How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
    1. Display the article in your Web browser and scroll to the end of the article.
    2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
    3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

    Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Chapter 1. Overview and new features for developing and deploying applications

Use the links provided in this topic to learn more about developing applications for deployment on this product.

"What is new for developers" on page 16

> This topic provides an overview of new and changed features of the programming model and application serving environment as it pertains to development and test efforts.

"Learn about WebSphere applications: Overview and new features"

> This topic provides an overview of the programming model.

"Accessing the Samples (Samples Gallery)" on page 11

> The Samples are a good way to become familiar with the programming model.

Learn about WebSphere applications: Overview and new features

Use the **Learn about WebSphere applications** section as a starting point to study the programing model, encompassing the many parts used in and by various application types supported by the application server.

The programming model for applications deployed on this product has the following aspects.
- Java specifications and other open standards for developing applications
- WebSphere programming model extensions to enhance application functionality
- Containers and services in the application server, used by deployed applications, and which sometimes can be extended

The diagram shows a single application server installation. The parts pertaining to the programming model are discussed here. Other parts comprise the product architecture, independent of the various application types outlined by the programming model.

1
J2EE application components

Web applications run in the Web container

The Web container is the part of the application server in which Web application components run. Web applications are comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit. Combined, they perform a business logic function.

The Web container processes servlets, JSP files, and other types of server-side includes. Each application server runtime has one logical Web container, which can be modified, but not created or removed. Each Web container provides the following.

Web container transport chains

Requests are directed to the Web container using the Web container inbound transport chain. The chain consists of a TCP inbound channel that provides the connection to the network, an HTTP inbound channel that serves HTTP requests, a Web container channel over which requests for servlets and JSP files are sent to the Web container for processing.

Servlet processing

When handling servlets, the Web container creates a request object and a response object, then invokes the servlet service method. The Web container invokes the servlet's destroy method when appropriate and unloads the servlet, after which the JVM performs garbage collection.

Servlets can perform such tasks as supporting dynamic Web page content, providing database access, serving multiple clients at one time, and filtering data.

JSP files enable the separation of the HTML code from the business logic in Web pages. IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to Web pages, without being experts in Java programming.

HTML and other static content processing

Requests for HTML and other static content that are directed to the Web container are served by the Web container inbound chain. However, in most cases, using an external Web server and Web server plug-in as a front end to the Web container is more appropriate for a production environment.

Session management

Support is provided for the javax.servlet.http.HttpSession interface as described in the Servlet application programming interface (API) specification.

An *HTTP session* is a series of requests to a servlet, originating from the same user at the same browser. Sessions allow applications running in a Web container to keep track of individual users. For example, many Web applications allow users to dynamically collect data as they move through the site, based on a series of selections on pages they visit. Where the user goes next, or what the site displays next, might depend on what the user has chosen previously from the site. To maintain this data, the application stores it in a ″session.″

SIP applications and their container

SIP applications are Java programs that use at least one Session Initiation Protocol (SIP) servlet. SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

Portlet applications and their container

Portlet applications are special reusable Java servlets that appear as defined regions on portal pages. Portlets provide access to many different applications, services, and Web content.

EJB applications run in the EJB container

The EJB container provides all of the runtime services needed to deploy and manage enterprise beans. It is a server process that handles requests for both session and entity beans.

Enterprise beans are Java components that typically implement the business logic of J2EE applications, as well as accessing data. The enterprise beans, packaged in EJB modules, installed in an application server do not communicate directly with the server. Instead, the EJB container is an interface between EJB components and the application server. Together, the container and the server provide the enterprise bean runtime environment.

The container provides many low-level services, including threading and transaction support. From an administrative perspective, the container handles data access for the contained beans. A single container can host more than one EJB Java archive (JAR) file.

Client applications and other types of clients

In a client-server environment, clients communicate with applications running on the server. *Client applications* or *application clients* generally refers to clients implemented according to a particular set of

Java specifications, and which run in the client container of a J2EE-compliant application server. Other clients in the WebSphere Application Server environment include clients implemented as Web applications (*Web clients*), clients of Web services programs (*Web services clients*), and clients of the product systems administration (*administrative clients*).

Client applications and their container

The client container is installed separately from the application server, on the client machine. It enables the client to run applications in an EJB-compatible J2EE environment. The diagram shows a Java client running in the client container.

This product provides a convenient "launchClient tool" on page 333 for starting the application client, along with its client container runtime.

Depending on the source of technical information, client applications sometimes are called application clients. In this documentation, the two terms are synonymous.

Web clients, known also as web browser clients

The diagram shows a Web browser client, which can be known simply as a Web client, making a request to the Web container of the application server. A Web client or Web browser client runs in a Web browser, and typically is a Web application.

Web services clients

Web services clients are yet another kind of client that might exist in your application serving environment. The diagram does not depict a Web services client. The Web services information includes information about this type of client.

Administrative clients

The diagram shows two kinds of administrative clients: a scripting client and the administrative console that is the graphical user interface (GUI) for administering this product. Both are accessing parts of the systems administration infrastructure. In the sense that they are basically the same for whatever kind of applications you are deploying on the server, administrative clients are part of the product architecture. However, because many of these clients are programs you create, they are discussed as part of the programming model for completeness.

Web services

Web services

The diagram shows the Web services engine, part of the Web services support in the application server runtime. Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

The product acts as both a Web services provider and as a requestor. As a provider, it hosts Web services that are published for use by clients. As a requester, it hosts applications that invoke Web services from other locations. The diagram shows the Web services engine in this capacity, contacting a Web services provider or gateway.

Data access, messaging, and J2EE resources

Data access resources

Connection management for access to enterprise information systems (EIS) in the application server is based on the J2EE Connector Architecture (JCA) specification. The diagram shows JCA services helping an application to access a database in which the application retrieves and persists data.

The connection between the enterprise application and the EIS is done through the use of EIS-provided resource adapters, which are plugged into the application server. The architecture specifies the connection management, transaction management, and security contracts between the application server and EIS.

The Connection Manager (not shown) in the application server pools and manages connections. It is capable of managing connections obtained through both resource adapters defined by the JCA specification and data sources defined by the JDBC 2.0 Extensions specification.

JDBC resources (JDBC providers and data sources) are a type of *J2EE resource* used by applications to access data. Although data access is a broader subject than that of JDBC resources, this information often groups data access under the heading of J2EE resources for simplicity.

JCA resource adapters are another type of J2EE resource used by applications. The JCA defines the standard architecture for connecting the J2EE platform to heterogeneous EIS. Imagine an ERP, mainframe transaction processing, database systems, and legacy applications not written in the Java programming language.

The JCA resource adapter is a system-level software driver supplied by EIS vendors or other third-party vendors. It provides the connectivity between J2EE application servers or clients and an EIS. To use a resource adapter, install the resource adapter code and create configurations that use that adapter. The product provides a predefined relational resource adapter for your use.

Messaging resources and messaging engines

JMS support enables applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). Applications can use message-driven beans to automatically to automatically retrieve messages from JMS destinations and JCA endpoints without explicitly polling for messages.

For inbound non-JMS requests, message-driven beans use a Java Connector Architecture (JCA) 1.5 resource adapter written for that purpose. For JMS messaging, message-driven beans can use a JCA-based messaging provider such as the default messaging provider that is part of WebSphere Application Server.

The messaging engine supports the following types of message providers.

Default messaging provider (service integration bus)

The default messaging provider uses the service integration bus for transport. The default message provider provides point-to-point functions, as well as publish and subscribe functions. Within this provider, you define JMS connection factories and destinations that correspond to service integration bus destinations.

WebSphere MQ provider

You can use WebSphere MQ as the external JMS provider. The application server provides the JMS client classes and administration interface, while WebSphere MQ provides the queue-based messaging system.

Generic JMS provider

You can use another messaging provider as long as it implements the ASF component of the JMS 1.0.2 specification. JMS resources for this provider cannot be configured using the administrative console.

transition: Version 6 replaces the Version 5 concept of a JMS server with a messaging engine built into the application server, offering the various kinds of providers mentioned previously. The Version 5 messaging provider is offered for configuring resources for use with Version 5 embedded messaging. You also can use the Version 5 default messaging provider with a service integration bus.

EJB 2.1 introduces an ActivationSpec for connecting message-driven beans to destinations. For compatibility with Version 5, you still can configure JMS message-driven beans (EJB 2.0) against a listener port. For those message-driven beans, the message listener service provides a listener manager that controls and monitors one or more JMS listeners, each of which monitors a JMS destination on behalf of a deployed message-driven bean.

Service integration bus

The service integration bus provides a unified communication infrastructure for messaging and service-oriented applications. The service integration bus is a JMS provider that provides reliable message transport and uses intermediary logic to adapt message flow intelligently into the network. It supports the attachment of Web services requestors and providers. Its capabilities are fully integrated into product architecture, including the security, system administration, monitoring, and problem determination subsystems.

The service integration bus is often referred to as just a bus. When used to host JMS applications, it is often referred to as a messaging bus. It consists of the following parts (not shown at this level of detail in the diagram).

Bus members
Application servers added to the bus.

Messaging engine
The component that manages bus resources. It provides a connection point for clients to produce or from where to consume messages.

Destinations
The place within the bus to which applications attach to exchange messages. Destinations can represent Web services endpoints, messaging point-to-point queues, or messaging publish and subscribe topics. Destinations are created on a bus and hosted on a messaging engine.

Message store
Each messaging engine uses a set of tables in a supported data store (such as a JDBC database) to hold information such as messages, subscription information, and transaction states.

Through the service integration bus Web services enablement, you can:

- Make an internal service that is already available at a service destination available as a Web service.
- Make an external Web service available at a service destination.
- Use the Web Services Gateway to map an existing service, either an internal service or an external Web service, to a new Web service that appears to be provided by the gateway.

Mail, URLs, and other J2EE resources
The following kinds of J2EE resources are used by applications deployed on a J2EE-compliant application server.

- JDBC resources and other technology for data access (previously discussed)
- JCA resource adapters (previously discussed)
- JMS resources and other messaging support (previously discussed)
- JavaMail support, for applications to send Internet mail

  The **JavaMail APIs** provide a platform and protocol-independent framework for building Java-based mail client applications. The APIs require service providers, known as protocol providers, to interact with mail servers that run on the appropriate protocols.

  A mail provider encapsulates a collection of protocol providers, including Simple Mail Transfer Protocol (SMTP) for sending mail; Post Office Protocol (POP) for receiving mail; and Internet Message Access Protocol (IMAP) as another option for receiving mail. To use another protocol, you must install the appropriate service provider for the protocol.

  JavaMail requires not only service providers, but also the JavaBeans Activation Framework (JAF), as the underlying framework to handle complex data types that are not plain text, such as Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

- URLs, for describing logical locations

URL providers implement the functionality for a particular URL protocol, such as HTTP, enabling communication between the application and a URL resource that is served by a particular protocol. A default URL provider is included for use by any URL resource with protocols based on the supported Java 2 Standard Edition specification, such as HTTP, FTP, or File. You also can plug in your own URL providers that implement additional protocols.

- Resource environment entries, for mapping logical names to physical names

The java:comp/env environment provides a single mechanism by which both the JNDI name space objects and local application environment objects can be looked up. The product provides numerous local environment entries by default.

The J2EE specification also provides a mechanism for defining customer environment entries by defining entries in the standard deployment descriptor of an application. The J2EE specification uses the following methods to separate the definition of the resource environment entry from the application.

- – Requiring the application server to provide a mechanism for defining separate administrative objects that encapsulate a resource environment entry. The administrative objects are accessible using JNDI in the application server local name space (java:comp/env).
- – Specifying the administrative object's JNDI lookup name and expected returned object type. This specification is performed in the aforementioned resource environment entry in the deployment descriptor.

The product supports the use of resource environment entries with the following administrative concepts.

- – A *resource environment entry* defines the binding target (JNDI name), factory class, and return object type (via the link to a referenceable) of the resource environment entry.
- – A *referenceable* defines the class name of the factory that returns object instances implementing a Java interface.
- – A *resource environment provider* groups together the referenceable, resource environment entries and any required custom properties.

Security

Security programming model and infrastructure

The product provides security infrastructure and mechanisms to protect sensitive J2EE resources and administrative resources and to address enterprise end-to-end security requirements on authentication, resource access control, data integrity, confidentiality, privacy, and secure interoperability.

Security infrastructure and mechanisms protect Java 2 Platform, Enterprise Edition (J2EE) resources and administrative resources, addressing your enterprise security requirements. In turn, the security infrastructure of this product works with the existing security infrastructure of your multiple-tier enterprise computing framework. Based on open architecture, the product provides many plug-in points to integrate with enterprise software components to provide end-to-end security.

The security infrastructure involves both a programming model and elements of the product architecture that are independent of the application type.

Additional services for use by applications

Naming and directory

Each application server provides a naming service that in turn provides a Java Naming and Directory Interface (JNDI) name space. The service is used to register resources hosted on the application server. The JNDI implementation is built on top of a Common Object Request Broker Architecture (CORBA) naming service (CosNaming).

JNDI provides the client-side access to naming and presents the programming model used by application developers. CosNaming provides the server-side implementation and is where its name

space is actually stored. JNDI essentially provides a client-side wrapper of the name space stored in CosNaming, and interacts with the CosNaming server on behalf of the client.

Clients of the application server use the naming architecture to obtain references to objects related to those applications. The objects are bound into a mostly hierarchical structure called the name space. It consists of a set of name bindings, each one of which is a name relative to a specific context and the object bound with that name. The name space can be accessed and manipulated through a name server.

This product provides the following naming and directory features.
- Distributed name space, for additional scalability
- Transient and persistent partitions, for binding at various scopes
- Federated name space structure across multiple servers
- Configured bindings for defining bindings bound by the system at server startup
- Support for CORBA Interoperable Naming Service (INS) object URLs

Note that with the addition of virtual member manager to provide federated repository support for product security, the product now offers more extensive and sophisticated identity management capabilities than ever before, especially in combination with other WebSphere and Tivoli products.

Object Request Broker (ORB)

The product uses an ORB to manage interaction between client applications and server applications, as well as among product components. An ORB uses IIOP to enable clients to make requests and receive requests from servers in a network distributed environment.

The ORB provides a framework for clients to locate objects in the network and call operations on those objects as though the remote objects were located in the same running process as the client, providing location transparency.

Although not shown in the diagram, one place in which the ORB comes into play is where the client container is contacting the EJB container on behalf of a Java client.

Transactions

Part of the application server is the transaction service. The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a J2EE environment. These measures include ActivitySessions (described below).

Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work such that all or none of the updates are made permanent. Transactions are started and ended by applications or the container in which the applications are deployed.

The application server is a transaction manager that supports coordination of resource managers and participates in distributed global transactions with other compliant transaction managers.

The server can be configured to interact with databases, JMS queues, and JCA connectors through their local transaction support when distributed transaction support is not required.

How applications use transactions depends on the type of application, for example:
- A session bean either can manage its transactions itself, or delegate the management of transactions to the container.
- Entity beans use container-managed transactions.
- Web components, such as servlets, use bean-managed transactions.

The product handles transactions with the following components.
- A transaction manager supports the enlistment of recoverable XAResources and ensures each resource is driven to a consistent outcome, either at the end of a transaction, or after a failure and restart of the application server.

- A container manages the enlistment of XAResources on behalf of deployed applications when it performs updates to transactional resource managers such as databases. Optionally, the container can control the demarcation of transactions for EJB applications that have enterprise beans configured for container-managed transactions.
- An API handles bean-managed enterprise beans and servlets, allowing such application components to control the demarcation of their own transactions.

WebSphere extensions

WebSphere programming model extensions are the programming model benefits you gain by purchasing this product. They represent leading edge technology to enhance application capability and performance, and make programming and deployment faster and more productive.

In addition, now your applications can use the Eclipse extension framework. Your applications are extensible as soon as you define an extension point and provide the extension processing code for the extensible area of the application. You can also plug an application into another extensible application by defining an extension that adheres to the target extension point requirements. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement Eclipse tools and to provide plug-in modules to contribute functionality such as actions, tasks, menu items, and links at predefined extension points in the WebSphere application. For more information about this feature, see "Application extension registry" on page 97.

The various WebSphere programming model extensions, and the corresponding application services that support them in the application server runtime, can be considered in three groups: Business Object Model extensions, Business Process Model extensions, and extensions for producing Next Generation Applications.

Extensions pertaining to the Business Object Model

Business object model extensions operate with business objects, such as enterprise bean (EJB) applications.

Application profiling
> Application profiling is a WebSphere extension for defining strategies to dynamically control concurrency, prefetch, and read-ahead.
>
> Application profiling and access intent provide a flexible method to fine-tune application performance for enterprise beans without impacting source code. Different enterprise beans, and even different methods in one enterprise bean, can have their own intent to access resources. Profiling the components based on their access intent increases performance in the application server runtime.

Dynamic query
> Dynamic query is a WebSphere programming extension for unprecedented application flexibility. It lets you dynamically build and submit queries that select, sort, join, and perform calculations on application data at runtime. Dynamic Query service provides the ability to pass in and process EJB query language queries at runtime, eliminating the need to hard-code required queries into deployment descriptors during application development.
>
> Dynamic query improves enterprise beans by enabling the client to run custom queries on EJB components during runtime. Until now, EJB lookups and field mappings were implemented at development time and required further development or reassembly in order to be changed.

Dynamic cache

The dynamic cache service improves performance by caching the output of servlets, commands, and JSP files. This service within the application server intercepts calls to cacheable objects and either stores the output of the object or serves the content of the object from the dynamic cache.

Because J2EE applications have high read-write ratios and can tolerate small degrees of latency in the currency of their data, the dynamic cache can create opportunity for significant gains in server response time, throughput, and scalability.

Features include cache replication among clusters, cache disk offload, Edge side include caching, and external caching - the ability to control caches outside of the application server, such as that of your Web server.

Extensions pertaining to the Business Process Model

Business process model extensions provide process, workflow functionality, and services for the application server. Use them in conjunction with business integration capabilities.

ActivitySessions

ActivitySessions are a WebSphere extension for reducing the complexity of dealing with commitment rules and limitations associated with one-phase commit resources.

ActivitySessions provide the ability to extend the scope of multiple local transactions, and to group them. This enables them to be committed based on deployment criteria or through explicit program logic.

Web services

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Extensions for creating next generation applications

Next generation applications can be used in applications that need the specific extensions. These enable next generation development by leveraging the latest innovations that build on today's J2EE standards. This provides greater control over application development, execution, and performance than was ever possible before.

Asynchronous beans

Asynchronous beans offer performance enhancements for resource-intensive tasks by enabling single tasks to run as multiple tasks. Asynchronous scheduling facilities can also be used to process parallel processing requests in ″batch mode″ at a designated time. The product provides full support for asynchronous execution and invocation of threads and components within the application server. The application server provides execution and security context for the components, making them an integral part of the application.

Startup beans

Startup beans allow the automatic execution of business logic when the application server starts or stops. For example, they might be used to pre-fill application-specific caches, initialize application-level connection pools, or perform other application-specific initialization and termination procedures.

Object pools

Object pools provide an effective means of improving application performance at runtime, by allowing multiple instances of objects to be reused. This reuse reduces the overhead associated with instantiating, initializing, and garbage-collecting the objects. Creating an object pool allows an application to obtain an instance of a Java object and return the instance to the pool when it has finished using it.

Internationalization

The internationalization service is a WebSphere extension for improving developer productivity. It allows you to automatically recognize the time zone and location information of the calling client, so that your application can act appropriately. The technology enables you to deliver each user, around the world, the right date and time information, the appropriate currencies and languages, and the correct date and decimal formats.

Scheduler

The scheduler service is a WebSphere programming extension responsible for starting actions at specific times or intervals. It helps minimize IT costs and increase application speed and responsiveness by maximizing utilization of existing computing resources. The scheduler service provides the ability to process workloads using parallel processing, set specific transactions as high priority, and schedule less time-sensitive tasks to process during low traffic off-hours.

Work areas

Work areas are a WebSphere extension for improving developer productivity. Work areas provide a capability much like that of ″global variables.″ They provide a solution for passing and propagating contextual information between application components.

Work areas enable efficient sharing of information across a distributed application. For example, you might want to add profile information as each customer enters your application. By placing this information in a work area, it will be available throughout your application, eliminating the need to hand-code a solution or to read and write information to a database.

To delve deeper into learning about any of the extensions, see "Learn about WebSphere programming extensions" on page 1119.

Accessing the Samples (Samples Gallery)

The Samples Gallery offers a set of Samples that demonstrate common enterprise application tasks. The Gallery also contains descriptions of where to find additional Samples and coding examples.

You can upgrade the Samples Gallery, including the server samples and client samples. For detailed information, refer to *app_server_root*/`samples/readme.html`.

Quick start - Accessing the Samples Gallery
Your application server must be running. The Samples must be installed. ▶ Windows On Windows systems, click (for example) **Start > Programs > IBM WebSphere > Application Server v6.1 > Profiles > profile_name > Samples Gallery**. ▶ Windows On Windows systems, click (for example) **Start > Programs > IBM WebSphere > Application Server v6.0 > Profiles > profile_name > Samples Gallery**. In the following examples, *hostname* is a variable. ▶ Windows `http://hostname:9080/WSsamples` ▶ Linux `http://hostname:9080/WSsamples` Client Samples: `install_root/samples/index.html` (local file system)

The Samples are for demonstration purposes only. See the following limitations for details.

First time here? Read the following information. A little setup is involved.

Samples Gallery

- Samples Gallery contents
- Installing and accessing the Samples Gallery
- Changing the Samples Gallery port number and troubleshooting

Client Samples Gallery
- Client Samples Gallery contents
- Installing and viewing the Client Samples Gallery

General information
- Limitations of the Samples
- Additional Samples and examples

Samples Gallery contents

The Samples Gallery includes the following materials:

Plants by WebSphere application
> This application demonstrates several Java 2 Platform, Enterprise Edition (J2EE) functions, using an online store that specializes in plant and garden tool sales.

Faces Client Tutorial - Sample Portfolio
> Sample Portfolio is a sample application that demonstrates the use of faces client components. The Hello world sample demonstrates how the faces client framework keeps a data model consistent in the browser.

Technology Samples
> These Samples demonstrate various core components in J2EE applications.

Web Services Samples
> These Samples demonstrate J2EE beans and JavaBeans components that are available as Web services.

Service Data Objects (SDO) Sample
> This Sample demonstrates data access to a relational database through Service Data Objects (SDO) and Java DataBase Connectivity (JDBC) Mediator technologies.

BeenThere workload management Sample
> This Sample demonstrates the workload management and clustering capabilities of the product, and is the only Sample that is supported in a multi-server, clustered environment.

JACL scripts
> These scripts enable you to configure resources and install the Sample applications.

Programming model extensions Samples in the Samples Gallery
> These Samples demonstrate WebSphere programming model extension features such as dynamic query service, work area service, internationalization service, ActivitySessions service, application profiling, Java Transaction API (JTA) extensions, asynchronous beans, and scheduler.

Installing and accessing the Samples Gallery

Follow these steps to install and configure the Samples Gallery.
1. Install the product.

   Select to install the Application Server Samples package.

   The Samples are installed in the *app_server_root*/samples directory.
2. Create a stand-alone application server profile.

If you already created a profile without the Samples, and you want to create additional profiles that contain the Samples, you have to use the graphical profile creation interface.

The Samples are installed in the directory *profile_root*/installedApps/*cell_name*. The Sample source code is placed in the directory *profile_root*/installedApps/*cell_name*/samples.

You can build or modify the Samples source code to support your project.

To run the Samples in a distributed WebSphere Application Server Network Deployment environment, install and configure the Samples in a stand-alone application server profile installation, and then use **addNode** to federate the node into the deployment manager cell. When running the **addNode** command, use the dmgr_host argument, and -includeapps and -includebuses options. For a complete list of the **addNode** parameters and their usage, see addNode command.

For example:

```
addNode.sh/bat dmgr_hostname -includeapps -includebuses
```

3. Start the application server.
4. Access the Samples Gallery.

   The Plants by WebSphere application is installed on the application server by default. That is, you need not deploy the PlantsByWebSphere.ear file onto the application server. This application is listed as an installed Sample in the Samples Gallery.

   Try it out! See the quick start instructions on this page.

   If you have difficulty accessing the Samples Gallery, check the port number.

5. Install additional Samples.

   Additional Samples are initially listed as installable Samples in the Samples Gallery.

   To deploy them to the application server, use the install script in the *app_server_root*/samples/samples/bin directory. See the Samples Gallery for more detailed instructions.

For information about configuring security for Samples, see the Samples Gallery.

Changing the Samples Gallery port number and troubleshooting

If you are unable to access the Samples Gallery, verify the following items.
- Verify that the application server is running.
- Verify that the samples are installed. In the administrative console, expand **Applications** and click **Enterprise applications**. Confirm that the Samples Gallery is listed as an installed application.

  If the Samples Gallery is not listed as an installed application:
  – Create a new profile using the default profile template.
- Verify the port number.

  The default port is 9080, which is the default value of the HTTP transport of the application server. If the Samples Web address fails, confirm the port number.

  ▶ Windows ◀ You can change the port number in the **Properties** window by clicking **Start > Programs > IBM WebSphere > Application Server Network Deployment v6.0 > profiles > profile_name > Samples Gallery**.
- You must specify a Samples password when using the manageprofiles command to create a profile for which administrative security is enabled. Otherwise, you will be allowed to create the profile successfully, but when you run the application server containing the Samples, exceptions and failures will be thrown to the server system out log.

Client Samples Gallery contents

The Client Samples Gallery demonstrates the following clients.
- J2EE application client
- Java thin client

- Applet client
- ActiveX to EJB Bridge client

Installing and viewing the Client Samples Gallery

To view the Client Samples Gallery, install the WebSphere Application Server client on a distributed machine.

See "Installing Application Client for WebSphere Application Server" on page 326 for more information.

Access the Client Samples Gallery on your local file system at *app_server_root*/samples/samples/index.html.

Limitations of the Samples

- The Samples are for demonstration purposes only.

    The code that is provided is not intended to run in a secured production environment. The Samples support Java 2 Security, therefore the Samples implement policy-based access control that checks for permissions on protected system resources, such as file I/O. The Samples also support administrative security.

- The BeenThere workload management Sample is the only Sample that is supported in a multi-server, clustered environment. For information on the BeenThere Sample, see the `readme_BeenThere.html` file in the Samples directory.

- Many of the WebSphere Application Server Samples connect to a Cloudscape database using the Cloudscape-embedded framework. The Cloudscape-embedded framework has a limitation that only one Java virtual machine (JVM) can access a given database instance. As a result, in a clustered WebSphere environment, the second server in the node fails to start the Sample applications, because the first server (JVM) already holds a connection to that database instance.

    For applications that require multiple Java virtual machines to access the same Cloudscape instance, use the Cloudscape networkServer framework.

Additional Samples and examples

IBM Telephone Directory
> The IBM Telephone Directory business application is shipped separately from WebSphere Application Server. For information about obtaining and using the IBM Telephone Directory application, see IBM Telephone Directory V5.2 in the *e-business and Web serving* topic of the iSeries Information Center.

Samples on developerWorks
> Additional WebSphere Application Server Samples are available on WebSphere developerWorks

Samples in tutorials
> Many WebSphere Application Server tutorials rely on Sample code. To find tutorials that demonstrate specific technologies, browse the links in Tutorials.

Examples in the product documentation
> The product documentation contains many code snippets and examples. To locate these examples easily, see the developer examples in the **Reference** section of the information center navigation for the product edition that you are using.

Java Samples on the Sun Microsystems Web site
> Although they do not showcase the capabilities added by purchasing WebSphere Application Server, the Samples on the java.sun.com Web site demonstrate the basic functionality of various technologies.

Web resources for learning

This topic familiarizes you with the many Web sites containing technical information for understanding and using your WebSphere Application Server product. A wealth of online information is available to complement the product documentation.

Choose an area of interest.
- Learning and education
- Developer resources
- Architect, planner, installer, and administrator resources
- Partner resources
- Redbooks, white papers, and documentation
- Troubleshooting and support

Also, throughout the documentation, you will find additional resources for learning pages, each focused on a specific technology, such as Web services. The pages provide links to particular documents of interest.

Learning and education

IBM Education Assistant

Find tutorials, multimedia demonstrations, and presentations for WebSphere servers and Rational development tools.

Training and certification

It's easy to learn about WebSphere® software. IBM has several educational options available to you. From classroom courses to onsite assistance and Internet-based training, if you're ready to learn, we're ready to teach.

Developer resources

developerWorks - WebSphere Application Server zone

Use this page to search for information, download software including trial code and fixes, learn about the application server, and find support and migration information.

Samples Gallery (locally installed)

The Samples Gallery is a locally installable application that offers a set of Samples that demonstrate common Web application tasks.

Architect, planner, installer, and administrator resources

Detailed system requirements page

These pages describe the minimum product levels you should have installed before opening a problem report with the WebSphere Application Server support team.

Patterns for e-business

Patterns for e-business are a group of reusable assets that can help speed the process of developing Web-based applications. The Patterns leverage the experience of IBM architects to create solutions quickly, whether for a small local business or a large multinational enterprise.

