server provides several ways to update modules.
2. Update the application files using
   - Administrative console
   - wsadmin scripts
   - Java application programming interfaces
   - WebSphere rapid deployment of J2EE applications

   In some situations, you can update applications or modules without restarting the application server using hot deployment. Do not use hot deployment unless you are an experienced user and are updating applications in a development or test environment.
3. Start the deployed application files using
   - Administrative console
   - wsadmin startApplication
   - Java programs that use ApplicationManager or AppManagement MBeans

Save the changes to your administrative configuration.

When saving the configuration, synchronize the configuration with the nodes where the application is expected to run.

Next, test the application. For example, point a Web browser at the URL for a deployed application (typically http://*hostname*:9060/*Web_module_name*, where *hostname* is your valid Web server and 9060 is the default port number) and examine the performance of the application. If the application does not perform as desired, edit the application configuration, then save and test it again.

Ways to update application files

You can update application files deployed on a server or cluster in several ways.

Table 51. Ways to update application files

Option	Method	Comments	Starting after update
Administrative console update wizard See "Updating applications with the console" on page 1422.	Briefly, do the following: 1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree. 2. Select the application to update and click **Update**. 3. On the Preparing for application update page, identify the application, module or files to update and click **Next**. 4. Complete steps in the update wizard and click **Finish**.	On the Preparing for application update page: • Use **Full application** to update an `.ear` file. • Use **Single module** to update a `.war`, `.sar`, enterprise bean `.jar`, or connector `.rar` file. • Use **Single file** to update a file other than an `.ear`, `.war`, `.sar`, EJB `.jar`, or `.rar` file. • Use **Partial application** to update or remove multiple files.	On the Enterprise Applications page, select the updated application and click **Start**.
wsadmin scripts	Use the **update** command or the **updateInteractive** command in a script or at a command prompt. For more information on the **update** and **updateInteractive** commands, see the Commands for the AdminApp object topic.	Getting started with scripting provides an overview of wsadmin.	Start the application using the **invoke** command and the startApplication attribute. For more information about the **invoke** command, see the Commands for the AdminControl object topic.
Java application programming interfaces See Using administrative programs (JMX).	Update deployed applications by completing the steps in Managing applications through programming.	Update an application in the following ways: • Update the entire application • Add to, replace or delete multiple files in an application • Add a module to an application • Update a module in an application • Delete a module in an application • Add a file to an application • Update a file in an application • Delete a file in an application	• Invoke the AdminApp *startApplication* command. • Invoke the *startApplication* method on an ApplicationManager MBean using AdminControl.

Table 51. Ways to update application files (continued)

Option	Method	Comments	Starting after update
WebSphere rapid deployment See topics under Rapid deployment of J2EE applications in this information center.	Briefly, do the following: 1. Update your J2EE application files. 2. Set up the rapid deployment environment. 3. Create a free-form project. 4. Launch a rapid deployment session. 5. Drop your updated application files into the free-form project.	WebSphere rapid deployment offers the following advantages: • You do not need to assemble your J2EE application files prior to deployment. • You do not need to use other installation tools mentioned in this table to deploy the files.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.
Hot deployment and dynamic reloading	Briefly, do the following: 1. Update your application (.ear), Web module (.war), enterprise bean .jar or HTTP plug-in configuration file. 2. Follow instructions in Hot deployment and dynamic reloading to update your file.	If you are new to WebSphere Application Server, use the administrative console to update applications. That option is easier. Hot deployment and dynamic reloading is more difficult to complete. You must directly manipulate the application or module file on the server where the application is deployed.	Use any of the above options to start the application. Clicking **Start** on the Enterprise Applications page is the easiest option.

You can update .ear, enterprise bean .jar, Web module .war, Session Initiation Protocol (SIP) module (.sar), connector .rar, application client .jar, and any other files used by an installed application.

If the application is updated while it is running, WebSphere Application Server automatically stops the application, updates the application logic and restarts the application. If the application does not start automatically, start it manually using one of the **Starting** options. For more information on the restarting of updated applications, refer to Fine-grained recycle behavior in *IBM WebSphere Developer Technical Journal: System management for WebSphere Application Server V6 -- Part 5 Flexible options for updating deployed applications*.

Updating applications with the console

Updating applications consists of adding a new file or module to an installed application, or replacing or removing an installed application, file or module.

Before you update the application files on a server, ensure that the files are assembled in deployable modules.

Next, refer to "Ways to update application files" on page 1420 and decide how to update your application files. You can update enterprise applications or modules using the administrative console, the wsadmin tool, or Java MBean programming. These ways provide similar updating capabilities.

Further, ensure that the updated files can be installed to your deployment targets.

This topic describes how to update deployed applications or modules using the administrative console.

1. Back up the installed application.

   a. Go to the Enterprise Applications page of the administrative console. Click **Applications > Enterprise Applications** in the console navigation tree.

b. Export the application to an EAR file. Select the application you want uninstalled and click **Export**. Exporting the application preserves the binding information.

2. With the application selected on the Enterprise Applications page, click **Update**. The Preparing for application update page is displayed.

3. Under **Specify the EAR, WAR, SAR or JAR module to upload and install**:

   a. Ensure that **Application to be updated** refers to the application to be updated.

   b. Under **Application update options**, select the installed application, module, or file that you want to update.

   The online help Preparing for application update settings provides detailed information on the options.

4. If you selected the **Replace the entire application** or **Replace or add a single module** option:

   a. Click **Next** to display a wizard for updating application files.

   b. Complete the steps in the update wizard.

   This update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Refer to information on installing applications and on the settings page for application installation for guidance.

   Note that the installation steps have the merged binding information from the new version and the old version. If the new version has bindings for application artifacts such as EJB JNDI names, EJB references or resource references, then those bindings will be part of the merged binding information. If new bindings are not present, then bindings are taken from the installed (old) version. If bindings are not present in the old version and if the default binding generation option is enabled, then the default bindings will be part of the merged binding information.

   You can select whether to ignore bindings in the old version or ones in the new version.

5. Click **Finish**.

6. If you did not use the Manage modules page of the update wizard, after updating the application, map the installed application or module to servers or clusters.

   Use the Manage modules page accessed from the Enterprise Applications page.

   a. Go to the Manage modules page. Click **Applications > Enterprise Applications >** *application_name* **> Manage modules**.

   b. Specify the application server where you want to install modules contained in your application and click **OK**.

   You can deploy J2EE 1.4 modules to servers on Version 6.x nodes or to clusters that contain cluster members on Version 6.x nodes only.

After replacement of a full application, the old application is uninstalled. After replacement of a module, file or partial application, the old installed module, file or partial application is removed from the installed application.

After the application file or module installs successfully, do the following:

1. If a changed application or module is deployed on a cluster, roll out the changes to all cluster members of the cluster on which the application or module is deployed. Click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

   Tip: At the end of the *Installing* messages displayed by the console during application or module installation, click **Manage applications** to go to the Enterprise Applications page. Do not save changes to your configuration until after you roll out the changes.

2. Save the changes to your configuration.

In the Network Deployment product, after you click **Save** the old application files are deleted and new files are copied when the configuration on the deployment manager synchronizes with the configuration on the node where the application is installed.

If the application is running when you update it, the application stops running before its files are copied to the destination directory of the node and restarts after the copy operation completes. Thus, the application is unavailable on the node during the time the node is synchronizing its configuration with the deployment manager.

3. If needed, restart the application manually so the changes take effect.

If the application is updated while it is running, WebSphere Application Server automatically stops the application or only its changed components, updates the application logic, and restarts the stopped application or its components. For more information on the restarting of updated applications, refer to Fine-grained recycle behavior in *IBM WebSphere Developer Technical Journal: System management for WebSphere Application Server V6 -- Part 5 Flexible options for updating deployed applications*.

4. If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, restart the server.

Preparing for application update settings

Use this page to update enterprise applications, modules or files already installed on a server.

To view this administrative console page, do the following:
1. Click **Applications > Enterprise Applications**.
2. Select the installed application or module that you want to update.
3. Click **Update**.

Clicking **Update** displays a page that helps you update application files deployed in the cell. You can update the full application, a single module, a single file, or part of the application. If a new file or module has the same relative path as a file or module already existing on the server, the new file or module replaces the existing file or module. If the new file or module does not exist on the server, it is added to the deployed application.

Application to be updated

Specifies the name of the installed (or deployed) application that you selected on the Enterprise Applications page.

Replace the entire application

Under **Application update options**, specifies to replace the application already installed on the server with a new (updated) enterprise application `.ear` file.

After selecting this option, do the following:

1. Specify whether the `.ear` file is on a local or remote file system and the full path name of the application. The path provides the location of the updated `.ear` file before installation.

   Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

   Use **Remote file system** if the application file resides on any node in the current cell context. You can browse the entire file system of a node if the node agent or deployment manager is running on that selected node. Only `.ear`, `.jar`, `.sar`, or `.war` files are shown during the browsing.

   Also use the **Remote file system** option to specify an application file already residing on the machine running the application server. For example, the field value might be `app_server_install_root/installableApps/test.ear`. If you are installing a standalone WAR module, then specify the context root as well.

   Tip: During application installation, application files typically are uploaded from a client machine running the browser to the server machine running the administrative console, where they are deployed. In such cases, use the Web browser running the administrative console to select `.ear`,

.war, .sar, or .jar modules to upload to the server machine. In some cases, however, the application files reside on the file system of any of the nodes in a cell. To have the application server install these files, use the **Remote file system** option.

2. If you are installing a standalone Web application (WAR) or a Session Initiation Protocol (SIP) module (SAR), specify the context root of the WAR or SAR file.

   The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is /gettingstarted and the servlet mapping is MySession, then the URL is http://host:port/gettingstarted/MySession.

3. Specify whether to show only installation options that require you to supply information or to show all installation options.

   The **Prompt me only when additional information is required** option enables you to install your application more easily because you do not need to examine all available installation options.

   However, to use the **Generate default bindings** option, which might be the quickest and easiest option for installing your application, you must select the **Show me all installation options and parameters** and then select **Generate default bindings** on the next panel.

4. Click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing application binding information. Complete the steps in the update wizard as needed.

When the full application is updated, the old application is uninstalled and the new application is installed. When the configuration changes are saved and subsequently synchronized, the application files are expanded on the node where application will run. If the application is running on the node while it is updated, then the application is stopped, application files are updated, and application is started.

Replace or add a single module

Under **Application update options**, specifies to replace a module in or add a module to an installed application. The module can be a Web module (.war file), enterprise bean module (EJB .jar file), SIP module (.sar file), or resource adapter module (connector .rar file).

After selecting this option, specify whether the module is on a local or remote file system and the full path name of the module. The path provides the location of the updated module before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Replace the entire application** above.

To replace a module, the specified relative path (module URI) must match the path of the module to be updated in the installed application.

To add a new module to the installed application, the specified relative path must *not* match the path of a module in the installed application. The value specifies the desired path for the new module.

If you are installing a standalone Web or SIP module, specify a value for **Context root**. The context root is combined with the defined servlet mapping (from the .war file) to compose the full URL that users type to access the servlet. For example, if the context root is /gettingstarted and the servlet mapping is MySession, then the URL is http://host:port/gettingstarted/MySession.

Next, specify whether to show only installation options that require you to supply information or to show all installation options.

After specifying the required information on the module, click **Next** to display a wizard for updating application files. The update wizard, which is similar to the installation wizard, provides fields for specifying or editing module binding information. Complete the steps in the update wizard as needed.

After a single module is added or updated, when configuration changes are saved, the new or updated module is stored in the deployed application in the WebSphere Application Server configuration repository.

When these changes are synchronized with the node, the module is added or updated to the node's file system. If the application is running on the node when the module is added or updated, then one of the following occurs:

- For updates to a Web module, the running Web module is stopped, Web module files are updated, and then the Web module is started.
- For module additions, the added module is started on the application servers where the application is running after it is expanded on the node. An application restart is not necessary.
- If the class loader policy for the application is set to `Single` so that all modules share a class loader, then the entire application is stopped and restarted for module level changes.
- If the security provider configured with WebSphere Application Server does not support dynamic updates, then the entire application is stopped and restarted for module level changes.
- For all other updates to a module, the entire application is stopped, the module files are updated, then the entire application is started.

Replace or add a single file

Under **Application update options**, specifies to replace a file in or add a file to an installed application.

Use this option to update a file used by the application that is not an `.ear`, `.war`, `.sar`, `.rar` or, in some instances, a `.jar` file. You can use this option to add or update `.jar` files that are not defined as modules in the application. To update an `.ear`, file use the **Replace the entire application** option. To update a `.war` file, `.sar` file, `.rar` file, or `.jar` file that is defined as a module in the application, use the **Replace or add a single module** option.

After selecting this option, specify whether the file is on a local or remote file system and the full path name of the file. The path provides the location of the updated file before installation. For information on **Local file system** and **Remote file system**, refer to the description of **Replace the entire application** above.

For the relative path, specify a relative path to the file that starts from the root of the `.ear` file. For example, if the file is located at `com/company/greeting.class` in module `hello.jar`, specify a relative path of `hello.jar/com/company/greeting.class`.

To replace a file, the relative path must match the path of the file to be updated in the installed application.

To add a new file to the installed application, the relative path must *not* match the path of a file in the installed application. The value specifies the desired path for the new file.

After you specify the file system and relative paths, click **Next**.

After a single file is added or updated, when configuration changes are saved, the new or updated file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the file is added or updated to the node's file system. If the application is running on the node when the file is added or updated, then one of the following occurs:

- When files are added at application metadata scope (`META-INF` directory) or updated at any application scope or in non-Web modules, the entire application is stopped, the file is added or updated, and then the entire application is restarted.
- When files are added at application non-metadata scope (outside of `META-INF` directory but not in any module), the changes are saved in the file system without restarting the running application.
- When files are added or updated to Web module metadata (`META-INF` or `WEB-INF` directory), the running Web module is stopped, the Web module file is added or updated, and then the Web module is started.
- For all other files in Web modules, the file is added or updated on the node's file system without stopping the application or any of its components.

Replace, add, or delete multiple files

Under **Application update options**, specifies to update multiple files of an installed application by uploading a compressed file. Depending on the contents of the compressed file, a single use of this option

can replace files in, add new files to, and delete files from the installed application. Each entry in the compressed file is treated as a single file and the path of the file from the root of the compressed file is treated as the relative path of the file in the installed application.

After selecting this option, specify whether the compressed file is on a local or remote file system and the full path name of the compressed file. You will likely use **Local file system** because you are uploading a compressed file and remote browsing only works for `.ear`, `.sar`, `.war` or `.jar` files. Specify a valid compressed file format such as `.zip` or `.gzip`. The path provides the location of the compressed file before installation. This option unzips the compressed file into the installed application directory.

Use **Local file system** if the browser and the updated files or modules are on the same machine, whether or not the server is on that machine too. **Local file system** is available for all update options.

To replace a file, a file in the compressed file must have the same relative path as the file to be updated in the installed application.

To add a new file to the installed application, a file in the compressed file must have a different relative path than the files in the installed application.

The relative path of a file in the installed application is formed by concatenation of the relative path of the module (if the file is inside a module) and the relative path of the file from the root of the module separated by /.

To remove a file from the installed application, specify metadata in the compressed file using a file named `META-INF/ibm-partialapp-delete.props` at any archive scope. The `ibm-partialapp-delete.props` file must be an ASCII file that lists files to be deleted in that archive with one entry for each line. The entry can contain a string pattern such as a regular expression that identifies multiple files. The file paths for the files to be deleted must be relative to the archive path that has the `META-INF/ibm-partialapp-delete.props` file.

Level of files to delete	Metadata .props file to include in compressed file
Application	Include `META-INF/ibm-partialapp-delete.props` in the compressed file. In the metadata `.props` file, list files to be deleted. File paths are relative to the location of the `META-INF/ibm-partialapp-delete.props` file. For example, to delete a file named `utils/config.xmi` from the root of the `my.ear` file, include the line `utils/config.xmi` in the `META-INF/ibm-partialapp-delete.props` file.
Module	Include `module_uri/META-INF/ibm-partialapp-delete.props` in the compressed file. To delete one file from a module, include the file path relative to the module in the metadata `.props` file. For example, to delete `a/b/c.jsp` from the `my.jar` module, include `a/b/c.class` in `my.jar/META-INF/ibm-partialapp-delete.props` file in the compressed file. To delete multiple files within a module, list the files to be deleted in the metadata `.props` file with one entry on each line. For example, to delete all JavaServer Pages (`.jsp` files) from the `my.war` file, include the line `.*jsp` in the `my.war/META-INF/ibm-partialapp-delete.props` file. The line uses a regular expression, `.*jsp`, to identify all `.jsp` files in `my.war`.

You can use a single partial application file to add, delete and update multiple files.

After you specify a file system path, click **Next**.

After a partial application update, when configuration changes are saved, the new or updated application file is stored in the deployed application in the WebSphere Application Server configuration repository. When these changes are synchronized with the node, the files are added or updated to the node's file system. Because the partial application option updates multiple files, the application components that are restarted are determined using individual files in the partial application.

An example of entries in a partial application compressed file follows:

```
util.jar
META-INF/ibm-partialapp-delete.props
foo.jar/com/mycomp/xyz.class
xyz.war/welcome.jsp
xyz.war/WEB-INF/web.xml
webmod.war/META-INF/ibm-partialapp-delete.props
```

For this example, the `META-INF/ibm-partialapp-delete.props` file contains the `.*.dat` and `tools/test.jar` files. The `webmod.war/META-INF/ibm-partialapp-delete.props` file contains the `com/test/.*.jsp` and `WEB-INF/test.xmi` files.

The partial application update option does the following:
- Adds or replaces `util.jar` in the deployed application.
- Adds or replaces `com/mycomp/xyz.class` inside the `foo.jar` file of the deployed application.
- Deletes `*.dat` files from the application, but not from any modules.
- Deletes `tools/test.jar` from the application.
- Adds or replaces `welcome.jsp` inside the `xyz.war` module of the deployed application.
- Replaces `WEB-INF/web.xml` inside the `xyz.war` module of the deployed application.
- Deletes `com/test/*.jsp` from the `webmod.war` module.
- Deletes `WEB-INF/test.xmi` from the `webmod.war` module.

Hot deployment and dynamic reloading

You can make various changes to applications and their modules without having to stop the server and start it again. Making these types of changes is known as *hot deployment and dynamic reloading*.

This topic assumes that your application files are deployed on a server and you want to upgrade the files.

See "Ways to update application files" on page 1420 and determine whether hot deployment is the appropriate way for you to update your application files. Other ways are easier and hot deployment is appropriate only for experienced users.

Important: Do not use hot deployment to update components in a production deployment manager managed cell. Hot deployment is well-suited for development and testing, but poses unacceptable risks to production environments. Full or partial resynchronization might erase hot deployed components. Also, running the `restoreconfig` command might overwrite changes made to expanded application files. Further, hot deployed components are not migrated between versions of WebSphere Application Server. To add new components or modules to an enterprise application, reassemble the application EAR file so it has the new components or modules and then redeploy the EAR file.

Hot deployment is the process of adding new components (such as WAR files, EJB Jar files, enterprise Java beans, servlets, and JSP files) to a running server without having to stop the application server process and start it again.

Dynamic reloading is the ability to change an existing component without needing to restart the server in order for the change to take effect. Dynamic reloading involves:

- Changes to the implementation of a component of an application, such as changing the implementation of a servlet
- Changes to the settings of the application, such as changing the deployment descriptor for a Web module

As opposed to the changes made to a deployed application described in "Updating applications" on page 1420, changes made using hot deployment or dynamic reloading do not use the administrative console or a wsadmin scripting command. You must directly manipulate the application files on the server where the application is deployed.

If the application you are updating is deployed on a server that has its application class loader policy set to `Single`, you might not be able to dynamically reload your application. At minimum, you must restart the server after updating your application.

1. Locate your expanded application files.

   The application files are in the directory you specified when installing the application or, if you did not specify a custom target directory, are in the default target directory, *app_server_root*/`installedApps/`*cell_name*. Your EAR file, `${APP_INSTALL_ROOT}/`*cell_name*/*application_name*.`ear`, points to the target directory. The `variables.xml` file for the node defines `${APP_INSTALL_ROOT}`.

   It is important to locate the expanded application files because, as part of installing applications, a WebSphere application server unjars portions of the EAR file onto the file system of the computer that will run the application. These expanded files are what the server looks at when running your application. If you cannot locate the expanded application files, look at the binariesURL attribute in the `deployment.xml` file for your application. The attribute designates the location the run time uses to find the application files.

   For the remainder of this information on hot deployment and dynamic reloading, *application_root* represents the root directory of the expanded application files.

2. Locate application metadata files. The metadata files include the deployment descriptors (`web.xml`, `application.xml`, `ejb-jar.xml`, and the like), the bindings files (`ibm-web-bnd.xmi`, `ibm-app-bnd.xmi`, and the like), and the extensions files (`ibm-web-ext.xmi`, `ibm-app-ext.xmi`, and the like).

   Metadata XML files for an application can be loaded from one of two locations. The metadata files can be loaded from the same location as the application binary files (such as *application_root*/`META-INF`) or they can be loaded from the WebSphere configuration tree, `${CONFIG_ROOT}/cells/`*cell_name*/ `applications ` /*application_EAR_name*/`deployments/`*application_name*/. The value of the useMetadataFromBinary flag specified during application installation controls which location is used. If specified, the metadata files are loaded from the same location as the application binary files. If not specified, the metadata files are loaded from the application deployment folder in the configuration tree.

   For the remainder of this information, *metadata_root* represents the location of the metadata files for the specified application or module.

3. **Required:** If you are running WebSphere Application Server on a group of machines using Network Deployment and you are changing an application on a particular node, disable automatic synchronization.

   a. Click **System administration > Node agents >** *node_agent_name* **> File synchronization service** in the console navigation tree.

   b. On the File synchronization service page, clear the check box for **Automatic synchronization** and click **OK**.

   When you run WebSphere Application Server on a group of machines using Network Deployment and you change a file on the disk in the expanded application directory for a particular node, you can lose those changes the next time node synchronization occurs. In the Network Deployment environment, the configuration stored by the deployment manager is the master copy and any changes detected between that master copy and the copy on a particular machine trigger the master copy to be downloaded to the node.

4. **Optional:** Examine the values specified for **Reload classes when application files are updated** and **Polling interval for updated files** on the settings page for your application's class loader.

   If reloading of classes is enabled and the polling interval is greater than zero (0), the application files are reloaded after the application is updated. For JavaServer Pages (JSP) files in a Web module, a Web container reloads JSP files only when the IBM extension jspReloadingEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`. You can set jspReloadingEnabled to `true` when editing your Web module's extended deployment descriptors in an assembly tool.

5. Change or add the following components or modules as needed:
   - Application files
   - WAR files
   - EJB Jar files
   - HTTP plug-in configuration files

6. For changes to take effect, you might need to start, stop, or restart an application. "Starting or stopping applications" on page 1416 provides information on using the administrative console to start, stop, or restart an application. Starting applications with scripting and Stopping applications with scripting provide information on using the wsadmin scripting tool.

7. If you disabled automatic synchronization in step 3, enable automatic synchronization again:

   a. Return to the File synchronization service page.

   b. Select **Automatic synchronization**.

   c. Click **OK**.

Changing or adding application files

You can change or add application files on application servers without having to stop the server and start it again.

There are several changes that you can make to deployed application files without stopping the server and starting it again.

Important: See "Ways to update application files" on page 1420 and determine whether hot deployment is the appropriate way for you to update your application files. Other ways are easier and hot deployment is appropriate only for experienced users. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server.

This topic describes how to make the following changes by manipulating an application file on the server where the application is deployed:
- Updating an existing application on a running server, providing a new enterprise application (EAR file)
- Adding a new application to a running server
- Removing an existing application from a running server
- Changing or adding files to existing enterprise bean (EJB) or Web modules
- Changing the `application.xml` file for an application
- Changing the `ibm-app-ext.xmi` file for an application
- Changing the `ibm-app-bnd.xmi` file for an application
- Changing a non-module Jar file contained in the EAR file

Updating an existing application on a running server (providing a new EAR file)

Reinstall an updated application using the administrative console or the wsadmin `$AdminApp install` command with the `-update` option.

Both reinstallation methods enable you to update an existing application using any of the other steps listed in this file, including changing classes, adding modules, removing modules, changing modules, or changing metadata files. The application reinstallation methods detect the changes in your application and prompt you for additional binding data that might be needed to install the application. The reinstallation process automatically stops and restarts your application on the appropriate servers.

Hot deployment   Yes
Dynamic reloading   Yes

Adding a new application to a running server

Install an application using the administrative console or the wsadmin `install` command.

Hot deployment   Yes
Dynamic reloading   No

Removing an existing application from a running server

Stop the application and then uninstall it from the server. Use the administrative console to stop the application and then uninstall it. Or run the wasadmin `stopApplication` command and then the `uninstall` command.

Hot deployment   Yes
Dynamic reloading   No

Changing or adding files to existing EJB or Web modules
1. Update the application files in the *application_root* location.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Yes
Dynamic reloading   No

Changing the application.xml file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Not applicable
Dynamic reloading   Yes

Changing the ibm-app-ext.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Not applicable
Dynamic reloading   Yes

Changing the ibm-app-bnd.xmi file for an application

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Not applicable
Dynamic reloading   Yes

Changing a non-module Jar file contained in the EAR file
1. Update the non-module Jar file in the *application_root* location.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

   If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Yes

Changing or adding WAR files

You can change Web application archives (WAR files) on application servers without having to stop the server and start it again.

There are several changes that you can make to WAR files without stopping the server and starting it again.

Important: See "Ways to update application files" on page 1420 and determine whether hot deployment is the appropriate way for you to update your WAR files. Other ways are easier and hot deployment is appropriate only for experienced users. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server.

This topic describes how to make the following changes by manipulating a WAR file on the server where the application is deployed:
- Changing an existing JavaServer Pages (JSP) file
- Adding a new JSP file to an existing application
- Changing an existing servlet class (editing and recompiling)
- Changing a dependent class of an existing servlet class
- Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application
- Adding a new servlet, including a new definition of the servlet in the `web.xml` deployment descriptor for the application
- Changing the `web.xml` file of a WAR file
- Changing the `ibm-web-ext.xmi` file of a WAR file
- Changing the `ibm-web-bnd.xmi` file of a WAR file

Changing an existing JSP file

Place the changed JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The change will be automatically detected and the JSP will be recompiled and reloaded.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new JSP file to an existing application

Place the new JSP file directly in the *application_root*/*module_name* directory or the appropriate subdirectory. The new file will be automatically detected and compiled on the first request to the page.

Hot deployment	Yes
Dynamic reloading	Yes

Changing an existing servlet class (editing and recompiling)

1. Place the new version of the servlet `.class` file directly in the *application_root*/*module_name*/WEB-INF/`classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root*/*module_name*/WEB-INF/`lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

    If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing a dependent class of an existing servlet class
1. Place the new version of the dependent `.class` file directly in the *application_root*/*module_name*/WEB-INF/`classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root*/*module_name*/WEB-INF/`lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

    If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Not applicable
Dynamic reloading	Yes

Adding a new servlet using the Invoker (Serve Servlets by class name) facility or adding a dependent class to an existing application
1. Place the new `.class` file directly in the *application_root*/*module_name*/WEB-INF/`classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root*/*module_name*/WEB-INF/`lib`. In either case, the change will be detected, the Web application will be shut down and reinitialized, picking up the new class.

    This case is treated the same as changing an existing class. The difference is that adding the servlet or class does not immediately cause the Web application to reload because the class has never been loaded before. The class simply becomes available for execution.
2. If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

    If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

Hot deployment	Yes
Dynamic reloading	Not applicable

Adding a new servlet, including a new definition of the servlet in the web.xml deployment descriptor for the application
1. Place the new `.class` file directly in the *application_root*/*module_name*/WEB-INF/`classes` directory. If the `.class` file is part of a Jar file, you can place the new version of the Jar file directly in *application_root*/*module_name*/WEB-INF/`lib`.

    You can edit the `web.xml` file in place or copy it into the *application_root*/*module_name*/WEB-INF/`classes` directory. The new `.class` file will not trigger a reloading of the application.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands. After the application restarts, the new servlet is available for service.

| **Hot deployment** | Yes |
| **Dynamic reloading** | Not applicable |

Changing the web.xml file of a WAR file
1. Edit the `web.xml` file in place or copy it into the *metadata_root*/*module_name*/`WEB-INF` directory.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

| **Hot deployment** | Yes |
| **Dynamic reloading** | Yes |

Changing the ibm-web-ext.xmi file of a WAR file

Edit the extension settings as needed. You can change all of the extension settings. The only warning is if you set the reloadInterval property to zero (0) or the reloadEnabled property to `false`, the application no longer automatically detects changes to class files. Both of these changes disable the automatic reloading function. The only way to re-enable automatic reloading is to change the appropriate property and restart the application. See other task descriptions in this file for information on restarting an application.

| **Hot deployment** | Not applicable |
| **Dynamic reloading** | Yes |

Changing the ibm-web-bnd.xmi file of a WAR file
1. Edit the bindings as needed. You can change all of the values but ensure that the entities you are binding to are present in the configuration of the server.
2. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

| **Hot deployment** | Not applicable |
| **Dynamic reloading** | Yes |

Changing or adding EJB Jar files
You can change enterprise bean (EJB) Jar files on application servers without having to stop the server and start it again.

There are several changes that you can make to EJB Jar files without stopping the server and starting it again.

Important: See "Ways to update application files" on page 1420 and determine whether hot deployment is the appropriate way for you to update your EJB Jar files. Other ways are easier and hot deployment is appropriate only for experienced users. You can use the update wizard of the administrative console to make the changes without having to stop and restart the server.

This topic describes how to make the following changes by manipulating an EJB file on the server where the application is deployed:
- Changing the `ejb-jar.xml` file of an EJB Jar file
- Changing the `ibm-ejb-jar-ext.xmi` or `ibm-ejb-jar-bnd.xmi` file of an EJB Jar file
- Changing the `Table.ddl` file for an EJB Jar file
- Changing the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file
- Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file
- Updating the Home/Remote interface class for an EJB file
- Adding a new EJB file to an existing EJB Jar file

Changing the ejb-jar.xml file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Change the ibm-ejb-jar-ext.xmi or ibm-ejb-jar-bnd.xmi file of an EJB Jar file

Restart the application. Automatic reloading will not detect the change. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Changing the Table.ddl file for an EJB Jar file

Rerun the DDL file on the user database server. Changing the `Table.ddl` file has no effect on the application server and is a change to the database table schema for the EJB files.

Hot deployment	Not applicable
Dynamic reloading	Not applicable

Changing the Map.mapxmi or Schema.dbxmi file for an EJB Jar file
1. Change the `Map.mapxmi` or `Schema.dbxmi` file for an EJB Jar file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. Restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Updating the implementation class for an EJB file or a dependent class of the implementation class for an EJB file
1. Update the class file in the *application_root/module_name*.jar file.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application of which the EJB file is a member. If the updated module is used by other modules in other applications, restart those applications as well. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment	Not applicable
Dynamic reloading	Yes

Updating the Home/Remote interface class for an EJB file
1. Update the interface class of the EJB file.
2. Regenerate the deployed code artifacts for the EJB file.
3. Apply the new EJB Jar file to the server.
4. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

If automatic reloading is not enabled, restart the application of which the EJB file is a member. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Not applicable
Dynamic reloading   Yes

Adding a new EJB file to an existing EJB Jar file
1. Apply the new or updated Jar file to the *application_root* location.
2. If automatic reloading is enabled, you do not need to take further action. Automatic reloading will detect the change.