Partner resources

PartnerWorld

Find product, business, and technical inforamtion. The PartnerWorld program is designed to offer IBM Business Partners benefits, technical support, education, marketing campaigns, sales tools and more to help you grow your business and drive profits.

Redbooks, white papers, and documentation

Redbooks - WebSphere

Find Redbooks pertaining to WebSphere, including the newest, latest, and most popular Redbooks and Redpapers in draft and published form.

White papers

This link performs a query for white papers that are relevant to WebSphere Application Server.

Library page

A new, improved Web page for finding product documentation, including the online information center, documentation plug-ins for offline viewing with the WebSphere help system, and PDF books. This page links to a variety of other kinds of product information, such as WebSphere Redbooks.

Troubleshooting and support

WebSphere Application Server - Support

This page provides a convenient starting point for querying technical documents, solving problems, downloading fixes, planning, learning, and communicating.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

*   http://www.ibm.com/software/webservers/appserv/was/support/

Support - Recent updates

This document lists valuable resources and newly created content.

Support - Resource reference list

This document is an introduction to available documentation and educational resources.

Support - Quick links

This document provides a reference of direct links to available documentation and educational resources.

Notes

*   The WebSphere Application Server product documentation found in the information center and PDF books documents supported configurations. Many of the above sites could contain information that describes unsupported configurations.
*   Information residing on non-IBM sites is provided for your convenience. Its technical accuracy is controlled by the owner of the site. Use the information at your own risk.

What is new for developers

This version contains many new and changed features for application developers.

New in Version 6.1! indicates new features or changes implemented at the Version 6.1 level. Unmarked items are Version 6.0 improvements that apply also to Version 6.1, which should interest anyone migrating to Version 6.1 from Version 5.x.

Deprecated and removed features describes features that are being replaced or removed in this or future releases.

Web services

Web services

This product has been a leader in advocating support for Web services standards that allow more automated, less hand-coded cross-platform computing. Standards support includes WS-Security, which authenticates communications between web services, and WS-Transactions, which is designed to assure that Web Services transactions are consistently delivered. Additionally, the product supports the WS-I Basic Profile 1.1 for development of interoperable Web services supporting the integration of Web services solutions.

See "Implementing Web services applications" on page 371.

WS-Transaction affinity, routing, and authorization

New in Version 6.1! The implementation in this product version removes 6.0 limitations to provide Web services the same level of distributed transaction support as enterprise beans using CORBA:

- WS-AT contexts use virtual host names and can span firewalls
- Application requests with WS-AT contexts can place transactional affinity constraints on client-side workload management.
- WS-AT protocol messages can be secured.

This product implements a standards-based solution to allow Web services on disparate systems to take part in global transactions with ACID properties. Transactions can span between JTA and J2EE and WS-AT/Web services domains in a seamless manner, requiring no additional programming.

Web services on disparate systems can take part in a compensation model in which compensational scopes span J2EE components and WS-BA/Web services domains in a seamless manner, requiring no additional programming. Applications distributed between WebSphere Application Server and other vendor solutions, for example Microsoft .NET, can take part in the same global transaction.

See "Web Services Atomic Transaction support in WebSphere Application Server" on page 1101.

WS-Notification support – "pub/sub for Web services"

New in Version 6.1! The WS-Notification v1.3 specifications have been added to the WebSphere programming model. Informally described as 'pub/sub for web services,' this family of specifications define web service message exchanges (such as an application interface) to enable web service applications to utilize the 'publish and subscribe' messaging pattern. Traditionally, publish and subscribe messaging is used in message oriented middle ware scenarios to implement a one-to-many distribution pattern.

In the publish and subscribe pattern a producing application inserts (publishes) a message (event notification) into the messaging system, having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic and have the appropriate authority, receive an independent copy of the message that was published by the producing application.

WS-Notification also allows interchange of event notification between WS-Notification applications and other clients of the service integration bus. By exploiting other service integration bus functionality, you can use this function to interchange messages with other IBM publish and subscribe brokers such as Event Broker or Message Broker.

For more information, search the information center for the text: tjwsn_ep

WS-Addressing support -- "protocol independent interoperability for Web services"	**New in Version 6.1!** The product offers support and interoperability with the latest WS-Addressing specifications from W3C, while maintaining interoperability with the pre-W3C specification. This family of specifications provides transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing.

This product version provides a programming interface to support referencing and targeting of Web service endpoints that represent WS-Resource instances, as defined by the WS-Resource Framework specification. Additionally, this version introduces a programming interface to allow programmers to create, reason about and manipulate WS-Addressing artifacts. Programmers can specify the WS-Addressing Message Addressing Properties for outbound messages and also acquire WS-Addressing Message Properties from the incoming message at the receiving endpoint.

See "Web Services Addressing support" on page 466.

Enterprise beans can be invoked from a Web services client using RMI-IIOP	WebSphere Application Server Version 6.0.x supports directly accessing an enterprise JavaBean (EJB) as a Web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client.

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can invoke Web services using protocols with the transport such as SOAP and Remote Method Invocation (RMI).

With Version 6.0.x, you can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings. Using RMI-IIOP with JAX-RPC enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard J2EE programming model. When a Web service is implemented by an EJB, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients.

Using the RMI/IIOP protocol instead of a SOAP- based protocol yields better performance and enables you to get support for client transactions, which are not standard for Web services. Benefits include -- XML processing is not required to send and receive messages; Java serialization is used instead. The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

For more information, refer to "Using WSDL EJB bindings to invoke an EJB from a Web services client" on page 438.

New extensions to the JSR-101 and JSR-109 programming models	WebSphere Application Server Version 6.0.x provides extensions to the Java Specification Request JSR-101 and JSR-109 client programming models. These extensions include the following:

- The REQUEST_TRANSPORT_PROPERTIES property and RESPONSE_TRANSPORT_PROPERTIES property can be added to a Java API for XML-based RPC (JAX-RPC) client Stub to enable a Web services client to send or retrieve HTTP transport headers.
- Implementation-specific support for javax.xml.rpc.ServiceFactory.loadService() as described by the JSR-101 and JAX-RPC specifications. The loadService methods create an instance of the generated service implementation class in an implementation-specific manner. The loadService methods are new for JAX-RPC 1.1 and include three public.javax.xml.rpc.Service loadService signatures.

For more information, refer to "Extensions to the JAX-RPC and Web Services for J2EE programming models" on page 399.

Updates to options used by the emitter tools Java2WSDL and WSDL2Java	The **Java2WSDL** command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based remote procedure call (JAX-RPC) 1.1 specification. The Java2WSDL command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the Java2WSDL command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments. The Java2WSDL command is protocol independent; when you run the Java2WSDL command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the Java2WSDL command has a binding generator to generate the WSDL for that binding.
	New option: Use the -bindingTypes option of the Java2WSDL command to create a WSDL file that contains non-SOAP protocol bindings. The -bindingTypes option specifies the binding types to be written to the output of the WSDL document. Review the Java2WSDL article for more information on using the -bindingTypes option.
	The WSDL2Java command is run against a Web Services Description Language (WSDL) file to create Java APIs and deployment descriptor templates. A WSDL file describes a Web service. The Java API for XML-based remote procedure call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the Web service. The Java Specification Requirements (JSR) 109 1.1 specification defines deployment descriptors that deploy a Web service in a Java 2 Platform Enterprise Edition (J2EE) environment. The WSDL2Java command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.
	For more information, refer to "Java2WSDL command" on page 415 and "WSDL2Java command" on page 419.
Additional HTTP transport properties for Web services applications	JVM custom properties are available to manage the connection pool for Web services HTTP outbound connections. Establishing a connection is an expensive operation. Connection pooling improves performance by avoiding the overhead of creating and disconnecting connections. When an application invokes a Web service over an HTTP transport, the HTTP outbound connector for the Web service locates and uses an existing connection from a pool of connections. When the response is received, the connector returns the connection to the connection pool for reuse. The overhead to create and disconnect the connection is avoided.
	See "Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console" on page 429.

Additions to the programming model

J2EE 1.4 support	J2EE 1.4 specification support is the basis of this product's programming model. It enables you to take advantage of the latest Java technology, as described in Java 2 Platform, Enterprise Edition (J2EE) specification.
WebSphere extensions	Several more WebSphere extensions are now available in this product edition. As a starting point for learning about each extension, see "Learn about WebSphere programming extensions" on page 1119. See also the WebSphere extensions section in "Learn about WebSphere applications: Overview and new features" on page 1.
Portlet application support (JSR 168)	**New in Version 6.1!** Developers can write portlets, in addition to servlets. Administrators can configure, manage, and run portlet applications. Users can access the portlets with URLs, as they do servlets.

Remote RequestDispatch calls are handled the same as local calls	**New in Version 6.1!** Now you can deploy portlets in web applications into separate application server instances with their own virtual machines, but call the portlets with the request dispatcher, just as you would call portlets in local Web applications. This supports application isolation to keep one portlet from bringing down the entire portal server. Complexity and differentiation between remote and local calls is minimized for the administrator.
	See "Remote request dispatcher" on page 88.
Real time collaboration features in applications (JSR 116)	**New in Version 6.1!** The application programming model has been extended to include Session Initiation Protocol (SIP) servlet applications. Developers can write SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet. SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.
	An IETF standard, the SIP protocol (JSR 116) supports clients registration, presence management, and media session negotiation. Media sessions can include such diverse media as text chat, IP audio/video, application sharing, and electronic whiteboards. Applications are growing rapidly, from telecoms and wireless providers, call centers, pervasive computing, and Customer Relationship Management (CRM). The SIP proxy can route SIP or HTTP with enterprise class availability.
Java 5 Software Development Kit (SDK)	**New in Version 6.1!** Developers can use many new API libraries, including generics, auto boxing of primitives, annotations, and enumerated types.
Reliable World Type and Devanagari font availability	**New in Version 6.1!** The World Type fonts and Devanagari font are available as an e-fix from the product Support site. This is to help mitigate the variance in font coverage among Linux distributions, especially the Asian language versions.
64-bit support can affect applications using JNI	WebSphere Application Server now supports 64-bit environments. For most J2EE applications, support for 64-bit environments is not a concern. However, it is a concern for applications that use Java Native Interface (JNI) code. An application that uses JNI code might not start after deployment. The JNI allows Java code running in a virtual machine to operate with applications and libraries written in other languages, such as C, C++, and assembly. If your J2EE application uses JNI in a 32-bit environment, you must recompile your code in a 64-bit environment. The JNI calls might be different after the compilation because JNI specifications can change from version to version.
Added serialVersionUID (SUID) to handle imposing explicit version control for serialized classes	Classes implementing the Serializable interface have added serialVersionUID (SUID) to impose explicit version control for Java serialization. A serialVersionUID identifies the unique original class version for which a class is capable of writing streams and also from which that class can be read.
	best-practices: As you develop your applications, it is recommended that your classes implementing the Serializable interface use serialVersionUID (SUID) to impose explicit version control for Java serialization.

IBM JSF widget library for improved Web pages	**New in Version 6.1!** IBM JSF Widget Library (JWL) is provided as an optional library in WAS. Applications can use the library when it is included in the Shared Library path. FacesClient Framework enabled Web pages are able to sustain longer interactions with the end user without requiring roundtrips back to the server. By creating what effectively is an MVC (Model View Controller) model inside the page, a developer is able to define a working set and a set of controls that dynamically bind to that data. The user can then interact with the working data set, using those controls, and until a roundtrip back to the server is really necessary (for example, to submit data), the user benefits from response times and a freedom to interact with the page that is uncommon in regular Web pages.

For an enterprise that deploys FacesClient Framework enabled Web pages, in addition to increased user satisfaction due to a more interactive and more responsive application, it also benefits in other areas such as lower consumption of server-side resources. Because of the lower amount of roundtrips, and smaller page size relatively speaking, the enterprise is able to scale its server infrastructure and bandwidth further, accommodating more users in the current setup. Applications overall are simpler to develop and maintain. By enabling an MVC-like model on the page, the FacesClient Framework enables a development model based on standards such as JSF (Java Server Faces).

See "JavaServer Faces widget library (JWL)" on page 80. |
| *Java Server Faces (JSF) 1.1 support* | **New in Version 6.1!** Version 6.1 introduces the ability to use JSF 1.1 (JSR 127) in your Java-based Web applications without including the JSF runtime libraries in your application, meaning you can produce smaller applications. The JSF 1.1 DTD will be provided as part of the application server runtime. The JSF specification provides migration instructions and does not list any deprecations. Your JSF 1.0 applications will continue to run without modification.

See "JavaServer Faces" on page 76. |

Data access resources

Service Data Objects (SDO)	As Introduction to Service Data Objects explains, the SDO framework makes the J2EE data programming model simpler, so you can focus on the business logic of your applications.

See "Data access with Service DataObjects" on page 717. |
| *Easier programming of disconnected data objects* | **New in Version 6.1!** An enhanced EJB Service Data Object (SDO) Mediator simplifies the programming model. Current techniques for implementing a disconnected data objects involve a combination of copy helper objects, session beans and EJB access beans. Using the EJB mediator reduces the amount of programming. Dynamic data objects provide flexibility and eliminate the need to define copy helper type objects. Increased performance can be achieved with optimized queries and having the EJB mediator read and write directly to the data store, bypassing the need to activate EJB instances. In addition, the EJB Mediator allows the EJB entity bean programming model and the EJB query language to provide services that can send or receive SDOs.

See "Enterprise JavaBeans Data Mediator Service" on page 733. |

| Cloudscape 10.1.x database support | **New in Version 6.1!** WebSphere Application Server supports Cloudscape v10.1.x as a test and development database. The new Cloudscape is a pure Java database server. The code base, which the open source community calls Derby, is a product of the Apache Software Foundation (ASF) open source relational database project. Cloudscape 10.1.x highlights include: |

* com.ibm.db2j.* becomes org.apache.derby.*:
* org.apache.derby.drda contains the networkServerControl to manipulate the NetworkServer process
* org.apache.derby.jdbc contains the JDBC classes
* org.apache.derby.tools contains the tools like ij and sysinfo dblook
* db2j.properties file becomes derby.properties
* db2j.system.home becomes derby.system.home
* db2j.drda.* becomes derby.drda.*

See the Cloudscape section of ibm.com: http://www-306.ibm.com/software/data/cloudscape/.

Messaging resources

| *Easier to configure access to WebSphere MQ queues from the service integration bus* | **New in Version 6.1!** The service integration bus offers improved, easier to configure connectivity to WebSphere MQ software. An application connected to the bus now can read messages directly from any z/OS WMQ queue, reducing your need to repeat MQ configuration details. |

Version 6.0 did not allow pulling messages directly from MQ queues, which could only be configured as "foreign destinations." In this version, a bus destination can act as a proxy for a z/OS WMQ Queue. JMS applications (including those using message driven beans) can access WMQ queues through such destinations. Requests to both send and receive messages against a destination that is acting as a proxy are delegated to the Queue Manager of the MQ queue, using MQ client protocols including XA flows. This capability enables queue access to be coordinated as part of a global transaction running in WebSphere Application Server.

As a starting point, see **Learn about WebSphere applications > Service integration** in the WebSphere Application Server information center navigation.

| *Flexibility in storage options* | **New in Version 6.1!** Storage options now include using the file system instead of a relational database. The message store component of a service integration bus messaging engine can be configured to use the file system for persistent storage as an alternative to using a relational database. New messaging engines are configured with a file-system-based message store by default. Options are provided in the console wizard and related scripting commands to specify directories and storage file sizes. Options also exist to select a relational-database-based message store. |

As a starting point, see **Learn about WebSphere applications > Service integration** in the WebSphere Application Server information center navigation.

Improved development and assembly tools

| *Easier deployment* | Deploying applications has never been easier -- particularly redeploying updated applications or modules. |

Updates to the Application Server Toolkit	The Application Server Toolkit has new capability:

The Application Server Toolkit has new capability:

- The server editor now has an option to optimize a WebSphere Application Server v6.x server for testing and developing. This option can reduce the startup time of the server. For details on the **Optimize server for testing and developing** check box, see *Reducing the startup time for WebSphere Application Server v6.0* in the online help.

- For EJB 2.x container managed persistence (CMP) entity beans, you can now use a partial operation to specify how you want to update the persistent attributes of the CMP bean to the database. Use the UPDATE_ONLY option for the partial operation to limit updates to the database to only persistent attributes of the CMP bean that have been modified. You can specify the partial operation as a persistent option at the bean-level in the access intent policy configured for the bean. For details on how to use the **Partial Operation** check box, see *Partial operation for container managed persistence* in the online help.

- You can now specify Derby v10 as a valid database vendor backend ID when generating EJB deployment code. See *The ejbdeploy command* in the online help.

- You can now specify the `-dbvendor` option for a mapped JAR file. In releases previous to v6.0.2, if the `-dbvendor` option is specified for mapped JAR files, the database vendor specification is ignored. Specifying the database vendor in the ejbdeploy command is used for generating new top-down maps. If omitted, then the ejbdeploy command uses a default value: `DB2UDB_V81`. For 2.x CMP beans, multiple mappings to different database vendors are supported. 1.1 CMP beans can only be mapped once. For details on the `-dbvendor` option, see the online help.

See "Assembly tools."

Assembly tools

WebSphere Application Server supports two tools that you can use to develop, assemble, and deploy J2EE modules: Application Server Toolkit (AST) and Rational Application Developer. These tools are referred to in this information center as the *assembly tools*.

The AST is available in your WebSphere Application Server CD-ROM package. Rational Application Developer is available only on a trial basis in the WebSphere Application Server CD-ROM package.

The assembly feature of the AST and Rational Application Developer products runs on Windows and Linux Intel platforms. Users of WebSphere Application Server on other platforms must assemble their modules using an assembly tool installed on Windows or Linux Intel platforms. To install an assembly tool, follow instructions available with the tool.

Although this information center refers to the AST and Rational Application Developer products as the *assembly tools*, you can use the products to do more than assemble modules. Rational Application Developer is an integrated development environment that provides development, testing, assembly and deployment capabilities. However, topics on application assembly in this information center focus on assembling J2EE modules using the J2EE Perspective of the assembly tools. Each assembly tool provides extensive online documentation; the topics on application assembly in this information center supplement that documentation. The **Application Server Toolkit** information center is available with this information center.

Enterprise (J2EE) applications

Enterprise applications (or J2EE applications) are applications that conform to the Java 2 Platform, Enterprise Edition, specification.

Enterprise applications can consist of the following:
- Zero or more EJB modules (packaged in JAR files)

- Zero or more Web modules (packaged in WAR files)
- Zero or more connector modules (packaged in RAR files)
- Zero or more Session Initiation Protocol (SIP) modules (packaged in SAR files)
- Zero or more application client modules
- Additional JAR files containing dependent classes or other components required by the application
- Any combination of the above

A J2EE application is represented by, and packaged in, an enterprise archive (EAR) file.

Service Data Objects: Resources for learning

Use the following links to find relevant supplemental information about the service data object and various other functions that can be used with it. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Service Data Objects

For an introduction to Service Data Objects, refer to:
- Introduction to Service Data Objects

For an overview of the Service Data Objects specification, refer to:
- Specifications: Service Data Objects

A good place to start to learn about the Eclipse Modeling Framework is:
- EMF Eclipse Modeling Framework

Information about XSD to SDO/EMF mapping for Version 6 can be found at:
- XML Schema to Ecore Mapping

Web application presentation layer technologies

For a brief overview of JavaServer Faces, refer to:
- IBM Faces Component Catalog
- Java Sun J2EE 1.4 tutorial

Good places to start to learn about JavaServer Pages Standard Tag Library are:
- JavaServer Pages Standard Tag Library
- A JSTL primer, Part 1: The expression language

Chapter 2. Designing applications

This topic highlights Web sites and other ideas for finding best practices for designing WebSphere applications, particularly in the realm of WebSphere extensions to the Java 2 Platform, Enterprise Edition (J2EE) specification.

When designing WebSphere applications, follow the example set by the Samples. Refer to the code in the Samples Gallery that is available with the product. In particular, the Samples Gallery highlights new and WebSphere-specific aspects of the programming model.

Use the following links to find relevant supplemental information about designing WebSphere applications. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Web resources for learning

- The top 10 (more or less) J2EE best practices

  The authors, who are IBM consultants and performance experts, describe this document in the following way: Over the last five years, a lot has been written about J2EE best practices. There now are probably 10 or more books along with dozens of articles that provide insight into how J2EE applications should be written. In fact, there are so many resources, often with contradictory recommendations, navigating the maze has become an obstacle to adopting J2EE itself. To provide some simple guidance for customers entering this maze, we set out to compile the following ″top 10″ list of what we feel are the most important best practices for J2EE.

- IBM Patterns for e-Business

  Patterns for e-business are a group of reusable assets that can help speed the process of developing Web-based applications. The patterns leverage the experience of IBM architects to create solutions quickly, whether for a small local business or a large multinational enterprise.

- WebSphere Best Practices and Performance Considerations

  This document is older (2001), but its focus on the fundamentals of Web and Enterprise JavaBeans (EJB) application programming helps it stand the test of time.

- Best practices for using XSLT in WebSphere Application Server applications

  The author states: In this article I explore the reasons why some WebSphere Application Server applications use XSL for HTML production instead of JavaServer Pages (JSP) files. I will compare the performance of XSLT for HTML/XHTML production against JSP files and browser formatting. I will then provide guidance on how to improve XSLT performance in WebSphere Application Server should you decide to go this route. While this article focuses on the use of XSLT for the production of HTML, the performance best practices are directly applicable to other WebSphere Application Server uses of XSLT, such as XML-to-XML transformations and XML-to-text transformations.

- Rational on developerWorks

  This page provides quick links to technical resources and best practices for Rational software. Browse information by product or by technology. Find resources for learning, support, and developer communities.

- developerWorks site

  developerWorks is IBM's technical resource for developers, providing a wide range of tools, code, and education on DB2, eServer, Lotus, Rational, Tivoli, and WebSphere as well as on open standards technology such as Web services, Wireless, Linux, XML, Java technologies, and more. By providing focused and relevant technical information for developers, developerWorks offers choices you can apply

to building and deploying applications across heterogeneous systems. Using developerWorks, you can take full advantage of open standards and the IBM Software Development Platform in an on demand world.

- Resource reference list

  WebSphere Application Server has a large amount of existing documentation. Use the following user communities and other non-IBM sites that gather knowledge about using WebSphere products as a guideline to find the documentation that you require.
  - http://www.websphere-world.com/
  - http://www.websphere.org/
  - http://www.webspherepro.com/wphome/
  - http://www.sys-con.com/websphere/
  - http://websphereadvisor.com/

See also the documentation for the type of application that you are developing, such as Web applications, EJB applications, Web services applications, or applications that use messaging. Many sections contain *Web resources for learning* topics that bring attention to specific documents that become available.

Reference: Generated API documentation

The generated API documentation provides the details of the supported WebSphere Application Server application programming interfaces (APIs).

The generated API documentation is available in the information center table of contents:

- **Reference > Developer > API documentation** for developing J2EE applications to deploy on the application server
- **Reference > Administrator > API documentation** for extending the administrative infrastructure

To open the information center table of contents to the location of this reference information, click the **Show in Table of Contents** button ( ) on your information center border.

API documentation is organized by the package and class name, for easy lookup.

The API documentation is displayed in the content frame of the information center. If you would like more room to view the API documentation, double-click the gray bar located above the content area. This will expand the content area, while hiding the navigation area (the area containing the table of contents or search results list). Double-click the gray bar again when you are ready to restore the navigation area.

Chapter 3. Obtaining an integrated development environment (IDE)

This topic describes obtaining an integrated development environment (IDE). Use Rational products from IBM to design, construct, and manage changes to applications for deployment on your WebSphere Application Server products.

- See Packaging for a description of the Rational Application Developer Trial that is shipped with the product.

  Insert the disc and use the documentation and the installation program on the disc to install and set up the trial development environment.

- See Assembly tools for a description of the Application Server Toolkit that is shipped with product.

Chapter 4. Developing WebSphere applications

Web applications

Task overview: Developing and deploying Web applications

A developer creates the files comprising a Web application, and then assembles the Web application components into a Web module. Next, the deployer (typically the developer in a unit-testing environment or the administrator in a production environment) installs the Web application on the server.

1. **(Optional)** Migrate existing Web applications to run in the new version of WebSphere Application Server.

2. Design the Web application and develop its code artifacts: Servlets, JavaServer Pages (JSP) files, and static files, as for example, images and Hyper Text Markup Language (HTML) files. See the "Web applications: Resources for learning" on page 66 topic for links to design documentation.

   JavaServer Pages programming tips:
   - Disable session state of JavaServer Pages files using `<%@ page language="java" contentType="text/html" session="false" %>` instead of `<%@ page language="java" contentType="text/html" %>`
   - Replace setProperties calls in your JavaServer Pages files with direct calls to the appropriate setxxx methods.

3. Develop the Web application, using WebSphere Application Server extensions to enhance its functionality.

4. Assemble the Web application into a Web module using an assembly tool. Web module assembly properties might include the ability to:
   - Configure servlet page lists.
   - Configure servlet filters.
   - Serve servlets by class name.
   - Enable file serving.

5. Deploy the Web module or application module that contains the Web application.

   Following deployment, you might find it handy to use the tool that enables batch compiling of the JSP files for quicker initial response times.

6. **(Optional)** Troubleshoot your Web application.

7. **(Optional)** Modify the default Web container configuration in the application server in which you deployed the Web module or application module containing the Web application.

8. **(Optional)** Manage the deployed Web application.

Web applications

A Web application is comprised of one or more related servlets, JavaServer Pages technology (JSP files), and Hyper Text Markup Language (HTML) files that you can manage as a unit.

The files in a Web application are related in that they work together to perform a business logic function. For example, one of the WebSphere Application Server samples is a *Simple Greeting* Web application. This application, comprised of a servlet and Web pages, greets new users when they access the application.

The Web application is a concept supported by the Java Servlet Specification. Web applications are typically packaged as `.war` files.

web.xml file

The web.xml file provides configuration and deployment information for the Web components that comprise a Web application. Examples of Web components are servlet parameters, servlet and JavaServer Pages (JSP) definitions, and Uniform Resource Locators (URL) mappings.

The Java Servlet 2.4 specification defines the web.xml deployment descriptor file in terms of an XML schema document. For backwards compatibility of applications written to the Java Servlet 2.2 Specification, Web containers are also required to support the Java Servlet 2.2 specification. For backwards compatibility of applications written to the Java Servlet 2.3 specification, Web containers are also required to support the Java Servlet 2.3 specification.

If you use Rational Application Developer version 6 to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file:

```
<taglib id="PortletTLD">
   <taglib-uri>http://java.sun.com/portlet</taglib-uri>
   <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
  </taglib>
```

Location

The web.xml file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a Web application.

For example, if the application is client.war, then the web.xml file is placed in the *install_root*/*client war*/`WEB-INF` directory.

Usage notes

*   Is this file read-only?

    No
*   Is this file updated by a product component?

    This file is updated by the Application Server Toolkit.
*   If so, what triggers its update?

    The Application Server Toolkit updates the web.xml file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
*   How and when are the contents of this file used?

    WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

Default Application

WebSphere Application Server provides a default configuration that allows administrators to easily verify
that the Application Server is running. When the product is installed, it includes an application server called
server1 and an enterprise application called *Default Application*.

Default Application contains a Web module called *DefaultWebApplication* and an enterprise bean Java
archive (JAR) file called *Increment*. The *Default Application* provides a number of servlets, described
below. These servlets are available in the product.

For additional code examples, visit the Samples Gallery. Learn how to locate and install the Samples Gallery by viewing the Samples Gallery reference page.

Snoop servlet

Use the Snoop servlet to retrieve information about a servlet request. This servlet returns the following information:
- Servlet initialization parameters
- Servlet context initialization parameters
- URL invocation request parameters
- Preferred client locale
- Context path
- User principal
- Request headers and their values
- Request parameter names and their values
- HTTPS protocol information
- Servlet request attributes and their values
- HTTP session information
- Session attributes and their values

The Snoop servlet includes security configuration so that when WebSphere Security is enabled, clients must supply a user ID and password to initiate the servlet.

The URL for the Snoop servlet is: `http://localhost:9080/snoop/`.

HelloHTML servlet

Use the HelloHTML pervasive servlet to exercise the PageList support provided by the WebSphere Web container. This servlet extends the PageListServlet, which provides APIs that allow servlets to call other Web resources by name or, when using the *Client Type detection* support, by type.

You can invoke the Hello servlet from an HTML browser, speech client, or most Wireless Application Protocol (WAP) enabled browsers using the URL: `http://localhost:9080/HelloHTML.jsp`.

transition: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

HitCount application

Use the HitCount demonstration application to demonstrate how to increment a counter using a variety of methods, including:
- A servlet instance variable
- An HTTP session
- An enterprise bean

You can instruct the servlet to execute any of these methods within a transaction that you can commit or roll back. If the transaction is committed, the counter is incremented. If the transaction is rolled back, the counter is not incremented.