   If automatic reloading is not enabled, restart the application. Use the administrative console to restart the application. Or run the wasadmin `stopApplication` and `startApplication` commands.

Hot deployment   Yes
Dynamic reloading   Yes

Changing the HTTP plug-in configuration
You can change the HTTP plug-in configuration without having to stop the server and start it again.

There are several change that you can make to the HTTP plug-in configuration without stopping the server and starting it again.

Important: See "Ways to update application files" on page 1420 and determine whether hot deployment is the appropriate way for you to update your HTTP plug-in configuration. Other ways are easier and hot deployment is appropriate only for experienced users.

This file describes--
* Changing the `application.xml` file to change the context root of a Web application archive (WAR file)
* Changing the `web.xml` file to add, remove, or modify a servlet mapping
* Changing the `server.xml` file to add, remove, or modify an HTTP transport or changing the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias

Changing the application.xml file to change the context root of a WAR file
1. Change the `application.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the `application.xml` file changes. (See Web server plug-in properties settings for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment   Yes
Dynamic reloading   No

Changing the web.xml file to add, remove, or modify a servlet mapping
1. Change the `web.xml` file.
2. If the plug-in configuration property Automatically propagate plug-in configuration file is selected for this plug-in, it is automatically regenerated whenever the `web.xml` file changes. (See Web server plug-in properties settings for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

   If the Web application has file serving enabled or has a servlet mapping of /, the plug-in configuration does not have to be regenerated. In all other cases a regeneration is required.

Hot deployment   Yes
Dynamic reloading   Yes

Changing the server.xml file to add, remove, or modify an HTTP transport or changing the virtualhost.xml file to add or remove a virtual host or to add, remove, or modify a virtual host alias

1. Change the `server.xml` file to add, remove, or modify an HTTP transport or change the `virtualhost.xml` file to add or remove a virtual host or to add, remove, or modify a virtual host alias.

2. If the plug-in configuration property **Automatically propagate plug-in configuration file** is selected for this plug-in, it is automatically regenerated whenever the `server.xml` file changes. (See Web server plug-in properties settings for information on how to set this property.) You can also run the `GenPluginCfg.bat/sh` script, or issue a wsadmin command to regenerate the plug-in configuration file.

Hot deployment   Yes
Dynamic reloading   Yes

Uninstalling applications

After an application no longer is needed, you can uninstall it.

Uninstalling an application deletes the application from the WebSphere Application Server configuration repository and it deletes the application binaries from the file system of all nodes where the application modules are installed.

1. Click **Applications > Enterprise Applications** in the administrative console navigation tree to access the Enterprise Applications page.

2. If you need to retain a copy of the application, back up the application.

    a. Select the application you want uninstalled.

    b. Click **Export**.

    The application is exported to an enterprise application (`.ear` file), preserving the binding information.

3. Uninstall the application.

    a. Select the application you want uninstalled.

    b. Click **Uninstall**.

4. Save changes made to the administrative configuration.

Application binaries are deleted when configuration changes on the deployment manager synchronize with configurations for individual nodes.

Removing a file

After a file is no longer needed, you can remove the file from an application or module deployed on a server.

Removing a file deletes the file from the WebSphere Application Server configuration repository and it deletes the file from the file system of all nodes where the file is installed.

- Remove a file from an application.

    1. Go to the Enterprise Applications page. Click **Applications > Enterprise Applications** in the console navigation tree.

    2. Select the application that contains a file you want removed.

    3. Click **Remove File**. The Remove a file page is displayed

    4. Select the URI of the file that you want removed from the application.

    5. Back up the application.

        Under **Export before removing file**, select the application name and then specify the location to which you want the file exported.

6. Click **OK** to remove the file.
- Remove a file from a module.
  1. Go to the Manage modules page.

     Click **Applications > Enterprise Applications >** *application_name* **> Manage modules** in the console navigation tree.
  2. Select the module from which you want to delete a file.
  3. Click **Remove File**. The Remove a file from a module page is displayed.
  4. Select the URI of the file that you want removed from the module.
  5. Back up the application.

     Under **Export before removing file**, select the application name and then specify the location to which you want the file exported.
  6. Click **OK** to remove the file.

The file is exported to the designated location and removed from the application or module. The application or standalone Web module that had a file removed is restarted so the changes take effect.

If the application or module is deployed on a cluster and you have no more configuration changes to make, click **Rollout Update** on the Enterprise Applications page to propagate the changed configuration on all cluster members of the cluster on which the application or module is deployed. **Rollout Update** sequentially updates the configuration on the nodes that contain cluster members.

Save the changes to your administrative configuration. Application binaries are deleted when configuration changes on the deployment manager synchronize with configurations for individual nodes.

Common deployment framework

The *common deployment framework* enables you to implement plug-ins that add steps to default Java 2 Platform, Enterprise Edition (J2EE) application management operations such as install, uninstall, edit and update.

Using the framework, you can implement management operations on specific types of deployable contents. For example, the deployable contents might include EAR, WAR, JAR or other J2EE modules and the management operations might include install and uninstall. Each operation is divided into a number of steps. For example, the install operation has steps for EJBDeploy and JavaServer Pages (JSP) compilation, among others. Using the common deployment framework, you can add steps to the default logic for J2EE operations.

Version 6.1 supports framework plug-ins that extend deployment of EAR files. An EAR file has operations such as createEarWrapper, installApplication, uninstallApplication and editApplication. Using a framework plug-in, you can add steps to default install operations that support, for example, creating additional configuration artifacts in a configuration session, modifying an input EAR file using code generation, or additional validating of input parameters.

To extend application management operations using the framework, a plug-in must do the following:
- Implement each step.

  A *step* runs logic that performs an operation. A step can access the deployment context and the deployable object. The *deployment context* provides information such as the operation name, the configuration session identifier, the temporary location for creating temporary files, operations parameters, and the like. A step is added by the extension provider.
- Implement an extension provider that adds each implemented step.

  An *extension provider* is a class that provides steps for an operation on a given type. For Version 6.1, it is the EAR file type.

- Register the plug-in with a WebSphere Application Server server.

  The plug-in is implemented as an Eclipse plug-in and is placed in *app_server_root*/`plugins` directory. Add the extension point for the extension provider in the `META-INF/plugin.xml` file within the plug-in JAR file.

For an example of these steps, refer to Extending application management operations through programming.

Deploying and administering applications: Resources for learning

Use the following links to find relevant supplemental information about deploying and administering applications using the administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Refer to "Web resources for learning" on page 15 for links to information applicable to WebSphere Application Server generally, such as lists of IBM technical papers, Redbooks and samples.

View links to additional information about:
- "Programming model and decisions"
- "Programming instructions and examples"
- "Administration"

Programming model and decisions

Chapter 10. Troubleshooting deployment

- Select the problem you are having with deploying or installing developed code for WebSphere Application Server.
  - Errors or problems deploying, installing, or promoting applications
  - Class loader exceptions
- To troubleshoot other deployment issues, use the following resources.
  - For current information available from IBM Support on known problems and their resolution, see the IBM Support page.
  - IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.
  - If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

Errors or problems deploying, installing, or promoting applications

This topic describes problems that you might encounter when deploying, installing, or promoting applications and suggests ways to resolve the problems.

What kind of problem are you having?
- "I installed my application using the wsadmin tool, but the application does not display under Applications > Enterprise Applications " on page 1442
- "Unable to save a deployed application" on page 1442
- "I get a java.lang.RuntimeException: Failed_saving_bytes_to_wor_ERROR_ error in the assembly tool, administrative console or the wsadmin tool." on page 1442
- "WASX7015E error running wsadmin command $AdminApp installInteractive or $AdminApp install" on page 1443
- "Data definition language (DDL) generated by an assembly tool throws SQL error on target platform " on page 1443
- "Error message ADMA0004E: Validation error in task Specifying the Default Datasource for EJB Modules returned when installing application using the administrative console or the wsadmin tool" on page 1443
- "Cannot load resource WEB-INF/ibm-web-bnd.xmi in archive file" on page 1444
- "Error message No valid target is specified in ObjectName anObject for module module_name from installation " on page 1444
- "addNode -includeapps option does not appear to upload all applications to the deployment manager" on page 1445
- ""Timeout!!!" error displays when attempting to install an enterprise application in the administrative console " on page 1445
- "I get a NameNotFoundException message when deploying an application that contains an EJB module" on page 1445
- "During application installation, the call to EJB deploy throws an exception" on page 1445
- "I get compilation errors and EJB deploy fails when installing an EJB JAR file generated for Version 5.x or earlier" on page 1445
- "While uploading documents, addNode -includeapps fails with an OutOfMemoryError exception" on page 1446

Check the following first:
- Verify that the logical name that you have specified to appear on the console for your application, enterprise bean module or other resource does not contain invalid characters such as these: - / \ : * ? " < > |.

- If the application was installed using the wsadmin $AdminApp install command with the **-local** flag, restart the server or rerun the command without the `-local` flag.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, check to see if the problem is identified and documented by looking at available online support including hints and tips, technotes, and fixes. If the problem has not been identified, see Troubleshooting help from IBM.

I installed my application using the wsadmin tool, but the application does not display under Applications > Enterprise Applications

The application might be installed but you have not saved the configuration:
1. Verify that the application subdirectory is located under the *app_server_root*/installedApps directory.
2. Run the $AdminApp list command and verify that the application is not among those displayed.
   - In the bin directory, run the wsadmin.bat or wsadmin.sh command.
   - From the wsadmin prompt, enter `$AdminApp list` and verify that the problem application is not among the items that display.
3. Reinstall your application using the wsadmin tool. Run the $AdminConfig save command in the wsadmin tool before exiting.

Unable to save a deployed application

If you are unable to save a deployed application, the problem might be that too many files are opened, exceeding the limit of the operating system.

On the SuSE9 or other Linux platform, you can either increase the number of files that can be opened to resolve the problem or you can modify the application to close files with disciplines. To increase the number of files that you can open at the same time, run the following command in the shell before invoking the process that needs to open a number of files:

```
ulimit -n number_of_files
```

Only root has authority to adjust the maximum number of files for each process. Complete the following steps to modify the application to close files with disciplines:

1. After you open a file and complete your work, call the close method of the file to release the file handle back to the operating system.

2. Using the java.io.FileInputStream and the FileOutputStream classes as examples, you can invoke their close method to release any system resources that are associated with the stream.

I get a `java.lang.RuntimeException: Failed_saving_bytes_to_wor_ERROR_` error in the assembly tool, administrative console or the wsadmin tool.

If you see this error when attempting to generate deployed code in an assembly tool, installing an application or module in the administrative console, or using the wsadmin tool to install an application or module, the file path length of the temporary system file might be exceeded. This situation is typically an issue only on Windows platforms.

To verify this problem, check the `TEMP` and `TMP` environment variables for your system. Long environment variables add path length to the file names accessed by the EJB deployment tool.

To resolve the problem:
1. Stop all WebSphere Application Server processes and close all DOS prompts.
2. Set the `TMP` and `TEMP` environment variables to something short, for example `C:\TMP` and `C:\TEMP`.
3. Reinstall the application.

Otherwise, try rebooting and redeploying or reinstalling the application.

WASX7015E error running wsadmin command `$AdminApp installInteractive` or `$AdminApp install`

This problem has two possible causes:
* If the full text of the error is similar to:

```
WASX7015E: Exception running command: "$AdminApp installInteractive C:/Documents and Settings/
myUserName/Desktop/MyApp/myapp.ear"; exception information:
com.ibm.bsf.BSFException: error while
eval'ing Jacl expression: can't find method "installInteractive"
with 3 argument(s) for class
"com.ibm.ws.scripting.AdminAppClient"
```

  The file and path name are incorrectly specified. In this case, since the path included spaces, it was interpreted as multiple parameters by the wsadmin program.

  Enter the path of the `.ear` file correctly. In this case, by enclosing it in double quotes:

```
$AdminApp installInteractive "C:\Documents
and Settings\myUserName\Desktop\MyApps\myapp.ear"
```

* If the full text of the error is similar to:

```
WASX7015E: Exception running command: "$AdminApp installInteractive c:\MyApps\myapp.ear ";
exception information: com.ibm.ws.scripting.ScriptingException:  WASX7115E:
Cannot read input file
"c:\WebSphere\AppServer\bin\MyAppsmyapp.ear"
```

  The application path is incorrectly specified. In this case, you must use ″forward-slash″ (/) separators in the path.

Data definition language (DDL) generated by an assembly tool throws SQL error on target platform

If you receive SQL errors in attempting to execute data definition language (DDL) statements generated by an assembly tool on a different platform, for example if you are deploying a container-managed persistence (CMP) enterprise bean designed on Windows onto a UNIX operating system server, try the following actions:
* Browse the DDL statements for dependencies on specific user identifiers and passwords, and correct as necessary.
* Browse the DDL statements for dependencies on specific server names, and correct as necessary.
* Refer to the message reference of the vendor for causes and suggested actions regarding specific SQL errors. For IBM DB2, you can view the message references online at http://www.ibm.com/cgi-bin/db2www/data/db2 /udb/winos2unix/support/index.d2w/report.

If you receive the following error after executing a DDL file created on the Windows operating system or on operating systems such as AIX or Linux, the problem might come from a difference in file formats:

```
SQL0104N  An unexpected token "CREATE TABLE AGENT  (COMM DOUBLE,  PERCENT  DOUBLE,  P"
was found following "       ".  Expected tokens may include:  " ".
SQLSTATE=42601
```

To resolve this problem:
* For operating systems other than Linux, edit the DDL in the vi editor, removing the Ctl-M character at the beginning of each line.
* For Linux systems, regenerate the deployment code for the application `EAR` file on a Linux platform.

Error message `ADMA0004E: Validation error in task Specifying the Default Datasource for EJB Modules` returned when installing application using the administrative console or the wsadmin tool

If you see the following error when trying to install an application through the administrative console or the wsadmin command prompt:

```
AppDeploymentException: [ADMA0014E: Validation failed.
ADMA0004E: Validation error in task Specifying the Default Datasource for
EJB Modules  JNDI name is not
specified for module beannameBean Jar with URI filename.jar,META-INF/ejb-jar.xml.
You have not specified the
data source for each CMP bean belonging to this module. Either specify the data
source for each CMP beans or
specify the default data source for the entire module.]
```

one possible cause is that in WebSphere Application Server version 4.0, it was mandatory to have a data source defined for each CMP bean in each JAR. In versions 5.0 and later releases, you can specify either a data source for a container-managed persistence (CMP) bean or a default data source for all CMP beans in the JAR file. Thus during installation interaction, such as the installation wizard in the administrative console, the data source fields are optional, but the validation performed at the end of the installation checks to see that at least one data source is specified.

To correct this problem, step through the installation again, and specify either a default data source or a data source for each CMP-type enterprise bean. If you are using the wsadmin tool:
- Use the `$AdminApp installInteractive` *filename* command to receive prompts for data sources during installation, or to provide them in a response file.
- Specify data sources as an option to the `$AdminApp install` command. For details on the syntax, see Installing applications with the wsadmin tool.

Cannot load resource `WEB-INF/ibm-web-bnd.xmi` in archive file

The Web application `tmp.war` installs on WebSphere Application Server versions 5.0 and 5.1, but fails on a WebSphere Application Server version 6 server. The application fails to install because the `WEB-INF/ibm-web-bnd.xmi` file contains `xmi` tags that the underlying WCCM model no longer recognizes.

The following error messages display:
```
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
[2/24/05 14:53:10:297 CST] 000000bc SystemErr     R
AppDeploymentException:
com.ibm.etools.j2ee.commonarchivecore.exception.ResourceLoadException:
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
[2/24/05 14:53:10:297 CST] 000000bc SystemErr     R
com.ibm.etools.j2ee.commonarchivecore.exception.ResourceLoadException:
IWAE0007E Could not load resource "WEB-INF/ibm-web-bnd.xmi" in archive "tmp.war"
!Stack_trace_of_nested_exce!
com.ibm.etools.j2ee.exception.WrappedRuntimeException: Exception occurred loading
WEB-INF/ibm-web-bnd.xmi
!Stack_trace_of_nested_exce!
```

To work around this problem, remove the `xmi:type=EJBLocalRef` tag from the `ibm-web-bnd.xmi` file. Removing this tag does not affect the application because the tag was previously used for matching the cross document reference type. The application now works for the WebSphere Application Server v5.1, v6.0, and later releases.

Error message `No valid target is specified in ObjectName` *anObject* `for module` *module_name* `from installation`

This error can occur in a clustered environment if the target cell, node, server or cluster into which the application is to be installed is incorrectly specified. For example, it can occur if the target is misspelled.

To correct this problem, check the target names against the actual WebSphere Application Server topology and reenter them with corrections.

addNode -includeapps option does not appear to upload all applications to the deployment manager

This error can occur when some or all applications on the target node are already uploaded to the deployment manager. The addNode program detects which applications are already installed and does not upload them again.

Use the administrative console to browse the deployment manager configuration and see the applications that are already installed.

″Timeout!!!″ error displays when attempting to install an enterprise application in the administrative console

This error can occur if you attempt to install an enterprise application that has not been deployed.

To correct this problem:
* Open the *file_name*.ear file in an assembly tool and then click **Deploy**. This action creates a file with a name like Deployed_*file_name*.ear.
* In the administrative console, install the deployed .ear file.

I get a NameNotFoundException message when deploying an application that contains an EJB module

If you specify that EJB deploy be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input JAR or EAR file does not contain source files. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

To work around this problem, either remove the source files or include all dependent classes and resource files on the class path. Otherwise, the source files or the lack of access to dependent classes and resource files might cause problems during rebuilding of your application on the server.

During application installation, the call to EJB deploy throws an exception

When you specify that the EJB deployment tool be run during application installation and if installation fails with the error command line too long, the problem is that the deployment command generated during installation exceeds the character limit for a command line on the Windows platform. This problem occurs only on Windows platforms.

To work around this problem, you can reduce the length of the EAR file name, reduce the length of the JAR file name within the EAR file, reduce the class path or other options specified for deployment, or change the %TEMP% location of the Windows system to make its path shorter.

I get compilation errors and EJB deploy fails when installing an EJB JAR file generated for Version 5.x or earlier

When installing an old application that uses EJB modules that were built to run on WebSphere Application Server Version 5.x or earlier, compilation errors result and EJB deploy fails. The EJB JAR file contains Java source for the old generated code. The old Java source was generated for Version 5.x or before but, when deployed to a WebSphere Application Server Version 6.x product, it is compiled using the Version 6.x run-time JAR files.

To work around this problem, remove all .java files from the application .ear file. After the Java source files are removed, you can deploy the application onto a server successfully.

While uploading documents, addNode -includeapps fails with an OutOfMemoryError exception

This error can occur when you use addNode -includeapps while you are installing applications with large EAR files. To correct this problem:

- If you are using addNode to add a node from the base server, modify the addNode script to include the following parameter:

  -Xmx_size_

- If you are adding a node from the administrative console, increase the _maximumHeapSize_ in the Java virtual machine settings of the deployment manager, then restart the deployment manager. See addNode command and Java virtual machine settings for details.

For example, the addNode.bat file that follows sets a maximum heap size of 512 MB on a Windows platform:

```
"%JAVA_HOME%\bin\java" -Xmx512m %DEBUG% %WAS_TRACE% %CONSOLE_ENCODING%
"%CLIENTSOAP%" "%CLIENTSAS%" "-classpath" "%WAS_CLASSPATH%"
"-Dws.ext.dirs=%WAS_EXT_DIRS%" %USER_INSTALL_PROP%
-Dwas.install.root=%WAS_HOME%" "com.ibm.ws.bootstrap.WSLauncher"
"com.ibm.ws.management.tools.NodeFederationUtility" "%CONFIG_ROOT%" "%WAS_CELL%"
"%WAS_NODE%" %*
```

Troubleshooting testing and first time run problems

Select the problem you are having with testing or the first run of deployed code for WebSphere Application Server:
- The server process does not start or starts with errors.
- "The application does not start or starts with errors" on page 1451.
- "A Web resource does not display" on page 1453.
- Cannot access a data source.
- "Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client" on page 151.
- Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client.
- Access problems after enabling security.
- Errors after enabling security.
- Errors after configuring or enabling Secure Sockets Layer.
- Errors in messaging.
- Errors returned to a client sending a SOAP request.
- A client program does not work.
- Errors connecting to WebSphere MQ and creating WebSphere MQ queue connection factory.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the Must gather documents page for information to gather to send to IBM Support page.

Errors starting an application

Use this information for troubleshooting problems that occur when starting an application.

What kind of error do you see when you start an application?
- "HTTP server and Application Server are working separately, but requests are not passing from HTTP server to Application Server"
- "File serving problems" on page 1448
- "Graphics do not appear in the JSP file or servlet output" on page 1448
- "SRVE0026E: [Servlet Error]-[Unable to compile class for JSP file" on page 1449
- "After modifying and saving a JSP file, the change does not show up in the browser (the old JSP file displays)" on page 1450
- "Message like ″Message: /jspname.jsp(9,0) Include: Mandatory attribute page missing″ appears when attempting to browse JSP file" on page 1450
- "The Java source generated from a JSP file is not retained in the temp directory (only the class file is found)" on page 1450
- "The JSP Batch Compiler fails with the message ″Enterprise Application [application name you typed in] not found.″" on page 1450
- "There is a translation problem with non-English browser input" on page 1450
- "Scroll bars do not appear around items in the browser window" on page 1451
- "Error ″Page cannot be displayed... server not found or DNS error″ appears when attempting to browse a JavaServer Pages (JSP) file using Internet Explorer" on page 1451

HTTP server and Application Server are working separately, but requests are not passing from HTTP server to Application Server

If your HTTP server appears to be functioning correctly, and the Application Server also works on its own, but browser requests sent to the HTTP server for pages are not being served, a problem exists in the WebSphere Application Server plug-in.

In this case:

1. Determine whether the HTTP server is attempting to serve the requested resource itself, rather than forwarding it to the WebSphere Application Server.
   a. Browse the HTTP server access log (*IHS install root*/logs/access.log for IBM HTTP Server). It might indicate that it could not find the file in its own document root directory.
   b. Browse the plug-in log file as described below.

2. Refresh the plugin-cfg.xml file that determines which requests sent to the HTTP server are forwarded to the WebSphere Application Server, and to which Application Server.

   Use the console to refresh this file:
   - In the WebSphere Application Server administrative console, expand the Environment tree control.
   - Click **Update WebSphere Plugin**.
   - Stop and restart the HTTP server.
   - Retry the Web request.

3. Browse the *plugin_install_root*/logs/*web_server_name*/http_plugin.log file for clues to the problem. Make sure the timestamps with the most recent plug-in information stanza, which is printed out when the plug-in is loaded, correspond to the time the Web server started.

4. Turn on plug-in tracing by setting the LogLevel attribute in the plugin-cfg.xml file to Trace and reloading the request. Browse the *plugin_install_root*/logs/*Web_server_name*/http_plugin.log file. You should be able to see the plug-in attempting to match the request URI with the various URI definitions for the routes in the plugin-cfg.xml. Check which rules the plug-in is not matching against and then figure out if you need to add additional ones. If you just recently installed the application you might need to manually regenerate the plug-in configuration to pick up the new URIs related to the new application.

For further details on troubleshooting plug-in-related problems, see Web server plug-in troubleshooting tips.

File serving problems

If text output appears on your JSP- or servlet-supported Web page, but image files do not:

- Verify that your files are in the right place: the **document root** directory of your Web application WebSphere Application Server follows the J2EE standard, which means that the document root is the *Web_module_name*.war directory of your deployed Web application.

  Typically this directory will be found in the *install_root*/installedApps/*nodename*/*appname*.ear directory or *install_root*/installedApps/*nodename*/*appname*Network.ear directory.

  If the files are in a subdirectory of the document root, verify that the reference to the file reflects that. That is, if the invoices.html file is stored in Windows directory *Web_module_name*.war\invoices, then links from other pages in the Web application to display it should read "invoices\invoices.html", not "invoices.html".

- Verify that your Web application is configured to enable file serving (in other words, that it is enabled to display static resources like image and .html files):
  1. View the file serving property of the hosting Web module by browsing the source .war file in an assembly tool. If necessary, update the property and redeploy the module.
  2. Edit the **fileServingEnabled** property in the deployed Web application ibm-web-ext.xmi configuration file.

     The file typically is found in the *install_root*/config/cells/*nodename* or *nodename*Network/ applications/*application_name*/deployments/*application name*/*Web_module_name*/web-inf directory.

Graphics do not appear in the JSP file or servlet output

If text output appears on your JSP- or -servlet-supported Web page, but image files do not:

- Verify that your graphic files are in the right place: the **document root** directory of your Web application. WebSphere Application Server Version 5 follows the J2EE standard, which means that the document root is the *Web_module_name*.war directory of your deployed Web application.

  Typically, this directory is found in the *install_root*/installedApps/*nodename*/*appname*.ear directory or *install_root*/installedApps/*nodename*/*appname*Network.ear directory.

  If the graphics files are in a subdirectory of the document root, verify that the reference to the graphic reflects that; for example, if the banner.gif file is stored in Windows directory *Web_module_name*.war/ images, the tag to display it should read: **<img SRC="images/banner.gif">**, not <img SRC="banner.gif">.

- Verify that your Web application is configured to enable file serving (that is, display of static resources like image and .html files).
  1. View the file serving property of the hosting Web module by browsing the source .war file in an assembly tool. If necessary, update the property and re-deploy the module.
  2. Edit the **fileServingEnabled** property in the deployed Web application ibm-web-ext.xmi configuration file.

     The file typically is found in the *install_root*/config/cells/*nodename* or *nodename*Network/ applications/*application_name*/deployments/*application name*/*Web_module_name*/web-inf directory.
  3. After completing the previous step:
     - In the administrative console, expand the **Environment** tree control .
     - Click **Update WebSphere Plugin**.
     - Stop and restart the HTTP server and retry the Web request.

SRVE0026E: [Servlet Error]-[Unable to compile class for JSP file

If this error appears in a browser when trying to access a new or modified .jsp file for the first time, the most likely cause is that the JSP file Java source failed (was incorrect) during the javac compilation phase.

Check the SystemErr.log file for a compiler error message, such as:

```
C:\WASROOT\temp\ ... test.war\_myJsp.java:14: \Duplicate variable declaration: int myInt was int myInt
int myInt = 122;
String myString = "number is 122";
static int myStaticInt=22;
int myInt=121;
       ^
```

Fix the problem in the JSP source file, save the source and request the JSP file again.

If this error occurs when trying to serve a JSP file that was copied from another system where it ran successfully, then there is something different about the new server environment that prevents the JSP file from running. Browse the text of the error for a statement like:

```
Undefined variable or class name: MyClass
```

This error indicates that a supporting class or jar file is not copied to the target server, or is not on the class path. Find the MyClass.class file, and place it on the Web module WEB-INF/classes directory, or place its containing .jar file in the Web module WEB-INF/lib directory.

Verify that the URL used to access the resource is correct by doing the following:

- For a JSP file, `html` file, or image file: **`http://host_name/Web_module_context_root/subdir under doc root, if any/filename.ext`**. The document root for a Web application is the `application_name`.WAR directory of the installed application.
  - For example, to access the myJsp.jsp file, located in c:\WebSphere\ApplicationServer\installedApps\ myEntApp.ear\myWebApp.war\invoices on myhost.mydomain.com, and assuming the context root for the myWebApp Web module is myApp, the URL is `http://myhost.mydomain.com/myApp/invoices/ myJsp.jsp`.
  - JSP serving is enabled by default. File serving for HTML and image files must be enabled as a property of the Web module, in an assembly tool, or by setting the **`fileServingEnabled`** property to **true** in the `ibm-web-ext.xmi` file of the installed Web application and restarting the application.
- For servlets served by class name, the URL is `http://hostname/Web_module_context_root/servlet/packageName.className`.

  For example, to access myCom.myServlet.class, located in c:\WebSphere\ApplicationServer\ installedApps\ myEntApp.ear\myWebApp.war\WEB-INF\classes, and assuming the context root for the myWebApp module is ″myApp″, the URL would be `http://myhost.mydomain.com/myApp/servlet/ myCom.MyServlet`.
- Serving servlets by class name must be enabled as a property of the Web module, and is enabled by default. File serving for HTML and image files must be enabled as a property of the Web application, in an assembly tool, or by setting the **`fileServingEnabled`** property to **true** in the **`ibm-web-ext.xmi`** file of the installed Web application and restarting the application.

Correct the URL in the ″from″ HTML file, servlet or JSP file. An HREF with no leading slash (/) inherits the calling resource context. For example:
- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to ″ServletB″ resolves to ″http://hostname/myapp/servlet/ServletB″
- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to ″servlet/ServletB″ resolves to ″http://hostname/myapp/servlet/servlet/ServletB″ (an error)
- an HREF in `http://[hostname]/myapp/servlet/MyServlet` to ″/ServletB″ resolves to ″http://hostname/ServletB″ (an error, if `ServletB` requires the same context root as `MyServlet`)

After modifying and saving a JSP file, the change does not show up in the browser (the old JSP file displays)

It is probable that the Web application is not configured for servlet reloading, or the reload interval is too high.

To correct this problem, in an assembly tool, check the **Reloading Enabled** flag and the **Reload Interval** value in the IBM Extensions for the Web module in question. Enable reloading, or if it is already enabled, then set the Reload Interval lower.

Message like ″Message: /jspname.jsp(9,0) Include: Mandatory attribute page missing″ appears when attempting to browse JSP file

It is probable that the JSP file failed during the translation to Java phase. Specifically, a JSP directive, in this case an Include statement, was incorrect or referred to a file that could not be found.

To correct this problem, fix the problem in the JSP source, save the source and request the JSP file again.

The Java source generated from a JSP file is not retained in the temp directory (only the class file is found)

It is probable that the JSP processor is not configured to keep generated Java source.

In an assembly tool, check the **JSP Attributes** under **Assembly Property Extensions** for the Web module in question. Make sure the **keepgenerated** attribute is there and is set to `true`. If not, set this attribute and restart the Web application. To see the results of this operation, delete the class file from the temp directory to force the JSP processor to translate the JSP source into Java source again.

The JSP Batch Compiler fails with the message ″Enterprise Application [application name you typed in] not found.″

It is probable that the full enterprise application path and name, starting with the `.ear` subdirectory that resides in the `applications` directory is expected as an argument to the JspBatchCompiler tool, not just the display name.

The directory path is *install_root*\config\cells*node_name*Network\applications.

For example:
- ″JspBatchCompiler -enterpriseapp.name sampleApp.ear/deployments/sampleApp″ is correct, as opposed to
- ″JspBatchCompiler -enterpriseapp.name sampleApp″, which is incorrect.