The enterprise bean method uses a container-managed persistence enterprise bean that persists the counter value to a Cloudscape database. This enterprise bean is configured to use the Default Datasource, which is set to the DefaultDB database.

When using the enterprise bean method, you can instruct the servlet to look up the enterprise bean, either in the WebSphere global namespace, or in the namespace local to the application.

The URL for the HitCount application is: `http://localhost:9080/HitCount.jsp`.

Servlets

Servlets are Java programs that use the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to the application server. *Servlets* run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Servlets can support dynamic Web page content, provide database access, serve multiple clients at one time, and filter data.

For the purposes of WebSphere Application Server, discussions of servlets focus on Hyper Text Transfer Protocol (HTTP) servlets, which serve Web-based clients.

With the introduction of Java Servlet 2.4 specification, you can define servlets as welcome files. Non-servlet resources are served only when the FileServingEnabled attribute is set to true. Serving welcome files is connected to serving static content, therefore fileServing enabled is set in the Web module.

JavaServer Pages

JavaServer Pages (JSP) are application components coded to the JavaServer Pages Specification. JavaServer Pages enable the separation of the Hypertext Markup Language (HTML) code from the business logic in Web pages so that HTML programmers and Java programmers can more easily collaborate in creating and maintaining pages.

JSP files support a division of roles:

HTML authors
  Develop JSP files that access databases and reusable Java components, such as servlets and beans.
Java programmers
  Create the reusable Java components and provide the HTML authors with the component names and attributes.
Database administrators
  Provide the HTML authors with the name of the database access and table information.

WebSphere Application Server Version 6.1 supports the JSP 2.0 specification. The sub-topics below discuss WebSphere Application Server's JSP 2.0 implementation, focusing on configuration, tools and extensions.

JSP class file generation: At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server `temp` directory or a Web module's `WEB-INF/classes` directory. The WebSphere Application Server `temp` directory is typically *WAS_INSTALL_ROOT*`/AppServer/profiles/default/temp/`*node_name/server_name*. The JSP engine first searches for a class file in the `temp` directory and then it searches in the Web module's `WEB-INF/classes` directory. Figure 1 shows the processing logic of the JSP engine at runtime.
Request for a JSP.

Is the class file found in WebSphere Application Server temp directory?

No

Is the class file found in WEB-INF/classes

No

Yes

Yes

Is the class file outdated?

No

Yes

Yes

Generate the class file into WebSphere Application Server temp directory.

Load the class file.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables you to deploy the Web module as a self-contained Web archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; *compileToWebInf* not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; *compileToWebInf* is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory, usually `{WAS_ROOT}/profiles/profilename/temp`
compileToDir is supplied; *compileToWebInf* not supplied, or is either true or false	The class files are compiled into the directory indicated by *compileToDir*.	The class files are compiled into the directory indicated by *compileToDir*.

Packages and directories for generated .java and .class files:

By default, the .java files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The .java files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the .java files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. See "JSP class loading" on page 36 for more information. The table below gives examples of packages and directory structures for generated .java and .class files.

	Java package		Location of .java or .class files in file system	
JSP file	**default**	**useFullPackageNames=true**	**default**	**useFullPackageNames=true**
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/ jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with_20_spaces	/dir with spaces	/_ibmjsp/ dir_20_with_20_spaces

Generated .java files: When the JSP engine's **keepgenerated** configuration parameter is set to true, the `.java` file that is generated for JavaServer Pages (JSP) is retained. This file contains information that is useful in debugging.

Dependency information

In the `.java` file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP
2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the Web module's context root. For example:
   /dir1/frag1.jspf
2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
  implements com.ibm.ws.jsp.runtime.JspClassInformation {

  private static String[] _jspx_dependants;
  static {
  _jspx_dependants = new String[5];
  _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
  _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
  _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
  _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
  _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
  }
```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the `.java` file was generated
- The version, build number and build date of the WebSphere Application Server on which the `.java` file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any `<jsp-config>` elements in the `web.xml` file that pertained to the source JSP file.

JSP class loading:

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the Web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the Web module's class loader under either of the following scenarios.

1. 1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the <servlet-class> scenario in the table below.

2. 2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.

2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames
<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a `web.xml` fragment file named `generated_web.xml` which is located in the binaries `WEB-INF` directory of a Web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the `web.xml` file to configure JavaServer Pages files as servlets.

Take note of the location of the `web.xml` that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the `WEB-INF/web.xml` file is looked for in a Web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is `{WAS_ROOT}/profiles/profilename/config/cells/`*cellname*`/applications/`*enterpriseappname*`/deployments/`*deployedname*`/webmodulename*
- An example of an application binaries directory is: `{WAS_ROOT}/profiles/`*profilename*`/installedApps/`*nodename*`/EnterpriseAppName/`*WebModuleName*`/`

If the JSP batch compiler is executed on a pre-deployed application then the `web.xml` file is in the Web module's `WEB-INF` directory.

Configuring JSP run time reloading: JSP files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading. JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the `WEB-INF/ibm-web-ext.xmi` file:

`<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>`

The following table contains the recommended reload settings for production and development environments.

Configuration Attribute	Recommended settings	
	Production Environment	Development Environment
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
disableJspRuntimeCompilation	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compiled on subsequent requests even if the JSP source file is modified or the class file is deleted unless **reloadEnabled** is true

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter:

`<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>`

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval

timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

Disabling compilation

Disablement of run time compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a Web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.
Figure 1. Reload processing sequence when **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.
Figure 2. Additional reload processing performed when **trackDependencies** *is true.*

JSP reload options for Web modules settings:

Use this panel to configure the class reloading of Web modules such as JavaServer Pages (JSP) files

To view this administrative console panel, click **Applications > Enterprise Applications >** *application_name* **> JSP reload options for Web modules**. This panel is the same as the **Provide JSP reloading options for Web modules** panel on the application installation and update wizards.

Web module:

Specifies the name of a JSP file in the application.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

JSP enable class reloading:

Specifies whether to enable class reloading when JSP files are updated.

A Web container reloads JSP files only when the IBM extension jspReloadingEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`.

JSP reload interval in seconds:

Specifies the number of seconds to scan the application's file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-application-ext.xmi`) file of the EAR file.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Disabling JavaServer Pages run time compilation: By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behaviour by indicating a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in WebSphere Application Server.

You can disable run time JSP file compilation on a global or an individual Web application basis:

- To disable the translation and compilation of JSP files for all Web applications, set the Web container custom property `disableJspRuntimeCompilation` to `true`.

  Set this property through the Web container `Custom properties` panel in the administrative console. To view this administrative console page, click:

  Servers > **Application servers** > *server_name* > **Web container settings** >
    Web container > **Custom properties** > *property_name*

  Valid values for this setting are `true` or `false`. If this property is set to `true`, then translation and compilation of the JSP files is disabled at run time for all Web applications.
- To disable the translation and compilation of JSP files for a specific Web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the Web container custom property setting.

  Set this parameter through the `JavaServer Pages attribute assembly settings` panel in the Chapter 7, "Assembling applications," on page 1345.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific Web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the Web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the Web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns HTTP error 500 (Internal server error) to the browser. In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs.

If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

Provide options to compile JavaServer Pages settings:

Use this panel to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console panel is a step in the application installation and update wizards. To view this panel, you must select **Precompile JavaServer Pages files** on the **Select Installation options** panel. Thus, to view this panel, click **Applications > Install New Application >** *application_path* **> Show me all installation options and parameters > Next > Next > Precompile JavaServer Pages files > Next > Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this panel only when installing or updating an application that contains Web modules. After the application is installed, you must edit the JSP engine configuration parameters of a Web module's `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

Web module:

Specifies the name of a module within the application.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

JSP class path:

Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple Web modules use the same class path:
1. In the list of Web modules, select the **Select** check box beside each Web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

Use full package names:

Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options useFullPackageNames and disableJspRuntimeCompilation are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the useFullPackageNames JSP engine parameter.

JDK source level:

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are `13`, `14`, and `15`. The default value is `13`, which specifies source level 1.3.

Disable JSP runtime compilation:

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single Web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the disableJspRuntimeCompilation JSP engine parameter.

JSP batch compilation:

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on Web modules that support Servlet 2.2 and up through Servlet 2.4 The batch compiler works on JSP pages written to the JSP 2.0 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.4 deployment descriptor, `web.xml`, and can use any jsp-config elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any taglib elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a Web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a Web module's `WEB-INF/classes` directory enables the Web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

Also, you can use shared libraries with the JSP batch complier. When you use the JSP batch compiler, you must either add the JAR to the WAR in the <WEB-INF>/lib directory, or add the JAR to the JVM class path to use shared libraries.

JSP batch compiler tool: The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production Web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and Web application archive (WAR) files, as well as enterprise applications and Web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of Web modules

The batch compiler operates on one Web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one Web module, the batch compiler operates on each Web module individually. This is done because JSP pages are configured on a Web module basis, through the Web module's web.xml deployment descriptor file. Within a Web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes

the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:
1. Standard JSP file extensions
   - *.jsp
   - *.jspx
   - *.jsw
   - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 Web modules
3. The **jsp.file.extensions** JSP engine configuration parameter (for pre-Servlet 2.4 Web modules)
4. The batch compiler configuration parameter **jsp.file.extensions**

The standard extensions are always used by the batch compiler. If the Web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter **jsp.file.extensions**, then those extensions are also processed. If the batch compiler configuration parameter **jsp.file.extensions** is present, the extensions given are also processed and will override the JSP engine configuration parameter **jsp.file.extensions**.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension .jspf for such files.

Batch compiler command

Both a Windows batch file, JspBatchCompiler.bat and UNIX shell script JspBatchCompiler.sh for running the batch compiler from the command line are found in the {WAS_ROOT}/bin directory. An Ant task is also available for executing the batch compiler using Ant. See the topic, Batch Compiler Ant Task for additional information.

The batch compiler target is the only required parameter. The target is one of -ear.path, -war.path or -enterpriseapp.name.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
    [-response.file <filename>]
    [-webmodule.name <name>]
    [-filename <jsp name | directory name>
    [-recurse <true | false>]
    [-config.root <path>]
    [-cell.name <name>]
    [-node.name <name>]
    [-server.name <name>]
    [-profileName <name>]
    [-extractToDir <path>]
    [-compileToDir <path>]
    [-compileToWebInf <true | false>]
    [-translate <true | false>]
    [-compile <true | false>]
    [-removeTempDir <true | false>]
    [-forceCompilation <true | false>]
    [-useFullPackageNames <true | false>]
    [-trackDependencies <true | false>]
    [-createDebugClassfiles <true | false>]
```

```
[-keepgenerated <true | false>]
[-keepGeneratedclassfiles <true | false>]
[-usePageTagPool <true | false>]
[-useThreadTagPool <true | false>]
[-classloader.parentFirst <true | false>]
[-classloader.singleWarClassloader <true | false>]
[-additional.classpath <classpath to additional JAR files and classes>]

[-verbose <true | false>]
[-deprecation <true | false>]
[-javaEncoding <encoding>
[-jdkSourceLevel <13 | 14 | 15>]
[-compilerOptions <space-separated list of java compiler options>]
[-useJikes <true | false>]
[-jsp.file.extensions <file extensions to process>]
[-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]

*** See batchcompiler.properties.default in WAS_ROOT/bin for more information. ***
*** See JspCBuild.xml in WAS_ROOT/bin for information about the public WebSphere Ant task JspC. ***
```

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a Web module.

   See the topic, JSP engine configuration parameters.

2. Batch compiler response file configuration parameters.

   These are the parameters that are found in a batch compiler response file. See -response.file, below.

3. Batch compiler command line configuration parameters.

   These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.

2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.

3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the Web module's JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; -profileName is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at run time, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a Web module and you use the -useFullPackageNames true option, the JSP files will be compiled to support that option. But the JSP engine parameter useFullPackageNames must also be set to true in order for the JSP runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed Web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter the following command on a single line at an operating system command prompt.

- **ear.path | war.path | enterpriseapp.name**

Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or Web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:

- – `JspBatchCompiler -ear.path c:\myproject\sampleApp.ear`
- – `JspBatchCompiler -war.path c:\myWars\examples.war`
- – `JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename aDir/main.jsp`

- **response.file**

  Specifies the path to a file that contains configuration parameters used by the batch compiler. The *response.file* is used only if it is given on the command line; it is ignored if it is present in a response file.

  In a default installation, the template response file, batchcompiler.properties.default, is found in the `{WAS_ROOT}/bin` directory. Copy this template to create your own response files containing defaults for the parameters in which you are interested. All the required and optional parameters (except response.file) can be configured in a response file. **For example:** JspBatchCompiler -response.file c:\myproject\batchc.props

  Default : null

- **webmodule.name**

  Represents the name of the specific Web module that you want to batch compile. If this argument is not set, all Web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific Web module within a deployed enterprise application need to be regenerated, because all shared library dependencies are picked up.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war

  Default: All Web modules in an EAR file or enterprise application are compiled if this parameter is not given.

- **filename**

  Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the Web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are complied. The name is relative to the context root of the Web module.

  Example 1: If you want to compile the file, `myTest.jsp`, and it is found in `/subdir/myJSPs`, you would enter `-filename /subdir/myJSPs/myTest.jsp`.

  Example 2: If you want to compile all JSP files in `/subdir/myJSPs` and its child directories, you would enter `-filename subdir/myJSPs`.

  Default: All JSP files in the Web module are compiled. Entering `-filename /` is equivalent to the default.

- **recurse**

  Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false.

  Default: true; All directories beneath the target directory are processed.

- **config.root**

  Specifies the location of the WebSpehere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

  Default: `{WAS_ROOT}/profiles/profilename/config`

- **cell.name**

  Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.

- **node.name**

  Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.

- **server.name**

  Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: server1

- **profileName**

  Specifies the name of the profile you want to use. This parameter is used only when `enterpriseapp.name` is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3

  Default: The default profile is used. This is obtained from the file `setupCmdLine` script in the `install_root`/bin directory. The symbolic name is DEFAULT_PROFILE_SCRIPT.

- **extractToDir**

  Specifies the directory into which predeployed enterprise archive (EAR) files and Web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The extractToDir parameter is used as described in the table below.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir c:\myTempDir.

  Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

  Default values:

	Expanded archive	Compressed archive
extractToDir supplied	The batch compiler extracts the archive to extractToDir before operating on it. If a file or directory of the same name as the archive already exists in the extractToDir, the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the extractToDir, even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	
extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property ″java.io.tmpdir″. The rest of the behavior described above, when extractToDir is supplied, is the same in this case.

  The default is `server1`.

- **compileToDir**

  Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

  Example:: JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir c:\myTargetDir

  Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

Default values:

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the Web module's `WEB-INF/classes` directory	The class files are compiled into the Web module's `WEB-INF/classes` directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the Web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory (usually `{WAS_ROOT}/temp`).
compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- **compileToWebInf**

  Specifies whether the target directory for the compiled JSP class files should be the Web module's `WEB-INF/classes` directory. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

  The batch compiler's default behavior is to compile to the Web module's `WEB-INF/classes` directory. The batch compiler's behavior when compiling class files is described in the table above.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false.

  Use-case: Set this parameter to false when enterpriseApp.name is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the Web module's `WEB-INF/classes` directory. Recommendation: if this parameter is set to false, set forceCompilation to true if there are any JSP class files in the `WEB-INF/classes` directory.

  Default: true; see the table above.

- **forceCompilation**

  Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -forceCompilation true.

  Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

  Default: false

- **useFullPackageNames**

  Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the Web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes **useFullPackageNames** and **disableJspRuntimeCompilation** are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the `web.xml` file.

  When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP pages are loaded as servlets by the Web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at run time if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

  Example: JspBatchCompiler –enterpriseApp.name sampleApp –useFullPackageNames true

  Use-case: Enables JSP classes to be loaded by a single class loader.

  Default: false

- **removeTempDir**

  Specifies whether the Web module's temp directory is removed. The batch compiler by default generates JSP class files into a Web module's `WEB-INF/classes` directory. JSP class files are generated into the `temp` directory at run time if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a Web module and also removing the `temp` directory, disk resources are preserved. You can only use the removeTempDir parameter when -enterpriseApp.name is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory.

  Default: false
- **translate**

  Specifies whether JSP pages are translated and compiled. Set translate to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.

  Use-case: Free up disk space by clearing out a Web application's `temp` directory, without invoking JSP processing.

  Default: true
- **compile**

  Specifies whether JSP pages go through the Java compilation phase. Set compile to `false` if you do not want JSP pages to go through the Java compilation phase.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compile false

  Use-case: If you only want JSP pages to be syntax-checked, set -compile to false. You can set -keepgenerated to true if you want to see the `.java` files that are generated during the translation phase.

  Default: true
- **trackDependencies**

  Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :
  1. Files statically included in the JSP page
  2. Tag files used by the JSP page (excluding tag files that are in JAR files)
  3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -trackDependencies true.

  Use-case: Useful in a development environment.

  Default: false
- **createDebugClassfiles**

  Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, **Debugging support for Other Languages**.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true

  Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

  Default: false
- **keepgenerated**

  Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

  If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepgenerated true

Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

Default: false

- **keepGeneratedclassfiles**

  Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false

  Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with -keepgenerated false, this parameter results in all generated files being removed before the batch compiler completes.

  Default: true

- **usePageTagPool**

  Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -usePageTagPool true

  Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

  Default: false

- **useThreadTagPool**

  Enables or disables the reuse of custom tag handlers on a per request thread basis per Web module.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useThreadTagPool true

  Use-case: Use this parameter to enable Web module-based reuse of tag handlers.

  Default: false

- **classloader.parentFirst**

  Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.parentFirst false

  Use-case: Set this parameter to false when your Web module contains a JAR file that is also found in the server lib directory, and you want your Web module's JAR file to be picked up first.

  Default: true

- **classloader.singleWarClassloader**

  Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per Web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.singleWarClassloader true

  Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another Web module in the same enterprise application.

  Default: false; One class loader is created per WAR file with no visibility of classes in other Web modules.

- **additional.classpath**

  Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when `war.path` is given. When `war.path` is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give `war.path` and also use the `-extractToDir` parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use `-additional.classpath` in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

Example: JspBatchCompiler -war.path c:\myproject\examples.war -additional.classpath c:\myJars\someJar.jar;c:\myClasses

Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At run time, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

Default: null

- **verbose**

  Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -verbose true

  Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

  Default: false

- **deprecation**

  Indicates the compiler should generate deprecation warnings while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -deprecation true

  Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

  Default: false

- **javaEncoding**

  Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When -javaEncoding is set, that encoding is passed to the java compiler via the -encoding argument. Note that encoding is not supported by Jikes.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -javaEncoding Shift-JIS

  Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

  Default value: UTF-8.

- **jdkSourceLevel**

  This is a new JSP engine parameter which was introduced in WebSphere Application Server version 6.1 to support JDK 5. This parameter should be used instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

  The default value for this parameter is 13. This parameter requires regeneration of Java source. The following are jdkSourceLevel paramater values:

  - **13 (default)** - This value will disable all new language features of JDK 1.4 and JDK 5.0.
  - **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0.
  - **15** - This value will enable the use of the assertion facility and all new language features of JDK 5.0.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -jdkSourceLevel 14

  Use-case: Set this parameter when you want to enable or disable the language features of JDK 1.4 and JDK 5.0

  Default value: 13

- **compilerOptions**

  Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form ″arg1 arg2 argn″.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compilerOptions ″ -bootclasspath <path>″

  Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

  Default: null

- **useJikes**

Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useJikes true

Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

Default value: false

- **jsp.file.extensions**

    Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form ″*.ext1;*.ext2:*.extn″. Note that this parameter is not necessary for Servlet 2.4 Web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

    Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspt

    Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

    Default: null. See section, ″JSP file extensions″, in this topic for additional information.

- **log.level**

    Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

    Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

    Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

    Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It executes the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all the ant task attribute and their batch compiler equivalents.

JspC attribute	Equivalent batch complier parameter
earPath	-ear.path
warPath	-war.path
src Same as warPath, for backward compatiblity	-war.path
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir same as compileToDir, for backward compatibility	-compileToDir -compileToDir
compileToWebInf	-compileToWebInf
compilerOptions	-compilerOptions

recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassloader	-classloader.singleWarClassloader
additionalClasspath	-additional.classpath
classpath same as additionalClasspath, for backward compatibility	-additional.classpath
verbose	-verbose
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none
Classpathref	none
jdkSourceLevel	-jdkSourceLevel

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to execute the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On UNIX or i5/OS:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml Using the JspC Task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
 <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
 <target name="jspc1" description="example using  a path to an EAR, and extracting the EAR to a directory">
  <wsjspc wasHome="${was.home}"
          earpath="${ear.path}"
```

```
                forcecompilation="true"
                extractToDir="${extract.dir}"
                useThreadTagPool="true"
                keepgenerated="true"

 />
 </target>
 <target name="jspc2" description="example using an enterprise app and webmodule">
  <wsjspc wasHome="${was.home}"
                enterpriseAppName="${app.name}"
                webmoduleName="${webmodule.name}"
                removeTempDir="true"
                forcecompilation="true"
                keepgenerated="true"

 />
 </target>
 <target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
  <wsjspc wasHome="${was.home}"
                enterpriseAppName="${app.name}"
                webmoduleName="${webmodule.name}"
                fileName="${dir.name}"
                recurse="false"
                forcecompilation="true"
                keepgenerated="true"

 />
 </target>
</project>
```

Batch compiler class path:

The batch compiler builds its class path as shown in the table below. When the batch compiler target is a Web archive (WAR) file and `war.path` is supplied, the configuration *additional.classpath* parameter is used to give extra class path information.

	Batch compiler target		
Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes
JAR files listed in manifest class path for a Web module	yes	yes	yes, when the target WAR is inside an EAR and *–extractToDir* is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes

Global tag libraries:

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many Web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:
• manipulating XML documents
• supporting internationalization
• using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
    userid="db_user" passwd="user_password"
    url="jdbc:subprotocol:database"
    driver="database_driver_name"
    jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:
* **id**

  Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.
* **userid**

  Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

  Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.
* **passwd**

  Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

  Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.
* **url** and **driver**

  Respresents a required attribute if you want to establish a database connection. You must provide the URL and driver.

  The application server supports connection to JDBC databases and ODBC databases.
  – For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

    ```
    url="jdbc:db2:sample"
    driver="com.ibm.db2.jdbc.app.DB2Driver"
    ```

- For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

  The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

  If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

  If you use the bridge, the url syntax is `jdbc:odbc:database`. An example follows:

  ```
  url="jdbc:odbc:autos"
  driver="sun.jdbc.odbc.JdbcOdbcDriver"
  ```

  Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.

- **jndiname**

  Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The Web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

  If you specify the jndiname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbquery> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:
- **id**

  Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the <tsx:getProperty> tag, use `id` to display the query results.

  The `id` is a tsx reference to the bean and can be used to retrieve the bean from the page context. For example, if id is named mySingleDBBean, instead of using:
  - if (mySingleDBBean.getValue(″UISEAM″,0).startsWith(″N″))

  use:

– com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean =
(com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute(″mySingleDBBean″); if
(bean.getValue(″UISEAM″,0).startsWith(″N″)). . .

The bean properties are dynamic and the property names are the names of the columns in the results
set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT
command. In the following example, the database table contains columns named FNAME and LNAME,
but the SELECT statement uses the AS keyword to map those column names to FirstName and
LastName in the results set:

```
Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
```

* **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the
  database URL, driver name, and optionally, the user ID and password for the connection.
* **limit**

  Represents an optional attribute that constrains the maximum number of records returned by a query. If
  this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the
  number of records and the system caching capability.
* SELECT command and JSP syntax

  Represents the only valid SQL command, SELECT. The <tsx:dbquery> tag must return a results set.
  Refer to your database documentation for information about the SELECT command. See other articles
  in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax (deprecated):

The <tsx:dbmodify> tag establishes a connection to a database and then adds records to a database
table.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application
Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer
Pages Standard Tag Library (JSTL).

The <tsx:dbmodify> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information
   provided by that tag to determine the database URL and driver.

   Note: You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are
   provided in the <tsx:dbconnect> tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbmodify> tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:
* **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the
  database URL, driver name, and (optionally) the user ID and password for the connection.
* Database commands

  Represents valid database commands. Refer to your database documentation for details

tsx:getProperty tag JavaServer Pages syntax and examples (deprecated):

The `<tsx:getProperty>` tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the `<tsx:getProperty>` tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:
- **name**

  Represents the name of the bean declared by the `id` attribute of a <tsx:dbquery> syntax within the JSP file. See <tsx:dbquery> for an explanation. The value of this attribute is case-sensitive.
- **property**

  Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax (deprecated):

With the <tsx:userid> and <tsx:passwd> tags, you do not have to hard code a user ID and password in the <tsx:dbconnect> tag.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:userid> and <tsx:passwd> tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the *JSPEmployee.jsp* example that requests the database connection.

You must use <tsx:userid> and <tsx:passwd> tags within a <tsx:dbconnect> tag.

This section describes the syntax of the <tsx:userid> and <tsx:passwd> tags.

```
<tsx:dbconnect id="connection_id"
    <font color="red"><userid></font>
    <tsx:getProperty name="request" property=request.getParameter("userid") />
    <font color="red"></userid></font>
    <font color="red"><passwd></font>
    <tsx:getProperty name="request" property=request.getParameter("passwd") />
    <font color="red"></passwd></font>
    url="protocol:database_name:database_table"
    driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:
- **<tsx:getProperty>**

Represents the syntax as a mechanism for embedding variable data.

- **userid**

  Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.

- **passwd**

  Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax (deprecated):

The <tsx:getProperty> tag repeats a block of HTML tagging.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:
- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the `<tsx:repeat>` tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:
- **index**

  Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.

- **start**

  Represents an optional starting index value for this repeat block. The default is `0`.

- **end**

  Represents an optional ending index value for this repeat block. The maximum value is `2,147,483,647`.

  If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Example: Combining tsx:repeat and tsx:getProperty JavaServer Pages tags (deprecated): Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
   <td><tsx:getProperty name="empqs" property="EMPNO" />
   <tsx:getProperty name="empqs" property="FIRSTNME" />
   <tsx:getProperty name="empqs" property="WORKDEPT" />
```

```
    <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>
```

Example: tsx:dbmodify tag syntax (deprecated): Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
    (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />)
</tsx:dbmodify>
```

Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set (deprecated): Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:repeat> tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the <tsx:dbquery> syntax. The following table is a graphic representation of the contents of a bean called, *myBean*:

	col1	col2	col3
row0	friends	Romans	countrymen
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:
- The column names in the database table become the property names of the bean. The <tsx:dbquery> section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns `May`.
- The query results are in the rows. The <tsx:repeat> tag iterates over the rows, beginning at the start row.

The following table compares using the <tsx:repeat> tag to iterate over a static bean, versus a dynamically generated bean:

Static Bean Example	<tsx:repeat> Bean Example

myBean.class
 	
``
// Code to get a connection
 	
// Code to get the data
   Select * from myTable;
 	
// Code to close the connection
``
 	
JSP file
 	
``
<tsx:repeat index=abc>
  <tsx:getProperty name="myBean"
    property="col1(abc)" />
</tsx:repeat>
``
 	
Notes:
• The bean (myBean.class) is a static bean.
• The method to access the bean properties is myBean.get(*property*(*index*)).
• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row.
	JSP file
	
	``
	<tsx:dbconnect id="conn"
	userid="alice"passwd="test"
	url="jdbc:db2:sample"
	driver="COM.ibm.db2.jdbc.app.DB2Driver">
	</tsx:dbconnect >
	
	<tsx:dbquery id="dynamic"
	 connection="conn" >
	  Select * from myTable;
	</tsx:dbquery>
	
	<tsx:repeat index=abc>
	  <tsx:getProperty name="dynamic"
	    property="col1(abc)" />
	</tsx:repeat>
	``
	
	Notes:
	• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.
	• The method to access the bean properties is dynamic.getValue(″*property*″, *index*).
	• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
	• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

JavaServer Pages migration best practices and considerations:

The standard JavaServer Pages (JSP) tags from JSP 1.1 such as jsp:include, jsp:useBean, and <%@ page %>, a will migrate successfully to JSP 2.0. However, there are several areas that must be considered when migrating JavaServer Pages. This topic discusses the areas that you must consider when migrating JavaServer Pages.

Classes from the unnamed or default package

As of JSP 2.0, referring to any classes from the unnamed or default package is not allowed. This can result in a translation error on some containers, specifically those that run in a JDK 1.4 or greater environment which will also break compatibility with some older JSP applications. However, as of JDK 1.4, importing classes from the unnamed package is not valid. See Java 2 Platform, Standard Edition Version 1.4.2 Compatibility with Previous Releases for details. Therefore, for forwards compatibility, applications must not rely on the unnamed package. This restriction also applies for all other cases where classes are referenced, such as when specifying the class name for a tag in a Tag Library Descriptor (TLD) file.

Page encoding for JSP documents

There have been noticeable differences in internationalization behavior on some containers as a result of ambiguity in the JSP 1.2 specification. However, steps were taken to minimize the impact on backwards compatibility and overall, the internationalization abilities of JSP files have been greatly improved.

In JSP specification versions prior to JSP 2.0, JSP pages in XML syntax, JSP documents, and those in standard syntax determined their page encoding in the same fashion, by examining the pageEncoding or contentType attributes of their page directive, defaulting to ISO-8859-1 if neither was present.

As of JSP 2.0, the page encoding for JSP documents is determined as described in section 4.3.3 and appendix F.1 of the XML specification, and the pageEncoding attribute of those pages is only checked to

make sure it is consistent with the page encoding determined as per the XML specification. As a result of this change, JSP documents that rely on their page encoding to be determined from their pageEncoding attribute are no longer decoded correctly. These JSP documents must be changed to include an appropriate XML encoding declaration.

Additionally, in JSP 1.2, page encodings are determined on translation unit basis whereas in JSP 2.0, page encodings are determined on the basis of each file. Therefore, if the a.jsp file statically includes the b.jsp file, and a page encoding is specified in the a.jsp file but not in the b.jsp file, in JSP 1.2 the encoding for the a.jsp file is used for the b.jsp file, but in JSP 2.0, the default encoding is used for the b.jsp file.

web.xml file version

The JSP container uses the version of the web.xml file to determine whether you are running a JSP 1.2 application or a JSP 2.0 application. Various features can behave differently depending on the version of the web.xml file. The following is a list of things JSP developers should be aware of when upgrading their web.xml file from version Servlet 2.3 to version Servlet 2.4:

1. EL expressions are ignored by default in JSP 1.2 applications. When you upgrade a Web application to JSP 2.0, EL expressions are interpreted by default. You can use the escape sequence \$ to escape EL expressions that should not be interpreted by the container. Alternatively, you can use the isELIgnored page directive attribute, or the <el-ignored> configuration element to deactivate EL for entire translation units. Users of JSTL 1.0 must upgrade their taglib imports to the JSTL 1.1 uris or use the _rt versions of the tags, for example, use c_rt instead of c or fmt_rt instead of fmt.

2. Web applications that contain files with an extension of .jspx will have those files interpreted as JSP documents, by default. You can use the JSP configuration element <is-xml> to treat .jspx files as regular JSP pages, but there is no way to disassociate .jspx from the JSP container.

3. The escape sequence \$ was not reserved in JSP 1.2. The output for any template text or attribute value that appeared as \$ in JSP 1.2 was \$, however, the output now is just $.

jsp:useBean tag

WebSphere Application Server version 5.1 and later enforces more strict adherence to the specification for the jsp:useBean tag: with type and class attributes. Specifically, you should use the type attribute should be used to specify a Java type that cannot be instantiated as a JavaBean. For example, a Java type that is an abstract class, interface, or a class with no public no-args constructor. If the class attribute is used for a Java type that cannot be instantiated as a JavaBean, the WebSphere Application Server JSP container produces a unrecoverable translation error at translation time.

Generated packages for JSP classes

Any reliance on generated packages for JSP classes will result in non-portable JSP files. Packages for generated classes are implementation-specific and therefore you should not rely on these packages.

JspServlet class

Any reliance on the existence of a JspServlet class will cause unrecoverable error problems. WebSphere Application Server version 6.0 and later no longer uses a JspServlet class.

Web modules

A Web module represents a Web application. A Web module is created by assembling servlets, JavaServer Pages (JSP) files, and static content such as Hypertext Markup Language (HTML) pages into a single deployable unit. Web modules are stored in Web archive (WAR) files, which are standard Java archive files.

A Web module contains:
- One or more servlets, JSP files, and HTML files.

- A deployment descriptor, stored in an Extensible Markup Language (XML) file.

  The file, named `web.xml`, declares the contents of the module. It contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time.

You can create Web modules as stand-alone applications, or you can combine Web modules with other modules to create Java 2 Platform, Enterprise Edition (J2EE) applications. You install and run a Web module in the Web container of an application server.

Troubleshooting tips for Web application deployment

Deployment of a Web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser, or if you can access the application by following a link.

If you cannot access your application, follow these steps to eliminate some common errors that can occur during migration or deployment.

Web module does not run in WebSphere Application Server Version 5.x or 6.x

Symptom	Your Web module does not run when you migrate it to Version 5.x or 6.x
Problem	In Version 4.x, the classpath setting that affected visibility was *Module Visibility Mode*. In Versions 5.x and 6.x, you must use class loader policies to set visibility.
Recommended response	Reassemble an existing module, or change the visibility settings in the class loader policies. See "Class loaders" on page 1351 and Chapter 8, "Class loading," on page 1351 for more information.

Welcome page is not visible.

Symptom	You cannot access an application with a Web path of: `/webapp/myapp`
Problem	The default welcome page for a Web application is assumed to be *index.html*. You cannot access the default page of the *myapp* application unless it is named *index.html*.
Recommended response	To identify a different welcome page, modify the properties of the Web module during assembly. See the article "Assembling Web applications" on page 81 for more information.

HTML files are not found.

Symptom	Your Web application ran successfully on prior versions, but now you encounter errors that the welcome page (typically *index.html*), or referenced HTML files are not found:
	
	`Error 404: File not found: Banner.html`
	`Error 404: File not found: HomeContent.html`

Problem	For security and consistency reasons, Web application URLs are now case-sensitive on all operating systems.
	Suppose the content of the index page is as follows:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 5.0 Frameset//EN">
<HTML>
<TITLE>
Insurance Home Page
</TITLE>
    <frameset   rows="18,80">
    <frame      src="Banner.html"          name="BannerFrame"  SCROLLING=NO>
    <frame      src="HomeContent.html"      name="HomeContentFrame">
    </frameset>
</HTML>
```

However the actual file names in the \WebSphere\AppServer\installedApps\... directory where the application is deployed are:

```
banner.html
homecontent.html
```

Recommended response	To correct this problem, modify the *index.html* file to change the names *Banner.html* and *HomeContent.html* to *banner.html* and *homecontent.html* to match the names of the files in the deployed application.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Web applications: Resources for learning

Use the following links to find relevant supplemental information about Web applications. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

* ISO 8859 Specifications
* Java 2 Platform, Standard Edition (J2SE)

Developing servlets with WebSphere Application Server extensions

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

1. Review the supported specifications.

   Create Java components, referring to the Servlet specifications from Sun Microsystems.

   See Resources for learning for links to coding specifications and examples.

   The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the API documentation for the application server APIs in the `install_root\web\apidocs` directory for a default installation.

   All the public WebSphere Application Server APIs are located in the `com.ibm.websphere...` packages.

2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.

3. Test the code artifacts.

Assemble your code artifacts into a Web module using assembly tools as a prerequisite to deploying the code to the application server.

Application life cycle listeners and events

With application life cycle listeners and events, which are now part of the Servlet API, you can notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The life cycle listeners give the application developer greater control over interactions with ServletContext and HttpSession objects. Servlet context listeners manage resources at an application level. Session listeners manage resources that are associated with a series of requests from a single client. Listeners are available for life cycle events and for attribute modification events. The listener developer creates a class that implements the javax listener interface, corresponding to the listener functionality that you want.

At application startup time, the container uses *introspection* to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the contextInitialized method of your listener class is invoked, which creates the database connection for the servlets in your application to use if this context is for your application. All servlet context listeners are notified of context initialization before any servlet in the Web application is initialized.

When the servlet context is destroyed, your contextDestroyed method is invoked, which releases the database connection, if this context is for your application. You must destroy all servlets before any servlet context listeners are notified of context destruction.

Notifications to session listeners precedes notifications to context listeners.

Listener classes for servlet context and session changes

The following methods are defined as part of the javax.servlet.ServletContextListener interface:
- void contextInitialized(ServletContextEvent)

   Notification that the Web application is ready to process requests. Place code in this method to see if the created context is for your Web application and if it is, allocate a database connection and store the connection in the servlet context.
- void contextDestroyed(ServletContextEvent)

Notification that the servlet context is about to shut down. Place code in this method to see if the created context is for your Web application and if it is, close the database connection stored in the servlet context.

The following methods are defined as part of the `javax.servlet.ServletRequestListener` interface:
- `public void requestInitialized(ServletRequestEvent re)`
  - Notification that the request is about to come into scope

    A request is defined as coming into scope when it is about to enter the first filter in the filter chain that processes the request.
- `public void requestDestroyed(ServletRequestEvent re)`
  - Notification that the request is about to go out of scope

    A request is defined as going out of scope when it exits the last filter in its filter chain.

The following listener interfaces are defined as part of the javax.servlet package:
- ServletContextListener
- ServletContextAttributeListener

The following filter interface is defined as part of the javax.servlet package:
- FilterChain interface - methods: doFilter()

The following event classes are defined as part of the javax.servlet package:
- ServletContextEvent
- ServletContextAttributeEvent

The following interfaces are defined as part of the javax.servlet.http package:
- HttpSessionListener
- HttpSessionAttributeListener
- HttpSessionActivationListener

The following event class is defined as part of the javax.servlet.http package:
- HttpSessionEvent

Example: com.ibm.websphere.DBConnectionListener.java
The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
    // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

    // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

Servlet filtering
Servlet filtering provides a new type of object called a *filter* that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their life cycle is very similar.

Filters are handled in the following manner:

1. The Web container determines whether it needs to construct a `FilterChain` containing the `LoggingFilter` for the requested resource.

   The `FilterChain` begins with the invocation of the `LoggingFilter` and ends with the invocation of the requested resource.

2. If other filters need to go in the chain, the Web container places them after the `LoggingFilter` and before the requested resource.

3. The Web container then instantiates and initializes the `LoggingFilter` (if it was not done previously) and invokes its `doFilter(FilterConfig)` method to start the chain.

4. The `LoggingFilter` preprocesses the request and response objects and then invokes the filter chain `doFilter(ServletRequest, ServletResponse)` method.

   This method passes the processing to the next resource in the chain, the requested resource.

5. Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

transition: Java Specification 2.4 allows you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as REQUEST, FORWARD, INCLUDE, ERROR, instead of invoking filters with RequestDispatcher.

For example:

```
<filter-mapping>
<filter-name>Logging Filter</filter-name>
<url-pattern>/products/*</url-pattern>
<dispatcher>FORWARD</dispatcher>
<dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

This indicates that the filter should be applied to requests directly from the client as well as forward requests. Adding the INCLUDE and ERROR values also indicates that the filter should additionally be applied for included requests and `<error-page>` requests. If you do not specify any `<dispatcher>` elements, then the default is REQUEST.

Initial parameters for servlets settings

Use this page to specify initial parameters that are passed to the init method of Web module servlet filters. You can specify initial parameter values for servlets in Web modules during or after installation of an application onto a WebSphere Application Server deployment target. The `<param-value>` values specified in `<init-param>` statements in the `web.xml` file of Web modules are used by default.

To view this administrative console page, click **Applications > Enterprise Applications >** *application_name* **> Init parameters for servlets**. This page is the same as the Init parameters for servlets in each Web module panel on the application installation and update wizards.

Module:

Specifies the name of a module in the application that you are installing or that you are viewing after installation.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

Servlet:

Specifies a unique name for the servlet within the application.

A *servlet* is a Java program that uses the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to an application server. Servlets run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Name:

Specifies the name of the initial parameter passed to the init method of the Web module servlet filter.

The following example servlet filter statement in a `web.xml` file specifies an initial parameter name of `attribute`:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Value:

Specifies the value assigned to an initial parameter passed to the init method of the Web module servlet filter.

The following example servlet filter statement in a `web.xml` file specifies an initial parameter value of `tests.Filter.DoFilter_Filter.SERVLET_MAPPED` for the init parameter `attribute`:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Description:

Specifies information on the initial parameter.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the javax.servlet package:
- Filter interface - methods: doFilter, getFilterConfig, setFilterConfig
- FilterChain interface - methods: doFilter
- FilterConfig interface - methods: getFilterName, getInitParameter, getInitParameterNames, getServletContext

The following classes are defined as part of the javax.servlet.http package:
- HttpServletRequestWrapper - methods: See the Servlet 2.4 Specification
- HttpServletResponseWrapper - methods: See the Servlet 2.4 Specification

Example: com.ibm.websphere.LoggingFilter.java

The following example shows how to implement a filter:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class LoggingFilter implements Filter
{
    File _loggingFile = null;
```

```
    // implement the required init method
    public void init(FilterConfig fc)
    {
        // create the logging file
        xxx;
    }

    // implement the required doFilter method...this is where most of
   the work is done
    public void doFilter(ServletRequest request,
     ServletResponse response, FilterChain chain)
    {
        try
        {
            // add request info to the log file
            synchronized(_loggingFile)
            {
                xxx;
            }

            // pass the request on to the next resource in the chain
            chain.doFilter(request, response);
        }
        catch (Throwable t)
        {
            // handle problem...
        }
    }

    // implement the required destroy method
    public void destroy()
    {
        // make sure logging file is closed
        _loggingFile.close();
    }
}
```

Configuring page list servlet client configurations

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the Web Applications archive (WAR) file by an assembly tool.

To configure and implement page lists:
1. To configure page list information, use the Add Markup Language entry dialog of an assembly tool. On the **Servlets** tab of a Web deployment descriptor editor, select a servlet and click **Add** under **WebSphere Extensions**.
2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

   The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:
   • `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`

     where the method arguments are:
     pageName
             A page name defined in the PageListServlet configuration

request

        The HttpServletRequest object

response

        The HttpServletResponse object

- `callPage(String mlName, String pageName, HttpServletRequest request, HttpServletResponse response)`

  where the method arguments are:

  `mlName` A markup language type

  `pageName`

          A page name defined in the PageListServlet configuration

  `request`

          The HttpServletRequest object

  `response`

          The HttpServletResponse object

3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Page lists:

Page lists allow you to avoid hard-coding Uniform Resource Locators (URLs) in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following list of classes are deprecated:

- com.ibm.servlet.ClientList
- com.ibm.servlet.ClientListElement
- com.ibm.servlet.MLNotFoundException
- com.ibm.servlet.PageListServlet
- com.ibm.servlet.PageNotFoundException

WebSphere Application Server supplies the PageListServlet servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a Web module. This support allows you to access multiple URLs without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the PageListServlet servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the PageListServlet servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support:

In addition to providing the page list mapping capability, the PageListServlet also provides *Client Type Detection* support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the PageListServlet, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the `callPage` method, which calls a JSP file based on the markup-language type of the request.

The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

client_types.xml: The `client_types.xml` file provides client type detection support for servlets extending PageListServlet. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
                HttpServletResponse response)
```

where the arguments are:
* mlName - a markup language type
* pageName - a page name defined in the PageListServlet configuration
* request - the HttpServletRequest object
* response - the HttpServletResponse object

Review the Extending the PageListServlet code example to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequestrequest)`, provided by the PageListServlet, inspects the HttpServletRequest object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:
* Uses the input HttpServletRequest and the `client_types.xml` file, to check for a matching HTTP request name and value.
* Returns the markup-language value configured for the `<client-type>` element, if a match is found.
* If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
* If no match is found, returns the value of the markup-language for the default page defined in the PageListServlet configuration.

Location

The `client_types.xml` file is located in the *install_root*/`properties` directory.

Usage notes

*   Is this file read-only?

    No
*   Is this file updated by a product component?

    No
*   If so, what triggers its update?

    This file is created and updated manually by users.
*   How and when are the contents of this file used?

    Servlets that extending the PageListServlet servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>

      <markup-language>VXML</markup-language>
      <request-header>
           <name>user-agent</name>
           <value>IBM VoiceXML pre-release version 000303</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vxml</value>
      </request-header>
      </client-type>
      <client-type>
           <description>WML Browser</description>
           <markup-language>WML</markup-language>
      <request-header>
           <name>accept</name>
           <value>text/x-wap.wml</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vnd.wap.xml</value>
      </request-header>
    </client-type>
</clients>
```

Example: Extending PageListServlet:

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following example shows how a servlet extends the PageListServlet class and determines the markup-language type required by the client. The servlet then uses the callPage method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
    /*
     * doGet -- Process incoming HTTP GET requests
     */
    public  void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException
    {
       // This is the name of the page to be called:
       String pageName = "Hello.page";

       // First check if the servlet was invoked with a queryString that contains
   // a markup-language value.
       // For example, if this is how the  servlet is invoked:
       //  http://localhost/servlets/HeloPervasive?mlname=VXML
       //  then use the following method:
       String mlname= getMLNameFromRequest(request);

        // If no markup language type is provided in the queryString,
        // then try to determine the client
        // Type from the request, and use the markup-language name configured in
        // the client_types.xml file.
        if (mlName == null)
        {
         mlName = getMLTypeFromRequest(request);
        }
        try
        {
          // Serve the request page.
          callPage(mlName, pageName, request, response);
        }
        catch (Exception e)
        {
          handleError(mlName, request, response, e);
        }
    }
}
```

autoRequestEncoding and autoResponseEncoding

Starting with WebSphere Application Server Version 5, the Web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 Specification or later. If programmers choose not to use the character encoding methods, they can specify the `autoRequestEncoding` and `autoResponseEncoding` extensions, which enable the application server to set the encoding values and content type.

The values of the `autoRequestEncoding` and `autoResponseEncoding` extensions are either `true` or `false`. The default value for both extensions is `false`. If the value is `false` for both `autoRequestEncoding` and `autoResponseEncoding`, then the request and response character encoding is set to the Servlet 2.3 Specification default, which is ISO-8859-1. Also, if the value is set to `false` for a response, the Web container cannot set a response content type.

Use an assembly tool to change the default values for the `autoRequestEncoding` and `autoResponseEncoding` extensions.

Review the `autoRequestEncoding` and `autoResponseEncoding` encoding examples for a description of Web container behavior when these values are set to `true`.

Examples: autoRequestEncoding and autoResponseEncoding encoding examples

The default value of the `autoRequestEncoding` and `autoResponseEncoding` extensions is `false`, which means that both the request and response character encoding is set to the Servlet 2.3 Specification default of ISO-8859-1. Different character encodings are possible if the client defines character encoding in

the request header, or if the code includes the `setCharacterEncoding(String encoding)` method. Also, If the value is set to `false` for a response, the Web container cannot set a response content type.

If the `autoRequestEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the Web container tries to determine the correct character encoding for the request parameters and data.

The Web container performs each step in the following list until a match is found:
- Looks at the character set (charset) in the *Content-Type* header.
- Attempts to map the servers locale to a character set using defined properties.
- Attempts to use the `DEFAULT_CLIENT_ENCODING` system property, if one is set.
- Uses the ISO-8859-1 character encoding as the default.

If the `autoResponsetEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the Web container does the following:
- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

Developing Web applications

Design a Web application and the components that it needs.

For general Web application design information, see ″Resources for learning.″

There are two basic approaches to selecting tools for developing Web applications:
- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the Web application components. The IBM WebSphere Application Developer product is the recommended IDE. For more information, see the documentation for that product.
- If you decide to develop Web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.
1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the Web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product directory:
   - *<install_root>*`\lib`

   ▶ Windows   To compile that same servlet on the Windows NT version of WebSphere Network Deployment, specify:
   `javac -classpath D:\Program Files\WebSphere\DeploymentManager\lib\j2ee.jar MyServlet.java`
3. **(Optional)** Disable JavaServer Pages (JSP) runtime compilation, if necessary.

Assemble the application components in one or more Web modules.

JavaServer Faces
JavaServer Faces (JSF) is a user interface framework or API that eases the development of Java based Web applications. WebSphere Application Server version 6.1 supports JavaServer Faces 1.1 at a runtime level, therefore using JSF reduces the size of the Web application since runtime binaries no longer need to be included in your Web application.

The JSF runtime also :

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface
- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Allows custom user interface components to be easily build and reused

The Sun JSF Reference Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. However, some dependencies on Jakarta APIs have been removed and replaced with Application Server specific solutions as a result of potential problems that may occur when Open Source APIs are included in the Application Server runtime. For example, when included in the Application Server runtime, these Open Source APIs are made available to all applications installed within the Application Server, therefore bringing versioning, support and legal issues. The version of the JSF runtime provided by the Application Server resides in the normal runtime library location and is available to all Web applications that leverage JSF APIs. The loading of the JSF servlet works in the same manner as if the runtime was packaged with the Web application.

The following open source dependencies are replaced with other APIs or in-house versions:

- Jakarta Commons BeanUtils
- Jakarta Commons Collections
- Jakarta Commons Digester
- Jakarta Commons Logging
- Mozilla Assert API

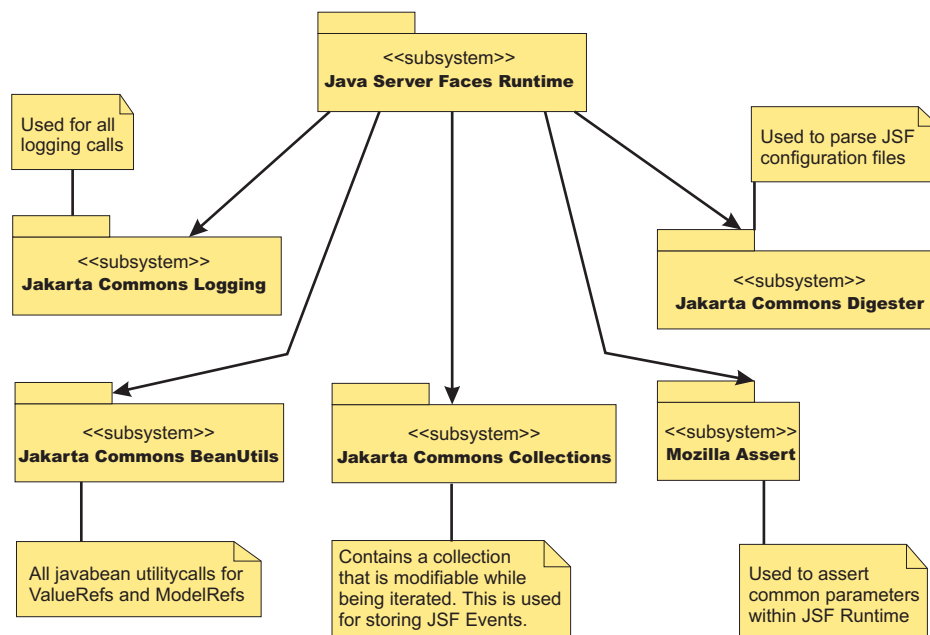
The JSF Specification requires JavaServer Pages Standard Tag Library (JSTL) as a dependency, therefore the required version of the JSTL from Jakarta is made available in the Application Server runtime.


Figure 3. Current external API dependencies from the Sun based JSF runtime

Figure 4. Replacement APIs
The specification related classes (javax.faces.*) for JSF and the IBM modified version of the JSF Sun reference implementation are packaged in the Application Server runtime.

Typically Web applications that leverage this API/Framework embed the JSF API and implementation JAR files within their WAR file. This is not required when these Web applications are deployed and run within WebSphere Application Server. Only the removal of these jars along with any JSTL JAR files from the WAR file is required.

If a Web application requires the use of its own version of JSF or JSTL embedded within it, you can change the class loader mode of the Web application. By default this is set to PARENT_FIRST mode. Changing this value to PARENT_LAST allows the Web application version of the JSF or JSTL classes to load before the WebSphere Application Server.

FacesAssert class

The Sun Reference implementation uses a utility class from Mozilla to perform assertion style calls to method parameters. The faces assert class provides equivalent functionality. The option of leveraging the assertion functionality available in JDK 1.4 is not possible due to the requirement of providing JVM level parameters to turn on assertion code support. The FacesAssert class only contains static method and has no life cycle.

FacesAssert
+ notEmpty ([in] str : String) : boolean
+ nonNull ([in] isNull : Object) : boolean
+ wsAssert ([in] message : String) : boolean
+ wsAssert ([in] argument : boolean , [in] message : String) : boolean

FacesBeanUtils class

The FacesBeanUtils class provides static method replacements for methods used in the Jakarta Commons BeanUtils API. The FacesBeanUtils class has no life cycle.

FacesBeanUtils
+ getProperty ([in] bean : Object , [in] property : String) : Object
+ getPropertyType ([in] bean : Object , [in] property : String) : Class
+ getSimpleProperty ([in] bean : Object, [in] property : String , [in] value : Object)
+ getProperty ([in] bean : Object , [in] property : String , [in] value : Object)
+ convertFromString ([in] value : String, [in] valueClass : Class) : Object
+ convert ([in] targetType : Class , [in] bean : String) : Object

Faces configuration parser

The Sun Reference Implementation of JavaServer Faces use the Jakarta Commons Digester API to parse Faces configuration files. An XML SAX based parser is provided for the Application Server . The Digester code uses reflection code to perform its parsing. This has been found to be quite slow when large configuration files are parsed. The FaceConfigParser class in the diagram below is custom written for the Faces Configuration DTD and therefore parses large configuration files more quickly.

Figure 5. Faces configuration parser

JavaServer Faces widget library (JWL)

FacesClient framework

JavaServer Faces widget library (JWL) is a IBM JSF-based Web widget library that integrates widgets from a number of sources. It includes the JSF components from Rational Web Developer (RWD), with the exception of the base JSF components which are already included in the Application Server runtime. This includes the IBM extended JSF components and the extended Odyssey components.

JWL also extends JSF with client-side features for rich Browser-based experiences in the form of the Odyssey Browser Framework (OBF).

JWL Java archive files

JWL is packaged into two jar files, odc-jsf.jar and jsf-ibm.jar files, which are located in the ${WAS_HOME}\optionalLibraries\IBM\jwl\2.0 directory.

To include JWL in your application, you can use the JWL shared library named JWLLib, which is created at install time. To assign the library to an application, see the article, Using installed optional packages.

Assembling Web applications

Assemble a Web module to contain servlets, JavaServer page (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a Web module, you can install it as a standalone application or combine it with other modules into an enterprise application.

This topic assumes that you have created and unit tested Servlets, JavaServer Pages (JSP) files and other Web components that you want to assemble in an enterprise application and deploy onto an application server.

Use the Application Server Toolkit (AST) or Rational Application Developer assembly tool to assemble a Web module in any of the following ways:
- Import an existing Web module (WAR file).
- Create a new Web module.
- Copy code artifacts (such as servlets) from one Web module into a new Web module.

Although you can input various properties for Web archives, available properties are specific to the Servlet, JSP, and J2EE specification level.

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new Web module.
5. Copy code artifacts (such as servlets) from one Web module into a new Web module.

A Web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

You can now deploy your Web project to an application server.

Web component security

A Web module consists of servlets, JavaServer Pages (JSP) files, server-side utility classes, static Web content, which includes HTML, images, sound files, cascading style sheets (CSS), and client-side classes or applets. You can use development tools such as Rational Application Developer to develop a Web module and enforce security at the method level of each Web resource.

You can identify a Web resource by its URI pattern. A Web resource method can be any HTTP method (GET, POST, DELETE, PUT, for example). You can group a set of URI patterns and a set of HTTP methods together and assign this grouping a set of roles. When a Web resource method is secured by associating a set of roles, grant a user at least one role in that set to access that method. You can exclude anyone from accessing a set of Web resources by assigning an empty set of roles. A servlet or a JavaServer Pages (JSP) file can run as different identities before invoking another enterprise bean component. All the secured Web resources require the user to log in by using a configured login mechanism. Three types of Web login authentication mechanisms are available: basic authentication, form-based authentication and client certificate-based authentication.

In WebSphere Application Server Version 6.1, a portlet resource that is part of a web module can also be protected when it is accessed directly through URL. The protection is similar to other Web based resources. For more information, see Portlet URL security.

For more detailed information on Web security, see the product architectural overview article.

Securing Web applications using an assembly tool

You can use three types of Web login authentication mechanisms to configure a Web application: basic authentication, form-based authentication and client certificate-based authentication. Protect Web resources in a Web application by assigning security roles to those resources.

To secure Web applications, determine the Web resources that need protecting and determine how to protect them.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

The following steps detail securing a Web application using an assembly tool:

1. In an assembly tool, import your Web archive (WAR) file or an application archive (EAR) file that contains one or more Web modules.

   For more information, see ″Importing Web archive (WAR) files″ and ″Importing an enterprise application EAR file″ in the Application Server Toolkit documentation.

2. In the Project Explorer folder, locate your Web application.

3. Right-click the deployment descriptor and click **Open With > Deployment Descriptor Editor**. The Deployment Descriptor window opens. To see online information about the editor, press F1 and click the editor name. If you select a Web archive (WAR) file, a Web deployment descriptor editor opens. If you select an enterprise application (EAR) file, an application deployment descriptor editor opens.

4. Create security roles either at the application level or at the Web module level. If a security role is created at the Web module level, the role also displays in the application level. If a security role is created at the application level, the role does not display in all of the Web modules. You can copy and paste a security role at the application level to one or more Web module security roles.

   - Create a role at a Web-module level. In a Web deployment descriptor editor, click the Security tab. Under **Security Roles**, click **Add.**. Enter the security role name, describe the security role, and click **Finish**.

   - Create a role at the application level. In an application deployment descriptor editor, click the Security tab. Under the list of security roles, click **Add**. In the Add Security Role wizard, name and describe the security role and then click **Finish**.