There is a translation problem with non-English browser input

If non-English-character-set browser input cannot be translated after being read by a servlet or JSP file, ensure that the request parameters are encoded according to the expected character set before reading. For example, if the site is Chinese, the target `.jsp` file should have a line:

```
req.setCharacterEncoding("gb2312");
```

before any req.getParameter method calls.

This problem affects servlets and `jsp` files ported from earlier versions of WebSphere Application Server, which converted characters automatically based upon the locale of the WebSphere Application Server.

Scroll bars do not appear around items in the browser window

In some browsers, tree or list type items that extend beyond their allotted windows do not have scroll bars to permit viewing of the entire list.

To correct this problem, right-click on the browser window and click **Reload** from the menu.

Error ″Page cannot be displayed... server not found or DNS error″ appears when attempting to browse a JavaServer Pages (JSP) file using Internet Explorer

This error can occur when an HTTP timeout causes the servant to be brought down and restarted. To correct this problem, increase the ConnectionIOTimeOut value:

1. From the administrative console, select **System administration > Deployment manager > Administration Services > Custom Properties**
2. Select ConnectionIOTimeOut.
3. Increase the ConnectionIOTimeOut value.
4. Click **OK**.

The application does not start or starts with errors

When an application is not starting or starting with errors, the problem could be from one of various sources.

What kind of error do you see when you start an application?
- A "java.lang.ClassNotFoundException: classname Bean_AdderServiceHome_04f0e027Bean" error occurs
- A "ConnectionFac E J2CA0102E: Invalid EJB component: Cannot use an EJB module with version 1.1 using The Relational Resource Adapter" on page 1452 error occurs
- "NMSV0605E: ″A Reference object looked up from the context...″ error when starting an application" on page 1452.
- "Deployed application that uses Java Native Interface (JNI) code does not start" on page 1453
- A parsing error when running an application that uses the JSF configuration occurs.

If none of these errors match the error you see:
- Browse the log files of the application server for this application looking for clues. By default, these files are: *install_dir*/logs/*server_name*/SystemErr.log and SystemOut.log.
- Look up any error or warning messages in the message reference table by clicking the Reference view and expanding the ″Messages″ heading.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

java.lang.ClassNotFoundException: *classname* Bean_AdderServiceHome_04f0e027Bean

An similar exception occurs when you try to start an undeployed application containing enterprise beans, or containing undeployed enterprise bean modules.

Enterprise JavaBeans modules created in an assembly tool intentionally have incomplete configuration information. Deploying these modules completes the configuration by reading the module's deployment descriptor and completing platform- or installation-dependent settings and adding related classes to the Enterprise JavaBeans JAR file.

To avoid this problem, do the following:

- Use an assembly tool and administrative console to generate deployment code and install the application or Enterprise JavaBeans module onto a server.
  1. Uninstall the application or Enterprise JavaBeans module in the administrative console.
  2. Configure your assembly tool so the target server is a WebSphere Application Server installation such as **WebSphere Application Server v6**. If you do not have access to the target server, you can specify a false location such as `c:\temp`. Specifying a false location enables you to assemble and generate deployment code for the enterprise bean.
  3. In the Project Explorer view of an assembly tool, right-click the enterprise bean (Enterprise JavaBeans) in the undeployed .ear file containing the Enterprise JavaBeans module or the standalone undeployed Enterprise JavaBeans JAR file, and click **Deploy**. If your assembly tool can access the WebSphere Application Server target server, deployment code is generated for the Enterprise JavaBeans and the assembly tool attempts to install the application or module onto the target server. If your assembly tool cannot access the WebSphere Application Server target server or the installation fails, use the deployment code that is generated for the next step.

     For information on using an assembly tool, refer to Chapter 7, "Assembling applications," on page 1345.
  4. Use the `wsadmin $AdminApp install` command or the administrative console to install the deployed version created by the assembly tool.
- If you use the `wsadmin $AdminApp install` command, uninstall it and then reinstall using the `-EJBDeploy` option. Follow the install command with the `$AdminConfig` save command.

ConnectionFac E J2CA0102E: Invalid EJB component: Cannot use an EJB module with version 1.1 using The Relational Resource Adapter

This error occurs when an enterprise bean developed to the Enterprise JavaBeans 1.1 specification is deployed with a WebSphere Application Server V5 J2C-compliant data source, which is the default data source. By default, persistent enterprise beans created under WebSphere Application Server V4.0's using the Application Assembly Tool fulfill the Enterprise JavaBeans 1.1 specification. To run on WebSphere Application Server V6, these enterprise beans must be associated with a WebSphere Application Server V4.0-type data source.

Either modify the mapping in the application of enterprise beans to associate 1.x container managed persistence (CMP) beans to associate them with a V4.0 data source or delete the existing data source and create a V4.0 data source with the same name.

To modify the mapping in the application of enterprise beans, in the WebSphere Application Server administrative console, select the properties for the problem application and use **map resource references to resources** or **Map data sources for all 1.x CMP beans** to switch the data source the enterprise bean uses. Save the configuration and restart the application.

To delete the existing data source and create a V4.0 data source with the same name:
1. In the administrative console, click **Resources**>**Manage JDBC Providers**>*JDBC_provider_name*>**Data sources**.
2. Delete the data source associated with the Enterprise JavaBeans 1.1 module.
3. Click **Resources**>**Manage JDBC Providers**>*JDBC_provider_name*>**Data sources (Version 4)**.
4. Create the data source for the Enterprise JavaBeans 1.1 module.
5. Save the configuration and restart the application.

NMSV0605E: ″A Reference object looked up from the context...″ error when starting an application

If the full text of the error is similar to:

```
[7/17/02 15:20:52:093 CDT] 5ae5a5e2 UrlContextHel W NMSV0605E: A Reference object looked up from the context
    "java:" with the name "comp/PM/WebSphereCMPConnectionFactory" was sent to the JNDI Naming Manager
    and an exception resulted. Reference data follows:
    Reference Factory Class Name: com.ibm.ws.naming.util.IndirectJndiLookupObjectFactory
```

```
        Reference Factory Class Location URLs:
        Reference Class Name: java.lang.Object
        Type: JndiLookupInfo
        Content: JndiLookupInfo: ; jndiName="eis/jdbc/MyDatasource_CMP"; providerURL=""; initialContextFactory=""
```

then the problem might be that the data source intended to support a CMP enterprise bean is not correctly associated with the enterprise bean.

To resolve this problem:
1. Select the **Use this Data Source in container managed persistence (CMP)** check box in the data source ″General Properties″ panel of the administrative console.
2. Verify that the JNDI Name given in administrative console under **Resources-> Manage JDBC Provider > DataSource > JNDI Name** for DataSource matches the JNDI Name given for CMP or BMP Resource Bindings at the time of assembling the application in an assembly tool, or
3. Check the JNDI Name for CMP or BMP resource bindings specified in the code by J2EE Application Developer. Open the deployed .ear folder in an assembly tool, and look for the JNDI Name for your entity beans under CMP or BMP resource bindings. Verify that the names match.

Deployed application that uses Java Native Interface (JNI) code does not start

An application that uses JNI code might not start after deployment. The JNI allows Java code running in a virtual machine to operate with applications and libraries written in other languages, such as C, C++, and assembly. If your J2EE application uses JNI in a 32-bit environment, you must recompile your code in a 64-bit environment. The JNI calls might be different after the compilation because JNI specifications can change from version to version. WebSphere Application Server now supports 64-bit environments.

For a ″pure″ Java application that does not use JNI code, 32-bit to 64-bit compatibility is not an issue.

Parsing error when running an application that uses the JSF configuration

If you are using double-byte characters in the profile name, you receive a parsing error when running an application that uses the JavaServer Faces™ (JSF) configuration. The problem is related to the JSF configuration that is part of the `jsf-ibm.jar`, which is included when building JSF applications in Rational® Application Development (RAD). The configuration files are referencing entities from inside the main `faces-config.xml` file.

Avoid using double-byte characters when you create a profile.

A Web resource does not display

If you are not able to display a resource in your browser, follow these steps:
1. Verify that your HTTP server is healthy by accessing the URL `http://server_name` from a browser and seeing whether the Welcome page appears. This action indicates whether the HTTP server is up and running, regardless of the state of WebSphere Application Server.
2. If the HTTP server Welcome page does not appear, that is, if you get a browser message like `page cannot be displayed` or something similar, try to diagnose your Web server problem.
3. If the HTTP server appears to function, the Application Server might not be serving the target resource. Try accessing the resource directly through the Application Server instead of through the HTTP server.

   If you cannot access the resource directly through the Application Server, Verify that the URL used to access the resource is correct.

   If the URL is incorrect and it is created as a link from another JSP file, servlet, or HTML file, try correcting it in the browser URL field and reloading, to confirm that the problem is a malformed URL. Correct the URL in the ″from″ HTML file, servlet or JSP file.

   If the URL appears to be correct, but you cannot access the resource directly through the Application Server, verify the health of the hosting Application Server and Web module:

a. View the hosting Application Server and Web module in the administrative console to verify that they are up and running.
b. Copy a simple HTML or JSP file (such as `SimpleJsp.jsp` in the WebSphere Application Server directory structure) to your Web module document root, and try to access it. If successful, the problem is with your resource.

   View the JVM log of your Application Server to find out why your resource cannot be found or served .
4. If you can access the resource directly through the Application Server, but not through an HTTP server, the problem lies with the HTTP plug-in -- the component that communicates between the HTTP server and the WebSphere Application Server.
5. If the JSP file and the servlet output are served, but not static resources such as `.html` and image files, see the steps for enabling file serving.
6. If some kinds of resources display correctly, but you cannot display a servlet by its class name:
   - Verify that the servlet is in a directory in the Web module class path, such as in the /*Web_module_name*.war/WEB-INF/classes directory.
   - Verify that you specify the full class name of the servlet, including its package name, in the URL.
   - Verify that `"/servlet"` precedes the class name in the URL. For example, if the root context of a Web module is `"myapp"`, and the servlet is `com.mycom.welcomeServlet`, then the URL reads:

     `http://hostname/myapp/servlet/com.mycom.welcomeServlet`
   - Verify that serving the servlets by class name is enabled for the hosting Web module by opening the source Web module in an assembly tool and browse the *serve servlets by classname* setting in the IBM Extensions property page. If necessary, enable this flag and redeploy the Web module.
   - For servlets or other resources served by mapped URLs, the URL is http://*hostname*/*Web module context root*/*mappedURL*.

If none of these steps fixes your problem, see if the problem has been identified and documented by looking at available online support (hints and tips, technotes, and fixes). If you do not find your problem listed there, see Troubleshooting help from IBM.

Diagnosing Web server problems

If you are unable to view the welcome page of your HTTP server, determine if the server is operating properly.

On Windows systems, look in the Services panel for the service corresponding to your HTTP server, and verify that the state is **Started**. If not, start it. If the service does not start, try starting it manually from the command prompt. If you are using IBM HTTP Server, the command is *IHS_install_dir*\apache .

On UNIX systems, execute the ps -ef | grep httpd command. There should be several processes running with a name of `"httpd"`. If not, start your HTTP server manually. If you are using IBM HTTP Server, the command is *IHS_install_dir*/bin/apachectl start.

If the HTTP server does not start:
- Examine the HTTP server error log for clues.
- Try restoring the HTTP server to its configuration prior to installing WebSphere Application Server and restarting it. If you are using IBM HTTP Server:
  – Rename the file *IHS_install_dir*\httpd.conf.
  – Copy the httpd.conf.default file to the httpd.conf directory.
  – If Apache is running, stop and restart it.
- For the Sun ONE (iPlanet) Web server, restore the obj.conf configuration file for Sun ONE V4.1 and both obj.conf and magnus.conf files for Sun ONE V6.0 and later.
- For the Microsoft Internet Information Server (IIS), remove the WebSphere Application Server plug-in through the IIS administrative GUI.

If restoring the HTTP server default configuration file works, manually review the configuration file that has WebSphere Application Server updates to verify directory and file names for WebSphere Application

Server files. If you cannot manually correct the configuration, you can uninstall and reinstall WebSphere Application Server to create a clean HTTP configuration file.

If restoring the default configuration file does not help, contact technical support for the Web server you are using. If you are using IBM HTTP Server with WebSphere Application Server, check available online support (hints and tips, technotes, and fixes). If you do not find your problem listed there, see Troubleshooting help from IBM

Accessing a Web resource through the application server and bypassing the HTTP server

Starting with WebSphere Application Server Version 4.0, you can bypass the HTTP server and access a Web resource through the application server. It is not recommended to serve a production Web site in this way, but it provides a good diagnostic tool when it is not clear whether a problem resides in the HTTP server, WebSphere Application Server, or the HTTP plug-in.

To access a Web resource through the Application Server:
1. Determine the port of the HTTP service in the target application server.
   a. In the WebSphere administrative console, click **Servers>Manage Application Servers**.
   b. Select the target server, then under Additional Properties click **Web Container**.
   c. Under the Additional Properties of the Web container, click **HTTP Transports**. You see the ports listed for virtual hosts served by the application server.
   d. There can be more than one port listed. In the default application server (server1), for example, 9060 is the port reserved for administrative requests, 9443 and 9043 are used for SSL-encrypted requests. To test the sample ″snoop″ servlet, for example, use the default application port 9080, unless it changes.
2. Use the HTTP transport port number of the application server to access the resource from a browser. For example, if the port is 9080, the URL is http://*hostname*:9080/myAppContext/myJSP.jsp.
3. If you are still unable to access the resource, verify that the HTTP transport port is in the ″Host Alias″ list:
   a. Click **Application Servers > Your_ApplicationServer > Web Container > HTTP Transports** to check the Default virtual host and the HTTP transport ports used by this application server.
   b. Click **Environment > Manage Virtual Hosts > default host > Host Aliases** to check if the HTTP transport port exists. Add an entry if necessary. For example, if the HTTP port for your application is server is 9080, add a host alias of *:9082.

Cannot uninstall an application or remove a node or application server

What kind of problem are you having?
- After uninstalling an application through wsadmin tool, the application continues to run and throws ″DocumentIOException″
- The removeNode command does not remove the installed application from the deployment manager
- I cannot display the syntax for the removeNode command.

If none of these steps fixes your problem:
- Make sure that the application and its Web and EJB modules are in a stopped state before uninstalling.
- If you are uninstalling or installing an application using **wsadmin**, make sure that you are using the **-conntype NONE** option to invoke **wsadmin** and enable local mode. To use the **-conntype NONE** option, stop the hosting application server before uninstalling the application.
- Check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).
- If you don't find your problem listed there contact IBM support

After uninstalling application through the wsadmin tool, the application throws "DocumentIOException"

If this exception occurs after the application was uninstalled using wsadmin with the `-conntype NONE` option:
- Restart the server or,
- Rerun the uninstall command without the `-conntype NONE` option.

The removeNode command does not remove the installed application from the deployment manager

If the applications were installed indirectly using the **addNode** program with the **-includeapps** option, then `removeNode` will not uninstall them, since they may be in use by other nodes. These applications must be explicitly uninstalled, for example through the administrative console.

I cannot display the syntax for the removeNode command

Unlike the `addNode` command, the `removeNode` command is valid with no parameters, so executing it will execute the operation, that is, remove the node, without displaying the command syntax.

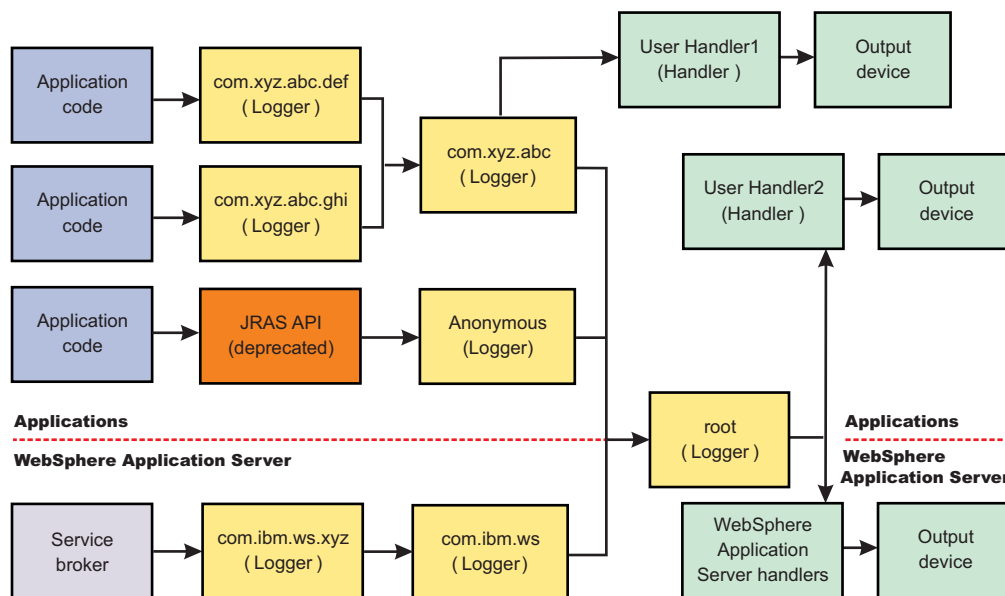
To see the valid options for removeNode, execute `removeNode -?` or `removeNode -help`.

Chapter 11. Add logging and tracing to your application

You can add logging and tracing to applications to help analyze performance and diagnose problems in WebSphere Application Server.

Deprecation: The JRas framework that is described in this information center is deprecated. However, you can achieve the same results using Java logging.

Designers and developers of applications that run with or under WebSphere Application Server, such as servlets, JavaServer Pages (JSP) files , enterprise beans, client applications, and their supporting classes, might find it useful to use Java logging for generating their application logging.

This approach has advantages over adding `System.out.println` statements to your code:
* Your messages are displayed in the WebSphere Application Server standard log files, using a standard message format with additional data, such as a date and time stamp that are added automatically.
* You can more easily correlate problems and events in your own application to problems and events that are associated with WebSphere Application Server components.
* You can take advantage of the WebSphere Application Server log file management features.
* You can view your messages with the Log and Trace Analyzer tool.


1. To use Java logging, configure properties using the administrative console.
2. Customize the properties to meet your logging needs. For example, enable or disable a particular log, specify the number of logs to be kept, and specify a format for log output.
3. Restart the application server after making static configuration changes.

Log and trace with Java logging

Java logging is the logging toolkit that is provided by the java.util.logging package. Java logging provides a standard logging API for your applications.

The application server redirects the system streams at the server startup. There is no way to allow the application to output logging to the console because the system streams can not be obtained by the application. If you would like to use console to monitor the application without using the console handler, you can either monitor the `SystemOut.log` file, or monitor a file created by another file handler.

Note: The application server uses Java logging internally and therefore certain restrictions apply for using system streams with this logging API by applications. During server startup, the standard output and error streams are replaced with special streams that write to the logging infrastructure, in order to include the output of the system streams in the log files. Because of this, applications can not use `java.util.logging.ConsoleHandler`, or any handler writing to `System.err` or `System.out` streams, attached to the root logger. If the user does attache the handler to the root logger, an infinite loop is created within the logging infrastructure, leading to stack overflow and server crash.

If the use of a handler that writes to system streams is necessary, attach it to a non-root logger so that it does not publish log records to parent handlers. The data written to the system streams is then formatted and written to the corresponding system stream log file. To monitor what is being written system streams, the configured log files (`SystemOut.log` and `SystemErr.log` by default) can be monitored.

Developing, deploying and maintaining applications are complex tasks. When an application encounters an unexpected condition, it might not be able to complete a requested operation. You might want the application to inform the administrator that the operation failed and tell the administrator why the operation failed. This information enables the administrator to take the proper corrective action. Application developers might need to gather detailed information that relates to the path of a running application to determine the root cause of a failure that is due to a code bug. The facilities that are used for these purposes are typically referred to as *logging* and *tracing*.

Message logging (messages) and diagnostic trace (trace) are conceptually similar, but do have important differences. These differences are important for application developers to understand to use these tools properly. The following operational definitions of messages and trace are provided.

Message
A message entry is an informational record that is intended for end users, systems administrators, and support personnel to view. The text of the message must be clear, concise, and interpretable by an end user. Messages are typically localized and displayed in the national language of the end user. Although the destination and lifetime of messages might be configurable, enable some level of message logging in normal system operation. Use message logging judiciously because of performance considerations and the size of the message repository.

Trace A trace entry is an information record that is intended for service engineers or developers to use. As such, a trace record might be considerably more complex, verbose, and detailed than a message entry. Localization support is typically not used for trace entries. Trace entries can be fairly inscrutable, understandable only by the appropriate developer or service personnel. It is assumed that trace entries are not written during normal runtime operation, but can be enabled as needed to gather diagnostic information.

- To use Java logging, see "Configuring logging properties using the administrative console" on page 1500
- See the Java documentation for the java.util.logging class for a full description of the syntax and the construction of logging methods.

Loggers

Loggers are used by applications and runtime components to capture message and trace events.

When situations occur that are significant either due to a change in state, for example when a server completes startup or because a potential problem is detected, such as a timeout waiting for a resource, a message is written to the logs. Trace events are logged in debugging scenarios, where a developer needs a clear view of what is occurring in each component to understand what might be going wrong. Logged events are often the only events available when a problem is first detected, and are used during both problem recovery and problem resolution.

Loggers are organized hierarchically. Each logger can have zero or more child loggers.

Loggers can be associated with a resource bundle. If specified, the resource bundle is used by the logger to localize messages that are logged to the logger. If the resource bundle is not specified, a logger uses the same resource bundle as its parent.

You can configure loggers with a level. If specified, the level is compared by the logger to incoming events. The events that are less severe than the level set for the logger are ignored by the logger. If the level is not specified, a logger takes on the level that is used by its parent. The default level for loggers is Level.INFO.

Loggers can have zero or more attached handlers. If supplied, all events that are logged to the logger are passed to the attached handlers. Handlers write events to output destinations such as log files or network sockets. When a logger finishes passing a logged event to all of the handlers that are attached to that logger, the logger passes the event to the handlers that are attached to the parents of the logger. This process stops if a parent logger is configured not to use its parent handlers. Handlers in WebSphere Application Server are attached to the root logger. Set the useParentHandlers logger property to `false` to prevent the logger from writing events to handlers that are higher in the hierarchy.

Loggers can have a filter. If supplied, the filter is invoked for each incoming event to tell the logger whether or not to ignore it.

Applications interact directly with loggers to log events. To obtain or create a logger, a call is made to the Logger.getLogger method with a name for the logger. Typically, the logger name is either the package qualified class name or the name of the package that the logger is used by. The hierarchical logger namespace is automatically created by using the dots in the logger name. For example, the com.ibm.websphere.ras logger has a com.ibm.websphere parent logger, which has a com.ibm parent. The parent at the top of the hierarchy is referred to as the *root logger*. This root logger is created during initialization. The root logger is the parent of the com logger.

Loggers are structured in a hierarchy. Every logger, except the root logger, has one parent. Each logger can also have 0 or more children. A logger inherits log handlers, resource bundle names, and event filtering settings from its parent in the hierarchy. The logger hierarchy is managed by the LogManager function.

Loggers create log records. A log record is the container object for the data of an event. This object is used by filters, handlers, and formatters in the logging infrastructure.

The logger provides several sets of methods for generating log messages. Some log methods take only a level and enough information to construct a message. Other, more complex logp (log precise) methods support the caller in passing class name and method name attributes, in addition to the level and message information. The logrb (log with resource bundle) methods add the capability of specifying a resource bundle as well as the level, message information, class name, and method name. Using methods such as severe, warning, fine, finer, and finest you can log a message at a particular level. For more information on logging and how to use it in your applications read "Using loggers in an application" on page 1463. For a complete list of methods, see the java.util.logging documentation at http://java.sun.com/j2se/.

Log handlers

Log handlers write log record objects to output devices like log files, sockets, and notification mechanisms.

Loggers can have zero or more attached handlers. All objects that are logged to the logger are passed to the attached handlers, if handlers are supplied.

You can configure handlers with a level. The handler compares the level that is specified in the logged object to the level that is specified for the handler. If the level of the logged object is less severe than the level set in the handler, the object is ignored by the handler. The default level for handlers is ALL.

Handlers can have a filter. If a filter is supplied, the filter is invoked for each incoming object to tell the handler whether or not to ignore it.

Handlers can have a formatter. If a formatter is supplied, the formatter controls how the logged objects are formatted. For example, the formatter can decide to first include the time stamp, followed by a string representation of the level, followed by the message that is included in the logged object. The handler writes this formatted representation to the output device. Read "java.util.logging custom formatters" on page 1473 for information on using a custom formatter in your applications.

Both loggers and handlers can have levels and filters, and a logged object must pass all of these elements to be output. For example, you can set the logger level to FINE, but if the handler level is set at WARNING, only WARNING level messages are displayed in the output for that handler. Conversely, if your log handler is set to output all messages (level=All), but the logger level is set to WARNING, the logger never sends messages lower than WARNING to the log handler.

WebSphere Application Server uses the following set of log handlers that are available to all loggers:
* Diagnostic trace
* Java Management Extensions (JMX) notification object
* Service log
* SystemErr
* SystemOut

For instructions on how to configure these log handlers, see "Configuring logging properties using the administrative console" on page 1500.

Log levels

Levels control which events are processed by Java logging. WebSphere Application Server controls the levels of all loggers in the system.

The level value is set from configuration data when the logger is created and can be changed at run time from the administrative console. If a level is not set in the configuration data, a level is obtained by proceeding up the hierarchy until a parent with a level value is found. You can also set a level for each handler to indicate which events are published to an output device. When you change the level for a logger in the administrative console, the change is propagated to the children of the logger.

Levels are cumulative; a logger can process logged objects at the level that is set for the logger, and at all levels above the set level. Valid levels are:

Level	Content / Significance
Off	No events are logged.
Fatal	Task cannot continue and component cannot function.
Severe	Task cannot continue, but component can still function
Warning	Potential error or impending error
Audit	Significant event affecting server state or resources
Info	General information outlining overall task progress
Config	Configuration change or status
Detail	General information detailing subtask progress
Fine	Trace information - General trace + method entry / exit / return values
Finer	Trace information - Detailed trace

Level	Content / Significance
Finest	Trace information - A more detailed trace - Includes all the detail that is needed to debug problems
All	All events are logged. If you create custom levels, All includes your custom levels, and can provide a more detailed trace than Finest.

For instructions on how to set logging levels, see "Configuring logging properties using the administrative console" on page 1500

Note: Trace information, which includes events at the Fine, Finer and Finest levels, can be written only to the trace log. Therefore, if you do not enable diagnostic trace, setting the log detail level to Fine, Finer, or Finest does not effect the logged data.

Log filters

Log filters help control more detailed logging settings that are not handled by usual log level settings.

A filter provides an optional, secondary control over what is logged, beyond the control that is provided by setting the level. Applications can apply a filter mechanism to control logging output through the logging APIs. An example of filter usage is to suppress all the events with a particular message key.

A filter is attached to a logger or log handler using the appropriate setFilter method. Read "java.util.logging custom filters" on page 1473 for information on implementing custom filters. For a complete list of filter methods, see the java.util.logging documentation at http://java.sun.com/j2se/

Log formatters

Log formatters format log messages so they can be used by various log handlers.

Handlers can be configured with a log formatter that knows how to format log records. The event, which is represented by the log record object, is passed to the appropriate formatter by the handler. The formatter returns formatted output to the handler, which writes the output to the output device.

The formatter is responsible for rendering the event for output. This formatter uses the resource bundle that is specified in the event to look up the message in the appropriate language.

Formatters are attached to handlers using the setFormatter method.

With WebSphere Application Server, you can configure the formatter to work with trace, the `SystemOut.log`, and the `SystemErr.log` log files:
- **Basic (Compatible)**: Preserves only basic trace information. With this option, you can minimize the amount of space taken by the trace output.
- **Advanced**: Preserves more specific trace information. You can see detailed trace information for troubleshooting and problem determination.
- **Log analyzer trace format**: Preserves trace information in the same format as produced by Showlog tool.

You can select a formatter for a handler using the administrative console panels. See Diagnostic trace service settings for details.

You can find the java.util.logging documentation at http://java.sun.com/j2se/.

Logging properties for an application

Use the Logger.properties file to set logger attributes for specific loggers.

The properties file is loaded the first time that the Logger.getLogger(*logger_name*) method is called within an application.

Important: The name of the Logger.properties file is case sensitive. Use a capital ″L″ in the file name.

When an application calls the Logger.getLogger method for the first time, all the available logger properties files are loaded. Applications can provide Logger.properties files in:
- the META-INF directory of the Java archive (JAR) file for the application
- directories included in the class path of an application module
- directories included in the application class path

The properties file contains two categories of parameters, logger control and logger data:
- Logger control information
  - Minimum localization level: The minimum LogRecord level for which localization is attempted
  - Group: The logical group that this component belongs to
  - Event factory: The Common Base Event template file to use with the event factory. The naming convention for this template is the fully qualified component name, with a file extension of `.event.xml`. For example, a template that applies to the com.ibm.compXYZ package is called `com.ibm.compXYZ.event.xml`.
- Logger data information
  - Product name
  - Organization name
  - Component name
  - Extensions and additional properties

Syntax of the Logger.properties file

Use the following syntax to set logger properties:

`<logger base name>.<property>=value`

where:

`logger base name` is the starting part of the logger name to which the property applies. All loggers with names starting with this string have the property applied.

`property` is one of the following properties:
- organization
- product
- component
- minimum_localization_level
- group
- eventfactory

Sample Logger.properties file

In the following sample, the com.ibm.xyz.MyEventFactory event factory is used by any loggers in the com.ibm.websphere.abc package or any sub packages that do not override this value in their configuration file.

`com.ibm.websphere.abc.eventfactory=com.ibm.xyz.MyEventFactory`

Group Logger.properties file

In the following example, the group is MyTraceGroup and the components are com.ibm.stuff and com.ibm.morestuff:

```
com.ibm.stuff.group=MyTraceGroup
com.ibm.morestuff.group=MyTraceGroup
```

Sample security policy for logging

Set up a security policy to allow your applications to modify logging and handler properties.

The sample security policy that follows grants access to the file system and runtime classes. Include this security policy, with the entry `permission java.util.logging.LoggingPermission "control"`, in the META-INF directory of your application if you want your applications to programmatically alter controlled properties of loggers and handlers. The META-INF file is located in the following locations for the different module types:

EJB projects	ejbModule/META-INF/MANIFEST.MF
Application client projects	appClientModule/META-INF/MANIFEST.MF
Dynamic Web projects	WebContent/META-INF/MANIFEST.MF
Connector projects	connectorModule/META-INF/MANIFEST.MF

Below is a sample security policy that grants permission to modify logging properties:

```
//////////////////////////////////////////////
//
// WebSphere Application Server Security Policy
//
//////////////////////////////////////////////

////////////////////////////////////////////////////////////////////
// Allow all access to the file system and runtime classes
////////////////////////////////////////////////////////////////////
grant codeBase "file:${application}" {
    permission java.util.logging.LoggingPermission "control";
};
```

Using loggers in an application

This topic describes how to use Java logging within an application.