5. Create security constraints. Security constraints are a mapping of one or more Web resources to a set of roles.

   a. On the Security tab of a Web deployment descriptor editor, click **Security Constraints**. On the Security Constraints tab, you can do the following actions:
      - Add or remove security constraints for specific security roles.
      - Add or remove Web resources and their HTTP methods.
      - Define which security roles are authorized to access the Web resources.
      - Specify None, Integral, or Confidential constraints on user data.
        None The application does not require transport guarantees.
        Integral
              Data cannot be changed in transit between the client and the server.
        Confidential
              Data content cannot be observed while it is in transit.

      Integral and Confidential usually require the use of SSL.

   b. Under Security Constraints, click **Add**.

    c. Under Constraint name, specify a display name for the security constraint and click **Next**.

    d. Type a name and description for the Web resource collection.

    e. Select one or more HTTP methods. The HTTP method options are: GET, PUT, HEAD, TRACE, POST, DELETE, and OPTIONS.

    f. Beside the Patterns field, click **Add**.

    g. Specify a URL Pattern. For example, type – `/*`, `*.jsp`, `/hello`. Consult the Servlet specification Version 2.4 for instructions on mapping URL patterns to servlets. The security runtime uses the exact match first to map the incoming URL with URL patterns. If the exact match is not present, the security runtime uses the longest match. The wild card (`*.`,`*.jsp`) URL pattern matching is used last.

    h. Click **Finish**.

    i. Repeat these steps to create multiple security constraints.

6. Map security-role-ref and role-name elements to the role-link element. During the development of a Web application, you can create the security-role-ref element. The security-role-ref element contains only the role-name field. The role-name field contains the name of the role that is referenced in the servlet or JavaServer Pages (JSP) code to determine if the caller is in a specified role. Because security roles are created during the assembly stage, the developer uses a logical role name in the Role-name field and provides enough description in the Description field for the assembler to map the role actual. The Security-role-ref element is at the servlet level. A servlet or JavaServer Pages (JSP) file can have zero or more security-role-ref elements.

    a. Go to the References tab of a Web deployment descriptor editor. On the References tab, you can add or remove the name of an enterprise bean reference to the deployment descriptor. You can define five types of references on this tab:
   - EJB reference
   - Service reference
   - Resource reference
   - Message destination reference
   - Security role reference
   - Resource environment reference

    b. Under the list of Enterprise JavaBeans (EJB) references, click **Add**.

    c. Specify a name and a type for the reference in the **Name** and **Ref Type** fields.

    d. Select either **Enterprise Beans in the workplace** or **Enterprise Beans not in the workplace**.

    e. **Optional:** If you select **Enterprise Beans not in the workplace**, select the type of enterprise bean in the **Type** field. You can specify either an entity bean or a session bean.

    f. **Optional:** Click **Browse** to specify values for the local home and local interface in the **Local home** and **Local** fields before you click **Next**.

    g. Map every role-name that is used during development to the role using the previous steps. Every role name that is used during development maps to the actual role.

7. Specify the RunAs identity for servlets and JSP files. The RunAs identity of a servlet is used to invoke enterprise beans from within the servlet code. When enterprise beans are invoked, the RunAs identity is passed to the enterprise bean for performing an authorization check on the enterprise beans. If the RunAs identity is not specified, the client identity is propagated to the enterprise beans. The RunAs identity is assigned at the servlet level.

    a. On the Servlets tab of a Web deployment descriptor editor, under **Servlets and JSP**, click **Add**. The Add Servlet or JSP wizard opens.

    b. Specify the servlet or JavaServer Pages (JSP) file settings, including the name, initialization parameters, and URL mappings and click **Next**.

    c. Specify the class file destination.

    d. Click **Next** to specify additional settings or click **Finish**.

    e. Click **Run As** on the **Servlets** tab, select the security role and describe the role.

    f. Specify a RunAs identity for each servlet and JSP file that is used by your Web application.

8. Configure the login mechanism for the Web module. This configured login mechanism applies to all the servlets, JavaServer Pages (JSP) files and HTML resources in the Web module.

   a. Click the **Pages** tab of a Web deployment descriptor editor and click **Login**. Select the required authentication method. Available method values include: Unspecified, Basic, Digest, Form, and Client-Cert.

   b. Specify a realm name.

   c. If you select the Form authentication method, select a login page and an error page Web address. For example, you might use `/login.jsp` or `/error.jsp`. The specified login and error pages are present in the `.war` file.

   d. Install the client certificate on the browser or Web client and place the client certificate in the server trust keyring file, if `ClientCert` is selected.

9. Close the deployment descriptor editor and, when prompted, click **Yes** to save the changes.

After securing a Web application, the resulting Web archive (WAR) file contains security information in its deployment descriptor. The Web module security information is stored in the `web.xml` file. When you work in the Web deployment descriptor editor, you also can edit other deployment descriptors in the Web project, including information on bindings and IBM extensions in the `ibm-web-bnd.xmi` and `ibm-web-ext.xmi` files.

After using an assembly tool to secure a Web application, you can install the Web application using the administrative console. During the Web application installation, complete the steps in Deploying secured applications to finish securing the Web application.

Context parameters

A servlet context defines a server's view of the Web application within which the servlet is running. The context also allows a servlet to access resources available to it.

Using the context, a servlet can log events, obtain URL references to resources, and set and store attributes that other servlets in the context can use. These properties declare a Web application's parameters for its context. They convey setup information, such as a webmaster's e-mail address or the name of a system that holds critical data.

Security constraints

Security constraints determine how Web content is to be protected.

These properties associate security constraints with one or more Web resource collections. A constraint consists of a Web resource collection, an authorization constraint and a user data constraint.
- A Web resource collection is a set of resources (URL patterns) and HTTP methods on those resources. All requests that contain a request path that matches the URL pattern described in the Web resource collection are subject to the constraint. If no HTTP methods are specified, then the security constraint applies to all HTTP methods.
- An authorization constraint is a set of roles that users must be granted in order to access the resources described by the Web resource collection. If a user who requests access to a specified Uniform Resource Identifier (URI) is not granted at least one of the roles specified in the authorization constraint, the user is denied access to that resource.
- A user data constraint indicates that the transport layer of the client or server communications process must satisfy the requirement of either guaranteeing content integrity (preventing tampering in transit) or guaranteeing confidentiality (preventing reading while in transit).

Security settings

Use the administrative console to modify the security settings for all applications. You can enable security for applications by enabling the **Enable application security** option on the Secure administration, applications, and infrastructure panel.

Note that:

- Global settings apply to existing and future applications and cannot be customized.
- Default settings apply only to future applications and can be customized.

The default settings are used as a template or starting point for configuring individual applications. The administrator should still explicitly configure security settings for each application.

The following security settings are specified during application assembly:

Security role settings

When using the Assembly Toolkit at an application level (Enterprise Archive (EAR) file), security roles are synchronized with the security roles defined for the embedded modules of the application.

If a security role is manually added to the EAR file, it can be automatically removed when the file is saved if an embedded module does not reference the role, or the role is in conflict with an existing role. In this case, remove the manually added role, but then all roles with the same name are removed.

The role is automatically added again when the file is saved if it is still referenced in an embedded module file. If a duplicate role is added in an embedded module file, delete all roles with the same name and manually read the correct role.

Security constraints

Security constraints declare how to protect Web content. These properties associate security constraints with one or more Web resource collections. A *constraint* consists of a Web resource collection, an authorization constraint, and a user data constraint.

Security constraints are set when configuring a Web application in the Assembly Toolkit.

Security role references:

Web application developers or Enterprise JavaBeans (EJB) providers must use a role-name in the code when using the available programmatic security Java 2 Platform, Enterprise Edition (J2EE) application programming interfaces (APIs) isUserInRole(String roleName) and isCallerInRole(String roleName).

The roles used in the deployed run-time environment might not be known until the Web application and EJB components (for example, Web archive (WAR) files and `ejb-jar.xml` files) are assembled into an enterprise archive (EAR) file. Therefore, the role names used in the Web application or EJB component code are logical role names which the application assembler maps to the actual run-time environment roles during application assembly. The security role references provide a level of indirection that insulate Web application component and EJB developers from having to know the actual roles in the run-time environment.

The definition of the logical roles and the mapping to the actual run-time environment roles are specified in the security-role-ref element of both the Web application and the EJB JAR file deployment descriptors, `web.xml` and `ejb-jar.xml` respectively. Use the assembly tools to define the role names and map them to the actual run-time roles in the environment with the role-link element.

The following code sample is an example of a security-role-ref from an EJB `ejb-jar.xml` deployment descriptor.

```
... <enterprise-beans>
... <entity>
<ejb-name>AardvarkPayroll</ejb-name>
<ejb-class>com.aardvark.payroll.PayrollBean</ejb-class>
...
<security-role-ref>
<description>
```

This role should be assigned to the employees of the payroll department. Members of this role have access to the payroll record of everyone. The role has been linked to the payroll-department role. This role

should be assigned to the employees of the payroll department. Members of this role have access to all payroll records. The role has been linked to the payroll-department role.

```
</description> <role-name>payroll</role-name>
<role-link>payroll-department</role-link>
</security-role-ref>
 ...
</entity>
 ...
</enterprise-beans>
```

In the previous example, the string `payroll`, which appears in the <role-name> element, is what the EJB provider uses as the argument to the isCallerInRole() API. The <role-link> element is what ties the logical role to the actual role used in the run-time environment.

Note that for enterprise beans, the security-role-ref element must appear in the deployment descriptor even if the logical role name is the same as the actual role name in the environment.

The rules Web application components are slightly different. If no security-role-ref element matching a security-role element is declared, the container must default to checking the role-name element argument against the list of security-role elements for the Web application. The isUserInRole method references the list to determine whether the caller is mapped to a security role. The developer must be aware that the use of this default mechanism can limit the flexibility in changing role names in the application without having to recompile the servlet making the call.

See the EJB Version 2.0 and Servlet Version 2.3 specification in the Security: Resources for Learning article for complete details on this specification.

Servlet mappings

A servlet mapping is a correspondence between a client request and a servlet.

Web containers use URL paths to map client requests to servlets, and follow the URL path-mapping rules as specified in the Java Servlet specification. The container uses the URI from the request, minus the context path, as the path to map to a servlet. The container chooses the longest matching available context path from the list of Web applications that it hosts.

Serving of servlets by name or class name

This behavior is triggered by setting the serveServletsbyClassnameEnabled property within IBM extensions.

The attribute is used to specify the enablement of the serving of servlets by name or classname

Example attributes:

invoker.patterns
> This attribute allows you to specify the patterns that trigger invocation of the server component and allows the serving of servlets by name or by class name. This value is a list separated by either a space, colon, or semicolon.

File serving

File serving allows a Web application to serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

This behavior is implemented by setting the fileservingenabled property to true when configuring the Web module.

Example attributes:

bufferSize
>Sets buffer size that is used for serving static files.

extendedDocumentRoot
>Path that specifies the directory where static files are sent. Use this attribute in addition to the contextRoot attribute.

file.serving.patterns.allow
>Specifies that only files matching the specified pattern are served.

file.serving.patterns.deny
>Specifies that files that match the specified file pattern are denied

Initialization parameters

Initialization parameters are sent to a servlet in its HttpConfig object when the servlet is first started.

Servlet caching

You can use dynamic caching to improve the performance of a servlet and JavaServer Pages (JSP) files by serving requests from an in-memory cache. Cache entries contain the servlet's output and metadata.

Web components

A Web component is a servlet, JavaServer Pages (JSP) file, or HTML file. One or more Web components make up a Web module.

Web property extensions

Web property extensions are IBM extensions to the standard deployment descriptors for Web applications. These extensions include mime filtering and servlet caching.

Web resource collections

A Web resource collection defines a set of URL patterns (resources) and HTTP methods belonging to the resource.

HTTP methods handle HTTP-based requests, such as GET, POST, PUT, and DELETE. A URL pattern is a partial Uniform Resource Locator that acts as a template for matching the pattern with existing full URLs in an attempt to find a valid file.

Welcome files

A Welcome file is an entry point file (for example, `index.html`) for a group of related HTML files.

Welcome files are located by using a group of partial URIs. The Web container uses the partial URIs to find a valid file when the initial URI is not found.

Task overview: Assembling applications using remote request dispatcher

Remote request dispatcher (RRD) is a pluggable extension to the Web container which allows application frameworks, servlets and JavaServer Pages (JSP) to include content from outside the currently executing resource's Java Virtual Machine (JVM) as part of the response sent to the client.

You must have WebSphere Application Server Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, "Remote request dispatcher considerations" on page 92 for details.

Some statement about the process used to arrive here.

1. "Installing application files with the console" on page 1368

2. Configure the sending of include requests between the application and remote resources.
    *   "Configuring Web applications to dispatch remote includes" on page 89
    *   "Configuring Web applications to service remote includes" on page 89

After enabling at least one enterprise application to dispatch remote includes and at least one enterprise application to service remote includes, RRD is now enabled.

Restart the modified applications if already installed or start newly installed applications to enable RRD on each application.

Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the Web container that allows application frameworks, servlets and JavaServer Pages to include content from outside of the current executing resource's Java virtual machine (JVM) as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure to allow other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard J2EE `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using Web services to communicate between machines within a Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also leverage SSL for secure communications and WS-Security security context propagation between servers. See rrdSecurity.props file for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container to allow invocation of portlets outside of the current executing resource's JVM.

By utilizing the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

Capabilities

*   Requests on remote server are treated as include requests. Filters and request listeners are invoked as if the dispatch type is INCLUDE.
*   Serializable request attributes and query parameters are sent to remote server.
*   Security context is sent to a remote server through LTPA tokens.
*   Servlet parameters and OutputStream

    Request parameters are passed to remote server.
*   Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
*   All original request headers are passed to remote server
    *   Similar to WebSphere Application Server's plugin
    *   Method calls return the state as if they are on local server. For example, getServer returns the local server name or isSecure returns whether the request to the 'local' server has been secure.
*   Cookies and sessions
    *   Cookies are passed to the remote server as part of headers.
    *   Sessions in local and remote servers use the same cookie or session id for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
*   Exceptions

- If there is a exception on the remote server, the server returns an RRD specific Web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD specific ServletException is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache

  When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

  You can use SSL to encrypt RRD messages between application servers. This is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD leverages WS-Security to pass this information, but this security context propagation is disabled by default. See the topic, rrdSecurity.props file, for additional information.

Configuring Web applications to dispatch remote includes

You can configure Web modules in an application as remote request dispatcher clients to dispatch include requests to resources across Web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

You must have WebSphere Application Server for Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, "Remote request dispatcher considerations" on page 92 for details.

You can also configure this property when you install the application installation. See "Installing application files with the console" on page 1368

1. In the administrative console, click **Applications > Enterprise Applications >** *application_name* **> Remote Request Dispatcher Properties**.
2. Select **Enable remote resources to receive include requests**.

Web modules included in this application are enabled as remote request dispatcher clients that can dispatch remote includes.

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the remote server that includes the resource that you want to include, see article, "Configuring Web applications to service remote includes."

Configuring Web applications to service remote includes

You can configure Web modules in an application as remote request dispatcher servers that are remotely included by other Web applications.

You must have WebSphere Application Server Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, "Remote request dispatcher considerations" on page 92 for details.

The purpose of this task is to specify whether an application can service an include request from another application. You can also configure this property when you install the application installation. Some statement about the process used to arrive here. See "Installing application files with the console" on page 1368

1. In the administrative console, click **Applications > Enterprise Applications >** *application_name* **> Remote Request Dispatcher Properties**.
2. Select **Enable remote resources to service include requests**.

Web modules included in this application are enabled as remote request dispatcher servers that are resolved to service remote includes from another application.

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the local server to include a remote resource, see article, "Configuring Web applications to dispatch remote includes" on page 89.

Configuring remote request dispatcher caching

The creation and handling of the remote request dispatcher (RRD) message and the transfer of this data across a network creates substantial overhead. To improve performance, the local machine can receive the cache rules of the remote server and know when to cache the response locally to prevent the RRD call altogether.

Unsupported rules are cached remotely. However, remote request dispatcher does not support the entire set of rules of the cachespec.xml file for local caching. The following rules for the cachespec.xml file are supported for local caching.

parameters
Retrieves the named parameter value.

cookie
Retrieves the named cookie value.

header
Retrieves the named request header.

locale
Retrieves the request locale.

requestType
Retrieves the HTTP request method from the request.

Complete the following steps to enable RRD dynamic cache support.

1. Enable servlet caching on the local server See Configuring servlet caching for more information
2. Construct and install an application with a valid `Cachespec.xml file` policy with RRD supported rules. See the article, Configuring cacheable objects with the cachespec.xml file, for additional information.
3. Enable servlet caching on the remote server. See Configuring servlet caching for more information
4. Restart WebSphere Application Server. See Managing application servers for more information.

To verify that dynamic cache is enabled locally, you can enable RRD trace and verify that there is a CACHE HIT printed out for multiple requests to a resource that has an appropriate cache policy. You also have the option to use CacheMonior instead of turning on tracing. If the CacheMonitor on the remote machine is not receiving cache hits, then the response is cached locally. The local CacheMonitor will not receive hits because RRD uses its own custom cache.

Remote request dispatch property settings

Use this page to configure the sending of include requests between the application and remote resources.

To view this administrative console page, click **Applications > Enterprise Applications > **application_name** > Remote request dispatch properties**.

Allow dispatching includes to remote resources:

Specifies whether an application can dispatch include requests to resources across Web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

Data type   Boolean

Default   false

Allow servicing includes from remote resources:

Specifies whether an application can service an include request from another application.

Data type   Boolean
Default   false

Example: Locating resources in two different contexts using the Servlet programming model

The Servlet Programming Model for including resources remotely does not require you to use any non-Java 2 Platform, Enterprise Edition (J2EE) Servlet Application Programming Interfaces (APIs). The remote request dispatcher (RRD) component follows the same rules to obtain a ServletContext and a remote resource. By using JavaServer Pages standard tag library (JSTL), your application is further removed from obtaining a ServletContext object or RequestDispatcher that is required in the Framework example because the JSTL custom tag does this implicitly. Study the following example of a sample JavaServer Pages application to learn how to locate resources that are in two different contexts, investments and banking.

```
<HEAD>
<%@ page
language="java"
contentType="text/html; charset=ISO-8859-1"
pageEncoding="ISO-8059-1"
isELIgnored="false"
%>
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" $>
</HEAD>
<BODY>

<%--

Programming example using JavaServer Pages and JavaSever Pages
Standard Tag Library (JSTL).
JSTL provides a custom tag to import contents (in servlet and JSP
terms include) in the scope of the same request from outside of
the current Web module context by specifying a context parameter.

JSTL restriction: The Web module that is imported
must run inside of the same JVM as the calling resource
if imported URL is not fully qualified.

RRD extends this functionality by permitting the Web module to
be located within the scope of the current WebSphere Application
Server core group versus the scope of the JVM.
--%>

<hr size="5"/>
<%--  Include resource investmentSummary.jsp located in the
  Web application with context root of /investments. --%>

<c:import url="investmentSummary.jsp" context="/investments"/>

<hr size="5"/>
<%--  Include resource accountSummary.jsp located in the
  Web application with context root of /banking. --%>

<c:import url="accountSummary.jsp" context="/banking"/>
```

```
<hr size="5"/>

</BODY>
</HTML>
```

Example: Locating resources in two different contexts using the framework programming model

The Framework Programming Model for including resources remotely does not require you to use any non-Java 2 Platform, Enterprise Edition (J2EE) Servlet Application Programming Interfaces (APIs). When a request is initiated for a ServletContext name that is not presently running inside of the current Web container, the remote request dispatcher (RRD) component returns a ServletContext object that can locate a resource that exists anywhere inside a WebSphere Application Sever Network Deployment environment provided that the resource exists and RRD is enabled for that ServletContext object. Study the following sample framework snippet that demonstrates how to locate resources located in two different contexts, investments and banking.

```
/*
Programming example using a generic framework.
Servlet Specification provides an API to obtain
a servlet context in the scope of the same request
different from the current Web module context by
specifying a context parameter.

Servlet Specification restriction: The Web module that obtain
must run inside of the same JVM as the calling resource.

RRD extends this functionality by permitting the Web module to be located
within the scope of the current WebSphere Application Server core group
versus the scope of the JVM.

*/

protected void frameworkCall (ServletContext context, HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException(

    PrintWriter writer = response.getWriter();

    writer.write("<HTML>");
    writer.write("<HEAD>");
    writer.write("</HEAD>");
    writer.write("<BODY>");
    writer.write("<hr size=\"5/">);

    //Include resource investmentSummary.jsp located in Web application
    //with context root of /investments.
    RequestDispatcher rd = getRequestDispatcher ( context, "/investments", "/investmentSummary.jsp");
    rd.include(request, response);

    writer.write("<hr size=\"5/">);

    //Include resource accountSummary.jsp located in Web application
    //with context root of /banking.
    rd = getRequestDispatcher ( context, "/banking", "/accountSummary.jsp");
    rd.include(request, response);

    writer.write("</BODY>");
    writer.write("</HTML>");
}
private RequestDispatcher getRequestDispatcher (ServletContext context, String contextName, String resource) {
    return context.getContext(contexName).getRequestDispatcher(resource);
}
```

Remote request dispatcher considerations

This topic presents some considerations of which you need to be aware when using remote request dispatcher.

- If an application expects parameters in certain encoding, the application should set character encoding, as in a normal include, before the remote request dispatch (RRD) occurs.
  - ServletInputStream data of local server is not available to remote server. The local server parses POST data prior to sending the RRD request to the remote server and include parameters as request parameters. Multipart form data is inaccessible to remote server. An UnsupportedOperationException is created if the remote server attempts to obtain inputstream from the request.
  - No access to original request reference on the remote server.
  - Request and response wrappers created in the local server are not available in remote server. This cannot be done due to ServletRequestWrappers and WebSphere internal ServletRequest objects not implementing Serializable.
- Request attributes need to be serializable.
  - Class definition of attributes need to be available in both local and remote servers.
  - Request attributes are propagated to the remote server and back to the local server.
- HTTP Sessions
  - You cannot have cross session access between different Web applications when Web applications are remote.
  - When all Web applications are in a local server, an application can share sessions across Web applications by storing the session in a table that is accessible to multiple Web applications. This is not possible with RRD and not recommended in local case either.
  - Servlet Programming Model: You cannot access sessions in different Web applications.
  - Normal programming model in local case as well as remote case.
  - In local mode, application can cache away reference and share the session across the Web applications, which is not feasible in RRD case.
  - A session object that is stored as request attribute is not available on remote server as the Session class does not implement Serializable.
- Thread local variables that are set on the local server are not available on the remote server.
- Not all methods defined on ServletContext object are available for the RRD ServletContext object. See the SPI documentation for com.ibm.wsspi.rrd.context.RemoteServletContext for details.
- The remote server does not have access to output of local server when using RRD.
- Cookies and ServletRequestWrappers

  If customer application wrappers the HttpServletRequest.getCookies method and returns additional cookies or removes cookies, the modified cookies are not sent to the remote server because javax.servlet.http.Cookie does not implement Serializable. Cookies from the original request headers are sent to the remote server.

Servlet extension interfaces

You can use extension generators and handlers to add content to the remote message for servlet and portlets calls. The servlet extension can also modify existing behavior by leveraging the filter concept. The Remote Request Dispatcher (RRD) extension framework relies on extension generators, which attach arbitrary data to an outbound RRD request, and extension handlers, which consume the data and perform actions based on the data received.

- " Extension generators" on page 94
- "Extension handlers" on page 95
- "Extension delegators" on page 95
- "Custom EMF packages" on page 96

For more information on the com.ibm.wsspi.rrd.extension package, see "Reference: Generated API documentation" on page 26 for administrators.

Extension generators

Extension generators, which are part of an extension generator chain, are invoked prior to initiating an RRD request. This extension generator chain is defined in the com.ibm.wsspi.rrd.generators extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local Web application.

Each extension generator is defined by a generator element, which contains an id attribute, which is used to assign a unique identifier to the extension generator such that any extension generator can be targeted by extensions added to RRD response data. The class attribute is used to specify the class name of the extension generator, which must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface. Each extension generator can also have an execution order associated with it via the order attribute, which is useful for enforcing extension generator execution order in an environment where multiple extension generator descriptor files are present. Additionally, a generator has a mandatory attribute called type that defines the type of the generator. For servlet RRD, the value is "servlet" and the class must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface.

Additionally, each extension generator may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the generator element. An example extension generator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.generators">
  <generator id="int1"
       class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
       order="1"
       type="servlet">
   <init-param>
            <param-name>intValue</param-name>
            <param-value>100</param-value>
   </init-param>
  </generator>
  <generator id="string1"
       class="com.ibm.ws.rrd.example.extension.StringExtensionGenerator"
       order="2"
       type="servlet">
    <init-param>
            <param-name>stringValue</param-name>
            <param-value>This is an example string</param-value>
    </init-param>
  </generator>
  <generator id="int2"
       class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
       order="3"
       type="servlet">
    <init-param>
            <param-name>intValue</param-name>
            <param-value>200</param-value>
    </init-param>
  </generator>
</extension>
```

For more information on the `com.ibm.wsspi.rrd.extension.generator` package, see "Reference: Generated API documentation" on page 26 for administrators.

Extension handlers

Extension handlers, which are part of an extension handler chain, are invoked after an RRD request has been received. This extension handler chain is defined in the `com.ibm.wsspi.rrd.handlers` extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local Web application.

Each extension handler is defined by a handler element, which contains namespaceURI and localName attributes, the combination of which defines the qualified name of the extension data that the extension handler can process. Each extension handler additionally requires a unique identifier, specified by the id attribute. The value specified by this attribute must correspond to an extension generator, which generates extension data of a matching qualified name and identifier. The class attribute is used to specify the class name of the extension handler, which must implement the com.ibm.wsspi.extension.handler.ExtensionHandler interface. Additionally a handler has a mandatory attribute called type that defines the type of the handler. The value is "servlet" and the class must implement the com.ibm.wsspi.rrd.extension.handler.ExtensionHandler interface.

Additionally, each extension handler may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the handler element. An example extension handler declaration follows:

```
  <extension point="com.ibm.wsspi.rrd.handlers">
      <handler id="int1"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="1"
               type="servlet"/>
      <handler id="string1"
               class="com.ibm.ws.rrd.example.extension.StringExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="2"
               type="servlet"/>
      <handler id="int2"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="3"
               type="servlet"/>
</extension>
```

For more information on the `com.ibm.wsspi.rrd.extension.handler` package, see "Reference: Generated API documentation" on page 26 for administrators.

Extension delegators

An extension delegator enables RRD to handle arbitrary servlet containers by allowing users to specify the specific extension generator and handler chain instances that are to be used during an RRD call. RRD maintains a user-extendable list of extension delegators and selects an appropriate delegator at runtime based on the type of servlet request being issued.

Custom extension delegators may be defined in the `com.ibm.wsspi.rrd.rrd-extension-delegator` extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the WEB-INF directory of an RRD-enabled local Web application.

Each extension delegator is defined by an `ExtensionDelegator` element, which contains a priority attribute for defining the relative order in which an extension delegator is initiated, and a classname attribute that defines the implementing class for a particular extension delegator, which must implement the `com.ibm.wsspi.rrd.extension.factory.ExtensionDelegator` interface. Note that the execution order of two or more extension delegators with the same priority is not predictable. An example extension delegator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-extension-delegator">
  <ExtensionDelegatorRegistration>
    <ExtensionDelegator priority="1" classname="com.ibm.ws.rrd.extension.PortletExtensionDelegator"/>
    <ExtensionDelegator priority="2" classname="com.ibm.ws.rrd.extension.ServletExtensionDelegator"/>
  </ExtensionDelegatorRegistration>
</extension>
```

Custom EMF packages

Extension data produced by an extension generator and consumed by an extension handler is serialized using the Eclipse Modeling Framework (EMF). Users intending to use custom extension data should utilize the `com.ibm.wsspi.rrd.rrd-emf-packages` extension point in order to ensure that the proper EMF packages are initialized prior to use by RRD. This extension point is part of the plugin.xml file, which can reside in one of the following locations:

* Another OSGI Bundle.
* Any shared library. For example, a shared library bound to a server class loader.
* In the `WEB-INF` directory of an RRD-enabled local Web application.

Each EMF package is defined by an `emfPackage` element, which contains a className element that must point to the generated EMF factory implementation class for a particular EMF package (the generated model class which implements `org.eclipse.emf.ecore.impl.EFactoryImpl`). An example EMF package declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-emf-packages">
  <emfPackages>
    <emfPackage className="com.ibm.ws.rrd.webservices.types.emf.impl.TypesFactoryImpl" />
  </emfPackages>
</extension>
```

Note: If the same generated EMF model code is shared among multiple Web applications that the EMF model code must be part of a shared server library, but only in the case that all Web applications are running in the same application server. In production, this is usually not the case, and common EMF model code may exist at the Web application level.

Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

You must have an extensible application to define an extension for the registry filter.

Complete the following steps to filter out extensions for an application.

1. Define an extension for the registry filter extension point for a named registry instance in the plugin.xml file.

   ```
   <extension point="org.eclipse.extensionregistry.RegistryFilter">
    <filter name="AdminConsole*"
      class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
    </extension>
   ```

2. Add the filter implementation to the application by creating a class to implement the com.ibm.workplace.extension.IExtensionRegistryFilter interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
        :
}
```

3. The extensible application declares the registry name by defining an extension for the RegistryInstance extension point. This way, the registry can prepare an IExtensionRegistry instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>

</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup( lookupName );
```

Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications become extensible as soon as they define an extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible J2EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the J2EE application using a deployment tool that is based upon standard J2EE and portal Web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the plugin.xml file. The plugin.xml manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

You can find additional information about the Eclipse Plug-in Architecture at http://www.eclipse.org/articles/Article-Plug-in-architecture/plugin_architecture.html.

WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (J2EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.1.
- The identical plugin.xml syntax, however, some attributes are not used, for example, <runtime>.
- The discovery and addition of plug-ins to the registry, when the containing J2EE module starts, and plug-ins are dismissed and removed from the registry when the containing J2EE module stops.
- Access to an IExtensionRegistry object is through the Java Naming and Directory Interface (JNDI), instead of by using the Platform.getExtensionRegistry method in the Eclipse Workbench.

- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the API documentation for the IExtensionRegistryFilter interface for more details.

Available Eclipse 3.1 interfaces

The following Eclipse 3.1 interfaces are available on WebSphere Application Server:
- Extension registry API
- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:
- Executable extension API
- Executable extension factory API

Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

Registry filter API

Supported arguments include:

org.eclipse.core.runtime.IExtension[]
  doFilter(org.eclipse.core.runtime.IExtension[] extensions)

  This code returns an array of IExtension objects that are included in the valid extension list.

Registry instance extension point

The extension registry exposes the *RegistryInstance* . The instance name is declared in the application's plugin.xml file, and the application requests an registry instance for that name at runtime.

plugin.xml file

A plug-in is described in an XML manifest file, called plugin.xml, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server plugin.xml closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

Location

The `plugin.xml` file must reside in the WEB-INF directory under the context of the hierarchy of directories that exist for a Web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the `plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  ???
- If so, what triggers its update?

  The Application Server Toolkit updates the `web.xml` file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.
- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

```
SimpleToken := sequence of characters from ('a-z','A-Z','0-9')
ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)
PlugInId := ComposedToken
PlugInPrereq := PlugInId
ExtensionId := SimpleToken
ExtensionPointId := SimpleToken
ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)
```

Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule element* means zero or more occurrences of the element; element? means zero or one occurrence of the element; and element+ means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
>
<!ELEMENT requires (import+)>
<!ELEMENT import EMPTY>
<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
```

```
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>
```

WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

The `plugin` element

> The plugin element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the plugin element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

The `import` element

> The requires element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the match attribute has an option for a greater than or equal to match for versions (greaterOrEqual).

The `extension-point` element

> The extension-point element has the name attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (linkExtensionPoint) and an extension to this extension point (linkExtension). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the <extension> and </extension> tags in its manifest.

```
<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
    id="com.ibm.ws.console.core"
    version="1.0.0"
    provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
 <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>
 </requires>

 <!--declaration of link extension point -->
 <extension-point
    id="linkExtensionPoint"
    schema="/schemas/linkSchema.xsd"/>

 <!--declaration of an extension to the link extension point -->
 <extension
    point="com.ibm.ws.console.core.linkExtensionPoint"
    id="linkExtension">

  <link
    label="Example.displayName"
```

```
        actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
            forwardName=example.config.view&
            lastPage=ApplicationServer.config.view">
    </link>
 </extension>
</plugin>
```

Tuning URL invocation cache

The URL invocation cache holds information for mapping request URLs to servlet resources. A cache of the requested size is created for each worker thread that is available to process a request. The default size of the invocation cache is 50. If more than 50 unique URLs are actively being used (each JavaServer Page is a unique URL), you should increase the size of the invocation cache.

A larger cache uses more of the Java heap, so you might also need to increase the maximum Java heap size. For example, if each cache entry requires 2KB, maximum thread size is set to 25, and the URL invocation cache size is 100; then 5MB of Java heap are required.

The invocation cache is now Web container based instead of thread-based, and shared for all Web container threads.

To change the size of the invocation cache:

1. In the administrative console, click **Servers > Application servers** and select the application server you are tuning.
2. Click **Process Definition** under Additional Properties.
3. Click **Java Virtual Machine** under Additional Properties.
4. Click **Custom Properties** under Additional Properties.
5. Specify **invocationCacheSize** in the Name field and the size of the cache in the Value field. The default size for the invocation cache is 500 entries. Since the invocation cache is no longer thread-based, the invocation cache size specified by the user is multiplied by ten to provide similar function from previous releases. For example, if you specify an invocation cache size of 50, the Web container will create a cache size of 500.
6. Click **Apply** and then **Save** to save your changes.
7. Stop and restart the application server.

The new cache size is used for the URL invocation cache.

Task overview: Managing HTTP sessions

IBM WebSphere Application Server provides a service for managing HTTP sessions: Session Manager. The key activities for session management are summarized below.

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.4 API.

1. Plan your approach to session management, which could include session tracking and session recovery.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide "shopping carts" to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1's choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user's browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), Another alternative is to use SSL information to identify the session.

HTTP session migration

There are no programmatic changes required to migrate from version 5.x to version 6.x. This article describes features that are available after migration.

Migration from Version 5.x

Note: In Version 5 and later, default write frequency mode is TIME_BASED_WRITES, which is different from Version 4.0.x default mode of END_OF_SERVICE.

When you migrate between releases of WebSphere Application Server Version 5.x and later and you are using a database for session persistence, you can share the session database table between releases. For example, if you are accessing applications that are on WebSphere Application Server version 5.x you can share the session id with applications running on Version 6.x.

Session security support

You can integrate HTTP sessions and security in WebSphere Application Server. When security integration is enabled in the session management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on. You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the session management facility is not supported in form-based login with SWAM.

Note: SWAM is deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the com.ibm.websphere.servlet.session.IBMSession interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. WebSphere Application Server includes the com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException class, which is used when a session is requested without the necessary credentials.

The session management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the session management facility determines whether to return the session requested using a getSession call.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the session management facility.

	Unauthenticated HTTP request is used to retrieve a session	HTTP request is authenticated, with an identity of ″FRED″ used to retrieve a session
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is `anonymous`	A new session is created. The user name is `FRED`
A session ID for a valid session is passed in. The current session user name is ″anonymous″	The session is returned.	The session is returned. session management changes the user name to `FRED`
A session ID for a valid session is passed in. The current session user name is `FRED`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is returned.
A session ID for a valid session is passed in. The current session user name is `BOB`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is not returned. An UnauthorizedSessionRequestException error is created*

* A com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException error is created to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the javax.servlet.http.HttpSession interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the session management facility supports session scoping by Web modules. Only servlets in the same Web module can access the data associated with a particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the session management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session management can store session-related information in several ways:
* In application server memory (the default). This information cannot be shared with other application servers.
* In a database. This storage option is known as *database persistent sessions*.
* In another WebSphere Application Server instance. This storage option is known as *memory-to-memory sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for the failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than the one where the session was originally created. Session management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. session management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Session tracking options

There are several options for session tracking, depending on what sort of tracking method you want to use:
*   Session tracking with cookies
*   Session tracking with URL rewriting
*   Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies: Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting: An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
*   Program servlets to encode URLs
*   Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and the response.encodeURL method or encodeRedirectURL method is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information: No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Distributed sessions

WebSphere Application Server provides the following session mechanisms in a distributed environment:
- **Database session persistence**, where sessions are stored in the database specified.
- **Memory-to-memory Session replication**, where sessions are stored in one or more specified WebSphere Application Server instances.

When a session contains attributes that implement HttpSessionActivationListener, notification occurs anytime the session is activated (that is, session is read to the memory cache) or passivated (that is, session leaves the memory cache). Passivation can occur because of a server shutdown or when the session memory cache is full and an older session is removed from the memory cache to make room for a newer session. It is not guaranteed that a session is passivated in one application server prior to being activated in another.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions and memory-to-memory replication. Use session recovery support under the following conditions:
- When the user's session data must be maintained across a server restart
- When the user's session data is too valuable to lose through an unexpected server failure

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Distributed environment settings:

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Web container settings** > **Session management** > **Distributed environment settings**.

Distributed sessions:

Specifies the type of distributed environment to be used for saving sessions.

None	Specifies that the session management facility discards the session data when the server shuts down.
Database	Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click **Database** to change these data source settings.
Memory-to-memory replication	Specifies that the session management facility stores the session information in a data source in memory. The session information is copied to other session management facilities for failure recovery. Click **Memory-to-memory replication** to change these data source settings.

Memory-to-memory replication

WebSphere Application Server supports session replication to another WebSphere Application Server instance. This support is referred to as *memory-to-memory session replication*. In this mode, sessions can replicate to one or more WebSphere Application Server instances to address HTTP Session single point of failure (SPOF).

The WebSphere Application Server instance in which the session is currently processed is referred to as the *owner of the session*. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. In a peer-to-peer cluster, the hot failover feature causes the plug-in to failover to a server that already contains the backup copy of the session, avoiding the overhead of session retrieval from another server containing the backup. In a client/server cluster, the server retrieves the session from a server that has the backup copy of the session. The server now becomes the owner of the session and affinity is now maintained to this server.

There are three possible modes to run in:
- **Server mode:** Only store backup copies of other WebSphere Application Server sessions and not to send out copies of any session created in that particular server
- **Client mode:** Only broadcast or send out copies of the sessions it owns and not to receive backup copies of sessions from other servers
- **Both mode:** Simultaneously broadcast or send out copies of the sessions it owns and act as a backup table for sessions owned by other WebSphere Application Server instances.

You can select the replication mode of server, client, or both when configuring the session management facility for memory-to-memory replication. The default is both. This storage option is controlled by the mode parameter.

The memory-to-memory replication function is accomplished by the creation of a data replication service instance in an application server that talks to other data replication service instances in remote application servers. You must configure this data replication service instance as a part of a replication domain. Data replication service instances on disparate application servers that replicate to one another must be configured as a part of the same domain. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. For example, a server only data replication service instance and a both client and server data replication service instance cannot exist in the same replication domain. Multiple data replication service instances that exist on the same application server due to session manager memory-to-memory configuration at various levels that are configured to be part of the same domain must have the same mode.

With respect to mode, the following are the primary examples of memory-to-memory replication configuration:
- Peer-to-peer replication
- Client/server replication

Although the administrative console allows flexibility and additional possibilities for memory-to-memory replication configuration, only the configurations provided above are officially supported.

There is a single replica in a cluster by default. You can modify the number of replicas through the replication domain.

Memory-to-memory topology: Peer-to-peer function:

The basic peer-to-peer (both client and server function, or both mode) topology is the default configuration and has a single replica. However, you can also add additional replicas by configuring the replication domain.
In this basic peer-to-peer topology, each server Java Virtual Machine (JVM) can:

- Host the Web application leveraging the HTTP session
- Send out changes to the HTTP session that it owns
- Receive backup copies of the HTTP session from all of the other servers in the cluster

This configuration represents the most consolidated topology, where the various system parts are collocated and requires the fewest server processes. When using this configuration, the most stable implementation is achieved when each node has equal capabilities (CPU, memory, and so on), and each handles the same amount of work.

Session hot failover

A new feature called session hot failover has been added to this release. This feature is only applicable to the peer-to-peer mode. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. For a cluster configured to run in the peer-to-peer mode this feature causes the plug-in to failover to a server that already contains the backup copy of the session, therefore avoiding the overhead of session retrieval from another server containing the backup.

You must upgrade all WebSphere Application Server plug-in instances that front the Application Server cluster to version 6.0 to ensure session affinity when using the peer-to-peer mode.

Memory-to-memory topology: Client/server function: The following figure depicts the client/server mode. There is a tier of applications servers that host Web applications using HTTP sessions, and these sessions are replicated out as they are created and updated. There is a second tier of servers without a Web application installed, where the session manager receives updates from the replication clients.

Local

Backup

Benefits of the client/server configuration include:

Isolation (for failure recovery)
In this case we are isolating the handling of backup data from local data; aside from isolating the moving parts in case of a catastrophic failure in one of them, you again free up memory and processing in the servers processing the Web application

Isolation for stopping and starting
You can recycle a backup server without affecting the servers running the application (when there are two or more backups, failure recovery is possible), and conversely recycle an application JVM without potentially losing that backup data for someone.

Consolidation
There is most likely no need to have a one-to-one correspondence between servers handling backups and those processing the applications; hence, you are again reducing the number of places to which you transfer the data.

Disparate hardware:
While you run your Web applications on cheaper hardware, you may have one or two more powerful computers in the back end of your enterprise that have the capacity to run a couple of session managers in replication server mode; allowing you to free up your cheaper Web application hardware to process the Web application.

Timing consideration: Start the backup application servers first to avoid unexpected timing windows. The clients attempt to replicate information and HTTP sessions to the backup servers as soon as they come up. As a result, HTTP sessions that are created prior to the time at which the servers come up might not replicate successfully.

Memory-to-memory session partitioning

Session partitioning gives the administrator the ability to filter or reduce the number of destinations that the session object gets sent to by the replication service. You can also configure session partitioning by specifying the number of replicas on the replication domain. The Single replica option is chosen by default. Since the number of replicas is global for the entire replication domain, all the session managers connected to the replication domain use the same setting.

Single replica

You can replicate a session to only one other server, creating a single replica. When this option is chosen, a session manager picks another session manager that is connected to the same replication domain to replicate the HTTP session to during session creation. All updates to the session are only replicated to that single server. This option is set at the replication domain level. When this option is set, every session manager connected to this replication domain creates a single backup copy of HTTP session state information on a backup server.

Full group replica

Each object is replicated to every application server that is configured as a consumer of the replication domain. However, in the peer-to-peer mode, this topology is the most redundant because everyone replicates to everyone and as you add servers, more overhead (both CPU and memory) is needed to deal with replication. This mode is most useful for dynamic caching replication. Redundancy does not affect the client/server mode because clients only replicate to servers that are set to server mode.

Specific number of replicas

You can specify a specific number of replicas for any entry that is created in the replication domain. The number of replicas is the number of application servers that the user wants to use to replicate in the domain. This option eliminates redundancy that occurs in a full group replica and also provides additional backup than a single replica.   In peer-to-peer mode, the number of replicas cannot exceed the total number of application servers in the cluster. In the client/server mode, the number of replicas cannot exceed the total number of application servers in the cluster that are set to server mode.

Clustered session support

A clustered environment supports load balancing, where the workload is distributed among the application servers that compose the cluster. In a cluster environment, the same Web application must exist on each of the servers that can access the session. You can accomplish this setup by installing an application onto a cluster definition. Each of the servers in the group can then access the Web application

In a clustered environment, the session management facility requires an affinity mechanism so that all requests for a particular session are directed to the same application server instance in the cluster. This requirement conforms to the Servlet 2.3 specification in that multiple requests for a session cannot coexist in multiple application servers. One such solution provided by IBM WebSphere Application Server is *session affinity* in a cluster; this solution is available as part of the WebSphere Application Server plug-ins for Web servers. It also provides for better performance because the sessions are cached in memory. In clustered environments other than WebSphere Application Server clusters, you must use an affinity mechanism (for example, IBM WebSphere Edge Server affinity).

If one of the servers in the cluster fails, it is possible for the request to reroute to another server in the cluster. If distributed sessions support is enabled, the new server can access session data from the database or another WebSphere Application Server instance. You can retrieve the session data only if a new server has access to an external location from which it can retrieve the session.

Session management tuning

WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Click a feature for details about the feature. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Write frequency	Minimize database write operations.	Database and Memory-to-Memory
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database and Memory-to-Memory
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database and Memory-to-Memory
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2 only)

Base in-memory session pool size: The base in-memory session pool size number has different meanings, depending on session support configuration:
• With in-memory sessions, session access is optimized for up to this number of sessions.
• With distributed sessions (meaning, when sessions are stored in a database or in another WebSphere Application Server instance); it also specifies the cache size and the number of last access time updates saved in manual update mode.

For distributed sessions, when the session cache has reached its maximum size and a new session is requested, the Session Management facility removes the least recently used session from the cache to make room for the new one.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in non-distributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set overflow to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the HttpServletRequest getSession(true) method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

Tuning parameter settings:

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers > Application servers >** *server_name* **> Web container settings > Session management > Distributed environment settings > Custom tuning parameters**.

Tuning level:

Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds
Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes

Schedule sessions cleanup default   false

Tuning parameter custom settings:

Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* **Web container settings** > **Session management** > **Distributed environment settings** > **Custom tuning parameters** > **Custom settings**.

Write frequency:

Specifies when the session is written to the persistent store.

End of servlet service	A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.
Manual update	A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.
Time based	Session data writes to the database or another WebSphere Application Server instance based on the specified Write interval value. Default: 10 seconds

Write contents:

Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes	Only updated attributes are written to the persistent store.
All session attribute	All attributes are written to the persistent store.

Schedule sessions cleanup:

Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule	Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions.
	When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.
First Time of Day (0 - 23)	Indicates the first hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Second Time of Day (0 - 23)   Indicates the second hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP Sessions

best-practices: Browse the following recommendations for implementing HTTP sessions.

- **Enable Security integration for securing HTTP sessions**

  HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.

- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

  HttpSession objects live inside the Web container until:
  – The application explicitly and programmatically releases it using the javax.servlet.http.HttpSession.invalidate method; quite often, programmatic invalidation is part of an application logout function.
  – WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on session management settings. In case of distributed sessions, when maximum cache limit is reached in memory, the session management facility removes the least recently used (LRU) one from cache to make room for a session.

  .

- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

  The HttpSession object is a function of the HttpRequest (you can get it only through the req.getSession method), and a copy of it is valid only for the life of the service method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.

- **Implement the java.io.Serializable interface when developing new objects to be stored in the HTTP session.**

  Serializability of a class is enabled by the class implementing the java.io.Serializable interface. Implementing the java.io.Serializable interface allows the object to properly serialize when using distributed sessions. Classes that do not implement this interface will not have their states serialized or deserialized. Therefore, if a class does not implement the Serializable interface, the JVM cannot persist its state into a database or into another JVM. All subtypes of a serializable class are serializable. An example of this follows:

  ```
  public class MyObject implements java.io.Serializable {...}
  ```

  Make sure all instance variable objects that are not marked transient are serializable. You cannot cache a non-serializable object.

  In compliance with the Java Servlet specification, the distributed servlet container must create an IllegalArgumentException for objects when the container cannot support the mechanism necessary for migration of the session storing them. An exception is created only when you have selected distributable.

- **The HTTPSession API does not dictate transactional behavior for sessions.**

  Distributed HTTPSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactional aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.

- **Ensure the Java objects you add to a session are in the correct class path.**

If you add Java objects to a session, place the class files for those objects in the correct class path (the application class path if utilizing sharing across Web modules in an enterprise application, or the Web module class path if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server. In the case of session clustering, this action applies to every node in the cluster.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

- **Avoid storing large object graphs in the HttpSession object.**

  In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.

- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

  WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in reads the cookie data (or encoded URL) from the browser and helps direct the request to the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance

- **Maximize use of session affinity and avoid breaking affinity.**

  Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

  You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:
  - Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.
  - Create the session for the frame page, but do not create sessions for the pages within the frame when using multi-frame JSP files. (See discussion later in this topic.)

- **When using multi-framed pages, follow these guidelines:**
  - Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.
  - By default, JSP files get a HTTPSession using `request.getSession(true)` method. So by default JSP files create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that do not access the session. Then if the page needs access to the session information, the developer can use `<%HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
  - Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.

- Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

  When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the session management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

  The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these sessions from an unsecured page. When a request from an unsecured page occurs, access is denied and an `UnauthorizedSessionRequestException` error is created. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)
- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

  With END_OF_SERVICE as write frequency, when an application uses sessions and anytime data is read from or written to that session, the LastAccess time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

  To use manual update, turn it on in the session management service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic HttpSession. Within the IBMSession object there is a sync method. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

  Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.
- Implement the following suggestions to achieve high performance:
  - If your applications do not change the session data frequently, use Manual Update and the sync function (or timed interval update) to efficiently persist session information.
  - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
  - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
  - If using memory-to-memory sessions, employ partitioning (either group or single replica) as your clusters grow in size and scaling decreases.
  - Verify that you have the latest fix packs for the WebSphere Application Server.
- Utilize the following tools to help monitor session performance.
  - Run the com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
  - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
  - Use database tracking tools such as ″Monitoring″ in DB2. (See the respective documentation for the database system used.)

HTTP session manager troubleshooting tips

This article provides troubleshooting tips for problems creating or using HTTP sessions with your Web application hosted by WebSphere Application Server.

Here are some steps to take:
- See HTTP session aren't getting created or are getting dropped to see if your specific problem is discussed.
- View the JVM logs for the application server which hosts the problem application:
  - first, look at messages written while each application is starting. They will be written between the following two messages:

    ```
    Starting application: application
    ....................
    Application started: application
    ```
  - Within this block, look for any errors or exceptions containing a package name of com.ibm.ws.webcontainer.httpsession. If none are found, this is an indication that the session manager started successfully.
  - Error "**SRVE0054E: An error occurred while loading session context and Web application**" indicates that SessionManager didn't start properly for a given application.
  - Look within the logs for any Session Manager related messages. These messages will be in the format SESNxxxxE and SESNxxxxW for errors and warnings, respectively, where xxxx is a number identifying the precise error. Look up the extended error definitions in the Session Manager message table.
- See Best practices for using HTTP Sessions.
- To dynamically view the number of sessions as a Web application is running, enable performance monitoring for HTTP sessions. This will give you an indication as to whether sessions are actually being created.
- To learn how to view the http session counters as the application runs, see Monitoring performance with Tivoli Performance Viewer (formerly Resource Analyzer).
- Alternatively, a special servlet can be invoked that displays the current configuration and statistics related to session tracking. This servlet has all the counters that are in performance monitor tool and has some additional counters.
  - Servlet name: **com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - It can be invoked from any Web module which is enabled to serve by class name. For example, using default_app, **http://localhost:9080/servlet/ com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - If you are viewing the module via the serve-by-class-name feature, be aware that it may be viewable by anyone who can view the application. You may wish to map a specific, secured URL to the servlet instead and disable the serve-servlets-by-classname feature.
- Enable tracing for the HTTP Session Manager component:
  - Use the trace specification **com.ibm.ws.webcontainer.httpsession.*=all=enabled**. Follow the instructions for dumping and browsing the trace output to narrow the origin of the problem.
  - If you are using persistent sessions based on memory replication, also enable trace for **com.ibm.ws.drs.***.
- If you are using **database-based persistent sessions**, look for problems related to the **data source** the Session Manager relies on to keep session state information. For details on diagnosing database related problems see Errors accessing a datasource or connection pool

Error message `SRVE0079E Servlet host not found` after you define a port

Error message SRVE0079E can occur after you define the port in WebContainer > HTTP Transports for a server, indicating that you do not have the port defined in your virtual host definitions. To define the port,

1. On the administrative console, go to Environment > Virtual Hosts > default_host> Host Aliases> New
2. Define the new port on host "*"

The application server gets EC3 - 04130007 ABENDs

To prevent an EC3 - 04130007 abend from occuring on the application server, change the HTTP Output timeout value. The custom property *ConnectionResponseTimeout* specifies the maximum number of seconds the HTTP port for an individual server can wait when trying to read or write data. For instructions on how to set *ConnectionResponseTimeout*, see HTTP transport custom properties.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes). If you don't find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Problems creating or using HTTP sessions

This article provides troubleshooting information related to creating or using Hypertext Transfer Protocol (HTTP) sessions.

To view and update the session manager settings discussed here, use the administrative console. Select the application server that hosts the problem application, then under **Additional properties**, select **Web Container**, then **Session manager**.

What kind of problem are you having?
- HTTP Sessions are not getting created, or are lost between requests.
- HTTP Sessions are not persistent (session data lost when application server restarts, or not shared across cluster).
- Session is shared across multiple browsers on same client machine.
- Session is not getting invalidated immediately after specified session timeout interval.
- Unwanted sessions are being created by JavaServer Pages.
- Session data intended for one client is seen by another client.
- A ClassCastException error occurs during failover of a session that contains an Enterprise JavaBeans (EJB) reference.

If your problem is not described here, or none of these steps fixes the problem:
- Review "HTTP session manager troubleshooting tips" on page 117 for general steps on debugging session-manager related problems.
- Review "Task overview: Managing HTTP sessions" on page 101 for information on how to configure the session manager, and best practices for using it.
- Check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes).
- If you don't find your problem listed there contact IBM support.

HTTP sessions are not getting created, or are lost between requests

By default, the session manager uses cookies to store the session ID on the client between requests. Unless you intend to avoid cookie-based session tracking, ensure that cookies are flowing between WebSphere Application Server and the browser:
- Make sure the **Enable cookies** check box is checked under the **Session tracking Mechanism** property.
- Make sure cookies are enabled on the browser you are testing from or from which your users are accessing the application.
- Check the Cookie domain specified on the SessionManager (to view the or update the cookie settings, in the **Session tracking mechanism->enable cookies** property, click **Modify**).

- For example, if the cookie domain is set as ″.myCom.com″, resources should be accessed using that domain name. Example: http://www.myCom.com/myapp/servlet/sessionservlet.
- If the domain property is set, make sure it begins with a dot (.). Certain versions of Netscape do not accept cookies if domain name doesn't start with a dot. Internet Explorer honors the domain with or without a dot. For example, if the domain name is set to *mycom.com*, change it to *.mycom.com* so that both Netscape and Internet Explorer honor the cookie.

> **Note:** When the servers are on different hosts, ensure that session cookies flow to all the servers by configuring a front-end router such as a Web server with the plug-in or setting the Cookie domain.

- Check the **Cookie path** specified on the SessionManager. Check whether the problem URL is hierarchically below the Cookie path specified. If not correct the Cookie path.
- If the `Cookie maximum age` property is set, ensure that the client (browser) machine's date and time is the same as the server's, including the time zone. If the client and the server time difference is over the ″Cookie maximum age″ then every access would be a new session, since the cookie will ″expire″ after the access.
- If you have multiple Web modules within an enterprise application that track sessions:
  - If you want to have different session settings among Web modules in an enterprise application, ensure that each Web module specifies a different cookie name or path, or
  - If Web modules within an enterprise application use a common cookie name and path, ensure that the HTTP session settings, such as Cookie maximum age, are the same for all Web modules. Otherwise cookie behavior will be unpredictable, and will depend upon which application creates the session. Note that this does not affect session data, which is maintained separately by Web module.
- Check the cookie flow between browser and server:
  1. On the browser, enable ″cookie prompt″. Hit the servlet and make sure cookie is being prompted.
  2. On the server, enable SessionManager trace. Enable tracing for the HTTP session manager component, by using the trace specification ″com.ibm.ws.webcontainer.httpsession.*=all=enabled″. After trace is enabled, exercise your session-using servlet or jsp, then follow the instructions for dumping and browsing the trace output .
  3. Access the session servlet from the browser.
  4. The browser will prompt for the cookie; note the jsessionid.
  5. Reload the servlet, note down the cookie if a new cookie is sent.
  6. Check the session trace and look for the session id and trace the request by the thread. Verify that the session is stable across Web requests:
     - Look for **getIHttpsession(...)** which is start of session request.
     - Look for **releaseSesson(..)** which is end of servlet request.
- If you are using URL rewriting instead of cookies:
  - Ensure there are no static HTML pages on your application's navigation path.
  - Ensure that your servlets and JSP files are implementing URL rewriting correctly. For details and an example see "Session tracking options" on page 104.
- If you are using SSL as your session tracking mechanism:
  - Ensure that you have SSL enabled on your IBM HTTP Server or iPlanet HTTP server.
  - Review "Session tracking options" on page 104.
- If you are in a clustered (multiple node) environment, ensure that you have session persistence enabled.

HTTP Sessions are not persistent

If your HTTP sessions are not persistent, that is session data is lost when the application server restarts or is not shared across the cluster:
- Check the data source.
- Check the session manager's persistence settings properties:
  - If you intend to take advantage of session persistence, verify that Persistence is set to **Database**.
  - Persistence could also be set to **Memory-to-Memory Replication**.
  - If you are using **Database-based persistence**:
    - Check the JNDI name of the data source specified correctly on SessionManager.

- Specify correct userid and password for accessing the database.

  Note that these settings have to be checked against the properties of an existing data source in the administrative console. The session manager does not automatically create a session database for you.
  - The data source should be non-JTA, for example, non XA enabled.
  - Check the JVM logs for appropriate database error messages.
  - With DB2, for row sizes other than 4k make sure specified row size matches the DB2 page size. Make sure tablespace name is specified correctly.
- If you are using **memory-based persistence** (available only in a network deployment environment):
  - Review "Memory-to-memory replication" on page 106.
  - Review the **Internal Replication Domains properties** of your session manager.

Session is shared across multiple browsers on same client machine

This behavior is browser-dependent. It varies between browser vendors, and also may change according to whether a browser is launched as a new process or as a subprocess of an existing browser session (for example by hitting Ctl-N on Windows).