To create an application using Java logging, perform the following steps:

1. Create the necessary handler, formatter, and filter classes if you need your own log files.
2. If localized messages are used by the application, create a resource bundle, as described in "Creating log resource bundles and message files" on page 1468.
3. In the application code, get a reference to a logger instance, as described in "Using a logger."
4. Insert the appropriate message and trace logging statements in the application, as described in "Using a logger."

Using a logger

You can use Java logging to log messages and add tracing.

Use WsLevel.DETAIL level and above for messages, and lower levels for trace. The WebSphere Application Server Extension API (the com.ibm.websphere.logging package) contains the WsLevel class.

For messages use:

```
WsLevel.FATAL
Level.SEVERE
Level.WARNING
WsLevel.AUDIT
Level.INFO
Level.CONFIG
WsLevel.DETAIL
```

For trace use:

```
Level.FINE
Level.FINER
Level.FINEST
```

1. Use the logp method instead of the log or the logrb method. The logp method accepts parameters for class name and method name. The log and logrb methods will generally try to infer this information, but the performance penalty is prohibitive.

2. Avoid using the logrb method. This method leads to inefficient caching of resource bundles and poor performance.

3. Use the isLoggable method to avoid creating data for a logging call that does not get logged. For example:

```
if (logger.isLoggable(Level.FINEST)) {
  String s = dumpComponentState(); // some expensive to compute method
  logger.logp(Level.FINEST, className, methodName, "componentX state
dump:\n{0}", s);
  }
```

The following sample applies to localized messages:

```
// note - generally avoid use of FINE, FINER, FINEST levels for messages to be consistent with
// WebSphere Application Server

String componentName = "com.ibm.websphere.componentX";
String resourceBundleName = "com.ibm.websphere.componentX.Messages";
Logger logger = Logger.getLogger(componentName, resourceBundleName);

// "Convenience" methods - not generally recommended due to lack of class
/ method names
//   - cannot specify message substitution parameters
//   - cannot  specify class and method names
if (logger.isLoggable(Level.SEVERE))
 logger.severe("MSG_KEY_01");

if (logger.isLoggable(Level.WARNING))
 logger.warning("MSG_KEY_01");

if (logger.isLoggable(Level.INFO))
 logger.info("MSG_KEY_01");

if (logger.isLoggable(Level.CONFIG))
 logger.config("MSG_KEY_01");

// log methods are not generally used due to lack of class and method
names
//   - enable use of WebSphere Application Server-specific levels
//   - enable use of message substitution parameters
//   - cannot specify class and method names
if (logger.isLoggable(WsLevel.FATAL))
 logger.log(WsLevel.FATAL, "MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.SEVERE))
 logger.log(Level.SEVERE, "MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.WARNING))
 logger.log(Level.WARNING, "MSG_KEY_01", "parameter 1");
```

```
if (logger.isLoggable(WsLevel.AUDIT))
 logger.log(WsLevel.AUDIT, "MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.INFO))
 logger.log(Level.INFO, "MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.CONFIG))
 logger.log(Level.CONFIG, "MSG_KEY_01", "parameter 1");

if (logger.isLoggable(WsLevel.DETAIL))
 logger.log(WsLevel.DETAIL, "MSG_KEY_01", "parameter 1");

// logp methods are the way to log
//   - enable use of WebSphere Application Server-specific levels
//   - enable use of message substitution parameters
//   - enable use of class and method names
if (logger.isLoggable(WsLevel.FATAL))
 logger.logp(WsLevel.FATAL, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(Level.SEVERE))
 logger.logp(Level.SEVERE, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(Level.WARNING))
 logger.logp(Level.WARNING, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(WsLevel.AUDIT))
 logger.logp(WsLevel.AUDIT, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(Level.INFO))
 logger.logp(Level.INFO, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(Level.CONFIG))
 logger.logp(Level.CONFIG, className, methodName, "MSG_KEY_01",
"parameter 1");

if (logger.isLoggable(WsLevel.DETAIL))
 logger.logp(WsLevel.DETAIL, className, methodName, "MSG_KEY_01",
"parameter 1");

// logrb methods are not generally used due to diminished performance
of switching resource bundles dynamically
//   - enable use of WebSphere Application Server-specific levels
//   - enable use of message substitution parameters
//   - enable use of class and method names
String resourceBundleNameSpecial =
"com.ibm.websphere.componentX.MessagesSpecial";

if (logger.isLoggable(WsLevel.FATAL))
 logger.logrb(WsLevel.FATAL, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.SEVERE))
 logger.logrb(Level.SEVERE, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.WARNING))
 logger.logrb(Level.WARNING, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");
```

```
if (logger.isLoggable(WsLevel.AUDIT))
 logger.logrb(WsLevel.AUDIT, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.INFO))
 logger.logrb(Level.INFO, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");

if (logger.isLoggable(Level.CONFIG))
 logger.logrb(Level.CONFIG, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");

if (logger.isLoggable(WsLevel.DETAIL))
 logger.logrb(WsLevel.DETAIL, className, methodName, resourceBundleNameSpecial,
"MSG_KEY_01", "parameter 1");
```

For trace, or content that is not localized, the following sample applies:

```
// note - generally avoid use of FATAL, SEVERE, WARNING, AUDIT,
// INFO, CONFIG, DETAIL levels for trace
// to be consistent with WebSphere Application Server

String componentName = "com.ibm.websphere.componentX";
Logger logger = Logger.getLogger(componentName);

// Entering / Exiting methods are used for non trivial methods
if (logger.isLoggable(Level.FINER))
 logger.entering(className, methodName);

if (logger.isLoggable(Level.FINER))
 logger.entering(className, methodName, "method param1");

if (logger.isLoggable(Level.FINER))
 logger.exiting(className, methodName);

if (logger.isLoggable(Level.FINER))
 logger.exiting(className, methodName, "method result");

// Throwing method is not generally used due to lack of message - use
logp with a throwable parameter instead
if (logger.isLoggable(Level.FINER))
 logger.throwing(className, methodName, throwable);

// Convenience methods are not generally used due to lack of class
/ method names
//    - cannot specify message substitution parameters
//    - cannot specify class and method names
if (logger.isLoggable(Level.FINE))
 logger.fine("This is my trace");

if (logger.isLoggable(Level.FINER))
 logger.finer("This is my trace");

if (logger.isLoggable(Level.FINEST))
 logger.finest("This is my trace");

// log methods are not generally used due to lack of class and
method names
//    - enable use of WebSphere Application Server-specific levels
//    - enable use of message substitution parameters
//    - cannot specify class and method names
if (logger.isLoggable(Level.FINE))
 logger.log(Level.FINE, "This is my trace", "parameter 1");
```

```
if (logger.isLoggable(Level.FINER))
 logger.log(Level.FINER, "This is my trace", "parameter 1");

if (logger.isLoggable(Level.FINEST))
 logger.log(Level.FINEST, "This is my trace", "parameter 1");

// logp methods are the recommended way to log
//   - enable use of WebSphere Application Server-specific levels
//   - enable use of message substitution parameters
//   - enable use of class and method names
if (logger.isLoggable(Level.FINE))
 logger.logp(Level.FINE, className, methodName, "This is my trace",
"parameter 1");

if (logger.isLoggable(Level.FINER))
 logger.logp(Level.FINER, className, methodName, "This is my trace",
"parameter 1");

if (logger.isLoggable(Level.FINEST))
 logger.logp(Level.FINEST, className, methodName, "This is my trace",
"parameter 1");

// logrb methods are not applicable for trace logging because no localization
is involved
```

Logger hierarchy

WebSphere Application Server handlers are attached to the Java root logger, which is at the top of the logger hierarchy. As a result, any request from anywhere in the logger tree can be processed by WebSphere Application Server handlers.

With WebSphere Application Server, you can configure the system to do the following:

- Forward all application logging requests to the WebSphere Application Server handlers. This behavior is the default.
- Forward all application logging requests to your own custom handlers. Set the **useParentHandlers** option to `false` on one of your custom loggers, and then attach your handlers to that logger.
- Forward all application logging requests to both WebSphere Application Server handlers, and your custom handlers, but do not forward WebSphere Application Server logging requests to your custom handlers. Set the **useParentHandlers** option to `true` on one of your non-root custom loggers, and then attach your handlers to that logger.True is the default setting.
- Forward all WebSphere Application Server logging requests to both WebSphere Application Server handlers, and your custom handlers. WebSphere Application Server logging requests are always forwarded to WebSphere Application Server handlers. To forward WebSphere Application Server requests to your custom handlers, attach your custom handlers to the Java root logger, so that they are at the same level in the hierarchy as the WebSphere Application Server handlers.

The following example shows how these requirements can be met using the Java logging infrastructure.

Application code → com.xyz.abc.def (Logger)

Application code → com.xyz.abc.ghi (Logger)

Application code → JRAS API (deprecated) → Anonymous (Logger)

com.xyz.abc (Logger)

User Handler1 (Handler) → Output device

User Handler2 (Handler) → Output device

root (Logger)

Applications

WebSphere Application Server

Applications

WebSphere Application Server

Service broker → com.ibm.ws.xyz (Logger) → com.ibm.ws (Logger)

WebSphere Application Server handlers → Output device

Creating log resource bundles and message files

Every method that accepts messages localizes those messages. The mechanism for providing localized messages is the resource bundle support provided by the IBM Developer Kit, Java Technology Edition. If you are not familiar with resource bundles as implemented by the Developer Kit, you can get more information from various texts, or by reading the API documentation for the java.util.ResourceBundle, java.util.ListResourceBundle and java.util.PropertyResourceBundle classes, as well as the java.text.MessageFormat class.

The PropertyResourceBundle class is the preferred mechanism to use.

You can forward messages that are written to the internal WebSphere Application Server logs to other processes for display. For example, messages that are displayed on the administrative console, which can be running in a different location than the server process, can be localized using the *late binding* process. Late binding means that WebSphere Application Server does not localize messages when they are logged, but defers localization to the process that displays the message.

To properly localize the message, the displaying process must have access to the resource bundle where the message text is stored. You must package the resource bundle separately from the application, and install it in a location where the viewing process can access it.

By default, the WebSphere Application Server runtime localizes all the messages when they are logged. This localization eliminates the need to pass a `.jar` file to the application, unless you need to localize in a different location. However, you can use the early binding technique to localize messages as they log. An application that uses early binding must localize the message before logging it. The application looks up the localized text in the resource bundle and formats the message. Use the early binding technique to package the application resource bundles with the application.

To create a resource bundle, perform the following steps.
1. Create a text properties file that lists message keys and the corresponding messages. The properties file must have the following characteristics:
   - Each property in the file is terminated with a line-termination character.
   - If a line contains white space only, or if the first non-white space character of the line is the pound sign symbol (#) or exclamation mark (!), the line is ignored. The # and ! characters can therefore be used to put comments into the file.

- Each line in the file, unless it is a comment or consists of white space only, denotes a single property. A backslash (\) is treated as the line-continuation character.
- The syntax for a property file consists of a key, a separator, and an element. Valid separators include the equal sign (=), colon (:), and white space ( ).
- The key consists of all characters on the line from the first non-white space character to the first separator. Separator characters can be included in the key by escaping them with a backslash (\), but doing this process is not recommended, because escaping characters is error prone and confusing. Instead, use a valid separator character that does not display in any keys in the properties file.
- White space after the key and separator is ignored until the first non-white space character is encountered. All characters remaining before the line-termination character define the element.

See the Java documentation for the java.util.Properties class for a full description of the syntax and the construction of properties files.

2. Translate the file into localized versions of the file with language-specific file names. For example, a file named `DefaultMessages.properties` can be translated into `DefaultMessages_de.properties` for German and `DefaultMessages_ja.properties` for Japanese.

3. When the translated resource bundles are available, put the bundle in a directory that is part of the application class path.

4. When a message logger is obtained from the log manager, configure it to use a particular resource bundle. Messages logged with the Logger API use this resource bundle when message localization is performed. At run time, the user locale setting determines the properties file from which to extract the message that is specified by a message key, ensuring that the message is delivered in the correct language.

5. If the message loggers msg method is called, a resource bundle name must be explicitly provided.

The application locates the resource bundle based on the file location relative to any directory in the class path. For instance, if the DefaultMessages.properties property resource bundle is located in the *baseDir*/*subDir1*/*subDir2*/resources directory and *baseDir* is in the class path, the name *subdir1*.*subdir2*.resources.DefaultMessage is passed to the message logger to identify the resource bundle.

Resource bundle logging:

You can create resource bundles in several ways. The best and easiest way is to create a properties file that supports a properties resource bundle. This sample shows how to create such a properties file.

Resource bundle sample

For this sample, four localizable messages are provided. The properties file is created and the key-value pairs are inserted. All the normal properties file conventions and rules apply to this file. In addition, the creator must be aware of other restrictions that are imposed on the values by the Java MessageFormat class. For example, apostrophes must be escaped or they cause a problem. Avoid the use of non-portable characters. WebSphere Application Server does not support the use of extended formatting conventions that the MessageFormat class supports, such as {1, date} or {0,number, integer}.

Assume that the base directory for the application that uses this resource bundle is `baseDir` and that this directory is in the class path. Assume that the properties file is stored in the subdirectory `baseDir` that is not in the class path (for example, `baseDir/subDir1/subDir2/resources`). To allow the messages file to resolve, the `subDir1.subDir2.resources.DefaultMessage` name is used to identify the property resource bundle and is passed to the message logger.

For this sample, the properties file is named `DefaultMessages.properties`.

```
# Contents of the DefaultMessages.properties file
MSG_KEY_00=A message with no substitution parameters.
MSG_KEY_01=A message with one substitution parameter: parm1={0}
MSG_KEY_02=A message with two substitution parameters: parm1={0}, parm2 = {1}
MSG_KEY_03=A message with three parameter: parm1={0}, parm2 = {1}, parm3={2}
```

When the `DefaultMessages.properties` file is created, the file can be sent to a translation center where the localized versions are generated.

Changing the message IDs used in log files

You can change the default format for message IDs in server logs by setting the com.ibm.websphere.logging.messageId.version system property.

In new releases of WebSphere Application Server logging files will be formatted according to a standardized system, but the default runtime behavior is still configured to use the older format, In new releases of WebSphere Application Server the message IDs written to log files will be changed to ensure they do not conflict with other IBM products. The default runtime behavior is still configured to use the older message IDs, deprecated in Version 6.1.

The following is a sample of an entry in a trace.log file using a default message ID. Note that the message ID is PMON0001A

```
[1/26/05 10:17:12:529 EST] 0000000a PMIImpl      A   PMON0001A: PMI is enabled
```

A sample of the same entry using a new message ID follows. Note that the message ID is CWPMI0001A. All new WebSphere Application Server message IDs begin with 'CW'.

```
[1/26/05 10:17:12:529 EST] 0000000a PMIImpl      A   CWPMI0001A: PMI is enabled.
```

If you are using a logging tool that uses the new standardized format, you might want to change the default configuration settings to format the logging output appropriately. You will need to change the configuration for each JVM in the cell if you want the output formatting to be the same across application servers.

To configure logging files to be formatted according to the new system, use the following command in the wsadmin utility:

```
set jvmEntry [$AdminConfig list JavaVirtualMachine]
$AdminConfig create Property $jvmEntry {{name com.ibm.websphere.logging.messageId.version} {value 6} {required false}}
```

Note: You must restart the application server for the changes to take effect. Also, remember to do this for each JVM in the cell for consistent output formatting.

Message IDs written to log files will now be compliant with the new standard.

Converting log files to use IBM unique Message IDs:

The convertlog command creates a new log file with either new or old message IDs substituted in place of the message IDs in the source file.

Prior to Version 6.x, components were assigned message IDs that are not necessarily unique across IBM software products. In Version 6.0, a system property was provided to map the message IDs in output logs to a set of IBM unique message IDs (all WebSphere Application Server message IDs now start with CW) that do not conflict with other IBM software products. The default runtime behavior still uses the old message IDs.

To facilitate the migration of logging tools that are reliant on the old message IDs, the convertlog command is provided to convert the message IDs of log entries from the old standard to the new standard, or the new standard back to the old. By default, the software is configured to use the old message IDs when

logging, but you can change the default output with the com.ibm.websphere.logging.messageId.version system property. Read "Changing the message IDs used in log files" on page 1470 for more information.

Use the convertlog command to convert the log output:

```
convertlog <source file name> <destination file name> [options]
        options: -newMessageFormat convert message IDs to CCCCCnnnnS format
                    (cannot be used with -m5)
                 -oldMessageFormat convert message IDs to CCCCnnnnS format
                    (cannot be used with -m6)
```

After using the convertlog command you have a new file with message IDs in the chosen format.

convertlog command:

The convertlog command is used to convert the message IDs in log entries from the old standard to the new standard, or the new standard back to the old.

Previous versions of WebSphere Application Server used message IDs that are deprecated in WebSphere Application Server Version 6.1. To facilitate the migration of tools based on the old message IDs, the convertlog command is implemented to translate log files from one message ID standard to the other.

Use the convertlog command as follows:

```
convertlog <source file name> <destination file name> [options]
        options: -newMessageFormat convert message IDs to CCCCCnnnnS format
                    (cannot be used with -m5)
                 -oldMessageFormat convert message IDs to CCCCnnnnS format
                    (cannot be used with -m6)
```

MessageConverter class:

The com.ibm.websphere.logging.MessageConverter class provides a method to convert a message ID at the front of a String into either a new message ID or an old message ID. The direction of the conversion is controlled with the *conversionType* argument.

Use the MessageConverter class with log analysis tools to convert message IDs from earlier versions of WebSphere Application Server into the corresponding message IDs that are used in later releases, or to revert message IDs to an earlier format. See the article Message reference for list of message ID mappings.

Method

```
public static java.lang.String convert(java.lang.String in, short conversionType)
```

Parameters

Use the following parameters with the MessageConverter class:

Parameter Name	Description
in	The message to convert. The method assumes the message ID is the first part of the supplied message with no leading white space.
conversionType	CONVERSION_TYPE_WASV5_TO_WASV6
	CONVERSION_TYPE_WASV6_TO_WASV5

java.util.logging custom log handlers

There may be occasions when you want to propagate log records to your own log handlers rather than participate in integrated logging.

To use a stand-alone log handler, set the useParentHandlers flag to `false` in your application.

The mechanism for creating a customer handler is the Handler class support that is provided by the IBM Developer Kit, Java Technology Edition. If you are not familiar with handlers, as implemented by the Developer Kit, you can get more information from various texts, or by reading the API documentation for the java.util.logging API.

The following sample shows a custom handler:

```
import java.io.FileOutputStream;
import java.io.PrintWriter;
import java.util.logging.Handler;
import java.util.logging.LogRecord;

/**
 * MyCustomHandler outputs contents to a specified file
 */
public class MyCustomHandler extends Handler {

 FileOutputStream fileOutputStream;
 PrintWriter printWriter;

 public MyCustomHandler(String filename) {
  super();

  // check input parameter
  if (filename == null)
   filename = "mylogfile.txt";

  try {
   // initialize the file
   fileOutputStream = new FileOutputStream(filename);
   printWriter = new PrintWriter(fileOutputStream);
  }
  catch (Exception e) {
   // implement exception handling...
  }
 }

 /* (non-API documentation)
  * @see java.util.logging.Handler#publish(java.util.logging.LogRecord)
  */
 public void publish(LogRecord record) {
  // ensure that this log record should be logged by this Handler
  if (!isLoggable(record))
   return;

  // Output the formatted data to the file
  printWriter.println(getFormatter().format(record));
 }

 /* (non-API documentation)
  * @see java.util.logging.Handler#flush()
  */
 public void flush() {
  printWriter.flush();
 }

 /* (non-API documentation)
  * @see java.util.logging.Handler#close()
  */
```

```
  public void close() throws SecurityException {
   printWriter.close();
 }
}
```

java.util.logging custom filters

A custom filter provides optional, secondary control over what is logged, beyond the control that is provided by the level.

The mechanism for creating a customer filter is the Filter interface support that is provided by the IBM Developer Kit, Java Technology Edition. If you are not familiar with filters, as implemented by the Developer Kit, you can get more information from various texts, or by reading the API documentation the for java.util.logging API.

The following example shows a custom filter:

```
import java.util.Vector;
import java.util.logging.Filter;
import java.util.logging.LogRecord;

/**
 * MyCustomFilter rejects any log records whose Level is not contained in the
 * configured list of Levels.
 */
public class MyCustomFilter implements Filter {

 private Vector acceptableLevels;

 public MyCustomFilter(Vector acceptableLevels) {
  super();
  this.acceptableLevels = acceptableLevels;
 }

 /* (non-API documentation)
  * @see java.util.logging.Filter#isLoggable(java.util.logging.LogRecord)
  */
 public boolean isLoggable(LogRecord record) {
  return (acceptableLevels.contains(record.getLevel()));
 }

}
```

java.util.logging custom formatters

A formatter formats events. Handlers are associated with one or more formatters.

The mechanism for creating a customer formatter is the Formatter class support that is provided by the IBM Developer Kit, Java Technology Edition. If you are not familiar with formatters, as implemented by the Developer Kit, you can get more information from various texts, or by reading the API documentation for the java.util.logging API.

The following example shows a custom formatter:

```
import java.util.Date;
import java.util.logging.Formatter;
import java.util.logging.LogRecord;

/**
 * MyCustomFormatter formats the LogRecord as follows:
 * date   level   localized message with parameters
 */
public class MyCustomFormatter extends Formatter {

 public MyCustomFormatter() {
  super();
```

```
  }

  public String format(LogRecord record) {

    // Create a StringBuffer to contain the formatted record
    // start with the date.
    StringBuffer sb = new StringBuffer();

    // Get the date from the LogRecord and add it to the buffer
    Date date = new Date(record.getMillis());
    sb.append(date.toString());
    sb.append(" ");

    // Get the level name and add it to the buffer
    sb.append(record.getLevel().getName());
    sb.append(" ");

    // Get the formatted message (includes localization
    // and substitution of paramters) and add it to the buffer
    sb.append(formatMessage(record));

    return sb.toString();
  }
}
```

Custom handlers, filters, and formatters

In some cases you might want to have your own custom log files. Adding custom handlers, filters, and formatters enables you to customize your logging environment beyond what can be achieved by the configuration of the default WebSphere Application Server logging infrastructure.

The following example demonstrates how to add a new handler to process requests to the com.myCompany subtree of loggers (see "Logger hierarchy" on page 1467). The main method in this sample gives an example of how to use the newly configured logger.

```
import java.util.Vector;
import java.util.logging.Filter;
import java.util.logging.Formatter;
import java.util.logging.Handler;
import java.util.logging.Level;
import java.util.logging.Logger;

public class MyCustomLogging {

  public MyCustomLogging() {
    super();
  }

  public static void initializeLogging() {

    // Get the logger that you want to attach a custom Handler to
    String defaultResourceBundleName = "com.myCompany.Messages";
    Logger logger = Logger.getLogger("com.myCompany", defaultResourceBundleName);

    // Set up a custom Handler (see MyCustomHandler example)
    Handler handler = new MyCustomHandler("MyOutputFile.log");

    // Set up a custom Filter (see MyCustomFilter example)
    Vector acceptableLevels = new Vector();
    acceptableLevels.add(Level.INFO);
    acceptableLevels.add(Level.SEVERE);
    Filter filter = new MyCustomFilter(acceptableLevels);

    // Set up a custom Formatter (see MyCustomFormatter example)
    Formatter formatter = new MyCustomFormatter();

    // Connect the filter and formatter to the handler
```

```
  handler.setFilter(filter);
  handler.setFormatter(formatter);

  // Connect the handler to the logger
  logger.addHandler(handler);

  // avoid sending events logged to com.myCompany showing up in WebSphere
  // Application Server logs
  logger.setUseParentHandlers(false);

 }

 public static void main(String[] args) {
  initializeLogging();

  Logger logger = Logger.getLogger("com.myCompany");

  logger.info("This is a test INFO message");
  logger.warning("This is a test WARNING message");
  logger.logp(Level.SEVERE, "MyCustomLogging", "main", "This is a test SEVERE message");
 }
}
```

When the above program is run, the output of the program is written to the MyOutputFile.log file. The
content of the log is in the expected log file, as controlled by the custom handler, and is formatted as
defined by the custom formatter. The warning message is filtered out, as specified by the configuration of
the custom filter. The output is as follows:

```
C:\>type MyOutputFile.log
Sat Sep 04 11:21:19 EDT 2004 INFO This is a test INFO message
Sat Sep 04 11:21:19 EDT 2004 SEVERE This is a test SEVERE message
```

Configuring applications to use Jakarta Commons Logging

Jakarta Commons Logging provides a simple logging interface and thin wrappers for several logging
systems. WebSphere Application Server supports Jakarta Commons Logging by providing a logger. The
support does not change interfaces defined by Jakarta Commons Logging.

The WebSphere Application Server logger is a thin wrapper for the WebSphere Application Server logging
facility. The logger name is *com.ibm.websphere.commons.logging.WsJDK14Logger*. The logger can handle
logging objects defined by either of the following:
- Java Logging found in Java Specification Request 47: Logging API Specification
- Common Base Event

A *logging object* is an object that holds logging entry information.

To better understand Jakarta Commons Logging, read Jakarta Commons and the specifications for Java
Logging and for Common Base Event. To better understand use of the WebSphere Application Server
logger, read "Jakarta Commons Logging" on page 1476.

WebSphere Application Server provides the Jakarta Commons Logging binary distribution in its `libraries`
directory. By default, the product uses the Jakarta Commons Logging LogFactory implementation and
JDK14Logger.

For an application to use the WebSphere Application Server logger, the application must provide its own
configuration for the logger. To configure an application to use the WebSphere Application Server logger,
complete the steps that follow.
1. Examine "Configurations for the WebSphere Application Server logger" on page 1478 and determine
   which configuration best suits your application.

2. Change your application configuration as needed to enable use of the WebSphere Application Server logger.

After the application starts, Jakarta Commons Logging routes the application's logging output to the WebSphere Application Server logger.

Jakarta Commons Logging

Jakarta Commons Logging provides a simple logging interface and thin wrappers for several logging systems. The logging interface enables application logging to be simple and independent of the logging system that the application uses. You can change the logging implementation for a deployed application without having to change the application logging code. However, the simplicity of the logging interface prevents the application from leveraging all the functionality of the logging systems.

This topic provides the following information about Jakarta Commons Logging in WebSphere Application Server:
- "Support for Jakarta Commons Logging"
- "Benefits of support for Jakarta Commons Logging"
- "Overview of the process for using Jakarta Commons Logging"
- "Classes used to obtain a logger factory and logger" on page 1477
- "Logger level configuration and mapping" on page 1478

Support for Jakarta Commons Logging

WebSphere Application Server supports Jakarta Commons Logging by providing a logger, a thin wrapper for the WebSphere Application Server logging facility. The logger can handle both Java Logging (JSR-47) and Common Base Event logging objects. A *logging object* is an object that holds logging entry information.

The WebSphere Application Server support for Jakarta Commons Logging does not change interfaces defined by Jakarta Commons Logging.

Benefits of support for Jakarta Commons Logging

The WebSphere Application Server support for Jakarta Commons Logging provides the following benefits:
- WebSphere Application Server is pre-configured to use Jakarta Commons Logging.

  All of the functionality of Jakarta Commons Logging is provided for any application or WebSphere Application Server component. Logging calls are routed by default to the underlying WebSphere Application Server logging facility.
- A logger that uses the WebSphere Application Server logging facility.

  Applications and components can pass both Java Logging and Common Base Event logging objects to the WebSphere Application Server logger without conversion to strings, providing applications with enhanced logging. Further, Jakarta Commons Logging Logger levels are integrated into WebSphere Application Server administrative facilities.

Overview of the process for using Jakarta Commons Logging

Logging with Jakarta Commons Logging consists of the steps that follow. "Configurations for the WebSphere Application Server logger" on page 1478 provides details on configuring your application to use the WebSphere Application Server logger.
1. Obtain an instance of a logger factory.

  To obtain a logger factory, use Jakarta Commons Logging code. You can configure the code to meet your needs. In WebSphere Application Server, Jakarta Commons Logging is configured by default to instantiate the Jakarta Commons Logging default logger factory. Applications or WebSphere Application

Server components can provide their own configuration if they use a different logger factory implementation. Applications can use more than one factory.

2. Obtain an instance of a logger.

   To obtain a logger, use code implemented by a logger factory. Configuration of the code is implementation specific.

   The WebSphere Application Server logger implements the methods defined in the logging interface. The logging methods take at least one argument, which can be any Java object. The WebSphere Application Server logger, the WsJDK14Logger logger described in "Classes used to obtain a logger factory and logger," handles the following objects passed into the following logging methods:

   CommonBaseEvent
   > Wrapped into CommonBaseEventLogRecord

   CommonBaseEventLogRecord
   > Passed without change

   LogRecord
   > Passed without change

   Other objects
   > Converted to String

   Applications or WebSphere Application Server components can provide their own configuration if they use an implementation of a logger that is not specific to WebSphere Application Server. An application must know what factory is being used in order to configure it.

3. Start your application. Jakarta Commons Logging routes the application's logging output to the designated logger

Classes used to obtain a logger factory and logger

Class name	Description
LogFactory	*LogFactory* is a Jakarta Commons Logging class that implements initialization logic. LogFactory is an abstract class that every logger factory implementation has to extend. It provides static methods for obtaining: • An instance of a factory class • Instances of a logger, using an instance of the factory class LogFactory provides methods for obtaining instances of loggers, although these methods delegate the logger instantiation and configuration to an instance of a logger factory class. Logger factories, once instantiated, are cached on a per context class loader basis. The instances in a cache can be released. This functionality is designed for platform container implementations rather than for applications.
LogFactoryImpl	*LogFactoryImpl* is a Jakarta Commons Logging concrete class that implements the default logger factory using methods in LogFactory. To use Java Logging, there must always be at least one instance of a logger factory class, even if the application has not explicitly obtained one. If the configuration does not name a logger factory class, LogFactoryImpl is used as the default.
Log	*Log* is a Jakarta Commons Logging interface for loggers. Commons logging loggers have to implement the Log interface. Because the goal of Jakarta Commons Logging is to wrapper any logging system, the Log interface defines a small set of common logging methods. In WebSphere Application Server, WsJDK14Logger implements the Log interface. Logger instantiation and configuration is specific to every logger factory. Logging in WebSphere Application Server uses the default logger factory provided in Jakarta Commons Logging, which keeps instantiated loggers in cache, on a per class loader context basis.

Class name	Description
WsJDK14Logger	*WsJDK14Logger* is a WebSphere Application Server class that provides a Jakarta Commons Logging logger by implementing the Log interface. The WsJDK14Logger logger differs from the Java Logging logger in that the WsJDK14Logger logger enables Java Logging or Common Base Event objects to be passed over without converting them into String objects. This prevents any information loss the conversion to String might cause as well as allows the logging output to be more descriptive and precise. In contrast, the Java Logginglogger that is provided in Jakarta Commons Logging converts objects passed into the logging calls to String objects before passing them over to the underlying Java Logging.