The Cookie maximum age property of the session manager also affects this behavior, if cookies are used as the session-tracking mechanism. If the maximum age is set to some positive value, all browser instances share the cookies, which are persisted to file on the client for the specified maximum age time.

Session is not getting invalidated immediately after specified session timeout interval

The SessionManager invalidation process thread runs every x seconds to invalidate any invalid sessions, where x is determined based on the session timeout interval specified in the session manager properties. For the default value of 30 minutes , x is around 300 seconds. In this case, it could take up to 5 minutes (300 seconds) beyond the timeout threshold of 30 minutes for a particular session to become invalidated.

Unwanted sessions are being created by JavaServer Pages

As required by the JavaServer Pages (JSP) specification, JSP pages by default perform a request.getSession(true), so that a session is created if none exists for the client. To prevent JSP pages from creating a new session, set the session scope to **false** in the .jsp file using the page directive as follows:

```
<% @page session="false" %>
```

Session data intended for one client is seen by another client

In rare situations, usually due to application errors, session data intended for one client might be seen by another client. This situation is referred to as session data crossover. When the *DebugSessionCrossover* custom property is set to true, code is enabled to detect and log instances of session data crossover. Checks are performed to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected. These messages provide a starting point for debugging this problem. This additional checking is only performed when running on the WebSphere-managed dispatch thread, not on any user-created threads.

For additional information on how to set this property, see article, Web container custom properties.

A ClassCastException error occurs during failover of a session that contains an Enterprise JavaBeans (EJB) reference

If you run WebSphere® Application Server for z/OS® Version 6.0.1 and configure a session manager to replicate EJB references, a session failover might trigger display of the following exception in the server region job log:

```
java.lang.ClassCastException: cannot cast class
        org.omg.stub.java.rmi._Remote_Stub to interface javax.ejb.EJBObject
```

The log also displays a null pointer exception. The problem results from the session outbound request, where WebSphere Application Server for z/OS issued a CORBA::COMM_FAILURE exception with a C9C21355 minor code. This behavior occurs because your application server contains all of the following configurations:

1. SAF is both the local operating system, as well as the user registry

2. Attribute propagation is enabled

3. An unauthenticated user initiated the session outbound request

To correct this problem apply the APAR PK06777 fix to WebSphere Application Server for z/OS V6.0.1. You can retain the previously mentioned server configurations.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/software/webservers/appserv/was/support/

HTTP sessions: Resources for learning

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Developing session management in servlets

This information, combined with the coding example SessionSample.java, provides a programming model for implementing sessions in your own servlets.

1. Get the HttpSession object.

   To obtain a session, use the getSession() method of the javax.servlet.http.HttpServletRequest object in the Java Servlet 2.3 API.

   When you first obtain the HttpSession object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

   Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each

subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

In Step 1 of the code sample, the Boolean(create) is set to `true` so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to `true` and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.

4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a Web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that Web page during the session.

5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.

6. End the session. You can end a session:
   - Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
   - By coding the servlet to call the invalidate() method on the session object.

Example: SessionSample.java

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample  extends HttpServlet {
  public void doGet (HttpServletRequest request, HttpServletResponse response)
      throws ServletException, IOException {

  // Step 1: Get the Session object

     boolean create = true;
     HttpSession session = request.getSession(create);

  // Step 2: Get the session data value

     Integer ival = (Integer)
     session.getAttribute ("sessiontest.counter");
     if (ival == null) ival = new Integer (1);
     else ival = new Integer (ival.intValue () + 1);
     session.setAttribute ("sessiontest.counter", ival);

  // Step 3: Output the page

     response.setContentType("text/html");
```

```
        PrintWriter out = response.getWriter();
        out.println("<html>");
        out.println("<head><title>Session Tracking Test</title></head>");
        out.println("<body>");
        out.println("<h1>Session Tracking Test</h1>");
        out.println ("You have hit this page " + ival + " times" + "<br>");
        out.println ("Your " + request.getHeader("Cookie"));
        out.println("</body></html>");
    }
}
```

Assembling so that session data can be shared

In accordance with the Servlet 2.3 API specification, by default the Session Management facility supports session scoping by Web module. Only servlets in the same Web module can access the data associated with a particular session. WebSphere Application Server provides an option that you can use to extend the scope of the session attributes to an enterprise application. Therefore, you can share session attributes across all the Web modules in an enterprise application. This option is provided as an IBM extension.

Restriction: To use this option, you must install all the Web modules in the enterprise application on a given server. You cannot split up Web modules in the enterprise application by servers. For example, with an enterprise application containing two Web modules, you cannot use this option when one Web module is installed on one server and second Web module is installed on a different server. In such split installations, applications might share session attributes across Web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different Web modules. It also severely restricts use of some Session Management features, like TIME_BASED_WRITES. For enterprise applications on which this option is enabled, the Session Management configuration on the Web module inside the enterprise application is ignored. Then Session Management configuration defined on enterprise application is used if Session Management is overwritten at the enterprise application level. Otherwise, the Session Management configuration on the Web container is used.

Servlet API Behavior

Note: If shared HttpSession context is turned on in an enterprise application, HttpSession listeners defined in all the Web modules inside the enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Do the following to share session data across Web modules in an enterprise application:

1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
2. In the assembly tool, right-click the application (EAR file) you want to share and click **Open With > Deployment Descriptor Editor**.
3. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under **WebSphere Extensions**. Make sure the class definition of attributes put into session are available to all Web modules in the enterprise application. The shared session context does not fully meet the requirements of the Specifications.
4. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Portlet applications

Task overview: Managing portlets

You can use this task to manage deployed portlet applications.

Before you begin this task, you must have a portlet application installed. See "Installing application files" on page 1364 for additional information.

You can complete the following steps to manage portlets.

- Render a portlet.
  - Access a single portlet using "Portlet Uniform Resource Locator (URL) addressability" on page 131.
  - Access multiple portlets using "Portlet aggregation using JavaServer Pages" on page 125.
  - Access portlets using "Remote request dispatcher" on page 88.
- Change the location of "Portlet preferences" on page 132. By default, portlet preferences for each portlet window are stored in a cookie. However, you can change the location of where to store portlet preferences.
- Disable URL addressability. By default, you can access a portlet through an Uniform Resource Locator (URL), however, you can disable this feature.
- Enable portlet fragment caching. Portlet fragment caching is disabled by default.

Portlets

Portlets are reusable Web modules that provide access to Web-based content, applications, and other resources. Portlets can run on WebSphere Application Server because it has an embedded JSR168 Portlet Container. You can assemble portlets into a larger portal page, with multiple instances of the same portlet displaying different data for each user.

From a user's perspective, a portlet is a window on a portal site that provides a specific service or information, for example, a calendar or news feed. From an application development perspective, portlets are pluggable Web modules that are designed to run inside a portlet container of any portal framework. You can either create your own portlets or select portlets from a catalog of third-party portlets.

Each portlet on the page is responsible for providing its output in the form of markup fragments to be integrated into the portal page. The portal is responsible for providing the markup surrounding each portlet. In HTML, for example, the portal can provide markup that gives each portlet a title bar with minimize, maximize, help, and edit icons.

You can also include portlets as fragments into servlets or JavaServer Pages files. This provides better communication between portlets and the J2EE Web technologies provided by the application server.

If you use Rational Application Developer version 6 (RAD) to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file to run the portlets outside of RAD:

```
<taglib id="PortletTLD">
 <taglib-uri>http://java.sun.com/portlet</taglib-uri>
 <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

Also if you use RAD version 6 to create portlets, note that portlets created by using the Struts Portlet Framework are not supported on WebSphere Application Server.

Portlet applications

If the portlet application is a valid Web application written to the Java Portlet API, the portlet application can operate on both the Portal Server and the WebSphere Application Server without requiring any changes. A JSR 168 compliant portlet application must not use extended services provided by WebSphere Portal to operate on the WebSphere Application Server.

Portlet container

The *portlet container* is the runtime environment for portlets using the JSR 168 Portlet Specification, in which portlets are instantiated, used, and finally destroyed. The JSR 168 Portlet API provides standard interfaces for portlets. Portlets based on this JSR 168 Portlet Specification are referred to as standard portlets.

A simple portal framework is provided by the PortletServingServlet servlet. The PortletServingServlet servlet registers itself for each Web application that contains portlets. You can use the PortletServingServlet servlet to directly render a portlet into a full browser page by a URL request and invoke each portlet by its context root and name. See "Portlet Uniform Resource Locator (URL) addressability" on page 131 for additional information. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article "Portlet aggregation using JavaServer Pages" for additional information. The PortletServingServlet servlet can be disabled in an extended portlet deployment descriptor called the ibm-portlet-ext.xmi file.

Remote request dispatcher support for portlets

The remote request dispatcher (RRD) support allows the invocation of portlets outside of the current Java virtual machine (JVM) within an Network Deployment single core group environment. The request related data is passed to the remote JVM where the portlet is invoked. The response is transmitted back and processed on the local JVM. Thus it guarantees that URLs contained in the portlet markup are created according to the local portal context.

Portlet container settings

Use this page to configure and manage the portlet container of this application server.

To view this administrative console page, click **Servers** > **Application servers** > *server_name* > **Portlet Container Settings** > **Portlet container**.

Enable portlet fragment cache:

Specifies whether to create a cached entry when a portlet is invoked, similar to servlet caching of the Web container settings.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Portlet aggregation using JavaServer Pages

The aggregation tag library generates a portlet aggregation framework to address one or more portlets on one page If you write JavaServer Pages, you can aggregate multiple portlets on one page using the aggregation tag library. This tag library does not provide full featured portal aggregation implementation, but provides a good migration scenario if you already have aggregating servlets and JavaServer Pages and want to switch to portlets.

To allow the customer to create a simple portal aggregation, the aggregation tag library also provides the following features.
- Invoke a portlet's action method
- Render multiple portlets on one page
- Provide links to change the portlet's mode or window state
- Display the portlet's title
- Retain the portlet cookie state

The aggregation tag library and JavaServer Pages that use the aggregation tag library will only work with the WebSphere Application Server portlet container implementation because the protocol between the tags and the container is not standardized.

The following diagram depicts how an HTML page would look like and what tags are used in order to create the page. See "Aggregation tag library attributes" for information on the aggregation tag library attributes.

When you use the aggregation tag library, you must set the portletUrlPrefix attribute of the init tag to the aggregating application. You need to:

- Ensure that the portletUrlPrefix attribute is set to the following in the aggregator page.

  ```
  "http://" + <server_address> + ":" + <server_port> + "/" + <aggregator context> + "/" <aggregator mapping>
  ```

- Reference the aggregation JSP page within the web.xml file through a servlet mapping ending with /*. For example, `/aggregation/*`

When aggregating multiple portlets on a single page, special care must be used with the naming conventions of form attribute names in your portlets. Because your portlets are all on the same page, they all share the same HttpServletRequest. When one portlet is viewed the entire page is refreshed and form data is re-posted. Therefore, if there are multiple portlets that are aggregated on a single page with the same form attribute names, there could be logic corruption when form data is re-posted.

Aggregation tag library attributes:

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the init tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The state and insert tags are sub-tags of the init tag.

The init tag has the following attributes:

- portletURLPrefix="<any string>"

  This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is a required attribute.

- portletURLSuffix="<any string>"

  This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

- portletURLQueryParams="<any string>"

  This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url="<context>/<portlet-name>"

  Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.

- windowId="<any string>"

  Defines the window ID for the portlet URL created by this tag. This is attribute optional.

- var="<any string>"

  If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.

- scope="page|request|session|application"

  This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.

- portletMode="view|help|edit|<custom>"

  This attribute sets the portlet mode.

- portletWindowState="maximized|minimized|normal|<custom>"

  This attribute sets the window state.

- action="true/false"

  This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name="<any string>"

  Indicates the name of the parameter. This is attribute required.

- value="<any string>"

Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url="<context>/<portlet-name>" (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet

  This is attribute required.

- windowId="<any string>"

  Defines the window ID of the portlet. This is attribute optional.

- contentVar="<any string>"

  If defined, the portlet's content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.

- contentScope="page|request|session|application"

  This attribute is only valid if the contentVar tag is used. If defined, the portlet's content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

- titleVar="<any string>"

  If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.

- titleScope="page|request|session|application"

  This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library:

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">

  <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
  <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
     portletWindowState="maximized">
      <portlet:urlParam name="namea" value="valuea"/>
      <portlet:urlParam name="nameb" value="valueb"/>
  </portlet:state>
  <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
      <portlet:urlParam name="name1" value="value1"/>
      <portlet:urlParam name="name2" value="value2"/>
  </portlet:state>
  <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
     portletWindowState="minimized">
      <portlet:urlParam name="namemin" value="valuemin"/>
      <portlet:urlParam name="namemin" value="valuemin"/>
```

```
        </portlet:state>

    <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
portletWindowState="maximized">
        <portlet:urlParam name="name3" value="value3"/>
        <portlet:urlParam name="name4" value="value4"/>
        <portlet:urlParam name="name5" value="value5"/>
        <portlet:urlParam name="name5" value="value5a"/>
        <portlet:urlParam name="name5" value="value5b"/>
        <portlet:urlParam name="name5" value="value5c"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
action="true" portletWindowState="normal">
        <portlet:urlParam name="name6" value="value6"/>
        <portlet:urlParam name="name6" value="value6z"/>
            </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
portletWindowState="minimized">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>

    <portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
    <portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
    <portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>

```
</STYLE>
```

Portlet Uniform Resource Locator (URL) addressability

You can request a portlet directly through a Uniform Resource Locator (URL) to display its content without portal aggregation. The PortletServingServlet servlet registers each Web application that contains portlets. It is similar to the FileServingServlet servlet of the Web container that serves resources. The PortletServingServlet servlet allows you to directly render a portlet into a full browser page by a URL request.

You can invoke each portlet by its context root and name with the URL mapping /<portlet-name> that is created for each portlet. The context root and name has the following format:

```
http://<host>:<port>/<context-root>/<portlet-name>
For example, http://localhost:9080/portlets/TestPortlet1
```

The context root identifies the Web archive (WAR) file that contains the portlet. The portlet name uniquely identifies the portlet with a portlet application of a WAR file. The DefaultDocumentFilter servlet only supports HTML, UTF8 encoding and an extended URL form based on the basic URL form as shown above.

You can only display one portlet at a time using the PortletServingServlet servlet. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article "Portlet aggregation using JavaServer Pages" on page 125 for additional information.

Because a portlet only delivers fragment output whereas a servlet usually delivers document output, a mechanism is introduced to convert the fragment into a document, called the PortletDocumentFilter filter. By default, the PortletDocumentFilter filter only supports converting HTML. The conversion is implemented using a servlet filter before the PortletServingServlet servlet is initiated to return the portlet's content inside of a document. This default document servlet filter only applies to URL requests, not for includes or forwards using the RequestDispatcher method. You can create servlet filters to support other markups additional document servlet filters. See the article, "Converting portlet fragments to an HTML document" on page 134, for additional information.

The PortletServingServlet servlet does not persist portlet preferences in a XML file or database. It places the portlet preferences directly into a cookie to store the preferences persistently. See the article, "Portlet preferences" on page 132, for additional information on how to change this behavior.

Portlet URL syntax

You can add additional portal context such as portlet mode or window state. You can access the PortletServingServlet servlet by using a URL mapping that has the following structure:

```
http://host:port/context/portlet-name [/portletwindow[/ver [/action] [/mode] [/state] [rparam][/?name]]]
```

Any differing URL structure results in a com.ibm.wsspi.portletcontainer.InvalidURLException exception. Empty strings are not permitted as parameter values and creates an InvalidURLException exception. The following is a list of valid parameters:

http:// host:port/context/*portlet-name*
> This is the minimum URL required to access a portlet. A default portlet window called 'default' is created. The *portlet-name* variable is case-sensitive.

/*portletwindow*
> This parameter identifies the portlet window. You must set this parameter if you choose to add more portal context information to the URL.

/ver=_major.minor_

> This optional parameter is used to define the version of the portlet API that is used. You must set this parameter if you choose to add more portal context information to the URL. Only the version '1.0' is allowed. Any differing version creates an InvalidURLException exception.

/action

> This is a required parameter if you call the action method of the portlet. The action parameter causes the action process of the portlet to be called. After the action has been completed, a redirect is automatically issued to call the render process. To control the subsequent render process, a document servlet filter can set a request attribute with name 'com.ibm.websphere.portlet.action' and value 'redirect' to specify that the portlet serving servlet directly returns after action without calling the render process.

/mode=view | edit | help | _custom-mode_

> This optional parameter defines the portlet mode that is used to render the portlet. The default mode is 'view'. The value is not case-sensitive, For example, 'View', 'view' or 'VIEW' results in the same mode.

/state=normal | maximized | minimized | _custom-state_

> This optional parameter defines the window state that is used to render the portlet. The default state is 'normal'. The value is not case-sensitive, For example, 'Normal', 'normal', or 'NORMAL' results in the same state.

* [/rparam=_name_ ***[=**_value_**]]**

> This optional parameter specifies render parameters for the portlet. Repeat this parameter chain to provide more than one render parameter. For example, /rparam=invitation/ rparam=days=Monday=Tuesday

?name=_value_**&**_name2_**=**_value2_ **...**

> Query parameters may follow optionally. They are not explicitly supported by the portlet container, but they do not invalidate the URL format.

The following list includes examples of valid URLs:

- http:// localhost:9080/sample/WorldClock
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/mode=edit/rparam=timezone=UTC
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/action/state=maximized?timezone=UTC

Portlet preferences

Preferences are set by portlets to store customized information. By default, the PortletServingServlet servlet stores the portlet preferences for each portlet window in a cookie. However, you can change the location to store them in either a session, an .xml file, or a database.

Storing portlet preferences in cookies

The attributes of the cookie are defined as follows:

Path

> _context_/_portlet-name_/_portletwindow_

Name:

> The name of the cookie has the fixed value of **PortletPreferenceCookie**.

Value

> The value of the cookie contains a list of preferences by mapping to the following structure:

```
*['/' pref-name *['=' pref-value]]
```

All preferences start with '/' followed by the name of the preference. If the preference has one or more values, the values follow the name separated by the '=' character. A null value is represented by the string '#*!0_NULL_0!*#'. As an example, the cookie value may look like, /locations=raleigh=boeblingen/ regions=nc=bw

Customizing the portlet preferences storage

You can override how the cookie is handled to store preferences in a session, an .xml file or database. To customize the storage, you must create a filter, servlet or JavaServer Pages file as new entry point that wraps the request and response before calling the portlet. Examine the following example wrappers to understand how to change the behavior of the PortletServingServlet to store the preferences in a session instead of cookies.

The following is an example of how the main servlet manages the portlet invocation.

```
public class DispatchServlet extends HttpServlet
{
    ...
    public void service(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
    {
 response.setContentType("text/html");

 // create wrappers to change preference storage
 RequestProxy req = new RequestProxy(request);
 ResponseProxy resp = new ResponseProxy(request, response);

 // create url prefix to always return to this servlet
            ...
            req.setAttribute("com.ibm.wsspi.portlet.url.prefix", urlPrefix);

 // prepare portlet url
 String portletPath = request.getPathInfo();
            ...

 // include portlet using wrappers
 RequestDispatcher rd = getServletContext().getRequestDispatcher(modifiedPortletPath);
            rd.include(req, resp);
    }
}
```

In the following example, the request wrapper changes the cookie handling to retrieve the preferences out of the session.

```
public class RequestWrapper extends HttpServletRequestWrapper
{
    ...
    public Cookie[] getCookies() {
        Cookie[] cookies = (Cookie[]) session.getAttribute("SessionPreferences");
        return cookies;
    }
}
```

In the following example, the response wrapper changes the cookie handling to store the preferences in the session:

```
public class ResponseProxy extends HttpServletResponseWrapper
{
   ...
    public void addCookie(Cookie cookie) {
        Cookie[] oldCookies = (Cookie[]) session.getAttribute("SessionPreferences");
        int newPos = (oldCookies == null) ? 0 : oldCookies.length;
        Cookie[] newCookies = new Cookie[newPos+1];
        session.setAttribute("SessionPreferences", newCookies);

        if (oldCookies != null) {
```

```
            System.arraycopy(oldCookies, 0, newCookies, 0, oldCookies.length);
            }
         newCookies[newPos] = cookie;
      }
}
```

Portlet deployment descriptor extensions

Extensions for the portlet deployment descriptor are defined within a file called ibm-portlet-ext.xmi. This deployment descriptor is an optional descriptor that you can use to configure WebSphere extensions for the portlet application and its portlets. For example, you can disable the PortletServingServlet servlet for the portlet application in the extended portlet deployment descriptor.

The ibm-portlet-ext.xmi extension file is loaded during application startup. If there are no extension files specified with this setting, the portlet container's default values are used.

The default for the portletServingEnabled attribute is true. The following is an example of how to configure that a PortletServingServlet servlet is not created for any portlet on the portlet application.

```
<?xml version="1.0" encoding="UTF-8"?>
<portletappext:PortletApplicationExtension xmi:version="1.0"
    xmlns:xmi="http://www.omg.org/XMI"
    xmlns:portletappext="portletapplicationext.xmi"
    xmlns:portletapplication="portletapplication.xmi"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmi:id="PortletApp_ID_Ext"
    portletServingEnabled="false">
  <portletappext:portletApplication href="WEB-INF/portlet.xml#myPortletApp"/>
</portletappext:PortletApplicationExtension>
```

Converting portlet fragments to an HTML document

A portlet only delivers fragment output whereas a servlet typically delivers document output. However, you can use the PortletServingServlet servlet, which is similar to the FileServingServlet servlet, to address portlets like servlets. A default document servlet filter, the DefaultFilter filter, is applied to the PortletServingServlet servlet to return the portlet's content inside of a document. This filter only applies to requests, not to includes or forwards using the RequestDispatcher method. A servlet filter that is used to embed the portlet's content into a document is called the document servlet filter. You can define additional document servlet filters in a .xml file.

The FilterRequestHelper attribute within com.ibm.wsspi.portletcontainer.util is provided to assist the document servlet filters in analyzing a request regarding filter chain and portlet information. It is used in supporting dynamic portlet titles, as a marker for redirection for document servlet filters and to ensure that document conversion is completed once.

Adding a new document servlet filter

The filter capability is a server feature, therefore all filters must be installed into the server to use the filter capability of the server. The filters need to be available in any classes or library directory on a server level. You must also register the filter in a plugin.xml file within the root of a Java archive (JAR) file. The following is an example of how to register the filter in a plugin.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.0"?>
<plugin id="sample.plugin" name="Customer_Plugin" provider-name="Customer" version="1.0.0">
  <extension point="com.ibm.ws.portletcontainer.portlet-document-filter-config">
    <portlet-document-filter class-name="sample.filter.CustomFilter" order="200" />
  </extension>
</plugin>
```

Dynamic portlet titles

The PortletServingServlet servlet supports dynamic portlet titles by providing the dynamic title as a request attribute, FilterRequestHelper.DYNAMIC_TITLE. This attribute returns the dynamic portlet title if it has been set by the portlet, otherwise it returns the static portlet title of the portlet.xml file if defined.

The FilterRequestHelper is used to assist in controling of the dynamic portlet title. The following constant is defined, `DYNAMIC_TITLE = 'javax.portlet.title'`

The DefaultFilter uses this request attribute to set the document title while converting the fragment into a document. If the filter wants to support browser caching or dynamic portlet titles, the complete portlet content must be cached

Redirection for document servlet filters

A document servlet filter can set a marker as request attribute, FilterRequestHelper.REDIRECT. This marker ensures that the portlet container returns to the document servlet filter after the portlet action has been called prior to any render calls. The following constants are defined, `REDIRECT = 'com.ibm.websphere.portlet.action'` and `REDIRECT_VALUE = 'redirect'`. The DefaultFilter uses this request attribute to provide special cache handling for the portlet rendering call to support dynamic title.

Document conversion

The conversion of the portlet's fragment into a valid document must be completed only once. Therefore each document servlet filter must ensure that the fragment has not yet been converted to a document previously. If the document servlet filter converts the fragment to a document, the request attribute FilterRequestHelper.DOCUMENT must be set to FilterRequestHelper.DOCUMENT_VALUE. This request attribute marks whether the conversion still needs to be completed. The following constants are defined, `DOCUMENT = 'com.ibm.websphere.portlet.filter'` and `DOCUMENT_VALUE = 'document'`. The DefaultFilter uses this request attribute to check whether it should convert the fragment to an Hypertext Markup Language (HTML) document. For example, this allows another document servlet filter in front to convert the fragment into a valid Wireless Markup Language (WML) document instead.

Portlet and PortletApplication MBeans

The MBeans of type portlet and portletapplication provide information about a given portlet application and its portlets. Through the MBean of type portletapplication, you can retrieve a list of names of all portlets that belong to a portlet application. By querying the MBean of type portlet with a given portlet name, you can retrieve portlet specific information from the MBean of type portlet.

Each MBean that corresponds to a portlet or portlet application is uniquely identifiable by its name. Portlet applications are not required to have a name set within the portlet.xml. Thus for MBeans of type portletapplication, the Web module name concatenated with the string ″_portletapplication″ has been chosen as the MBean name. The name chosen for the MBean of type portlet is the name of the MBean of type portletapplication the portlet belongs to, concatenated with the porlet name. A full stop separates the preceding Web module name from the portlet name. For more information about the Portlet and PortletApplication MBean types in the Generated API documentation. The generated API documentation is available in the information center table of contents from the path, **Reference** > **Administrator** > **API documentation** > **MBean interfaces**.

The following code is an example of how to invoke the MBean of type portletapplication for an application with the name ″Bookmark″.

```
String myPortletApplicationName = "Bookmark_war_portletapplication";
This name is composed by the Web module name concatenated with the substring "_portletapplication"

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
```

```
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=PortletApplication,name=" + myPortletApplicationName + ",*");

Iterator onIter = adminService.queryNames(on, null).iterator();
while(onIter.hasNext())
{
 on = (ObjectName)onIter.next();
}

String ctxRoot = (java.lang.String)adminService.getAttribute(on, "webApplicationContextRoot");
```

In the previous example, the MBeanServer is first queried for an MBean of type portletapplication. If this query is successful, the attribute webApplicationContextRoot is retrieved on that MBean or the first MBean that is found and the result is stored in the variable ctxRoot. This variable now contains the context root of the Web application that contains the portlet application that was searched. For example, this may be something like, ″/bookmark″.

The next code example demonstrates how to invoke the MBean of type portlet for a portlet with the name ″BookmarkPortlet″.

```
String myPortletName = "Bookmark_war_portletapplication.BookmarkPortlet";
This name is composed by the name of the MBean of type portletapplication and
the portlet name, separated by a full stop because the same portlet name may
be used within different Web modules, but must be unique within the system.