Logger level configuration and mapping

Because Jakarta Commons Logging loggers are thin wrappers for specific logging systems, the loggers do not have their own level, but use the level of the logger from the underlying logging system. Although the underlying system can provide methods for changing level, there are no methods for changing level defined on the Log interface, which all Jakarta Commons Logging logger must implement. WsJDK14Logger uses the level of its underlying Java Logging logger.

Following table shows, on the left, the mapping of Jakarta Commons Logging levels within WsJDK14Logger to levels in the WebSphere Application Server implementation of Java Logging. On the right, it shows the levels defined in Java Logging and the level mapping in the Jakarta Commons Logging JDK14Logger to the Java Logging levels.

WsJDK14Logger	Java Logging in WebSphere Application Server	Java Logging	JDK14Logger
Fatal	Fatal		
Error	Severe	Severe	Fatal, Error
Warning	Warning	Warning	Warning
	Audit		
Info	Info	Info	Info
	Config	Config	
	Detail		
Debug	Fine	Fine	Debug
	Finer	Finer	
Trace	Finest	Finest	Trace

The WsJDK14Logger level is synchronized with the underlying Java Logging logger level. WebSphere Application Server administration controls the WsJDK14Logger level.

Configurations for the WebSphere Application Server logger

This topic describes several ways to configure an application to use the WebSphere Application Server logger.

The type of configuration that best suits an application depends upon the following:

- Whether the Class loader order setting for the application is `Classes loaded with parent class loader first (Parent First)` or `Classes loaded with application class loader first (Parent Last)`. You can set the class loader delegation mode on a console Class loading and update detection page.
- Whether Jakarta Commons Logging is bundled with the application configuration
- Whether Jakarta Commons Logging is provided within the application

The following tables describe the conditions required to enable an application to use the WebSphere Application Server logger.

Class loader mode is `Parent First` and Jakarta Commons Logging is bundled with the application

Jakarta Commons Logging configuration	LogFactory instance	Log instance	Comments
The application provides the configuration by either of the following: • The properties file `commons-logging.properties` in the application classpath **is not read** by the LogFactory because the parent class loader finds the WebSphere properties file first. • The class name **is read** from the file `META-INF/services/ org.apache.commons .logging.LogFactory`	The log factory used is the LogFactory implementation specified in the WebSphere Application Server default configuration, unless the configuration is provided in a META-INF file of the application or module.	The log used is either of the following: • The Log implementation specified in the WebSphere Application Server default configuration • An application-specific Log implementation if an application-specific LogFactory that instantiates a different Log implementation is used.	The **application parent class loader** is the first class loader to load the Jakarta Commons Logging code. The **WebSphere bundle** that supports Jakarta Commons Logging provides the LogFactory static code that looks up the LogFactory configuration attributes. For the static LogFactory code to instantiate the LogFactory instance specified in the application configuration, the LogFactory instance must be on the classpath of the **parent class loader**.
Not provided by the application	The log factory used is the LogFactory implementation specified in the WebSphere default configuration.	The log used is the Log implementation specified in the WebSphere default configuration.	The Jakarta Commons Logging bundled with the application is not used.

Class loader mode is `Parent First` and Jakarta Commons Logging is not bundled with the application

Jakarta Commons Logging configuration	LogFactory instance	Log instance	Comments
The application provides the configuration by either of the following: • The properties file `commons-logging.properties` in the application classpath **is not read** by the LogFactory because the parent class loader finds the WebSphere Application Server properties file first. • The class name **is read** from the file `META-INF/services/ org.apache.commons .logging.LogFactory`	The log factory used is the LogFactory implementation specified in the WebSphere Application Server default configuration, unless the configuration is provided in a META-INF file of the application or module.	The log used is either of the following: • The Log implementation specified in the WebSphere Application Server default configuration • An application-specific Log implementation if an application-specific LogFactory that instantiates a different Log implementation is used.	The **application parent class loader** is the first class loader to load the Jakarta Commons Logging code. The **WebSphere bundle** that supports Jakarta Commons Logging provides the LogFactory static code that looks up the LogFactory configuration attributes. For the static LogFactory code to instantiate the LogFactory instance specified in the application configuration, the LogFactory instance must be on the classpath of the **parent class loader**.

Jakarta Commons Logging configuration	LogFactory instance	Log instance	Comments
Not provided by the application	The log factory used is the LogFactory implementation specified in the WebSphere Application Server default configuration.	The log used is the Log implementation specified in the WebSphere Application Server default configuration.	Same as in the previous row

Class loader mode is `Parent Last` and Jakarta Commons Logging is bundled with the application

Jakarta Commons Logging configuration	LogFactory instance	Log instance	Comments

The application provides the configuration by either of the following:
 	
• The properties file `commons-logging.properties` in the application classpath **is read** by the LogFactory because the parent class loader finds the WebSphere Application Server properties file first.
 	
• The class name **is read** from the file
 	
`META-INF/services/`
`org.apache.commons`
`.logging.LogFactory`
	The log factory used is either of the following:
	
	• The default Jakarta Commons Logging LogFactory
	
	• The LogFactory specified in the application configuration
		The log used is the Log implementation specified in the application configuration.
		
		If the log factory used is the default Jakarta Commons Logging LogFactory, the Log implementation must be on the classpath of the application class loader.
			The **application class loader** is the first class loader to load the Jakarta Commons Logging code. The **application bundle** that supports Jakarta Commons Logging provides the LogFactory static code that looks up the LogFactory configuration attributes.
			
			For the static LogFactory code to instantiate the LogFactory instance specified in the application configuration, the LogFactory instance must be on the classpath of the **application class loader**.

Not provided by the application	The log factory used is the LogFactory implementation specified in the WebSphere Application Server default configuration.	The log used is the Log implementation specified in the WebSphere Application Server default configuration.	

Class loader mode is `Parent Last` and Jakarta Commons Logging is not bundled with the application

Jakarta Commons Logging configuration	LogFactory instance	Log instance	Comments
The application provides the configuration by either of the following: • The properties file `commons-logging.properties` in the application classpath **is read** by the LogFactory because the parent class loader finds the WebSphere properties file first. • The class name **is read** from the file `META-INF/services/ org.apache.commons .logging.LogFactory`	The log factory used is either of the following: • The default Jakarta Commons Logging LogFactory • The LogFactory specified in the application configuration	The log used is the Log implementation specified in the application configuration. If the log factory used is the default Jakarta Commons Logging LogFactory, the Log implementation must be on the classpath of the application class loader.	There is no Jakarta Commons Logging code at the application class loader. Thus, the **WebSphere bundle** that supports Jakarta Commons Logging provides the LogFactory static code that looks up the LogFactory configuration attributes. For the static LogFactory code to instantiate the LogFactory instance specified in the application configuration, the LogFactory instance must be on the classpath of the **parent class loader**.
Not provided by the application	The log factory used is the LogFactory implementation specified in the WebSphere Application Server default configuration.	The log used is the Log implementation specified in the WebSphere Application Server default configuration.	

Programming with the JRas framework

Use the JRas extensions to incorporate message logging and diagnostic trace into WebSphere Application Server applications.

The JRas framework that is described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

The JRas extensions allow message logging and diagnostic trace to work with WebSphere Application Server applications. They are based on the stand-alone JRas logging toolkit.

1. Retrieve a reference to the JRas manager.
2. Retrieve message and trace loggers by using methods on the returned manager.
3. Call the appropriate methods on the returned message and trace loggers to create message and trace entries, as appropriate.

JRas logging toolkit

The JRas logging toolkit provides diagnostic information to help the administrator diagnose problems or tune application performance.

Deprecated: The JRas framework that is described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

Developing, deploying, and maintaining applications are complex tasks. For example, when a running application encounters an unexpected condition, it might not be able to complete a requested operation. In such a case, you might want the application to inform the administrator that the operation failed and provide information. This action enables the administrator to take the proper corrective action. Those who

develop or maintain applications might need to gather detailed information relating to the path of a running application to determine the root cause of a failure that is due to a code bug. The facilities that are used for these purposes are typically referred to as *message logging* and *diagnostic trace*.

Message logging (messages) and diagnostic trace (trace) are conceptually quite similar, but do have important differences. It is important for application developers to understand these differences to use these tools properly. To start with, the following operational definitions of messages and trace are provided.

Message

A message entry is an informational record that is intended for end users, systems administrators and support personnel to view. The text of the message must be clear, concise, and interpretable. Messages are typically localized, meaning that they display in the national language of the end user. Although the destination and lifetime of messages might be configurable, some level of message logging is always enabled in normal system operation. Message logging must be used judiciously due to both performance considerations and the size of the message repository.

Trace A trace entry is an information record that is intended for service engineers or developers to use. This trace record might be considerably more complex, verbose, and detailed than a message entry. Localization support is typically not used for trace entries. Trace entries can be fairly inscrutable, understandable only by the appropriate developer or service personnel. It is assumed that trace entries are not written during normal runtime operation, but might be enabled as needed to gather diagnostic information.

WebSphere Application Server provides a message logging and diagnostic trace API that applications can use. This API is based on the stand-alone JRas logging toolkit, which was developed by IBM. The stand-alone JRas logging toolkit is a collection of interfaces and classes that provide message logging and diagnostic trace primitives. These primitives are not tied to any particular product or platform. The stand-alone JRas logging toolkit provides a limited amount of support, which is typically referred to as *systems management support*, including log file configuration support based on property files.

As designed, the stand-alone JRas logging toolkit does not contain the support that is required for integration into the WebSphere Application Server run time or for use in a Java 2 Platform, Enterprise Edition (J2EE) environment. To overcome these limitations, WebSphere Application Server provides a set of extension classes to address these shortcomings. This collection of extension classes is referred to as the JRas extensions. The JRas extensions do not modify the interfaces that are introduced by the stand-alone JRas logging toolkit, but provide the appropriate implementation classes. The conceptual structure that is introduced by the stand-alone JRas logging toolkit is described in the following section. It is equally applicable to the JRas extensions.

JRas concepts

The section contains a basic overview of important concepts and constructs that are introduced by the stand-alone JRas logging toolkit. This information is not an exhaustive overview of the capabilities of this logging toolkit, nor is it intended as a detailed discussion of usage or programming paradigms. More detailed information, including code examples, is available in JRas extensions and its subtopics, including in the API documentation for the various interfaces and classes that make up the logging toolkit.

Event types

The stand-alone JRas logging toolkit defines a set of event types for messages and a set of event types for trace. Examples of message types include informational, warning, and error. Examples of trace types include entry, exit, and trace.

Event classes

The stand-alone JRas logging toolkit defines both message and trace event classes.

Loggers

A logger is the primary object with which the user code interacts. Two types of loggers are defined: message loggers and trace loggers. The set of methods on message loggers and trace loggers are different because they provide different functionality. Message loggers create message records only and trace loggers create trace records only. Both types of loggers contain masks that indicate which categories of events the logger processes and which to ignore. Although every JRas logger

is defined to contain both a message and trace mask, the message logger uses only the message mask and the trace logger uses the trace mask only. For example, by setting a message logger message mask to the appropriate state, it can be configured to process only error messages and ignore informational and warning messages. Changing the trace mask state of a message logger has no effect.

A logger contains one or more handlers to which it forwards events for further processing. When the user calls a method on the logger, the logger compares the event type that is specified by the caller to its current mask value. If the specified type passes the mask check, the logger creates an event object to capture the information relating to the event that passed to the logger method. This information can include information, such as the names of the class and method which logs the event, a message, and parameters to log, among others. When the logger creates the event object, it forwards the event to all handlers currently registered with the logger.

Methods that are used within the logging infrastructure do not make calls to the logger method. When an application uses an object that extends a thread class, implements the hashCode method, and makes a call to the logging infrastructure from that method, the result is a recursive loop.

Handlers

A handler provides an abstraction over an output device or event consumer. An example is a file handler, which knows how to write an event to a file. The handler also contains a mask that is used to further restrict the categories of events the handler processes. For example, a message logger might be configured to pass both warning and error events, but a handler attached to the message logger might be configured to pass error events only. Handlers also include formatters, which the handler invokes to format the data in the passed event before it is written to the output device.

Formatters

Handlers are configured with formatters, which know how to format events of certain types. A handler can contain multiple formatters, each of which knows how to format a specific class of event. The event object is passed to the appropriate formatter by the handler. The formatter returns formatted output to the handler, which then writes it to the output device.

JRas Extensions

JRas extensions is the collection of implementation classes that support JRas integration into the WebSphere Application Server environment.

JRas extensions

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

The stand-alone JRas logging toolkit defines interfaces and provides a variety of concrete classes that implement these interfaces. Because the stand-alone JRas logging toolkit is developed as a general purpose toolkit, the implementation classes do not contain the configuration interfaces and methods that are necessary for use in the WebSphere Application Server product. In addition, many of the implementation classes are not written appropriately for use in a Java 2 Platform, Enterprise Edition (J2EE) environment. To overcome these shortcomings, WebSphere Application Server provides the appropriate implementation classes that support integration into the WebSphere Application Server environment. The collection of these implementation classes is referred to as the *JRas extensions*.

Usage model

You can use the JRas extensions in three distinct operational modes:

Integrated

In this mode, message and trace records are written only to logs that are defined and maintained

by the WebSphere Application Server run time. This mode is the default mode of operation and is equivalent to the WebSphere Application Server V4.0 mode of operation.

stand-alone

In this mode, message and trace records are written solely to stand-alone logs that are defined and maintained by the user. You control which categories of events are written to which logs, and the format in which entries are written. You are responsible for configuration and maintenance of the logs. Message and trace entries are not written to WebSphere Application Server runtime logs.

Combined

In this mode, message and trace records are written to both WebSphere Application Server runtime logs and to stand-alone logs that you must define, control, and maintain. You can use filtering controls to determine which categories of messages and trace are written to which logs.

The JRas extensions are specifically targeted to an integrated mode of operation. The integrated mode of operation can be appropriate for some usage scenarios, but many scenarios are not adequately addressed by these extensions. Many usage scenarios require a stand-alone or combined mode of operation instead. A set of user extension points are defined that support JRas extensions in either a stand-alone or combined mode of operations.

JRas extension classes

WebSphere Application Server provides a base set of implementation classes that are collectively referred to as the *JRas extensions*. Many of these classes provide the appropriate implementations of loggers, handlers, and formatters for use in a WebSphere Application Server environment.

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

The collection of JRas classes is targeted at an integrated mode of operation. If you choose to use the JRas extensions in either stand-alone or combined mode, you can reuse the logger and manager class that are provided by the extensions, but you must provide your own implementations of handlers and formatters.

WebSphere Application Server message and trace loggers

The message and trace loggers that are provided by the stand-alone JRas logging toolkit cannot be directly used in the WebSphere Application Server environment. The JRas extensions provide the appropriate logger implementation classes. Instances of these message and trace logger classes are obtained directly and exclusively from the WebSphere Application Server Manager class. You cannot directly instantiate message and trace loggers. Obtaining loggers in any manner other than directly from the Manager class is not allowed and directly violates the programming model.

The message and trace logger instances that are obtained from the WebSphere Application Server Manager class are subclasses of the RASMessageLogger and RASTraceLogger classes that are provided by the stand-alone JRas logging toolkit. The RASMessageLogger and RASTraceLogger classes define the set of methods that are directly available. Public methods that are introduced by the JRas extensions logger subclasses cannot be called directly by user code because it is a violation of the programming model.

Loggers are named objects and are identified by name. When the Manager class is called to obtain a logger, the caller is required to specify a name for the logger. The Manager class maintains a name-to-logger instance mapping. Only one instance of a named logger is ever created within the lifetime of a process. The first call to the Manager class with a particular name results in the logger, which is configured by the Manager class. The Manager class caches a reference to the instance, then returns it to the caller. Subsequent calls to the Manager class that specify the same name result in a returned reference to the cached logger. Separate namespaces are maintained for message and trace loggers. You can use a single name obtain both a message logger and a trace logger from the Manager, without ambiguity, and without causing a namespace collision.

In general, loggers have no predefined granularity or scope. A single logger can be used to instrument an entire application. You might determine that having a logger per class is more effective, or the appropriate granularity might be somewhere in between. Partitioning an application into logging domains is determined by the application writer.

The WebSphere Application Server logger classes that are obtained from the Manager class are thread-safe. Although the loggers provided as part of the stand-alone JRas logging toolkit implement the serializable interface, loggers are not serializable. Loggers are stateful objects, tied to a Java virtual machine instance and are not serializable. Attempting to serialize a logger is a violation of the programming model.

Personal or individual logger subclasses are not supported in a WebSphere Application Server environment.

WebSphere Application Server handlers

WebSphere Application Server provides the appropriate handler class that is used to write message and trace events to the WebSphere Application Server run time logs. You cannot configure the WebSphere Application Server handler to write to any other destination. The creation of a WebSphere Application Server handler is a restricted operation and is not available to user code. Every logger that is obtained from the Manager comes preconfigured with an instance of this handler already installed. You can remove the WebSphere Application Server handler from a logger when you want to run in stand-alone mode. When you remove it, you cannot add the WebSphere Application Server handler again to the logger from which it is removed or any other logger. Also, you cannot directly call any method on the WebSphere Application Server handler. Attempting to create an instance of the WebSphere Application Server handler, to call methods on the WebSphere Application Server handler or to add a WebSphere Application Server handler to a logger by user code is a violation of the programming model.

WebSphere Application Server formatters

The WebSphere Application Server handler comes preconfigured with the appropriate formatter for data that is written to WebSphere Application Server logs. The creation of a WebSphere Application Server formatter is a restricted operation and not available to user code. No mechanism exists that allows the user to obtain a reference to a formatter installed in a WebSphere Application Server handler, or to change the formatter a WebSphere Application Server handler is configured to use.

WebSphere Application Server manager

WebSphere Application Server provides a Manager class in the com.ibm.websphere.ras package. All message and trace loggers must be obtained from this Manager class. A reference to the Manager class is obtained by calling the static Manager.getManager method. Message loggers are obtained by calling the createRASMessageLogger method on the Manager class. Trace loggers are obtained by calling the createRASTraceLogger method on the Manager class.

The manager also supports a *group* abstraction that is useful when dealing with trace loggers. The group abstraction supports multiple, unrelated trace loggers to register as part of a named entity called a *group*. WebSphere Application Server provides the appropriate systems management facilities to manipulate the trace setting of a group, similar to the way the trace settings of an individual trace logger work.

For example, suppose component A consists of 10 classes. Suppose each class is configured to use a separate trace logger. All 10 trace loggers in the component are registered as members of the same group, for example, Component_A_Group. You can turn on trace for a single class, or you can turn on trace for all 10 classes in a single operation using the group name, if you want a component trace. Group names are maintained within the namespace for trace loggers.

JRas framework (deprecated)

Because the JRas extensions classes do not provide the flexibility and behavior that are required for many scenarios, a variety of extension points are defined. You can write your own implementation classes to obtain the required behavior.

Deprecated: The JRas framework described in this topic is deprecated. However, you can achieve similar results using Java logging.

In general, the JRas extensions require you to call the Manager class to obtain a message logger or trace logger. No provision is made for you to provide your own message or trace logger subclasses. In general, user-provided extensions cannot be used to affect the integrated mode of operation. The behavior of the integrated mode of operation is solely determined by the WebSphere Application Server run time and the JRas extensions classes.

Handlers

The stand-alone JRas logging toolkit defines the RASIHandler interface. All handlers must implement this interface. You can write your own handler classes that implement the RASIHandler interface. Directly create instances of user-defined handlers and add them to the loggers that are obtained from the Manager class.

The stand-alone JRas logging toolkit provides several handler implementation classes. These handler classes are inappropriate for use in the Java 2 Platform, Enterprise Edition (J2EE) environment. You cannot directly use or subclass any of the Handler classes that are provided by the stand-alone JRas logging toolkit. Doing so is a violation of the programming model.

Formatters

The stand-alone JRas logging toolkit defines the RASIFormatter interface. All formatters must implement this interface. You can write your own formatter classes that implement the RASIFormatter interface. You can add these classes to a user-defined handler only. WebSphere Application Server handlers cannot be configured to use user-defined formatters. Instead, directly create instances of your formatters and add them to the your handlers appropriately.

As with handlers, the stand-alone JRas logging toolkit provides several formatter implementation classes. Direct use of these formatter classes is not supported.

Message event types

The stand-alone JRas toolkit defines message event types in the RASIMessageEvent interface. In addition, the WebSphere Application Server reserves a range of message event types for future use. The RASIMessageEvent interface defines three types, with values of $0x01$, $0x02$, and $0x04$. The values $0x08$ through $0x8000$ are reserved for future use. You can provide your own message event types by extending this interface appropriately. User-defined message types must have a value of $0x1000$ or greater.

Message loggers that are retrieved from the Manager class have their message masks set to `pass` or process all message event types defined in the RASIMessageEvent interface. To process user-defined message types, you must manually set the message logger mask to the appropriate state by user code after the message logger is obtained from the Manager class. WebSphere Application Server does not provide any built-in systems management support for managing message types.

Message event objects

The stand-alone JRas toolkit provides a RASMessageEvent implementation class. When a message logging method is called on the message logger, and the message type is currently enabled, the logger creates and distributes an event of this class to all handlers that are currently registered with that logger.

You can provide your own message event classes, but they must implement the RASIEvent interface. You must directly create instances of such user-defined message event classes. When it is created, pass your message event to the message logger by calling the message logger's fireRASEvent method directly. WebSphere Application Server message loggers cannot directly create instances of user-defined types in response to calling a logging method (`msg.message`) on the logger. In addition, instances of user-defined message types are never processed by the WebSphere Application Server handler. You cannot create instances of the RASMessageEvent class directly.

Trace event types

The stand-alone JRas toolkit defines trace event types in the RASITraceEvent interface. You can provide your own trace event types by extending this interface appropriately. In such a case, you must ensure that the values for the user-defined trace event types do not collide with the values of the types that are defined in the RASITraceEvent interface.

Trace loggers that are retrieved from the Manager class typically have their trace masks set to reject all types. A different starting state can be specified by using WebSphere Application Server systems management facilities. In addition, you can change the state of the trace mask for a logger at run-time, using WebSphere Application Server systems management facilities.

To process user-defined trace types, the trace logger mask must be manually set to the appropriate state by user code. WebSphere Application Server systems management facilities cannot be used to manage user-defined trace types, either at start time or run time.

Trace event objects

The stand-alone JRas toolkit provides a RASTraceEvent implementation class. When a trace logging method is called on the WebSphere Application Server trace logger and the type is currently enabled, the logger creates and distributes an event of this class to all the handlers that are currently registered with that logger.

You can provide your own trace event classes. Such trace event classes must implement the RASIEvent interface. You must create instances of such user-defined event classes directly. When it is created, pass the trace event to the trace logger by calling the trace logger's fireRASEvent method directly. WebSphere Application Server trace loggers cannot directly create instances of user-defined types in response to calling a trace method (`entry`, `exit`, `trace`) on the trace logger. In addition, instances of user-defined trace types are never processed by the WebSphere Application Server handler. You cannot create instances of the RASTraceEvent class directly.

User defined types, user defined events and WebSphere Application Server

By definition, the WebSphere Application Server handler processed user-defined message or trace types, or user-defined message or trace event classes. Message and trace entries of either a user-defined type or user-defined event class cannot be written to the WebSphere Application Server run-time logs.

JRas programming interfaces for logging (deprecated):

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

General considerations

You can configure the WebSphere Application Server to use Java 2 security to restrict access to protected resources such as the file system and sockets. Because user-written extensions typically access such protected resources, user-written extensions must contain the appropriate security checking calls, using AccessController doPrivileged calls. In addition, the user-written extensions must contain the appropriate

policy file. In general, locating user-written extensions in a separate package is a good practice. It is your responsibility to restrict access to the user-written extensions appropriately.

Writing a handler

User-written handlers must implement the RASIHandler interface. The RASIHandler interface extends the RASIMaskChangeGenerator interface, which extends the RASIObject interface. A short discussion of the methods that are introduced by each of these interfaces follows, along with implementation pointers. For more in-depth information on any of the particular interfaces or methods, see the corresponding product API documentation.

RASIObject interface

The RASIObject interface is the base interface for stand-alone JRas logging toolkit classes that are stateful or configurable, such as loggers, handlers, and formatters.
* The stand-alone JRas logging tookit supports rudimentary properties-file based configuration. To implement this configuration support, the configuration state is stored as a set of key-value pairs in a properties file. The public Hashtable getConfig and public void setConfig(Hashtable ht) methods are used to get and set the configuration state. The JRas extensions do not support properties-based configuration. Implement these methods as no-operations. You can implement your own properties-based configuration using these methods.
* Loggers, handlers, and formatters can be named objects. For example, the JRas extensions require the user to provide a name for the loggers that are retrieved from the manager. You can name your handlers. The public String getName and public void setName(String name) methods are provided to get or set the name field. The JRas extensions currently do not call these methods on user handlers. You can implement these methods as you want, including as no operations.
* Loggers, handlers, and formatters can also contain a description field. The public String getDescription and public void setDescription(String desc) methods can be used to get or set the description field. The JRas extensions currently do not use the description field. You can implement these methods as you want, including as no operations.
* The public String getGroup method is provided for use by the RASManager interface. Since the JRas extensions provide their own Manager class, this method is never called. Implement this as a no-operation.

RASIMaskChangeGenerator interface

The RASIMaskChangeGenerator interface is the interface that defines the implementation methods for filtering of events based on a mask state. It is currently implemented by both loggers and handlers. By definition, an object that implements this interface contains both a message mask and a trace mask, although both need not be used. For example, message loggers contain a trace mask, but the trace mask is never used because the message logger never generates trace events. Handlers, however, can actively use both mask values. For example, a single handler can handle both message and trace events.
* The public long getMessageMask and public void setMessageMask(long mask) methods are used to get or set the value of the message mask. The public long getTraceMask and public void setTraceMask(long mask) methods are used to get or set the value of the trace mask.

In addition, this interface introduces the concept of *calling back* to interested parties when a mask changes state. The callback object must implement the RASIMaskChangeListener interface.
* The public void addMaskChangeListener(RASIMaskChangeListener listener) and public void removeMaskChangeListener(RASIMaskChangeListener listener) methods are used to add or remove listeners to the handler. The public Enumeration getMaskChangeListeners method returns an enumeration over the list of currently registered listeners. The public void fireMaskChangedEvent(RASMaskChangeEvent mc) method is used to call back all the registered listeners to inform them of a mask change event.

For efficiency reasons, the JRas extensions message and trace loggers implement the RASIMaskChangeListener interface. The logger implementations maintain a composite mask in addition to the logger mask. The logger composite mask is formed by logically *or'ing* the appropriate masks of all handlers that are registered to that logger, then *and'ing* the result with the logger mask. For example, the message logger composite mask is formed by or'ing the message masks of all handlers that are registered with that logger, then and'ing the result with the logger message mask.

All handlers are required to properly implement these methods. In addition, when a user handler is instantiated, the logger that is added must be registered with the handler; use the addMaskChangeListener method. When either the message mask or trace mask of the handler is changed, the logger must be called back to inform it of the mask change. With this process, the logger can dynamically maintain the composite mask.

The RASMaskChangedEvent class is defined by the stand-alone JRas logging toolkit. Direct use of that class by user code is supported in this context.

In addition, the RASIMaskChangeGenerator interface introduces the concept of caching the names of all message and trace event classes that the implementing object process. The intent of these methods is to support a management program such as a graphical user interface to retrieve the list of names, introspect the classes to determine the event types that they might possibly process and display the results. The JRas extensions do not ever call these methods, so they can be implemented as no operations.
- The public void addMessageEventClass(String name) and public void removeMessageEventClass(String name) methodscan be called to add or remove a message event class name from the list. The method public Enumeration getMessageEventClasses returns an enumeration over the list of message event class names. Similarly, the public void addTraceEventClass(String name) and public void removeTraceEventClass(String name) methods can be called to add or remove a trace event class name from the list. The public Enumeration getTraceEventClasses method returns an enumeration over the list of trace event class names.

RASIHandler interface

The RASIHandler interface introduces the methods that are specific to the behavior of a handler.

The RASIHandler interface, as provided by the stand-alone JRas logging toolkit, supports handlers that run in either a synchronous or asynchronous mode. In asynchronous mode, events are typically queued by the calling thread and then written by a worker thread. Because spawning of threads is not supported in the WebSphere Application Server environment, it is expected that handlers do not queue or batch events, although this activity is not expressly prohibited.
- The public int getMaximumQueueSize() and public void setMaximumQueueSize(int size) methods create `IllegalStateException` exceptions to manage the maximum queue size. The public int getQueueSize method is provided to query the actual queue size.
- The public int getRetryInterval and public void setRetryInterval(int interval) methods support the notion of error retry, which implies some type of queueing.
- The public void addFormatter(RASIFormatter formatter), public void removeFormatter(RASIFormatter formatter) and public Enumeration getFormatters methods are provided to manage the list of formatters that the handler can be configured with. Different formatters can be provided for different event classes, if appropriate.
- The public void openDevice, public void closeDevice and public void stop methods are provided to manage the underlying device that the handler abstracts.
- The public void logEvent(RASIEvent event) and public void writeEvent(RASIEvent event) methods are provided to pass events to the handler for processing.

Writing a formatter

User-written formatters must implement the RASIFormatter interface. The RASIFormatter interface extends the RASIObject interface. The implementation of the RASIObject interface is the same for both handlers

and formatters. A short discussion of the methods that are introduced by the RASIFormatter interface follows. For more in-depth information on the methods introduced by this interface, see the corresponding product API documentation.

RASIFormatter interface
- The public void setDefault(boolean flag) and public boolean isDefault methods are used by the concrete RASHandler classes that are provided by the stand-alone JRas logging toolkit to determine if a particular formatter is the default formatter. Because these RASHandler classes must never be used in a WebSphere Application Server environment, the semantic significance of these methods can be determined by the user.
- The public void addEventClass(String name), public void removeEventClass(String name) and public Enumeration getEventClasses methods are provided to determine which event classes a formatter can use to format. You can provide the appropriate implementations.
- The public String format(RASIEvent event) method is called by handler objects and returns a formatted String representation of the event.

Programming model summary

The programming model that is described in this section builds upon and summarizes some of the concepts already introduced. This section also formalizes usage requirements and restrictions. Use of the WebSphere Application Server JRas extensions in a manner that does not conform to the following programming guidelines is prohibited.

Deprecated: The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

You can use the WebSphere Application Server JRas extensions in three distinct operational modes. The programming models concepts and restrictions apply equally across all modes of operation.
- You must not use implementation classes that are provided by the stand-alone JRas logging toolkit directly, unless specifically noted otherwise. Direct usage of those classes is not supported. IBM Support provides no diagnostic aid or bug fixes relating to the direct use of classes that are provided by the stand-alone JRas logging toolkit.
- You must obtain message and trace loggers directly from the Manager class. You cannot directly instantiate loggers.
- You cannot replace the WebSphere Application Server message and trace logger classes.
- You must guarantee that the logger names that are passed to the Manager class are unique, and follow the documented naming constraints. When a logger is obtained from the Manager class, you must not attempt to change the name of the logger by calling the setName method.
- Named loggers can be used more than once. For any given name, the first call to the Manager class results in the Manager class creating a logger that is associated with that name. Subsequent calls to the Manager class that specify the same name result in a returned reference to the existing logger.
- The Manager class maintains a hierarchical namespace for loggers. Use a dot-separated, fully qualified class name to identify any logger. Other than dots or periods, logger names cannot contain any punctuation characters, such as an asterisk (*), a comma (.), an equals sign (=), a colon (:), or quotes.
- Group names must comply with the same naming restrictions as logger names.
- The loggers returned from the Manager class are subclasses of the RASMessageLogger and the RASTraceLogger classes that are provided by the stand-alone JRas logging toolkit. You can call any public method that is defined by the RASMessageLogger and RASTraceLogger classes. You cannot call any public method that is introduced by the provided subclasses.
- If you want to operate in either stand-alone or combined mode, you must provide your own Handler and Formatter subclasses. You cannot use the Handler and Formatter classes that are provided by the stand-alone JRas logging toolkit. User written handlers and formatters must conform to the documented guidelines.
- Loggers that are obtained from the Manager class come with a WebSphere Application Server handler installed. This handler writes message and trace records to logs that are defined by the WebSphere Application Server run time. Manage these logs using the provided systems management interfaces.

- You can programmatically add and remove user-defined handlers from a logger at any time. Multiple additions and removals of user defined handlers are supported. You are responsible for creating an instance of the handler to add, configuring the handler by setting the handler mask value and formatter appropriately, then adding the handler to the logger using the addHandler method. You are responsible for programmatically updating the masks of user-defined handlers, as appropriate.
- You might get a reference to the handler that is installed within a logger by calling the getHandlers method on the logger and processing the results. You must not call any methods on the handler that are obtained in this way. You can remove the WebSphere Application Server handler from the logger by calling the logger removeHandler method, passing in the reference to the WebSphere Application Server handler. When removed, the WebSphere Application Server handler cannot be added again to the logger.
- You can define your own message type. The behavior of user-defined message types and restrictions on their definitions is discussed in Extending the JRas framework.
- You can define your own message event classes. The use of user-defined message event classes is discussed in Extending the JRas framework.
- You can define your own trace types. The behavior of user-defined trace types and restrictions on your definitions is discussed in Extending the JRas framework.
- You can define your own trace event classes. The use of user-defined trace event classes is discussed in Extending the JRas framework.
- You must programmatically maintain the bits in the message and trace logger masks that correspond to any user-defined types. If WebSphere Application Server facilities are used to manage the predefined types, these updates must not modify the state of any of the bits that correspond to those types. If you are assuming ownership responsibility for the predefined types, then you can change all bits of the masks.

JRas messages and trace event types

This topic describes JRas message and trace event types.

Event types

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

The base message and trace event types that are defined by the stand-alone JRas logging toolkit are not the same as the native types that are recognized by the WebSphere Application Server run-time. Instead, the basic JRas types are mapped onto the native types. This mapping can vary by platform or edition. The mapping is discussed in the following section.

Platform message event types

The message event types that are recognized and processed by the WebSphere Application Server runtime are defined in the RASIMessageEvent interface that is provided by the stand-alone JRas logging toolkit. These message types are mapped onto the native message types, as follows.

WebSphere Application Server native type	JRas RASIMessageEvent type
Audit	TYPE_INFO, TYPE_INFORMATION
Warning	TYPE_WARN, TYPE_WARNING
Error	TYPE_ERR, TYPE_ERROR

Platform trace event types

The trace event types that are recognized and processed by the WebSphere Application Server run time are defined in the RASITraceEvent interface that is provided by the stand-alone JRas logging toolkit. The RASITraceEvent interface provides a rich and complex set of types. This interface defines both a simple set of levels, as well as a set of enumerated types.

- For a user who prefers a simple set of levels, the RASITraceEvent interface provides `TYPE_LEVEL1`, `TYPE_LEVEL2`, and `TYPE_LEVEL3`. The implementations provide support for this set of levels. The levels are hierarchical, enabling level 2 also enables level 1, enabling level 3 also enables levels 1 and 2.
- For users who prefer a more complex set of values that can be *OR'd* together, the RASITraceEvent interface provides `TYPE_API`, `TYPE_CALLBACK`, `TYPE_ENTRY_EXIT`, `TYPE_ERROR_EXC`, `TYPE_MISC_DATA`, `TYPE_OBJ_CREATE`, `TYPE_OBJ_DELETE`, `TYPE_PRIVATE`, `TYPE_PUBLIC`, `TYPE_STATIC`, and `TYPE_SVC`.

The trace event types are mapped onto the native trace types as follows:

Mapping WebSphere Application Server trace types to the JRas RASITraceEvent level types.

WebSphere Application Server native type	JRas RASITraceEvent level type
Event	TYPE_LEVEL1
EntryExit	TYPE_LEVEL2
Debug	TYPE_LEVEL3

Mapping WebSphere Application Server trace types to the JRas RASITraceEvent enumerated types.

WebSphere Application Server native type	JRas RASITraceEvent enumerated types
Event	TYPE_ERROR_EXC, TYPE_SVC, TYPE_OBJ_CREATE, TYPE_OBJ_DELETE
EntryExit	TYPE_ENTRY_EXIT, TYPE_API, TYPE_CALLBACK, TYPE_PRIVATE, TYPE_PUBLIC, TYPE_STATIC
Debug	TYPE_MISC_DATA

For simplicity, it is recommended that one or the other of the tracing type methodologies is used consistently throughout the application. If you decide to use the non-level types, choose one type from each category and use those types consistently throughout the application, to avoid confusion.

Message and trace parameters

The various message logging and trace method signatures accept the `Object`, `Object[]` and `Throwable` parameter types. WebSphere Application Server processes and formats the various parameter types as follows:

Primitives
> Primitives, such as int and long are not recognized as subclasses of Object type and cannot be directly passed to one of these methods. A primitive value must be transformed to a proper Object type (Integer, Long) before passing as a parameter.

Object
> The toString method is called on the object and the resulting String is displayed. Implement the toString method appropriately for any object that is passed to a message logging or trace method. It is the responsibility of the caller to guarantee that the toString method does not display confidential data such as passwords in clear text, and does not cause infinite recursion.

Object[]
> The Object[] type is provided for the case when more than one parameter is passed to a message logging or trace method. The toString method is called on each Object in the array. Nested arrays are not handled, that is none of the elements in the Object array belong in an array.

Throwable

The stack trace of the Throwable type is retrieved and displayed.

Array of primitives

An array of primitive, for example, `byte[]`, `int[]`, is recognized as an Object, but is treated somewhat as a second cousin of Object by Java code. In general, avoid arrays of primitives, if possible. If arrays of primitives are passed, the results are indeterminate and can change, depending on the type of array passed, the API used to pass the array, and the release of the product. For consistent results, user code needs to preprocess and format the primitive array into some type of String form before passing it to the method. If such preprocessing is not performed, the following problems can result:

- [B@924586a0b - This message is deciphered as a byte array at location X. This message is typically returned when an array is passed as a member of an Object[] type and results from calling the toString method on the byte[] type.
- Illegal trace argument : array of long. This response is typically returned when an array of primitives is passed to a method taking an Object.
- 01040703: The hex representation of an array of bytes. Typically this problem can occur when a byte array is passed to a method taking a single Object. This behavior is subject to change and cannot be relied on.
- ″1″ ″2″: The String representation of the members of an int[] type formed by converting each element to an integer and calling the toString method on the integers. This behavior is subject to change and cannot be relied on.
- [Ljava.lang.Object;@9136fa0b : An array of objects. Typically this response is seen when an array containing nested arrays is passed.

Controlling message logging

Writing a message to a WebSphere Application Server log requires that the message type passes three levels of filtering or screening:

1. The message event type must be one of the message event types that is defined in the RASIMessageEvent interface.
2. Logging of that message event type must be enabled by the state of the message logger mask.
3. The message event type must pass any filtering criteria that is established by the WebSphere Application Server run-time.

When a WebSphere Application Server logger is obtained from the Manager class, the initial setting of the mask forwards all native message event types to the WebSphere Application Server handler. It is possible to control what messages get logged by programmatically setting the state of the message logger mask.

Some editions of the product support user specified message filter levels for a server process. When such a filter level is set, only messages at the specified severity levels are written to WebSphere Application Server. Message types that pass the mask check of the message logger can be filtered out by WebSphere Application Server.

Control tracing

Each edition of the product provides a mechanism for enabling or disabling trace. The various editions can support static trace enablement (trace settings are specified before the server is started), dynamic trace enablement (trace settings for a running server process can be dynamically modified), or both.

Writing a trace record to a WebSphere Application Server requires that the trace type passes three levels of filtering or screening:

1. The trace event type must be one of the trace event types that is defined in the RASITraceEvent interface.
2. Logging of that trace event type must be enabled by the state of the trace logger mask.
3. The trace event type must pass any filtering criteria that is established by the WebSphere Application Server run-time.

When a logger is obtained from the Manager class, the initial setting of the mask is to suppress all trace types. The exception to this rule is the case where the WebSphere Application Server run time supports static trace enablement and a non-default startup trace state for that trace logger is specified. Unlike message loggers, the WebSphere Application Server can dynamically modify the trace mask state of a trace logger. WebSphere Application Server only modifies the portion of the trace logger mask that corresponds to the values that are defined in the RASITraceEvent interface. WebSphere Application Server does not modify undefined bits of the mask that might be in use for user-defined types.

When the dynamic trace enablement feature that is available on some platforms is used, the trace state change is reflected both in the application server run time and the trace mask of the trace logger. If user code programmatically changes the bits in the trace mask corresponding to the values that are defined by in the RASITraceEvent interface, the mask state of the trace logger and the run time state become unsynchronized and unexpected results occur. Therefore, programmatically changing the bits of the mask corresponding to the values that are defined in the RASITraceEvent interface is not supported.

Instrumenting an application with JRas extensions

You can create an application using JRas extensions.

The JRas framework that is described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

To create an application using the WebSphere Application Server JRas extensions, perform the following steps:
1. Determine the mode for the extensions: integrated, stand-alone, or combined.
2. If the extensions are used in either stand-alone or combined mode, create the necessary handler and formatter classes.
3. If localized messages are used by the application, create a resource bundle.
4. In the application code, get a reference to the Manager class and create the manager and logger instances.
5. Insert the appropriate message and trace logging statements in the application.

Creating JRas resource bundles and message files

The WebSphere Application Server message logger provides the message and msg methods so the user can log localized messages. In addition, the message logger provides the textMessage method to log messages that are not localized. Applications can use either or both, as appropriate.

The JRas framework that is described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

The mechanism for providing localized messages is the resource bundle support that is provided by the IBM Developer Kit, Java Technology Edition. If you are not familiar with resource bundles as implemented by the Developer Kit, you can get more information from various texts, or by reading the API documentation for the java.util.ResourceBundle, java.util.ListResourceBundle and java.util.PropertyResourceBundle classes, as well as the java.text.MessageFormat class.

The PropertyResourceBundle class is the preferred mechanism to use. In addition, note that the JRas extensions do not support the extended formatting options such as {1, date} or {0, number, integer} that are provided by the MessageFormat class.

You can forward messages that are written to the internal WebSphere Application Server logs to other processes for display. For example, messages that are displayed on the administrative console, which can be running in a different location than the server process, can be localized using the *late binding* process. Late binding means that WebSphere Application Server does not localize messages when they are logged, but defers localization to the process that displays the message.

To properly localize the message, the displaying process must have access to the resource bundle where the message text is stored. You must package the resource bundle separately from the application, and install it in a location where the viewing process can access it. If you do not want to take these steps, you can use the early binding technique to localize messages as they are logged.

The two techniques are described as follows:

Early binding

The application must localize the message before logging it. The application looks up the localized text in the resource bundle and formats the message. When formatting is complete, the application logs the message using the textMessage method. Use this technique to package the application resource bundles with the application.

Late binding

The application can choose to have the WebSphere Application Server run time localize the message in the process where it displays. Using this technique, the resource bundles are packaged in a stand-alone `.jar` file, separately from the application. You must then install the resource bundle `.jar` file on every machine in the installation from which an administrative console or log viewing program might be run. You must install the `.jar` file in a directory that is part of the extensions class path. In addition, if you forward logs to IBM service, you must also forward the `.jar` file that contains the resource bundles.

To create a resource bundle, perform the following steps.

1. Create a text properties file that lists message keys and the corresponding messages. The properties file must have the following characteristics:
   - Each property in the file is terminated with a line-termination character.
   - If a line contains only white space, or if the first non-white space character of the line is the number sign symbol (#) or exclamation mark (!), the line is ignored. The # and ! characters can therefore be used to put comments into the file.
   - Each line in the file, unless it is a comment or consists only of white space, denotes a single property. A backslash (\) is treated as the line-continuation character.
   - The syntax for a property file consists of a key, a separator, and an element. Valid separators include the equal sign (=), colon (:), and white space ( ).
   - The key consists of all characters on the line from the first non-white space character to the first separator. Separator characters can be included in the key by escaping them with a backslash (\), but using this approach is not recommended because escaping characters is error prone and confusing. Instead, use a valid separator character that does not display in any keys in the properties file.
   - White space after the key and separator is ignored until the first non-white space character is encountered. All characters that remain before the line-termination character define the element.

   See the Java documentation for the java.util.Properties class for a full description of the syntax and construction of properties files.

2. Translate the file into localized versions of the file with language-specific file names for example, the DefaultMessages.properties file can be translated into `DefaultMessages_de.properties` for German and `DefaultMessages_ja.properties` for Japanese.

3. When the translated resource bundles are available, write them to a system-managed persistent storage medium. Resource bundles are used to convert the messages into the requested national language and locale.

4. When a message logger is obtained from the JRas manager, configure the logger to use a particular resource bundle. Messages logged through the `message` API use this resource bundle when message localization is performed. At run time, the user's locale setting is used to determine the properties file from which to extract the message that is specified by a message key, ensuring that the message is delivered in the correct language.

5. If the message loggers msg method is called, explicitly identify a resource bundle name.

The application locates the resource bundle based on the file location relative to any directory in the class path. For instance, if the DefaultMessages.properties property resource bundle is in the `baseDir/subDir1/subDir2/resources` directory and `baseDir` is in the class path, the name *subdir1.subdir2*.resources.DefaultMessage is passed to the message logger to identify the resource bundle.

JRas resource bundles:

You can create resource bundles in several ways. The best and easiest way is to create a properties file that supports a PropertiesResourceBundle resource bundle. This sample shows how to create such a properties file.

Resource bundle sample

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

For this sample, four localizable messages are provided. The properties file is created and the key-value pairs are inserted into it. All the normal properties files conventions and rules apply to this file. In addition, the creator must be aware of other restrictions that are imposed on the values by the Java MessageFormat class. For example, apostrophes must be escaped or they cause a problem. Avoid the use of non-portable characters. WebSphere Application Server does not support the use of extended formatting conventions that the MessageFormat class supports, such as {1, date} or {0, number, integer}.

Assume that the base directory for the application that uses this resource bundle is `baseDir` and that this directory is in the class path. Assume that the properties file is stored in the subdirectory `baseDir` that is not in the class path (*baseDir/subDir1/subDir2/resources*). To allow the messages file to resolve, the subDir1.subDir2.resources.DefaultMessage name is used to identify the PropertyResourceBundle resource bundle and is passed to the message logger.

For this sample, the properties file is named `DefaultMessages.properties`:

```
# Contents of the DefaultMessages.properties file
MSG_KEY_00=A message with no substitution parameters.
MSG_KEY_01=A message with one substitution parameter: parm1={0}
MSG_KEY_02=A message with two substitution parameters: parm1={0}, parm2 = {1}
MSG_KEY_03=A message with three substitution parameters: parm1={0}, parm2 = {1}, parm3={2}
```

When the `DefaultMessages.properties` file is created, the file can be sent to a translation center where the localized versions are generated.

JRas manager and logger instances

You can use the JRas extensions in integrated, stand-alone, or combined mode. Configuration of the application varies depending on the mode of operation, but use of the loggers to log message or trace entries is identical in all modes of operation.

Deprecated: The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

Integrated mode is the default mode of operation. In this mode, message and trace events are sent to the WebSphere Application Server logs.

In the combined mode, message and trace events are logged to both WebSphere Application Server and user-defined logs.

In the stand-alone mode, message and trace events are logged only to user-defined logs.

Using the message and trace loggers

Regardless of the mode of operation, the use of message and trace loggers is the same.

Using a message logger

The message logger is configured to use the DefaultMessages resource bundle. Message keys must be passed to the message loggers if the loggers are using the message API.

```
msgLogger.message(RASIMessageEvent.TYPE_WARNING, this,
    methodName, "MSG_KEY_00");
... msgLogger.message(RASIMessageEvent.TYPE_WARN, this,
    methodName, "MSG_KEY_01", "some string");
```

If message loggers use the msg API, you can specify a new resource bundle name.

```
msgLogger.msg(RASIMessageEvent.TYPE_ERR, this, methodName,
                "ALT_MSG_KEY_00", "alternateMessageFile");
```

You can also log a text message. If you are using the textMessage API, no message formatting is done.

```
msgLogger.textMessage(RASIMessageEvent.TYPE_INFO, this, methodName,"String and Integer",
"A String", new Integer(5));
```

Using a trace logger

Because trace is normally disabled, guard trace methods for performance reasons.

```
private void methodX(int x, String y, Foo z)
{
   // trace an entry point. Use the guard to make sure tracing is enabled.
Do this checking before you gather parameters to  trace.
   if (trcLogger.isLoggable(RASITraceEvent.TYPE_ENTRY_EXIT) {
        // I want to trace three parameters, package them up in an Object[]
        Object[] parms = {new Integer(x), y, z};
        trcLogger.entry(RASITraceEvent.TYPE_ENTRY_EXIT, this, "methodX", parms);
  }
... logic
  // a debug or verbose trace point
  if (trcLogger.isLoggable(RASITraceEvent.TYPE_MISC_DATA) {
        trcLogger.trace(RASITraceEvent.TYPE_MISC_DATA, this, "methodX" "reached here");
  }
  ...
  // Another classification of trace event. An important state change is
 detected, so a different trace type is used.
  if (trcLogger.isLoggable(RASITraceEvent.TYPE_SVC) {
     trcLogger.trace(RASITraceEvent.TYPE_SVC, this, "methodX", "an important event");
  }
 ...
  // ready to exit method, trace. No return value to trace
    if (trcLogger.isLoggable(RASITraceEvent.TYPE_ENTRY_EXIT)) {
        trcLogger.exit(RASITraceEvent.TYPE_ENTRY_EXIT, this, "methodX");
    }
}
```

Setting up for integrated JRas operation

Use JRas operations in integrated mode to send trace events and logging messages to only WebSphere Application Server logs.

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

In the integrated mode of operation, message and trace events are sent to WebSphere Application Server logs. This approach is the default mode of operation.

1. Import the requisite JRas extensions classes:

```
import com.ibm.ras.*;
import com.ibm.websphere.ras.*;
```

2. Declare logger references:

```
private RASMessageLogger msgLogger = null;
private RASTraceLogger trcLogger = null;
```

3. Obtain a reference to the Manager class and create the loggers. Because loggers are named singletons, you can do this activity in a variety of places. One logical candidate for enterprise beans is the ejbCreate method. For example, for the myTestBean enterprise bean, place the following code in the ejbCreate method:

```
com.ibm.websphere.ras.Manager mgr = com.ibm.websphere.ras.Manager.getManager();
msgLogger = mgr.createRASMessageLogger("Acme", "WidgetCounter", "RasTest",
        myTestBean.class.getName());

// Configure the message logger to use the message file that is created
// for this application.
msgLogger.setMessageFile("acme.widgets.DefaultMessages");
trcLogger = mgr.createRASTraceLogger("Acme", "Widgets", "RasTest",
        myTestBean.class.getName());
mgr.addLoggerToGroup(trcLogger, groupName);
```

Setting up for combined JRas operation

Use JRas operation in combined mode to output trace data and logging messages to both WebSphere Application Server and user-defined logs.

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

In combined mode, messages and trace are logged to both WebSphere Application Server logs and user-defined logs. The following sample assumes that:

- You wrote a user-defined handler named SimpleFileHandler and a user-defined formatter named SimpleFormatter.
- You are not using user-defined types or events.

1. Import the requisite JRas extensions classes:

```
import com.ibm.ras.*;
import com.ibm.websphere.ras.*;
```

2. Import the user handler and formatter:

```
import com.ibm.ws.ras.test.user.*;
```

3. Declare the logger references:

```
private RASMessageLogger msgLogger = null;
  private RASTraceLogger trcLogger = null;
```

4. Obtain a reference to the Manager class, create the loggers, and add the user handlers. Because loggers are named singletons, you can obtain a reference to the loggers in a number of places. One logical candidate for enterprise beans is the ejbCreate method. Make sure that multiple instances of the same user handler are not accidentally inserted into the same logger. Your initialization code must support this approach. The following sample is a message logger sample. The procedure for a trace logger is similar.

```
com.ibm.websphere.ras.Manager mgr = com.ibm.websphere.ras.Manager.getManager();
    msgLogger = mgr.createRASMessageLogger("Acme", "WidgetCounter", "RasTest",
            myTestBean.class.getName());
    // Configure the message logger to use the message file defined
    // in the ResourceBundle sample.
    msgLogger.setMessageFile("acme.widgets.DefaultMessages");

    // Create the user handler and formatter. Configure the formatter,
```

```
      // then add it to the handler.
      RASIHandler handler = new SimpleFileHandler("myHandler", "FileName");
      RASIFormatter formatter = new SimpleFormatter("simple formatter");
       formatter.addEventClass("com.ibm.ras.RASMessageEvent");
       handler.addFormatter(formatter);

      // Add the Handler to the logger. Add the logger to the list of the
      //handlers listeners, then set the handlers
      // mask, which updates the loggers composite mask appropriately.
      // WARNING - there is an order dependency here that must be followed.
      msgLogger.addHandler(handler);
      handler.addMaskChangeListener(msgLogger);
      handler.setMessageMask(RASIMessageEvent.DEFAULT_MESSAGE_MASK);
```

Setting up for stand-alone JRas operation

You can configure JRas operations to output trace data and logging messages to only user-defined locations.

The JRas framework described in this task and its sub-tasks is deprecated. However, you can achieve similar results using Java logging.

In stand-alone mode, messages and traces are logged only to user-defined logs. The following sample assumes that:

- You have a user-defined handler named SimpleFileHandler and a user-defined formatter named SimpleFormatter.
- You are not using user-defined types of events.

1. Import the requisite JRas extensions classes:

   ```
   import com.ibm.ras.*;
   import com.ibm.websphere.ras.*;
   ```

2. Import the user handler and formatter:

   ```
   import com.ibm.ws.ras.test.user.*;
   ```

3. Declare the logger references:

   ```
   private RASMessageLogger msgLogger = null;
     private RASTraceLogger trcLogger = null;
   ```

4. Obtain a reference to the Manager class, create the loggers, and add the user handlers. Because loggers are named singletons, you can obtain a reference to the loggers in a number of places. One logical candidate for enterprise beans is the ejbCreate method. Make sure that multiple instances of the same user handler are not accidentally inserted into the same logger. Your initialization code must support this approach. The following sample is a message logger sample. The procedure for a trace logger is similar.

   ```
   com.ibm.websphere.ras.Manager mgr = com.ibm.websphere.ras.Manager.getManager();
       msgLogger = mgr.createRASMessageLogger("Acme", "WidgetCounter", "RasTest",
               myTestBean.class.getName());
       // Configure the message logger to use the message file that is defined in
       //the ResourceBundle sample.
       msgLogger.setMessageFile("acme.widgets.DefaultMessages");

       // Get a reference to the Handler and remove it from the logger.
       RASIHandler aHandler = null;
       Enumeration enum = msgLogger.getHandlers();
       while (enum.hasMoreElements()) {
           aHandler = (RASIHandler)enum.nextElement();
           if (aHandler instanceof WsHandler)
               msgLogger.removeHandler(wsHandler);
       }

       // Create the user handler and formatter. Configure the formatter,
       // then add it to the handler.
       RASIHandler handler = new SimpleFileHandler("myHandler", "FileName");
   ```

```
    RASIFormatter formatter = new SimpleFormatter("simple formatter");
    formatter.addEventClass("com.ibm.ras.RASMessageEvent");
    handler.addFormatter(formatter);

    // Add the Handler to the logger. Add the logger to the list of the
    // handlers listeners, then set the handlers
    // mask, which will update the loggers composite mask appropriately.
    // WARNING - there is an order dependency here that must be followed.
    msgLogger.addHandler(handler);
    handler.addMaskChangeListener(msgLogger);
    handler.setMessageMask(RASIMessageEvent.DEFAULT_MESSAGE_MASK);
```

Configuring logging properties using the administrative console

Use this task to browse or change the properties of Java logging.

Before applications can log diagnostic information, you need to specify how you want the server to handle log output, and what level of logging you require. Using the administrative console, you can:

- Enable or disable a particular log, specify where log files are stored and how many log files are kept.
- Specify the level of detail in a log, and specify a format for log output.
- Set a log level for each logger.

You can change the log configuration statically or dynamically. Static configuration changes affect applications when you start or restart the application server. Dynamic or run time configuration changes apply immediately.

When a log is created, the level value for that log is set from the configuration data. If no configuration data is available for a particular log name, the level for that log is obtained from the parent of the log. If no configuration data exists for the parent log, the parent of that log is checked, and so on up the tree, until a log with a non-null level value is found. When you change the level of a log, the change is propagated to the children of the log, which recursively propagates the change to their children, as necessary.

To configure loggers and log handlers for Java logging, use the administrative console to complete the following steps:

1. Set the output properties for a log:
   a. In the navigation pane, click **Servers > Application Servers**.
   b. Click the name of the server that you want to work with.
   c. Under Troubleshooting, click **Logging and tracing**.
   d. Click the name of a system log to configure (Diagnostic Trace, JVM Logs, Process Logs or IBM Service Logs).
   e. To make a static change to the system log configuration, click the **Configuration** tab. To change the configuration dynamically, click the **Runtime** tab.
   f. Change the properties for the selected log according to your needs.
   g. Click **Apply**.
   h. Click **OK**.
2. Set the logging levels for your logs:
   a. In the navigation pane, click **Servers > Application Servers**.
   b. Click the name of the server that you want to work with.
   c. Under Troubleshooting, click **Logging and tracing**.
   d. Click **Change Log Detail levels**.

e. To make a static change to the configuration, click the **Configuration** tab. A list of well-known components, packages, and groups is displayed. To change the configuration dynamically, click the **Runtime** tab. The list of components, packages, and groups displays all the components that are currently registered on the running server.

f. Select a component, package, or group to set a logging level.

g. Click **Apply**.

h. Click **OK**.

3. To have static configuration changes take effect, stop then restart the application server.

Log level settings

Use this topic to configure and manage log level settings.

Using log levels you can control which events are processed by Java logging. When you change the level for a logger, the change is propagated to the children of the logger.

Change Log Detail Levels

Enter a log detail level that specifies the components, packages, or groups to trace. The log detail level string must conform to the specific grammar described in this topic. You can enter the log detail level string directly, or generate it using the graphical trace interface.

If you select the Configuration tab, a static list of well-known components, packages, and groups is displayed. This list might not be exhaustive.

If you select the Runtime tab, the list of components, packages, and group are displayed with all the components that are registered on the running application server and in the static list.

The format of the log detail level specification is:

```
<component> = <level>
```

where <component> is the component for which to set a log detail level, and <level> is one of the valid logger levels (off, fatal, severe, warning, audit, info, config, detail, fine, finer, finest, all). Separate multiple log detail level specifications with colons (:).

Components correspond to Java packages and classes, or to collections of Java packages. Use an asterisk (*) as a wildcard to indicate components that include all the classes in all the packages that are contained by the specified component. For example:

* Specifies all traceable code running in the application server, including the product system code and customer code.

com.ibm.ws.*
Specifies all classes with the package name beginning with com.ibm.ws.

com.ibm.ws.classloader.JarClassLoader
Specifies the JarClassLoader class only.

An error can occur when setting a log detail level specification from the administrative console if selections are made from both the Groups and Components lists. In some cases, the selection made from one list is lost when adding a selection from the other list. To work around this problem, enter the log detail level specification directly into the log detail level entry field.

Select a component or group to set a log detail level. The table following lists the valid levels for application servers at WebSphere Application Server Version 6 and later, and the valid logging and trace levels for earlier versions:

Version 6 logging level	Logging level before Version 6	Trace level before Version 6	Content / Significance

Off	Off	All disabled*	Logging is turned off. * In Version 6, a trace level of All disabled turns off trace, but does not turn off logging. Logging is enabled from the Info level.
Fatal	Fatal	-	Task cannot continue and component, application, and server cannot function.
Severe	Error	-	Task cannot continue but component, application, and server can still function. This level can also indicate an impending fatal error.
Warning	Warning	-	Potential error or impending error. This level can also indicate a progressive failure (for example, the potential leaking of resources).
Audit	Audit	-	Significant event affecting server state or resources
Info	Info	-	General information outlining overall task progress
Config	-	-	Configuration change or status
Detail	-	-	General information detailing subtask progress
Fine	-	Event	Trace information - General trace + method entry, exit, and return values
Finer	-	Entry/Exit	Trace information - Detailed trace
Finest	-	Debug	Trace information - A more detailed trace that includes all the detail that is needed to debug problems
All		All enabled	All events are logged. If you create custom levels, All includes those levels, and can provide a more detailed trace than finest.

When you enable a logging level in Version 6.0 or above, you are also enabling all of the levels with higher severity. For example, if you set the logging level to warning on your Version 6.x application server, then warning, severe and fatal events are processed.

Trace information, which are events at the Fine, Finer and Finest levels, can be written only to the trace log. Therefore, if you do not enable diagnostic trace, setting the log detail level to Fine, Finer, or Finest will not have an effect on the data that is logged.

HTTP error and NCSA access log settings

Use this page to configure an HTTP error log and National Center for Supercomputing Applications (NCSA) access logs for an HTTP transport channel. The HTTP error log contains HTTP errors. The level of error logging that occurs is dependent on the value that is selected for the Error log level field.

To view this administrative console page, click **Application servers** > *server name* > **HTTP error and NCSA access logging**.

The NCSA access log contains a record of all inbound client requests that the HTTP transport channel handles. All of the messages that are contained in these logs are in NCSA format.

After you configure the HTTP error log and the NCSA access logs, make sure that the Enable NCSA access logging field is selected for the HTTP channels for which you want logging to occur. To view the settings for an HTTP channel, click **Servers** > **Application Servers** > *server* > **Web Container Transport Chains** > **HTTP Inbound Channel**.

Enable service at server startup

When selected, either an NCSA access log or an HTTP error log, or both are initialized when the server starts.

Enable access logging

When selected, a record of inbound client requests that the HTTP transport channel handles is kept in the NCSA access log.

Access log file path

Indicates the directory path and name of the NCSA access log. Standard variable substitutions, such as $(SERVER_LOG_ROOT), can be used when specifying the directory path.

Access log maximum size

Indicates the maximum size, in megabytes, of the NCSA access log file. When this size is reached, the *logfile_name*.1 archive log is created. However, every time that the original log file overflows this archive file, the file is overwritten with the most current version of the original log file.

NCSA access log format

Indicates that the NCSA format is used when logging client access information. If Common is selected, the log entries contain the requested resource and a few other pieces of information, but does not contain referral, user agent, or cookie information. If Combined is selected, referral, user agent, and or cookie information is included.

Enable error logging

When selected, HTTP errors that occur while the HTTP channel processes client requests are recorded in the HTTP error log.

Error log file path

Indicates the directory path and the name of the HTTP error log. Standard variable substitutions, such as $(SERVER_LOG_ROOT), can be used when specifying the directory path.

Error log maximum size

Indicates the maximum size, in megabytes, of the HTTP error log file. When this size is reached, the *logfile_name*.1 archive log is created. However, every time that the original log file overflows this archive file, this file is overwritten with the most current version of the original log file.

Error log level

Indicates the type of error messages that are included in the HTTP error log.

You can select:

Critical

Only critical failures that stop the Application Server from functioning properly are logged.

Error The errors that occur in response to clients are logged. These errors require Application Server administrator intervention if they result from server configuration settings.

Warning

Information on general errors, such as socket exceptions that occur while handling client requests, are logged. These errors do not typically require Application Server administrator intervention.

Information

The status of the various tasks that are performed while handling client requests is logged.

Debug

More verbose task status information is logged. This level of logging is not intended to replace RAS logging for debugging problems, but does provide a steady status report on the progress of individual client requests. If this level of logging is selected, you must specify a large enough log file size in the Error log maximum size field to contain all of the information that is logged.

The Common Base Event in WebSphere Application Server

This topic describes how WebSphere Application Server takes advantage of the Common Base Events.

An application creates an event object whenever something happens that either needs to be recorded for later analysis or which might require the trigger of additional work. An *event* is a structured notification that reports information that is related to a situation. An event reports three kinds of information:
* The situation: What happened
* The identity of the affected component: For example, the server that shut down
* The identity of the component that is reporting the situation, which might be the same as the affected component

The application that creates the event object is called the *event source*. Event sources can use a common structure for the event. The accepted standard for such a structure is called the *Common Base Event*. The Common Base Event is an XML document that is defined as part of the autonomic computing initiative. The Common Base Event defines common fields, the values they can take, and the exact meanings of these values.

The Common Base Event model is a standard that defines a common representation of events that is intended for use by enterprise management and business applications. This standard, which is developed by the IBM Autonomic Computing Architecture Board, supports encoding of logging, tracing, management, and business events using a common XML-based format. This format makes it possible to correlate different types of events that originate from different applications. For more information about the Common Base Event model, see the Common Base Event specification (*Canonical Situation Data Format: The Common Base Event V1.0.1*). The common event infrastructure currently supports Version 1.0.1 of the specification.

The basic concept behind the Common Base Event model is the *situation*. A situation can be anything that happens anywhere in the computing infrastructure, such as a server shutdown, a disk-drive failure, or a failed user login. The Common Base Event model defines a set of standard situation types that accommodate most of the situations that might arise (for example, StartSituation and CreateSituation).

The Common Base Event contains all of the information that is needed by the consumers to understand the event. This information includes data about the runtime environment, the business environment, and the instance of the application object that created the event.

For complete details on the Common Base Event format, see the XML schema that is included in the Common Base Event specification document, at ftp://www6.software.ibm.com/software/developer/library/ac-toolkitdg.pdf .

Types of problem determination events

Problem determination involves multiple types of data, including at least two different classes of event data, log events, and diagnostic events.

Log events, which are also referred to as *message events*, are typically emitted by components of a business application during normal deployment and operations. Log events might identify problems, but these events are also normally available and emitted while an application and its components are in production mode. The target audience for log and message events is users and administrators of the application and the components that make up the application. Log events are normally the only events available when a problem is first detected, and are typically used during both problem recovery and problem resolution.

Diagnostic events, which are commonly referred to as *trace events*, are used to capture internal diagnostic information about a component, and are usually not emitted or available during normal deployment and operation. The target audience for diagnostic events is the developers of the components that make up the business application. Diagnostic events are typically used when trying to resolve problems within a component, such as a software failure, but are sometimes used to diagnose other problems, especially when the information provided by the log events is not sufficient to resolve the problem. Diagnostic events are typically used when trying to resolve a problem.

A *Common Base Event* is a common structure for an event. It defines common fields, the values that these fields can take, and the exact meanings of these values for an event. Common Base Events are primarily used to represent log events.

The structure of the Common Base Event

A *Common Base Event* is a common structure for an event. It defines common fields, the values that these fields can take, and the exact meanings of these values for an event.

The Common Base Event contains several structural elements. These elements include:
- Common header information
- Component identification, both source and reporter
- Situation information
- Message data
- Extended data
- Context data
- Associated events and association engine

Each of these structural elements has its own embedded elements and attributes.

The following table presents a summary of all the fields in the Common Base Event and their usage requirements for problem determination events. This table shows whether a particular element or attribute is required, recommended, optional, prohibited, or discouraged for log events, and the base specification.

Field name	Log events	Base specification
Version	Required	Required
creationTime	Required	Required
severity	Required	Optional
Msg	Required	Optional
sourceComponentId*	Required	Required
sourceComponentId.location	Required	Required
sourceComponentId.locationType	Required	Required

sourceComponentId.component	Required	Required
sourceComponentId.subComponent	Required	Required
sourceComponentId.componentIdType	Required	Required
sourceComponentId.componentType	Required	Required
sourceComponentId.application	Recommended	Optional
sourceComponentId.instanceId	Recommended	Optional
sourceComponentId.processId	Recommended	Optional
sourceComponentId.threadId	Recommended	Optional
sourceComponentId.executionEnvironment	Optional	Optional
situation*	Required	Required
situation.categoryName	Required	Required
situation.situationType*	Required	Required
situation.situationType.reasoningScope	Required	Required
situation.situationType.(specific Situation Type elements)	Required	Required
msgDataElement*	Recommended	Optional
msgDataElement .msgId	Recommended	Optional
msgDataElement .msgIdType	Recommended	Optional
msgDataElement .msgCatalogId	Recommended	Optional
msgDataElement .msgCatalogTokens	Recommended	Optional
msgDataElement .msgCatalog	Recommended	Optional
msgDataElement .msgCatalogType	Recommended	Optional
msgDataElement .msgLocale	Recommended	Optional
extensionName	Recommended	Optional
localInstanceId	Optional	Optional
globalInstanceId	Optional	Optional
priority	Discouraged	Optional
repeatCount	Optional	Optional
elapsedTime	Optional	Optional
sequenceNumber	Optional	Optional
reporterComponentId*	Optional	Optional
reporterComponentId.location	Required (2)	Required (2)
reporterComponentId.locationType	Required (2)	Required (2)
reporterComponentId.component	Required (2)	Required (2)
reporterComponentId.subComponent	Required (2)	Required (2)
reporterComponentId.componentIdType	Required (2)	Required (2)
reporterComponentId.componentType	Required (2)	Required (2)
reporterComponentId.instanceId	Optional	Optional
reporterComponentId.processId	Optional	Optional
reporterComponentId.threadId	Optional	Optional
reporterComponentId.application	Optional	Optional
reporterComponentId.executionEnvironment	Optional	Optional
extendedDataElements*	Note 3	Optional

contextDataElements*	Note 4	Optional
associatedEvents*	Note 5	Optional

Notes:

- Items followed by an asterisk (*) are elements that consist of sub elements and attributes. The fields in those elements are listed in the table directly following the parent element name.
- Some of the elements are optional, but when included, they include sub elements and attributes that are required. For example, the reporterComponentId element has a ComponentIdentification type. The component attribute in ComponentIdentification is required. Therefore, the reporterComponentId.component attribute is required, but only when the reporterComponentId parent element is included.
- The extendedDataElements element can be included multiple times to supply extended data information. See the Extended data section for more information on required and recommended extended data element values.
- The contextDataElements element can be included multiple times to supply context data information.
- The associatedEvents element can be included multiple times to supply correlation data. No recommended uses of this element exist for the producers of problem determination data, and the use of this element is discouraged.

Common header information

This topic provides additional information about how to format and use these fields for problem determination events, which can be used to clarify and extend the information provided in the other documents.

The Common Base Event specification [CBE101] provides information on the required format of these fields and the Common Base Event Developer's Guide [CBEBASE] provides general usage guidelines.

The common header information in the Common Base Event includes the following information about an event:

- Version: The version of this Common Base Event
- creationTime: The date and time when the event generated
- Severity and priority: The severity of the condition (situation) that is identified by the event
- extensionName: The type of event that was captured
- localInstanceId and globalInstanceId: Identifiers that can be used to quickly identify a specific event within a set of events
- repeatCount and elapsedTime: Information that supports a system to efficiently report multiple events of the same type, by consolidating those events into a single event
- sequenceNumber: Sequence information that supports a system to order a set of events in other ways than time of capture

severity

All problem determination events must provide an indication as to the relative severity of the condition (situation) being reported by providing appropriate values for the severity field in the Common Base Event. The severity field is required for problem determination events. This field is more restrictive than the base specification for the Common Base Event, which lists this field as optional because effective and efficient problem determination requires the ability to quickly identify the information that is needed to resolve a problem as well as prioritize the problems that need addressing. Typically, the following values are used for problem determination events:

10	Information	Log information events, normal conditions, and events that are supplied to clarify operations, for example, state transitions, operational changes. These events typically do not require administrator action or intervention.
20	Harmless	Similar to information events, but are used to capture audit items, such as state transitions or operational changes. These events typically do not require administrator action or intervention.
30	Warning	Warnings typically represent recoverable errors, for example a failure that the system can correct. These events can require administrator action or intervention.
40	Minor	Minor errors describe events that represent an unrecoverable error within a component. The failure affects the component ability to service some requests. The business application can continue to perform its normal functions, but its overall operation might be degraded. These events require administrator action or intervention to address the condition.
50	Critical	Critical errors describe events that represent an unrecoverable error within a component. The failure significantly affects the component ability to service most requests. The business application can continue most, but not all of its normal functions and its overall operation might be degraded. These events require administrator action or intervention to address the condition.
60	Fatal	Fatal errors describe events that represent an unrecoverable error within a component. The failure usually results in the complete failure of the component. The business application can continue some normal functions, but its overall operation might be degraded. These events require administrator action or intervention to address the condition.

msg

Refer to "Message data" on page 1512 for information on this attribute.

priority

The use of the priority field is discouraged for problem determination events. The severity field is typically used to communicate and evaluate the importance of problem determination events. Use the priority field to enhance the information that is provided in the severity field, that is. prioritize events of the same severity.

extensionName

The extensionName field is used to communicate the type of event that is reported, for example, what general class of events is being reported. In many cases this field provides an indication of what additional data you can expect with the event, for example, optional data values.

repeatCount

The repeatCount field is valid for problem determination events, but is not typically used or supplied by the event producers. This field is used for data reduction and consolidation by event management and analysis systems.

elapsedTime

The elapsedTime field is valid for problem determination events, but is not typically used or supplied by the event producers. This field is used for data reduction and consolidation by event management and analysis systems.

sequenceNumber

The sequenceNumber field is valid for problem determination events. It is typically used only by event producers when the granularity of the event time stamp (the creationTime field) is not sufficient in ordering events. The sequenceNumber field is typically used to sequence events that have the same time stamp value.

Event management and analysis systems can use the sequenceNumber field for a number of reasons, including providing alternative sequencing, not necessarily based on a time stamp. The recommendations here are provided primarily for event producers.

Component identification for source and reporter

The component identification fields in the Common Base Event are used to indicate which component in the system is experiencing the condition that is described by the event (the sourceComponentID) and which component emitted the event (the reporterComponentID). Typically, these components are the same, in which case only the sourceComponentID is supplied. Some notes and scenarios on when to use these two elements in the Common Base Event:

- The sourceComponentID is always used to identify the component experiencing the condition that is described by the event.

- The reporterComponentID is used to identify the component that actually produced and emitted the event. This element is typically used only within events that are emitted by a component that is monitoring another component and providing operational information regarding that component. The monitoring component (for example, a Tivoli agent or hardware device driver) is identified by the reporterComponentID and the component being monitored (for example, a monitored server or hardware device) is identified by the sourceComponentID.

  A potential misuse of the reporterComponentID is to identify a component that provides event conversion or management services for a component, for example, identifying an adapter that transforms the events that are captured by a component into Common Base Event format. The event conversion function is considered an extension of the component and not identified separately.

The information that is used to identify a component in the system is the same, regardless of whether it is the source component or reporter component:

location locationType	Component location	Identifies the location of the component.
component componentType	Component name	Identifies the asset name of the component, as well as the type of component.
subcomponent	Subcomponent name	Identifies a specific part or subcomponent of a component, for example a software module or hardware part.

application	Business application name	Identifies the business application or process the component is a part of and provides services for.
instanceId	Operational instance	Identifies the operational instance of a component, that is the actual running instance of the component.
processId threadId	Operational instance	Identifies the operational instance of a component within the context of a software operating system, that is he operating system process and thread running when the event was produced.
executionEnvironment	Operational instance Component location	Provides additional information about the operational instance of a component or its location by identifying the name of the environment hosting the operational instance of the component, for example the operating system name for a software application, the application server name for a Java 2 Platform, Enterprise Edition (J2EE) application, or the hardware server type for a hardware part.

The Common Base Event specification [CBE101] provides information on the required format of these fields and the Common Base Event Developer's Guide [CBEBASE] provides general usage guidelines. This section provides additional information about how to format and use some of these fields for problem determination events, which can be used to clarify and extend the information that is provided in the other documents.

Component
    The Component field in a problem determination event is used to identify the manageable asset that is associated with the event. A manageable asset is open for interpretation, but a good working definition is a manageable asset represents a hardware or software component that can be separately obtained or developed, deployed, managed, and serviced. Examples of typical component names are:

- IBM eServer xSeries model x330
- IBM WebSphere Application Server version 5.1 (5.1 is the version number)
- Microsoft Windows 2000
- The name of an internally developed software application for a component

subComponent
    The Subcomponent field in a problem determination event identifies the specific part of a component that is associated with the event. The subcomponent name is typically not a manageable asset, but provides internal diagnostic information when diagnosing an internal defect within a component, that is What part failed? Examples of typical subcomponents and their names are:

- Intel Pentium processor within a server system (Intel Pentium IV Processor)
- the enterprise bean container within a Web application server (enterprise bean container)
- the task manager within an operating system (Linux Kernel Task Manager)
- the name of a Java class and method (myclass.mycompany.com or myclass.mycompany.com.methodname).

The format of a subcomponent name is determined by the component, but use the convention shown previously for naming a Java class or the combination of a Java class and method is followed. The subcomponent field is required in the Common Base Event.

componentIdType

The componentIdType field is required by the Common Base Event specification, but provides minimal value for problem determination events. For problem determination events, the use of the application value is discouraged. The componentIdType field identifies the type of component; the application is identified by the application field.

application

The application field is listed as an optional value within the Common Base Event specification, but provide it within problem determination events whenever it this value is available. The only reason this field is not required for problem determination events is that instances exist where the issuing component might not be aware of the overall business application.

instanceId

The instanceId field is listed as an optional value within the Common Base Event specification, but provide this value within problem determination events whenever it is available.

Always provide the instanceID when a software component is identified and identify the operational instance of the component (for example, which operation instance of an installed software image is actually associated with the event). Provide this value for hardware components when these components support the concept of operational instances.

The format of the supplied value is defined by the component, but must be a value that an analysis system can use (either human or programmatic) to identify the specific running instance of the identified component. Examples include:

- **cell, node, server** name for the IBM WebSphere Application Server
- **deployed EAR file name** for a Java enterprise bean
- **serial number** for a hardware processor

processId

The processId field is listed as an optional value within the Common Base Event specification, but provide this value for problem determination events whenever it is available and applicable. Always provide this value for software-generated events, and identify the operating system process that is associated with the component that is identified in the event. Match the format of the thread ID with the format of the operating system (or other running environment, such as a Java virtual machine). This field is typically not applicable or used for events that are emitted by hardware (for example, firmware).

threadId

The threadId field is listed as an optional value within the Common Base Event specification, but provide this value for problem determination events whenever it is available and applicable. Always provide for software-generated events, and identify the active operating system thread when the event was detected or issued. A notable exception to this recommendation is some operating systems or running environments do not support threads. Match the format of the thread ID with the format of the operating system (or other running environment, such as a Java virtual machine). This field is typically not applicable or used for events that are emitted by hardware (for example, firmware).

executionEnvironment

The executionEnvironment field, when used, identifies the immediate running environment that is used by the component being identified. Some examples are:

- the operating system name when the component is a native software application.
- the operating system/Java virtual machine name when the component is a Java 2 Platform, Standard Edition (J2SE) application.
- the Web server name when the component is a servlet.
- the portal server name when the component is a portlet.
- the application server name when the component is an enterprise bean.

The Common Base Event specification [CBE101] provides information on the required format of these fields and the Common Base Event Developer's Guide [CBEBASE] provides general usage guidelines.

Situation information

The situation information is used to classify the condition that is reported by an event into a common set of situations.

The Common Base Event specification [CBE101] provides information on the set of situations defined for the Common Base Event, with the values and formats that are used to describe these situations. The Common Base Event Developer's Guide [CBEBASE] provides general usage guidelines.

Consider the following points regarding situation information for problem determination events:
- Whenever possible, use the situation categorizations and qualifiers that are described in the base Common Base Event specification. Avoid using your own situation definitions as much as possible.
- Not all messages and logs can be classified using the situation definitions that are supplied in the base Common Base Event specification. You can use the OtherSituation categorization to provide your own situation information, but the recommended course of action for problem determination events is to use the ReportSituation categorization, with reportCategory=Log.
- Warning events can be confusing. A warning event (that is an event with severity=warning) typically indicates a recoverable failure, but the situation settings can be interpreted as unrecoverable failures (for example ConnectSituation, successDisposition=UNSUCCESSFUL). Use the appropriate situation categorization so the severity setting indicates the severity of the situation, that is whether the component recovered from the failure.
- The recommended setting for the reasoningScope value is EXTERNAL for all message events.

Message data

All problem determination Common Base Events must provide human readable text that describes the specific reported event within the msg field of the Common Base Event.

The text that is associated with events representing actual messages or log entries is expected to be translated and localized. Include the msgDataElement element in the Common Base Event whenever internationalized text is provided in the event. This element provides information about how the message text is created and how to interpret it. This information is particularly invaluable when trying to interpret the event programmatically or when trying to interpret the message independent of the locale or language that is used to format the message text.

Prerequisite: Understand the concepts that are associated with creating internationalized messages. A good source of education on these concepts is provided by the documentation that is associated with internationalization of Java information and the usage of resource bundles within the Java language.

The msgDataElement element in the Common Base Event includes the following information about the value of the msg field that is provided with an event:
- The locale of the supplied message text, which identifies how the locale-independent fields within the message are formatted, as well as the language of the message (msgLocale).
- A locale-independent identifier that is associated with the message that can be used to interpret the message independent of the message language, message locale, and message format (msgId and msgIdType).
- Information on how a translated message is created, including:
  - The identifier that is used to retrieve the message template (msgCatalogId).
  - The name and type of message catalog that are used to retrieve the message template (msgCatalog and msgCatalogType).
  - Any locale-independent information that is inserted into the message template to create the final message (msgCatalogTokens).

The Common Base Event specification [CBE101] provides information on the required format of these fields and the Common Base Event Developer's Guide [CBEBASE] provides general usage guidelines. This section provides additional information about how to format and use these fields for problem determination events.

msg

All message, log, and trace events must provide a human-readable message in the msg field of the Common Base Event. The msg field is required for problem determination events, both log events and diagnostic events. This field is more restrictive than the base specification for the Common Base Event, which lists this field as optional; effective and efficient problem determination requires the ability to quickly identify the reported condition. The format and usage of this message is component-specific, but use the following general guidelines:

- Expect the message text that is supplied with messages and log events to be internationalized.
- Provide the locale of the supplied message text with the msgLocale field in the msgDataElement element of the Common Base Event.
- Provide additional information regarding the format and construction of internationalized messages whenever possible, using the msgDataElement element of the Common Base Event.

msgLocale

Provide the message locale whenever message text is provided within the Common Base Event, as is the case with all problem determination events. The msgLocale field is listed as an optional value within the Common Base Event specification, but provide this information within problem determination events whenever possible. The reason this field is not required for problem determination events is that instances exist where the locale information is not provided or available when formatting the Common Base Event.

msgId and msgIdType

Several companies include a locale-independent identifier within internationalized message text that you can use to interpret the described condition by the message text, independent of the message. For example, most messages issued by IBM software look like `IEE890I WTO Buffers in console backup storage = 1024`, where a unique, locale-independent identifier `IEE890I` precedes the translated message text. This identifier provides a way to uniquely detect and identify a message independent of location and language. This detection is invaluable for locale-independent and programmatic analysis.

The msgId field is listed as an optional value within the Common Base Event specification, but it must be provided within problem determination events whenever this identifier is included in the message text. Likewise, the msgIdType field is listed as an optional value within the Common Base Event specification, but it must be provided within problem determination events whenever a value is supplied for msgId. Do not supply these fields when the message text is not translated or localized, for example, for trace events.

msgCatalogId

The msgCatalogId field is listed as an optional value within the Common Base Event specification, but provide this value whenever the Common Base Event includes localized or translated message text, for example when providing problem determination events that represent issued messages or log events. This field is not required for problem determination events because not all problem determination events include translated message text Some cases exist where the value is not provided or available when formatting the Common Base Event. Do not supply this field when the message text is not translated or localized, for example, for trace events.

msgCatalogTokens

The msgCatalogTokens field is listed as an optional value within the Common Base Event specification, but provide this value whenever the Common Base Event includes localized or translated message text, for example when providing problem determination events that represent issued messages or log events. This field is not required for problem determination events because not all problem determination events include translated message text, and cases exist where the value is not

provided or available when formatting the Common Base Event. This value contains the list of locale-independent values or message tokens that are inserted into the localized message text when creating a translated message.

These values are difficult to extract from a translated message without knowing the translated message template that is used to create the message. Do not supply this field when the message text is not translated or localized

The Common Base Event provides several mechanisms for providing additional data about an event, including this field, extended data elements, and extensions to the schema. Always use the msgCatalogTokens field to supply the list of message tokens that is included in the message text associated with an event. These values can also be supplied in other parts of the Common Base Event, but they must be included in this field.

msgCatalog and msgCatalogType

The msgCatalog and msgCatalogType fields are listed as optional values within the Common Base Event specification, but provide this value whenever the Common Base Event includes localized or translated message text, for example when providing problem determination events that represent issued messages or log events. These fields are not required for problem determination events because not all problem determination events include translated message text, and cases exist where the values are not provided or available when formatting the Common Base Event. Do not complete these fields when the message text has is not translated or localized, for example, for trace events.

Extended data

The Common Base Event provides several methods for including this additional data, including extending the Common Base Event schema or supplying one or more ExtendedDataElement elements within the Common Base Event, which is the preferred approach.

The base information that is included in a Common Base Event might not be sufficient to represent all of the information captured by a component when creating a problem determination event.

Use an ExtendedDataElement element to represent a single data item. A Common Base Event can contain more than one of these elements, essentially one for each additional data item. A hint to the number and type of ExtendedDataElement elements is supplied by the extensionName value, but this information is only a hint. The usage of the attributes in the ExtendedDataElement element for problem determination events is the same as those for any other Common Base Event.

Sample Common Base Event instance

This XML document is an example of a Common Base Event instance that is generated by a WebSphere Application Server application.

Use the following example for reference:

```
<CommonBaseEvent  creationTime="2004-09-18T04:03:28.484Z"
   globalInstanceId="myhost:1095479647062:1899"
   msg="WSVR0024I: Server server1 stopped"
   severity="10"
   version="1.0.1">

 ... several extendedDataElements for WebSphere Application Server internal use only ...

<sourceComponentId  component="com.ibm.ws.runtime.component.ServerCollaborator"
   componentIdType="Unknown"
   executionEnvironment="Windows 2000[x86]#5.0"
   instanceId="myhost\myhost\server1"
   location="myhost"
   locationType="Hostname"
   processId="1095479647062"
   subComponent="Unknown"
   threadId="Alarm : 0"
   componentType="http://www.ibm.com/namespaces/autonomic/WebSphereApplicationServer"/>
```

```
<msgDataElement msgLocale="en_US">
 <msgCatalogTokens value="server1"/>
 <msgId>WSVR0024I< /msgId>
 <msgCatalogId>WSVR0024I< /msgCatalogId>
 <msgCatalog>com.ibm.ws.runtime.runtime< /msgCatalog>
</msgDataElement>

<situation categoryName="ReportSituation">
 <situationType xsi:type="ReportSituation" reasoningScope="EXTERNAL" reportCategory="LOG"/>
</situation>

</CommonBaseEvent>
```

A number of extendedDataElement elements in the XML are used by WebSphere Application Server, but are not for application use because these elements might change.

The CommonBaseEvent element defines the Common Base Event instance. This element has a set of attributes that are common for all Common Base Events. This set includes the extensionName attribute, which defines the type or class of the Common Base Event instance, the creation time, severity, and priority.

Nested within the CommonBaseEvent element are elements giving more detail about the situation. The first of these elements is the situation element. This classification is standardized.

The CommonBaseEvent element also includes the sourceComponentId and the (optional) reporterComponentId elements. The sourceComponentId element describes where the situation occurred; the reporterComponentId describes where the situation is detected. If the sourceComponentId and the reporterComponentId elements are the same, the reporterComponentId element is omitted.

The attributes of both the sourceComponentId and the reporterComponentId elements are the same. They identify the component type, name, operating system, and network location. The content of these attributes provides vertical correlation of the stack of IT resources that are active when the Common Base Event is created.

Also included in the CommonBaseEvent element are contextDataElements elements that describe the context in which the situation occurred. This context correlates Common Base Event instances that are part of the same work. This correlation is called *horizontal correlation* because an instance of a particular context type correlates events at the same level of abstraction, for example at the business level, the application level, or at the middleware level.

FExtended data elements contain additional data that is used to describe a situation. In this example, an extended data element is added by WebSphere Application Server to describe the Java 2 Platform, Enterprise Edition (J2EE) component that generated the Common Base Event instance and some application data.

Sample Common Base Event template

The content handler uses template information to fill in blanks in the Common Base Event when the Common Base Event complete method is called.

Components that use the WebSphere Application Server event factory home can include a Common Base Event template XML file to provide data to populate Common Base Events. Information that is already supplied in the event is not overridden if the same field is supplied in the template.

The following example illustrates a Common Base Event template:

```
<?xml version="1.0" encoding="UTF-8"?>

<TemplateEvent
```

```
  version="1.0.1"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="templateEvent.xsd">

 <CommonBaseEvent
  <sourceComponentId application="My Application" component="com.ibm.componentX"/>
  <extendedDataElements name="Sample ExtendedDataElement name" type="string">
   <values>Sample ExtendedDataElement value</values>
  </extendedDataElements>
 </CommonBaseEvent>

</TemplateEvent>
```

Component identification for problem determination

This topic describes types of problem determination events.

A business application is made up of multiple components. A component can be made up of several internal subcomponents. Consistent application of these concepts is critical for effective problem determination of a business application; all of the parts of the application must use the same concepts and assumptions when creating and formatting events. Use the following definitions and examples when creating Common Base Events for problem determination.

Business application
> A business application is the business logic and business data that is used to address a set of specific business requirements. A business application consists of several components of multiple types, combined in a unique manner by an enterprise, to provide the functions and resources that are needed to address those requirements. The primary creator and manager of a business application is the enterprise, and each enterprise or company creates unique business applications. Examples of business applications are the Payroll Application for the ACME Corporation and the Inventory Application for Spacely Sprockets.

Components
> A business application is created and managed by the enterprise as a set of components. Components are deployable assets, which are developed either by the enterprise or a vendor, and managed by the enterprise. A component might be created by the enterprise, typically for use within a specific business application. For example, the ACME Corporation might create a set of enterprise beans to represent the business logic that is required by their Payroll Application. A component might also be an asset that is produced by a vendor and acquired by an enterprise. Examples of these components are hardware products, such as IBM eServers or Sun Solaris systems, or software products, such as IBM WebSphere Application Server, Oracle Database Servers.

Subcomponents
> A specific component, depending on its complexity, might consist of several subcomponents. For example, the IBM WebSphere Application Server consists of many subcomponents, such as the enterprise bean container and the servlet engine. Subcomponent information is typically used only by the creator of the component to service the component, and as such are not separately deployable or manageable resources in the enterprise. The enterprise might deploy a change or update to a subcomponent, but only upon guidance from the component vendor and as part of the vendor's component. For example, a software fix for the enterprise bean container of the IBM WebSphere Application Server is packaged and deployed as a software update to the IBM WebSphere Application Server. Replacement of the processor in an IBM eServer is deployed as a physical part, but only as a part of the original deployed component, the IBM eServer.

Logging Common Base Events in WebSphere Application Server

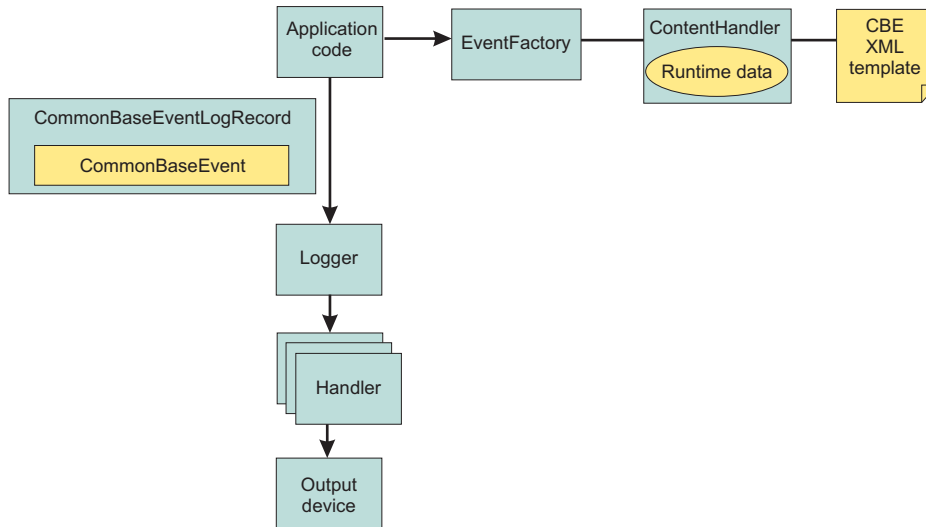
This topic describes how WebSphere Application Server takes advantage of the Common Base Events.

WebSphere Application Server uses Common Base Events within its logging framework. Common Base Events can be created explicitly and then logged through the Java logging API, or can be created implicitly

by using the Java logging API directly. For Common Base Event creation, the application server environment provides a Common Base Event factory with a content handler that provides both runtime data and template data for Common Base Events.

Logging with Common Base Event API and the Java logging API

In cases where the events that are generated by the Java logging API are insufficient to describe the event that needs capturing, you can create Common Base Events with the Common Base Event factory APIs.

When you create a Common Base Event, you can add data to the Common Base Event before it is logged. The following diagram illustrates how application code can create and log Common Base Events:


WebSphere Application Server is configured to use an event factory that automatically populates WebSphere Application Server-specific information into the Common Base Events that it generates. In general, it is good practice to create events using the WebSphere Application Server default Common Base Event factory because this approach ensures consistency of Common Base Event content across events. However, you can create and use other Common Base Event factories.

- Application code invokes the createCommonBaseEvent method on the EventFactory class to create a CommonBaseEvent.
- Application code wraps CommonBaseEvent event in a CommonBaseEventLogRecord record, and adds event-specific data.
- Application code calls the CommonBaseEvent event complete method.
- The CommonBaseEvent event invokes the ContentHandler completeEvent method.
- The ContentHandler handler adds XML template data to the CommonBaseEvent event. Not all ContentHandler handlers support templates.
- The ContentHandler handler adds runtime data to the CommonBaseEvent event.
- Application code passes the CommonBaseEventLogRecord record to the logger using the Logger.log method.
- Logger passes CommonBaseEventLogRecord record to Handlers.
- Handlers format data and write to the output device.

After completing all the above steps you will have a Common Base event based on your configuration settings.

Common Base Event content handler:

Content handlers populate data into Common Base Events when the Common Base Event complete method is invoked. You can associate content handlers with Common Base Event templates, which provide default information to transfer into each Common Base Event. Content handlers might also provide any other information that is relevant to completing the population of the Common Base Event, such as appropriate runtime defaults.

The use of content handlers ensures consistency of field use in the Common Base Event within a component or within a set of components that share the same runtime. For example, some content handlers support the specification of a template. If used consistently across a component, this template ensures that all events for that component have the same template information filled in. Similarly, some content handlers can also supply runtime information to their associated Common Base Events. If consistently used throughout the entire runtime, runtime information ensures that all events use runtime data in a similar way.

The event factory home that is used in the WebSphere Application Server runtime is associated with a content handler that both reads from a template, and supplies runtime data. Have components use Event Factories that are obtained from this event factory home with their own templates, to produce consistency between application events and server events.

More details can be found in"Creating custom Common Base Event content handlers" or the API documentation for org.eclipse.hyades.logging.events.cbe.ContentHandler at www.eclipse.org/hyades.

Creating custom Common Base Event content handlers:

Create a custom Common Base Event content handler or template to automate configuration or values for specific events.

A *content handler* is an object that automatically sets the property values of each event based on any arbitrary policies that you want to use.

The following content handler classes were added to WebSphere Application Server to facilitate the use of the Common Base Event infrastructure:

Class Name	Description
WsContentHandlerImpl	This provides an implementation of org.eclipse.hyades.logging.events.cbe.ContentHandler specifically for use in the WebSphere Application Server environment. This content handler completes Common Base Events using information from the WebSphere Application Server runtime, and it uses the same content handler as is used internally by the WebSphere Application Server when completing Common Base Events for logging.
WsTemplateContentHandlerImpl	This provides the same function as WsContentHandlerImpl, but it extends the org.eclipse.hyades.logging.events.cbe.impl.TemplateContentHandlerImpl class to enable the use of a Common Base Event template. Template content takes precedence in cases where the template data specifies values for the same Common Base Event fields as does the WsContentHandlerImpl.

In some situations, you might want some event property data set automatically for every event that you create. This automation is a way to fill in certain standard values that do not change, such as the application name, or to set some properties based on information that is available from the runtime environment, like creation time or thread information. You can set property data automatically by creating a content handler.

- Use the following code sample to implement the CustomContentHandler class:

```
public class CustomContentHandler extends WsContentHandlerImpl {

 public CustomContentHandler() {
  super();
  // TODO Custom initialization code goes here
 }

 public void completeEvent(CommonBaseEvent cbe) throws CompletionException {
  // following code will add WAS content to the Content Base Event
  super.completeEvent(cbe);
  // TODO Custom content can be added to the Content Base Event here
 }
}
```

- The following shows how to implement the CustomTemplateContentHandler class:

```
public class CustomTemplateContentHandler extends WsTemplateContentHandlerImpl {

 public CustomTemplateContentHandler() {
  super();
  // TODO Custom initialization code goes here
 }

 public void completeEvent(CommonBaseEvent cbe) throws CompletionException {
  // following code will add WAS content to the Content Base Event
  super.completeEvent(cbe);
  // TODO Custom content can be added to the Content Base Event here
 }
}
```

You now have a content handler or a custom content handler template based on the settings that you specified.

Common Base Event factory home:

Event Factory homes provide Event Factory instantiation that is based on a unique factory name.

Event Factory home implementations are tightly coupled with content handlers that are used to populate Common Base Events with template or default data. Event Factory instances are maintained by the associated Event Factory home, based on their unique name. For example, when application code requests a named Event Factory, the newly created Event Factory instance is returned and persisted for future requests for that named Event Factory. An abstract Event Factory home class provides the implementation for the APIs in the Event Factory home interface. Implementers extend the abstract Event Factory home class and implement the createContentHandler API to create a typed content handler that is based on the type of Event Factory home implementation.

In WebSphere Application Server, the default Event Factory home that is obtained with a call to EventFactoryContext.getInstance.getEventFactoryHome method is associated with a ContentHandler handler capable of supplying both event template information, as well as WebSphere Application Server runtime default information.

More details can be found in the API documentation for org.eclipse.hyades.logging.events.cbe.EventFactoryHome at www.eclipse.org/hyades.

Creating custom Common Base Event factory homes:

Use custom Common Base Event factory homes to control configuration and implementation of unique Event Factories.

Event Factory Homes create and provide homes for Event Factory instances. Each Event Factory Home has a Content Handler. This Content Handler is assigned to every Event Factory the Event Factory Home creates. In turn, when a Common Base Event is created, the Content Handler from the Event Factory is

assigned to it. Event Factory instances are maintained by the associated Event Factory Home, based on their unique name. For example, when application code requests a named Event Factory, the newly created Event Factory instance is returned and persisted for future requests for that named Event Factory.

The following classes were added to facilitate the use of Event Factory homes for logging Common Base Events:

Class Name	Description
WsEventFactoryHomeImpl	This class extends the org.eclipse.hyades.logging.events.cbe.impl.AbstractEventFactoryHome class. This Event Factory Home returns Event Factory instances associated with the WsContentHandlerImpl Content Handler. The WsContentHandlerImpl is the Content Handler used by the WebSphere Application Server by default when no Event Factory template is in use.
WsTemplateEventFactory HomeImpl	This class extends the org.eclipse.hyades.logging.events.cbe.impl.EventXMLFileEventFactoryHomeImpl class. This Event Factory Home returns Event Factory instances associated with the WsTemplateContentHandlerImpl Content Handler. The WsTemplateContentHandlerImpl is the Content Handler used by the WebSphere Application Server when an Event Factory template is required.

Custom event factory homes support the use of Common Base Event for logging in WebSphere Application Server and make logging easy and consistent between the WebSphere Application Server runtime and the exploiters of this API. The CustomEventFactoryHome and CustomTemplateEventFactoryHome classes will be used to obtain an event factory. These classes are there to make sure the correct content handler is being used with a particular event factory. The CustomEventFactoryHelper class is an example of how the infrastructure provider can hide the factory selection details from infrastructure users, using their own set of parameters to decide which the appropriate event factory is.

- The following code samples provide examples of how to implement and use the CustomEventFactoryHome class.

  1. Implementation of the CustomEventFactoryHome class is as follows:

```
public class CustomEventFactoryHome extends AbstractEventFactoryHome {

 public CustomEventFactoryHome() {
  super();
  // TODO Custom intialization code goes here
 }

 public ContentHandler createContentHandler(String arg0) {
  // Always use custom content handler
  return resolveContentHandler();
 }

 public ContentHandler resolveContentHandler() {
  // Always use custom content handler
  return new CustomContentHandler();
 }
}
```

  2. The following is an example of how to use the CustomEventFactoryHome class:

```
// get the event factory
 EventFactory eventFactory=(new CustomEventFactoryHome()).getEventFactory("XYZ");
 // create an event - call appropriate method
 eventFactory.createCommonBaseEvent();
 // log event ...
```

- For the CustomTemplateEventFactoryHome class you can use the following code for implementation and use:

1. Implement the CustomTemplateEventFactoryHome class by using this code:

```
public class CustomTemplateEventFactoryHome extends
  EventXMLFileEventFactoryHomeImpl {

 public CustomTemplateEventFactoryHome() {
  super();
  // TODO Custom intialization code goes here
 }

 public ContentHandler createContentHandler(String arg0) {
  // Always use custom content handler
  return resolveContentHandler();
 }

 public ContentHandler resolveContentHandler() {
  // Always use custom content handler
  return new CustomTemplateContentHandler();
 }
}
```

2. Use the CustomTemplateEventFactoryHome class by following this sample code:

```
// get the event factory
  EventFactory eventFactory=(new
    CustomTemplateEventFactoryHome()).getEventFactory("XYZ");
  // create an event - call appropriate method
  eventFactory.createCommonBaseEvent();
  // log event ...
```

- The CustomEventFactoryHelper class can be implemented and used by following the code below:

1. Implement the custom CustomEventFactoryHelper class using this code:

```
public class CustomTemplateEventFactoryHome extends
  EventXMLFileEventFactoryHomeImpl {

 public CustomTemplateEventFactoryHome() {
  super();
  // TODO Custom intialization code goes here
 }

 public ContentHandler createContentHandler(String arg0) {
  // Always use custom content handler
  return resolveContentHandler();
 }

 public ContentHandler resolveContentHandler() {
  // Always use custom content handler
  return new CustomTemplateContentHandler();
 }
}
Figure 4     CustomTemplateEventFactoryHome class
public class CustomEventFactoryHelper {
 // name of the event factory to use
 public static final String FACTORY_NAME="XYZ";

 public static EventFactory getEventFactory(String param1, String param2) {
  EventFactory factory=null;
  switch (resolveFactory(param1,param2)) {
  case 1:
   factory=(new CustomEventFactoryHome()).getEventFactory(FACTORY_NAME);
   break;
  case 2:
   factory=(new
    CustomTemplateEventFactoryHome()).getEventFactory(FACTORY_NAME);
   break;

  default:
   // Add default for event factory
```

```
   break;
  }
  return factory;
 }

 private static int resolveFactory(String param1, String param2) {
  int factory=0;
  // Add code here to resolve which factory to use
  return factory;
 }
}
```

2. To use the CustomEventFactoryHelper class, use the following code:

```
// get the event factory
  EventFactory eventFactory=
   CustomEventFactoryHelper.getEventFactory("param1","param2","param3");
  // create an event - call appropriate method
  eventFactory.createCommonBaseEvent();
  // log event ...
```

Use the information provided here to implement a custom content factory home and the associated classes based on the settings that you specify.

Common Base Event factory context:

The event factory context provides a service to look up event factory homes. Retrieve the event factory context using a call to the EventFactoryContext.getInstance method.

Using this class, you can look up the event factory homes by name, and avoid the need to include the typed home in code. The EventFactoryHome name must be located on the class path to be found. The EventFactoryContext context also stores an EventFactoryHome name as a default, which can be obtained with a call to the EventFactoryContext.getInstance.getEventFactoryHome method.

In WebSphere Application Server, the EventFactoryContext context is configured with a default EventFactoryHome name which is associated to a ContentHandler handler that is capable of supplying both event template information, as well as WebSphere Application Server runtime default information.

More details can be found in the API documentation for org.eclipse.hyades.logging.events.cbe.EventFactory at www.eclipse.org/hyades.

Common Base Event factory:

Use event factories to create Common Base Events and complete event properties with associated content handlers.

Content handlers populate data into Common Base Events when the Common Base Event invokes the complete method. All event properties set by the application code have priority over all properties that are specified by the content handler. Event factory implementations are tightly coupled with the content handler instance, which is associated with the event factory when the event factory is instantiated. Factory instances can be retrieved only from their associated event factory home. Event factory instances are retrieved and maintained based on unique names. Event factory names are hierarchical; they are represented using the standard Java dot-delimited, name-space naming conventions.

More details can be found in the API documentation for org.eclipse.hyades.logging.events.cbe.EventFactory at www.eclipse.org/hyades.

java.util.logging -- Java logging programming interface
The java.util.logging.Logger class provides a variety of methods with which data can be logged.

In the WebSphere Application Server, the Java logging API (java.util.logging) automatically creates Common Base Events for events that are logged at the WsLevel.DETAIL level or above (including WsLevel.DETAIL, Level.CONFIG, Level.INFO, WsLevel.AUDIT, Level.WARNING, Level.SEVERE, and WsLevel.FATAL). These Common Base Events are created using the event factory that is associated with the logger to which the message is logged. If no event factory is specified, WebSphere Application Server uses a default event factory which automatically fills in WebSphere Application Server-specific information.

The WebSphere Application Server uses a special implementation of the java.util.logging.Logger class that automatically creates Common Base Events for the following methods:

- config
- info
- warning
- severe
- log: All variants except log(LogRecord) when used with the WsLevel.DETAIL level or more severe levels
- logp: When used with the WsLevel.DETAIL level or more severe levels
- logrb: When used with the WsLevel.DETAIL level or more severe levels

The WebSphere Application Server logger implementation is used only for named loggers for example, loggers that are instantiated with calls, such as Logger.getLogger(″com.xyz.SomeLoggerName″). Loggers instantiated with calls to the Logger.getAnonymousLogger and Logger.getLogger, or Logger.global methods do not use the WebSphere Application Server implementation, and do not automatically create Common Base Events for logging requests made to them. Log records that are logged directly with the Logger.log(LogRecord) method are not automatically converted by WebSphere Application Server loggers into Common Base Events.

The following diagram illustrates how application code can log Common Base Events:

The Java logging API processing of named loggers and message-level events proceeds as follows:

1. Application code invokes the named logger (WsLevel.DETAIL or above) with event-specific data.
2. The logger creates a Common Base Event using the createCommonBaseEvent method on the event factory that is associated with the logger.
3. The logger creates a Common Base Event using the event factory associated to the logger.
4. The logger wraps the common base event in a CommonBaseEventLogRecord record, and adds event-specific data.
5. The logger calls the Common Base Event complete method.
6. The Common Base Event invokes the ContentHandler completeEvent method.

7. The content handler adds XML template data to the Common Base Event (including for example, the component name). Not all content handlers support templates.
8. The content handler adds runtime data to the Common Base Event (including for example, the current thread name).
9. The logger passes the CommonBaseEventLogRecord record to the handlers.
10. The handlers format data and write to the output device.

Logger.properties file
Use the Logger.properties file to set logger attributes for your component.

The properties file is loaded the first time the Logger.getLogger(loggername) method is called within an application. The Logger.properties file must be either on the WebSphere Application Server class path, or the context class path.

The logging subsystem uses Common Base Events to represent all the messages in the WebSphere Application Server activity.log file. You can specify your own event factory template to be used with your loggers. Use the eventfactory property in your Logger.properties file. See "Sample Common Base Event template" on page 1515 for details on the Common Base Event template.

By convention, the name of the event factory template file should be the fully qualified package name of the package using the template. The name of the file must end with the `.event.xml` extension. For example, a valid event factory template file name for the com.abc.somepackage package is:

`com.abc.somepackage.event.xml`

When you specify the property value for the eventfactory property in the Logger.properties file, include the full path name with no leading slash relative to the root of your class path entry. Do not include the `.event.xml` extension.

For example, if the template files from the example above are located in the `com/abc/templates` directory, the valid value for the eventfactory property is:

`com/abc/templates/com.abc.somepackage`

Finally, if this event factory template file is used by the com.abc.somepackage.SomeClass logger, then the following entry will appear in the Logger.properties file:

`com.abc.somepackage.SomeClass.eventfactory=com/abc/templates/com.abc.somepackage`

Generate Common Base Event content with the default event factory
A default Common Base Event content handler populates Common Base Events with WebSphere Application Server runtime information. This content handler can also use a Common Base Event template to populate Common Base Events.

The default content handler is used when the server creates CommonBaseEventLogRecords as would be the case in the following example:

```
// Get a named logger
Logger logger = Logger.getLogger("com.ibm.someLogger");
// Log to the logger -- implicitly the default content handler
// will be associated with the CommonBaseEvent contained in the
// CommonBaseEventLogRecord. logger.warning("MSG_KEY_001");
```

To specify a Common Base Event template in the above case, a Logger.properties file would need to be provided with an eventfactory entry for *com.ibm.someLogger*. If a valid template is found on the classpath, then the Logger's event factory will use the specified template's content in addition to the WebSphere Application Server runtime information when populating Common Base Events. If the template is not found on the classpath, or is invalid, then the Logger's event factory will only use the WebSphere Application Server runtime information when populating Common Base Events.

The default content handler is also associated with the event factory home supplied in the global event factory context. This is convenient for creating Common Base Events that need to be populated with content similar to that generated from the WebSphere Application Server:

```
// Request the event factory from the global event factory home
EventFactory eventFactory = EventFactoryContext.getInstance().getEventFactoryHome().getEventFactory(templateName);

// Create a Common Base Event
CommonBaseEvent commonBaseEvent = eventFactory.createCommonBaseEvent();

// Complete the Common Base Event using content from the template (if specified above)
// and the server runtime information.
eventFactory.getContentHandler().completeEvent(commonBaseEvent);
```

In the above example, if the template referenced by *templateName* is found on the classpath, and the template is valid, then the event factory home will return an event factory which uses a content handler that combines the template's content with the WebSphere Application Server runtime information when populating Common Base Events. If the template is not found on the classpath, or is invalid, then the event factory home will return an event factory which uses a content handler that uses only the WebSphere Application Server runtime information when populating Common Base Events.

The default content handler populates Common Base Events in the server environment with the following runtime information:

CommonBaseEvent.globalInstanceId
> **Value:** The *unique_record_id*

> Set this value only if the CommonBaseEvent.globalInstanceId value is null before the completeEvent method is called.

CommonBaseEvent.msg
> **Value:** A localized message that is based on the MsgDataElement element.

> Set this value only if the CommonBaseEvent.msg message is null before the completeEvent method is called.

CommonBaseEvent.severity
> **Value:** Set based on the value of level set on the CommonBaseEventLogRecord record, if level >= Level.SEVERE, set to 50; if level >= Level.WARNING, set to 30; the default is set to 10.

> Set this value only if the CommonBaseEvent.severity value is null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.component
> **Value:** Set based on the LoggerName value that is set on the CommonBaseEventLogRecord record.

> Set this value only if the CommonBaseEvent.ComponentIdentification.component is null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.componentIdType
> **Value:** ″Unknown″

> Set this value only if the CommonBaseEvent.ComponentIdentification.componentIdType value is null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.executionEnvironment
> **Value:** OSname[OSarch]#OSversion

> Set this value only if the CommonBaseEvent.ComponentIdentification.executionEnvironment value is null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.instanceId
> **Value:** cellName\nodeName\serverName

Set this value only if the CommonBaseEvent.ComponentIdentification.instanceId value is null before the completeEvent method is called. Set only in a server environment because this value is ignored in a client application.

CommonBaseEvent.ComponentIdentification.location
> **Value:**The host name

> Set this value only if both the CommonBaseEvent.ComponentIdentification.location and the CommonBaseEvent.ComponentIdentification.locationType values are null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.locationType
> **Value:** The host name

> Set this value only if both the CommonBaseEvent.ComponentIdentification.location and the CommonBaseEvent.ComponentIdentification.locationType values are null before the completeEvent method is called.

CommonBaseEvent.ComponentIdentification.processId
> **Value:** An internally generated representation of the process number.

> Set this value only if the CommonBaseEvent.ComponentIdentification.processId value is null before the completeEvent method is called

CommonBaseEvent.ComponentIdentification.subComponent
> **Value:** Set based on values of the sourceClassName and the sourceMethodName names that are set on the sourceClassName.sourceMethodName name of the CommonBaseEventLogRecord record.

> Set this value only if the CommonBaseEvent.ComponentIdentification.subComponent values is null before the completeEvent method is called and both the sourceClassName and the sourceMethodName names are set.

CommonBaseEvent.ComponentIdentification.threadId
> **Value:** Set to the value of the Java Virtual Machine (JVM) thread name.

> Set this value only if the CommonBaseEvent.ComponentIdentification.threadId values is null before the completeEvent value is called.

CommonBaseEvent.ComponentIdentification.componentType
> **Value:** http://www.ibm.com/namespaces/autonomic/WebSphereApplicationServer

> Set this value only if the CommonBaseEvent.ComponentIdentification.componentType values is null before the completeEvent method is called.

CommonBaseEvent.MsgDataElement.msgLocale
> **Value:** Set based on the default locale of the JVM.

> Set this value only if the CommonBaseEvent.msg value is null before the completeEvent method is called.

CommonBaseEvent.Situation.categoryName
> **Value:** `ReportSituation`

> Set this value only if the CommonBaseEvent.Situation value is null before the completeEvent method is called.

CommonBaseEvent.Situation.situationType.type
> **Value:** `ReportSituation`

> Set this value only if the CommonBaseEvent.Situation value is null before the completeEvent method is called.

CommonBaseEvent.Situation.situationType.reasoningScope
> **Value:** EXTERNAL

Set this value only if the CommonBaseEvent.Situation value is null before the completeEvent method is called.

CommonBaseEvent.Situation.situationType.reportCategory
> **Value:** LOG

> Set this value only if the CommonBaseEvent.Situation value is null before the completeEvent method is called.

The sourceComponentIdentification value is populated if no reporterComponentIdentification ID exists when the completeEvent method is invoked on the content handler. Otherwise, the reporterComponentIdentification ID is populated instead.

Best practices for logging Common Base Events in WebSphere Application Server

The following practices ensure consistent use of Common Base Events within your components, and between your components and WebSphere Application Server components.

Follow these guidelines:
- Use a different logger for each component. Sharing loggers across components gets in the way of associating loggers with component-specific information.
- Associate loggers with event templates that specify source component identification. This association ensures that the source of all events created with the logger is properly identified.
- Use the same template for directly created Common Base Events (events created using the Common Base Event factories) and indirectly created Common Base Events (events created using the Java logging API) within the same component.
- Avoid calling the complete method on Common Base Events until you are finished adding data to the Common Base Event and are ready to log it. This approach ensures that any decisions made by the content handler based on data already in the event are made using the final data.

The following sample `Logger.properties` file entry demonstrates how to associate the com.ibm.componentX logger with the com.ibm.componentX event factory:

```
com.ibm.componentX.eventfactory=com.ibm.componentX
```

The following sample code demonstrates the use of the same event factory setting for direct (Part 1) and indirect (Part 2) Common Base Event logging:

```
<?xml version="1.0" encoding="UTF-8"?>

<TemplateEvent
  version="1.0.1"
  xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
  xsi:noNamespaceSchemaLocation="templateEvent.xsd">

 <CommonBaseEvent
   <sourceComponentId application="My application" component="com.ibm.componentX"/>
   <extendedDataElements CommonBaseEventname="Sample ExtendedDataElement name" type="string">
   <values>Sample ExtendedDataElement value</values>
  </extendedDataElements>
 < /CommonBaseEvent>

< /TemplateEvent>
```

Appendix. Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories infer specific default directory locations. This topic describes the conventions in use for WebSphere Application Server Network Deployment.

Default product locations when the root user or an administrator user installs the product

The root user or administrator user (on a Windows system) is capable of registering shared products and installing into system-owned directories. The following default directories are system-owned directories.

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server Network Deployment products or components, of course, require multiple locations.

app_server_root - the install_root for WebSphere Application Server
>
> The following list shows default installation root directories for WebSphere Application Server Network Deployment:
>
> | AIX | /usr/IBM/WebSphere/AppServer
>
> | HP-UX | /opt/IBM/WebSphere/AppServer
>
> | Linux | /opt/IBM/WebSphere/AppServer
>
> | Solaris | /opt/IBM/WebSphere/AppServer
>
> | Windows | C:\Program Files\IBM\WebSphere\AppServer

profile_root
>
> The following list shows the default directory for a profile named *profile_name* on each distributed operating system:
>
> | AIX | /usr/IBM/WebSphere/AppServer/profiles/*profile_name*
>
> | HP-UX | /opt/IBM/WebSphere/AppServer/profiles/*profile_name*
>
> | Linux | /opt/IBM/WebSphere/AppServer/profiles/*profile_name*
>
> | Solaris | /opt/IBM/WebSphere/AppServer/profiles/*profile_name*
>
> | Windows | C:\Program Files\IBM\WebSphere\AppServer\profiles*profile_name*

plugins_root
>
> The following default installation root is for the Web server plug-ins for WebSphere Application Server:
>
> | AIX | /usr/IBM/HTTPServer/Plugins
>
> | HP-UX | /opt/IBM/HTTPServer/Plugins
>
> | Linux | /opt/ibm/HTTPServer/Plugins
>
> | Solaris | /opt/IBM/HTTPServer/Plugins
>
> | Windows | C:\Program Files\IBM\HTTPServer\Plugins

web_server_root
>
> The following default installation root directories are for the IBM HTTP Server:

> **AIX**   /usr/IBM/HTTPServer

> **HP-UX**   /opt/IBM/HTTPServer

> **Linux**   /opt/ibm/HTTPServer

> **Solaris**   /opt/IBM/HTTPServer

> **Windows**   C:\Program Files\IBM\HTTPServer

gskit_root

The following list shows the default installation root directories for Version 7 of the IBM Global Security Kit (GSKit):

> **AIX**   /usr/ibm/gsk7

> **HP-UX**   /opt/ibm/gsk7

> **Linux**   /opt/ibm/gsk7

> **Solaris**   /opt/ibm/gsk7

> **Windows**   C:\Program Files\IBM\GSK7

app_client_root

The following default installation root directories are for the WebSphere Application Client:

> **AIX**   /usr/IBM/WebSphere/AppClient (J2EE Application client only)

> **HP-UX**   /opt/IBM/WebSphere/AppClient (J2EE Application client only)

> **Linux**   /opt/IBM/WebSphere/AppClient (J2EE Application client only)

> **Solaris**   /opt/IBM/WebSphere/AppClient (J2EE Application client only)

> **Windows**   C:\Program Files\IBM\WebSphere\AppClient

updi_root

The following list shows the default installation root directories for the Update Installer for WebSphere Software:

> **AIX**   /usr/IBM/WebSphere/UpdateInstaller

> **HP-UX**   /opt/IBM/WebSphere/UpdateInstaller

> **Linux**   /opt/IBM/WebSphere/UpdateInstaller

> **Solaris**   /opt/IBM/WebSphere/UpdateInstaller

> **Windows**   C:\Program Files\IBM\WebSphere\UpdateInstaller

cip_app_server_root

The following list shows the default installation root directories for a customized installation package (CIP) produced by the Installation Factory.

A CIP is a WebSphere Application Server Network Deployment product bundled with one or more maintenance packages, an optional configuration archive, one or more optional enterprise archive files, and other optional files and scripts:

> **AIX**   /usr/IBM/WebSphere/AppServer/cip/*cip_uid*

> **HP-UX**   /opt/IBM/WebSphere/AppServer/cip/*cip_uid*

> **Linux**   /opt/IBM/WebSphere/AppServer/cip/*cip_uid*

/opt/IBM/WebSphere/AppServer/cip/*cip_uid*

C:\Program Files\IBM\WebSphere\AppServer\cip*cip_uid*

The *cip_uid* variable is the CIP unique ID generated during creation of the build definition file. You can override the generated value in the Build definition wizard. Use a unique value to allow multiple CIPs to install on the system.

component_root

The component installation root directory is any installation root directory described in this topic. Some programs are for use across multiple components. In particular, the Update Installer for WebSphere Software is for use with WebSphere Application Server Network Deployment, Web server plug-ins, the Application Client, and the IBM HTTP Server. All of these components are part of the product package.

Default product locations when a non-root user or a non-administrator user installs the product

The non-root user or non-administrator user (on a Windows system) is not capable of registering shared products and installing into system-owned directories. The following default directories are user-owned directories in the home directory of the non-root installer as opposed to being globally shared resources that are available to all users.

app_server_root

The following list shows the default installation directories for non-root installation of WebSphere Application Server Network Deployment:

AIX *user_home*/IBM/WebSphere/AppServer

HP-UX *user_home*/IBM/WebSphere/AppServer

Linux *user_home*/IBM/WebSphere/AppServer

Solaris *user_home*/IBM/WebSphere/AppServer

Windows C:\IBM\WebSphere\AppServer

profile_root

The following list shows the default directories for creating profiles:

AIX *user_home*/IBM/WebSphere/AppServer/profiles/

HP-UX *user_home*/IBM/WebSphere/AppServer/profiles/

Linux *user_home*/IBM/WebSphere/AppServer/profiles/

Solaris *user_home*/IBM/WebSphere/AppServer/profiles/

Windows C:\IBM\WebSphere\AppServer\profiles\

web_server_root

The following default installation root directories are for the IBM HTTP Server:

AIX *user_home*/IBM/HTTPServer

HP-UX *user_home*/IBM/HTTPServer

Linux *user_home*/ibm/HTTPServer

Solaris *user_home*/IBM/HTTPServer

Windows C:\IBM\HTTPServer

plugins_root

The following list shows the default installation root directories for the Web server plug-ins for WebSphere Application Server:

`AIX`   *user_home*/IBM/HTTPServer/Plugins

`HP-UX`   *user_home*/IBM/HTTPServer/Plugins

`Linux`   *user_home*/ibm/HTTPServer/Plugins

`Solaris`   *user_home*/IBM/HTTPServer/Plugins

`Windows`   C:\IBM\HTTPServer\Plugins

app_client_root

The following list shows the default installation root directories for the WebSphere Application Client:

`AIX`   *user_home*/IBM/WebSphere/AppServer/AppClient (J2EE Application client only)

`HP-UX`   *user_home*/IBM/WebSphere/AppClient (J2EE Application client only)

`Linux`   *user_home*/IBM/WebSphere/AppClient (J2EE Application client only)

`Solaris`   *user_home*/IBM/WebSphere/AppClient (J2EE Application client only)

`Windows`   C:\IBM\WebSphere\AppClient

updi_root

The following list shows the default installation directories for non-root installation of WebSphere Application Server Network Deployment:

`AIX`   *user_home*/IBM/WebSphere/UpdateInstaller

`HP-UX`   *user_home*/IBM/WebSphere/UpdateInstaller

`Linux`   *user_home*/IBM/WebSphere/UpdateInstaller

`Solaris`   *user_home*/IBM/WebSphere/UpdateInstaller

`Windows`   C:\Program Files\IBM\WebSphere\UpdateInstaller

cip_app_server_root

The following list shows the default installation root directories for a WebSphere Application Server Network Deployment product CIP:

`AIX`   *user_home*/IBM/WebSphere/AppServer/cip/*cip_uid*

`HP-UX`   *user_home*/IBM/WebSphere/AppServer/cip/*cip_uid*

`Linux`   *user_home*/IBM/WebSphere/AppServer/cip/*cip_uid*

`Solaris`   *user_home*/IBM/WebSphere/AppServer/cip/*cip_uid*

`Windows`   C:\IBM\WebSphere\AppServer\cip*cip_uid*