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=Portlet,name=" + myPortletName + ",*");
Iterator iter = adminService.queryNames(on, null).iterator();

while(iter.hasNext())
{
 on = (ObjectName)iter.next;
}

java.util.Locale locale = (java.util.Locale) adminService.getAttribute(on, "defaultLocale");
```

The locale returned by the method getAttribute method for the MBean is the default locale defined for this portlet.

SIP applications

Providing real time collaboration with SIP applications

Follow these procedures for creating SIP applications and configuring the SIP container.

Session Initiation Protocol (SIP) is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging. A *SIP application* is a Java program that uses at least one Session Initiation Protocol (SIP) servlet. A SIP servlet is a Java-based application component that is managed by a SIP servlet container.

The servlet container is a part of an application server that provides the network services over which requests and responses are received and sent. The servlet container decides which applications to invoke and in what order. A servlet container also contains and manages a servlet through its lifecycle.

SIP servlet containers can employ SIP proxy servers as surrogates to handle load balancing and security issues. For more information about the SIP proxy server, see: Session Initiation Protocol proxy server.

This topic is divided into the following subsections:

- Configure the SIP container: Information and instructions for configuring SIP container properties and timers.
- Developing SIP applications: Reference information for developers.
- Deploying SIP applications: Information for installing, starting, and stopping, your applications.
- Securing SIP applications: Instructions for enabling security providers and setting up a trust association interceptor (TAI).
- Tracing a SIP container: Troubleshoot SIP applications through traces on the SIP container.

SIP applications

A *SIP application* is a Java program that uses at least one Session Initiation Protocol (SIP) servlet.

A SIP servlet is a Java-based application component that is managed by a SIP servlet container and that performs SIP signaling. Like other Java-based components, servlets are platform-independent Java classes that are compiled to platform-neutral bytecode that can be loaded dynamically into and run by a Java-enabled SIP application server. Containers, sometimes called servlet engines, are server extensions that handle servlet interactions. SIP servlets interact with clients by exchanging request and response messages through the servlet container.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging. ″Presence″ in this context refers to user status such as ″Active,″ ″Away,″ or ″Do not disturb.″ The standard that defines a programming model for writing SIP-based servlet applications is JSR 116.

SIP container

A *SIP container* is a Web application server component that invokes the Session Initiation Protocol (SIP) action servlet and that interacts with the action servlet to process SIP requests.

The servlet container provides the network services over which requests and responses are received and sent. It decides which applications to invoke and in what order. The container also contains and manages servlets through their life cycle.

A SIP servlet container manages the network listener points on which it listens for incoming SIP traffic. A listener point is a combination of transport protocol, IP address, and port number. The SIP specification (JSR 116) requires all SIP elements to support both UDP and TCP, and optionally TLS, SCTP, and potentially other transports.

The SIP servlet container can employ a SIP proxy server to route, load balance, and improve response times between SIP requests and back-end SIP container resources. For more information about the SIP proxy server, see: Session Initiation Protocol proxy server.

Developing SIP applications

This section explains how to develop a SIP application for WebSphere Application Server.

When you develop Session Initiation Protocol (SIP) applications, you should be aware of certain considerations and of the SIP status codes.

Compliance with industry SIP standards

This product complies with various industry standards for the Session Initiation Protocol (SIP)

The standards bodies for these standards are as follows:

IETF Internet Engineering Task Force
JCP   Java Community Process
3GPP Third Generation Partnership Project

SIP and SIP proxy

This product complies with the SIP standards of IETF and JCP shown in Table 1.

Table 1. Compliance with SIP and SIP proxy standards

Standard	Body	Description	Support	Notes
JSR 116	JCP	SIP servlets API	Full	Application composition according to the cascaded services model is supported. Converged applications are supported in environments where session failover is disabled. **Note:** application composition is underspecified in JSR 116. WebSphere Application Server's SIP application composition details can be found in "SIP application composition" on page 143.
RFC 3261	IETF	SIP core protocol	Full	Supersedes RFC 2543 (SIP base protocol). Backward compatible.
RFC 3262	IETF	Reliability of provisional responses SIP	Full	
RFC 3263	IETF	Locating SIP servers	Full	
RFC 3515	IETF	SIP REFER method	Full	

SIP presence server

SIP Server complies with the SIP presence server standards shown in Table 2.

Table 2. Compliance with SIP presence server standards

Standard	Body	Description	Support	Notes
RFC 3265	IETF	Specific event notification	Full	This is a base protocol for the presence server.
RFC 3842	IETF	Message waiting indicator	Partial	This can be supported as part of the presence server as another event package.
RFC 3856	IETF	Presence event package for SIP	Full	This is a base protocol for the presence server.
RFC 3863	IETF	Presence Information Data Format (PIDF)	Full	
RFC 3903	IETF	SIP extension for event state publication	Full	

Other SIP applications

SIP Server complies with standards for other SIP applications as shown in Table 3 on page 139. 3GPP is the Third Generation Partnership Project.

Table 3. Compliance with standards for other SIP applications

Standard	Body	Description	Support	Notes
RFC 2976	IETF	The SIP INFO method	Full	SIP Server contains no explicit support in SLSP or the container for INFO methods, but an application is free to implement and act upon them.
RFC 3326	IETF	The Reason header field	Full	This field enables a SIP container to indicate a reason for a given SIP message. The Reason header is moved to the application for processing.
RFC 3327	IETF	Extension (Path) header field for registering nonadjacent contacts	Full	3GPP requires that registrar and location server applications implement and use the Path header.
RFC 3428	IETF	SIP extension for instant messaging	Full	MESSAGE methods extend SIP and are processed by the application.
RFC 3455	IETF	Private header extensions to SIP	Full	This is an informational RFC on 3GPP private headers. The container passes the headers to the application.
RFC 3725	IETF	Best current practices for third-party call control (3pcc)	Full	Applications running in the SIP container implement these practices.

Runtime considerations for SIP application developers

You should consider certain product runtime behaviors when you are writing Session Initiation Protocol (SIP) applications.

Container may accept non-SIP URI schemes

The SIP container will not reject a message if it doesn't recognize the scheme in the request URI because the container cannot know which URI schemes are supported by the applications. SIP elements may support a request URI with a scheme other than `sip` or `sips`, for example, the `pres:` scheme has a particular meaning for presence servers, but the container does not recognize it. It is up to the application to determine whether to accept or to reject a specific scheme. SIP elements may translate non-SIP URIs using any mechanism available, resulting in SIP URIs, SIPS URIs, or other schemes, like the `tel` URI scheme of RFC 2806 [9].

Directing requests in a multiple-container environment

In a multiple-container environment (SIP proxy plus SIP containers), when your application sends a request intended initially to be sent externally but later received, it should use the host and ports of the front-most load balancing element (either an IP sprayer for multiple SIP proxies, or the SIP proxy if only one exists). If the application uses the host name of a container instead of the front-most element, the request may be lost in the event of a failure.

For example, an application sends an INVITE request to itself, but the request must pass through an external accounting system through a pushed Route header. The application should set the INVITE request's URI to the host and port of the foremost element to ensure that failover occurs. The request will be routed to the accounting system via the pushed Route, and then sent back to the front load balancing element for processing.

Invoking session listener events

SipSessionListener and SipApplicationSessionListener events are invoked only if an application requests the corresponding session object. You do this by using in your application the method shown in Table 4 on page 140.

Table 4. Methods that invoke session listener events

Event	Method
SipSessionListener	getSession()
SipApplicationSessionListener	getApplicationSession()

Session activation and passivation

During normal operation, this product never migrates a session from one server to another. Session migration occurs only as a result of a server failure. Therefore the SipSessionActivationListener method's passivation callback is never invoked. However, the activation callback is invoked when a failure forces session failover to a different server.

Developing a custom trust association interceptor

When you develop Session Initiation Protocol (SIP) applications, you can create a custom trust association interceptor (TAI).

You may want to familiarize yourself with the general TAI information contained in the Trust Associations documentation. Developing a SIP TAI is similar to developing any other custom interceptors used in trust associations. In fact, a custom TAI for a SIP application is actually an extension of the trust association interceptor model. Refer to the Developing a custom interceptor for trust associations section for more details.

TAI can be invoked by a SIP servlet request or a SIP servlet response. To implement a custom SIP TAI, you need to write your own Java class.

1. Write a Java class that extends the `com.ibm.wsspi.security.tai.BaseTrustAssociationInterceptor` class and implements the `com.ibm.websphere.security.tai.SIPTrustAssociationInterceptor` interface. Those classes are defined in the *WASProductDir*/plugins/com.ibm.ws.sip.container_1.0.0.jar file, where *WASProductDir* is the fully qualified path name of the directory in which WebSphere Application Server is installed.

2. Declare the following Java methods:

   `public int initialize(Properties properties) throws WebTrustAssociationFailedException;`
   This is invoked before the first message is processed so that the implementation can allocate any resources it needs. For example, it could establish a connection to a database. `WebTrustAssociationFailedException` is defined in the *WASProductDir*/plugins/com.ibm.ws.runtime_1.0.0.jar file. The value of the `properties` argument comes from the **Custom Properties** set in this step.

   `public void cleanup();`
   This is invoked when the TAI should free any resources it holds. For example, it could close a connection to a database.

   `public boolean isTargetProtocolInterceptor(SipServletMessage sipMsg) throws WebTrustAssociationFailedException;`
   Your custom TAI should use this method to handle the `sipMsg` message. If the method returns `false`, WebSphere ignores your TAI for `sipMsg`.

   `public TAIResult negotiateValidateandEstablishProtocolTrust (SipServletRequest req, SipServletResponse resp) throws WebTrustAssociationFailedException;`
   This method returns a TAIResult that indicates the status of the message being processed and a user ID or the unique ID for the user who is trying to authenticate. If authentication succeeds, the TAIResult should contain the status HttpServletResponse.SC_OK and a principal. If authentication fails, the TAIResult should contain a return code of HttpServletResponse.SC_UNAUTHORIZED (401), SC_FORBIDDEN (403), or SC_PROXY_AUTHENTICATION_REQUIRED (407). The only indicates whether or not the container should accept a message for further processing. To challenge an incoming request,

the TAI implementation must generate and send its own SipServletResponse containing a challenge. The exception should be thrown for internal TAI errors. Table 5 describes the argument values and resultant actions for the negotiateValidateandEstablishProtocolTrust method.

Table 5. Description of negotiateValidateandEstablishProtocolTrust arguments and actions

Argument or action	For a SIP request	For a SIP response
Value of `req` argument	The incoming request	Null
Value of `resp` argument	Null	The incoming response
Action for valid response credentials	Return TAIResult.status containing SC_OK and a user ID or unique ID	Return TAIResult.status containing SC_OK and a user ID or unique ID
Action for incorrect response credentials	Return the TAIResult with the 4*xx* status	Return the TAIResult with the 4*xx* status

The sequence of events is as follows:

a. The SIP container maps initial requests to applications by using the rules in each applications deployment descriptor; subsequent messages are mapped based on JSR 116 mechanisms.

b. If any of the applications require security, the SIP container invokes any defined TAI implementations for the message.

c. If the message passes security, the container invokes the corresponding applications.

Your TAI implementation can modify a SIP message, but the modified message will not be usable within the request mapping process, because it finishes before the container invokes the TAI.

The com.ibm.wsspi.security.tai.TAIResult class, defined in the *WASProductDir*/plugins/ com.ibm.ws.runtime_1.0.0.jar file, has three static methods for creating a TAIResult. The TAIResult `create` methods take an int type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted as follows:

If the value is HttpServletResponse.SC_OK, this response tells WebSphere Application Server that the TAI has completed its negotiation. The response also tells WebSphere Application Server use the information in the TAIResult to create a user identity.

The created TAIResults have the meanings shown in Table 6.

Table 6. Meanings of TAIResults

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status should not be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a Hashtable, the principal is ignored. The contents of the Subject becomes part of the eventual user Subject.

`public String getVersion();`
This method returns the version number of the current TAI implementation.

`public String getType();`
This method's return value is implementation-dependent.

3. Compile the implementation after you have implemented it. For example: `/opt/WebSphere/AppServer/ java/bin/javac -classpath  /opt/WebSphere/AppServer/plugins/com.ibm.ws.runtime_1.0.0.jar;/`

```
opt/WebSphere/AppServer/lib/j2ee.jar;/opt/WebSphere/AppServer/plugins/
com.ibm.ws.sip.container_1.0.0.jar myTAIImpl.java
```

    a. For each server within a cluster, copy the class file to a location in the WebSphere class path (preferably the *WASProductDir*/plugin/ directory).

    b. Restart all the servers.

4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot-separated and appears in the class path.

5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the `initialize(Properties properties)` method of your implementation when it extends the `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` as described in the previous step.

6. Save and synchronize (if applicable) the configuration.

7. Restart the servers for the custom interceptor to take effect.

Developing SIP applications that support PRACK

A SIP response to an INVITE request can be final (sent reliably) or provisional (typically not sent reliably). For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional Response ACKnowledgement) method.

For you to be able to develop applications that support PRACK, the following criteria must be met:

- The client that sends the INVITE request must put a 100rel tag in the Supported or the Require header to indicate that the client supports PRACK.
- The SIP servlet must respond by invoking the sendReliabily() method instead of the send() method to send the response.

PRACK is described in the following standards:

- RFC 3262 ("Reliability of Provisional Responses in the Session Initiation Protocol (SIP)"), which extends RFC 3261 ("SIP: Session Initiation Protocol"), adding PRACK and the option tag 100rel.
- Section 6.7.1 ("Reliable Provisional Responses") of JSR 116 ("SIP Servlet API Version 1.0").
- For an application acting as a proxy, do this:
  - Make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- For an application acting as a user agent client (UAC), do this:
  - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
  - Within your application's doProvisionalResponse(...) method, prepare the application to create and send PRACK requests for incoming reliable provisional responses. The application must create the PRACK request on the response's dialog through a SipSession.createRequest(...) method, and it must set the RAck header according to RFC 3262 Section 7.2 ("RAck").
  - The application that acts as an UAC will not receive doPrack( ) methods. The UAC sends INVITE and receives Reliable responses. When the UAC receives the Reliable response, it sends PRACK a request to the UAS and receives a 200 OK on the PRACK so it should next implement doResponse( ) in order to receive it.
  - Within your application's doPrack(...) method, prepare the application to generate and send a final response to an incoming PRACK request.
- For an application acting as a user agent server (UAS), do this:
  - If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an Exception.
  - Make the application declare a SipErrorListener to receive noPrackReceived() events when a reliable provisional response is not acknowledged within 64*T1 seconds, where T1 is a SIP timer. Within the

noPrackReceived() event processing, the application should generate and send a 5*xx* error response for the associated INVITE request per JSR 116 Section 6.7.1.

– Make the application have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first's acknowledgement results in an Exception.

– Make sure that the application enforces the RFC 3262 offer/answer semantics surrounding PRACK requests containing session descriptions. Specifically, a servlet must not send a 2*xx* final response if any unacknowledged provisional responses contained a session description.

SIP application composition

Reference materials for the WebSphere Application Server implementation of JSR 116 standards

Application composition specification

The JSR 116 standard states in Section 2.4 that multiple applications may be invoked for the same SIP request.

This standard requires that implementations must obey a cascaded services model, stating: "Triggering of service applications on the same host, shall be performed in the same sequence as if triggering had occurred on different hosts." This means that responses will flow upstream, that they will hit applications in the reverse order of their corresponding requests.

JSR 116 does not specify how to implement this when developing SIP applications, thus there are many ways to comply with this standard.

Application composition in the WebSphere Application Server environment

Composition of the application depends on the deployed application order, and on the order of mapping rules within the deployment descriptor of each application.

- For an initial incoming request, the SIP container tries each potential rule in order. Upon finding the nth match, the container then invokes the corresponding servlet.
- If the servlet needs to proxy the request, the container re-scans the rules searching for additional matches. Upon finding the $(n+1)^{th}$ match, the container invokes the corresponding servlet.
- Matching the request excludes any servlet in the same application as the previously invoked servlet. As stated in the standards, no servlet will be invoked twice for the same SIP request.

Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java 2 Platform Enterprise Edition (J2EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

1. Open the administrative console.

   In a browser, go to URL `http://hostname:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.

2. In the left frame click **Applications** → **Install New Application**.

3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type /ThisApplication.

4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title "Preparing for the application installation", but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the web.xml file contents, and try to reload the SAR file.

5. Click **Next**. If you see a screen indicating "Application Security Warnings", click **Continue**.

6. The **Install New Application** screen should appear with "Step 1: Select application options" highlighted. Select the options you need and click **Next**.

7. "Step 2: Map modules to servers" should appear highlighted now. You can choose the cluster or server where you want to install the application's modules.
   - If you are installing the application in a stand-alone system, click **Next**.
   - If you are installing the application in a clustered system, select **WebSphere:cell=_cellname_,cluster=_cluster_name_** in the **Clusters and Servers** field, select the check box beside the Web module that you want to install, and click **Apply** and **Next**.

8. Now "Step 3: Map virtual hosts for Web modules" should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
   - If you are installing the application in a standalone system, set the value of the drop-down to **default_host**, and click **Next**.
   - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

   Remember: You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.

9. You should now see "Step 4: Summary" highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, Application _appname__sar installed successfully, where _appname_ is the name of the application.

10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.

11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.

12. To confirm that the installation succeeded, in the left frame click **Applications → Enterprise Applications**. The newly installed application should appear in the list of installed applications as _appname__sar.

13. To start the application so that it can service SIP requests, check the box beside _appname__sar, and click **Start**. You might also want to look at the logs for a successful startup message.

The application can service SIP requests now.

Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the GUI but also from the command line.

- Launch a scripting client. For more information, see AdminApp object for scripted administration.
- List applications.
- Install standalone archive files. For more information about installation, see Installation options for the AdminApp object.
- Edit application configurations.
- Uninstall applications.

EJB applications

Task overview: Using enterprise beans in applications

This article provides an overview of the tasks you must perform to use enterprise beans in a J2EE application.

1. Design a J2EE application and the enterprise beans that it needs. For links to design information that is specific to enterprise beans, see "Data access: Resources for learning" on page 688.
2. Develop any enterprise beans that your application will use.
3. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
4. Assemble the beans into one or more EJB modules using one of the assembly tools. This process includes setting security. For your EJB 2.x-compliant entity beans, you might also want to designate container-managed persistence (CMP) sequence groups.
5. Assemble the modules into a J2EE application using the assembly tool.
6. For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands or defer commands for container-managed persistence.
7. Deploy the application in an application server.
8. Test the modules.
   - As needed, debug problems with the container.
   - Debug access problems.
9. Assemble the production application using one of the assembly tools
10. Deploy the application to a production environment.
11. Manage the application:
    a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through the Assembly Service Toolkit.
    b. Manage other aspects of the J2EE application.
12. Update the module and redeploy it using one of the assembly tools.
13. Tune the performance of the application. See Best practices for developing enterprise beans.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create J2EE applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in EJB containers, which provide an interface between the beans and the application server on which they reside.

Entity beans store permanent data, so they require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage.

Session beans typically contain the high-level and mid-level business logic for an application. Each method on a session bean typically performs a particular high-level operation. For example, submitting an order or transferring money between accounts. Session beans often invoke methods on entity beans in the course of their business logic.

Session beans can be either *stateful* or *stateless*. A stateful bean instance is intended for use by a single client during its lifetime, where the client performs a series of method calls that are related to each other in time for that client. One example is a "shopping cart" where the client adds items to the cart over the course of an online shopping session. In contrast, a stateless bean instance is typically used by many clients during its lifetime, so stateless beans are appropriate for business logic operations that can be

completed in the span of a single method invocation. Stateful beans should be used only where absolutely necessary -- using stateless beans improves the ability to debug, maintain, and scale the application.

Message-driven beans enable asynchronous message servicing.
- The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through JMS, the EJB container forwards it through an onMessage() call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.
- The EJB container and a Java Connector Architecture (JCA) resource adapter work together to process messages from an enterprise information system (EIS). When a message arrives from an EIS, the resource adapter receives the message and forwards it to a message-driven bean, which then processes the message. The message-driven bean is provided services such as transaction support by the EJB container in the same way that other enterprise beans are provided service.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

For more information about enterprise beans, see "Enterprise beans: Resources for learning" on page 148.

EJB modules
An EJB module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:
- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a J2EE application. An EJB module is installed and run in an enterprise bean container.

For more information about EJB modules, see "Enterprise beans: Resources for learning" on page 148

EJB containers
An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:
- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an

application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

Between transactions, the state of an entity bean can be cached. The EJB container supports option A, B, and C caching.
- With option A caching, the application server assumes that the entity bean is used within a single container. Clients of that bean must direct their requests to the bean instance within that container. The entity bean has exclusive access to the underlying database, which means that the bean cannot be cloned or participate in workload management if option A caching is used.

  If you intend to use read-only scenarios, WebSphere Application Server provides an alternate, higher-performance variation of option A entity beans. This caching option is called *Multithreaded Read-Only*. Similar to standard option A behavior, the EJB container continues to activate the bean just once and leave it active until the EJB container needs space in its active instance cache. However, the EJB container differs from standard option A in the following behaviors:
  – It reloads the state of the bean from persistent storage periodically in response to the user invoking a method on it to pick up any changes that may have been made to the persistent store since the last time the bean was loaded. You can configure this function through a *Reload Interval* setting in the bean's deployment descriptor. For more information, see "Developing read-only entity beans" on page 155.
  – The state of the bean is not written to persistent store by the EJB container at the end of the transaction, nor is the bean's ejbStore() method be invoked.
  – The EJB container permits method invocations from more than one client (thread) on the same bean instance. This differs from the standard EJB component for the internals of a bean. You must keep this aspect in mind when developing your bean, and ensure that any logic in the bean's business methods is overall thread-safe.
- With option B caching, the entity bean remains active in the cache throughout the transaction but is reloaded at the start of each method call.
- With option C caching (the default), the entity bean is always reloaded from the database at the beginning of each transaction. A client can attempt to access the bean and start a new transaction on any container that has been configured to host that bean. This is similar to the session clustering facility described for HTTP sessions in that the entity bean's state is maintained in a shared database that can be accessed from any server when required.

This product supports the cloning of stateful session bean home objects among multiple application servers. However, it does not support the cloning of a specific instance of a stateful session bean. Each instance of a particular stateful session bean can exist in just one application server and can be accessed only by directing requests to that particular application server. State information for a stateful session bean cannot be maintained across multiple members of a server cluster. However, enabling stateful session bean failover and configuring the EJB container to use memory-to-memory replication does enable stateful session bean failover to be replicated to other servers in the cluster so that failover can occur to the backup server if the primary server for a stateful session bean stops for some reason. For more information about stateful session bean failover, see Stateful session bean failover for the EJB container.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans (because they must exist before messages are posted for them), Startup Beans (which must be processed at server startup time), and those EJB types that you specify to initialize at server start. For more information about disabling quick start for EJB types, see Changing enterprise bean types to initialize at application start time using the Application Server Toolkit.

All other EJB initialization is delayed until the first use of the EJB type. When using Local Interfaces, the first use is when you perform an *InitialContext.lookup()* method for the type. For Remote Interfaces, it is when you call the first method on an EJB or its Home.

For more information about EJB containers, see "Enterprise beans: Resources for learning" on page 148.

EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients making the method call. An example of a remote client is an enterprise Java bean (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs and on the same thread of execution as the EJB client.

Remote enterprise beans communicate by using the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is

created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open queue, due to the use of unbounded threads.

The following illustration depicts the two queuing options of enterprise beans.

EJB Queuing
The following are two tips for queueing enterprise beans:
- **Analyze the calling patterns of the EJB client**.

  When configuring the thread pool, it is important to understand the calling patterns of the EJB client. If a servlet is making a small number of calls to remote enterprise beans and each method call is relatively quick, consider setting the number of threads in the ORB thread pool to a value lower than the Web container thread pool size value.

Short-lived EJB calls

Remote Call   Remote Call

Servlet service()   Servlet service()
BEGIN   **END**
Execution timeline

Longer-lived EJB calls

Remote Call   Remote Call

Servlet service()   Servlet service()
BEGIN   **END**
Execution timeline
The degree to which the ORB thread pool value needs increasing is a function of the number of simultaneous servlets, that is, clients, calling enterprise beans and the duration of each method call. If the method calls are longer or the applications spend a lot of time in the ORB, consider making the ORB thread pool size equal to the Web container size. If the servlet makes only short-lived or quick calls to the ORB, servlets can potentially reuse the same ORB thread. In this case, the ORB thread pool can be small, perhaps even one-half of the thread pool size setting of the Web container.

- **Monitor the percentage of configured threads in use**.

    Tivoli Performance Viewer shows a metric called *percent maxed*, which is used to determine how often the configured threads are used. A value that is consistently in the double-digits, indicates a possible bottleneck a the ORB. Increase the number of threads.

See also Queuing network

Enterprise bean and EJB container troubleshooting tips

If you are having problems starting an EJB container, or encounter error messages or exceptions that appear to be generated on by an EJB container, follow these steps to resolve the problem:
- Use the Administrative Console to verify that the application server which hosts the container is running.
- Browse the JVM log files for the application server which hosts the container. Look for the message **server** *server_name* **open for e-business** in the SystemOut.log . If it does not appear, or if you see the message **problems occurred during startup**, browse the SystemErr.log for details.
- Browse the system log files for the application server which hosts the container.
- Enable tracing for the EJB Container component, by using the following trace specification EJBContainer=all=enabled. Follow the instructions for dumping and browsing the trace output to narrow the origin of the problem.

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Error in client log: Missing jar file:

The following error message appears in the client log file because a JAR file is missing from the classpath on the client machine. The Object Request Broker (ORB) needs this file to unmarshal the nested exception that is part of the EJB exception, returned by the server to the client application. For example, if the EJB returns a DB2® JCC SQL exception nested inside of the EJB exception that it returns to the client, the ORB is not able to unmarshal the nested exception if the db2jcc.jar file that contains the DB2 SQL exception is not in the client classpath.

```
java.rmi.MarshalException: CORBA MARSHAL 0x4942f89a No; nested exception is:
org.omg.CORBA.MARSHAL: Unable to read value
from underlying bridge : Custom marshaling (4) Sender's class does not match
local class  vmcid: 0x4942f000  minor  code: 2202  completed: No*
```

To avoid this error, include the JAR file that contains the class for the nested exception that is returned in the EJB exception.

Cannot access an enterprise bean from a servlet, a JSP file, a stand-alone program, or another client

This article provides troubleshooting tips for problems related to accessing enterprise beans.

What kind of error are you seeing?
* **javax.naming.NameNotFoundException: Name *name* not found in context ″local″ message** when access is attempted
* **BeanNotReentrantException** is thrown
* **CSITransactionRolledbackException / TransactionRolledbackException** is thrown
* Call fails, Stack trace beginning **EJSContainer E Bean method threw exception [exception_name]** found in JVM log file.
* Call fails, **ObjectNotFoundException or ObjectNotFoundLocalException** when accessing stateful session EJB found in JVM log file.
* Attempt to start CMP EJB module fails with **javax.naming.NameNotFoundException: *dataSourceName***
* **Transaction [tran ID] has timed out after 120 seconds** error accessing EJB.

* Symptom: **CNTR0001W: A Stateful SessionBean could not be passivated**
* Symptom: **org.omg.CORBA.BAD_PARAM: Servant is not of the expected type. minor code: 4942F21E completed: No** returned to client program when attempting to execute an EJB method

If the client is remote to the enterprise bean, which means, running in a different application server or as a stand-alone client, browse the JVM logs of the application server hosting the enterprise bean as well as log files of the client.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, perform these steps:
1. If the problem appears to be name-service related, which means that you see a NameNotFoundException, or a message ID beginning with NMSV, see these topics for more information:
   * Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client
   * Naming service troubleshooting tips

2. Check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning.

If you still cannot fix your problem, seeTroubleshooting help from IBM for further assistance.

ObjectNotFoundException or ObjectNotFoundLocalException when accessing stateful session EJB

A possible cause of this problem is that the stateful session bean timed out and was removed by the container. This event must be addressed in the code, according to the EJB 2.1 specification (available at `http://java.sun.com/products/ejb/docs.html`), section 7.6.2, Dealing with exceptions.

Stack trace beginning ″EJSContainer E Bean method threw exception [exception_name]″ found in JVM log file

If the exception name indicates an exception thrown by an IBM class that begins with ″com.ibm...″, then search for the exception name within the information center, and in the online help as described below. If ″exception name″ indicates an exception thrown by your application, contact the application developer to determine the cause.

javax.naming.NameNotFoundException: Name name not found in context ″local″

A possible reason for this exception is that the enterprise bean is not local (not running in the same Java virtual machine [JVM] or application server) to the client JSP, servlet, Java application, or other enterprise bean, yet the call is to a ″local″ interface method of the enterprise bean . If access worked in a development environment but not when deployed to WebSphere Application Server, for example, it might be that the enterprise bean and its client were in the same JVM in development, but are in separate processes after deployment.

To resolve this problem, contact the developer of the enterprise bean and determine whether the client call is to a method in the local interface for the enterprise bean. If so, have the client code changed to call a remote interface method, or to promote the local method into the remote interface.

References to enterprise beans with local interfaces are bound in a name space local to the server process with the URL scheme of `local:`. To obtain a dump of a server `local:` name space, use the name space dump utility described in the article ″Name space dump utility for `java:`, `local:` and `server` name spaces.″

BeanNotReentrantException is thrown

This problem can occur because client code (typically a servlet or JSP file) is attempting to call the same stateful SessionBean from two different client threads. This situation often results when an application stores the reference to the stateful session bean in a static variable, uses a global (static) JSP variable to refer to the stateful SessionBean reference, or stores the stateful SessionBean reference in the HTTP session object. The application then has the client browser issue a new request to the servlet or JSP file before the previous request has completed.

To resolve this problem, ask the developer of the client code to review the code for these conditions.

CSITransactionRolledbackException / TransactionRolledbackException is thrown

An enterprise bean container creates these high-level exceptions to indicate that an enterprise bean call could not successfully complete. When this exception is thrown, browse the JVM logs to determine the underlying cause.

Some possible causes include:

- The enterprise bean might throw an exception that was not declared as part of its method signature. The container is required to roll back the transaction in this case. Common causes of this situation are where the enterprise bean or code that it calls creates a NullPointerException, ArrayIndexOutOfBoundsException, or other Java runtime exception, or where a BMP bean encounters a JDBC error. The resolution is to investigate the enterprise bean code and resolve the underlying exception, or to add the exception to the problem method signature.
- A transaction might attempt to do additional work after being placed in a ″Marked Rollback″, ″RollingBack″, or ″RolledBack″ state. Transactions cannot continue to do work after they are set to one of these states. This situation occurs because the transaction has timed out which, often occurs because of a database deadlock. Work with the application database management tools or administrator to determine whether database transactions called by the enterprise bean are timing out.
- A transaction might fail on commit due to dangling work from local transactions. The local transaction encounters some ″dangling work″ during commit. When a local transactions encounters an ″unresolved action″ the default action is to ″rollback″. You can adjust this action to ″commit″ in an assembly tool. Open the enterprise bean .jar file (or the EAR file containing the enterprise bean) and select the Session Beans or Entity Beans object in the component tree on the left. The Unresolved Action property is on the IBM Extensions tab of the container properties.

Attempt to start EJB module fails with ″javax.naming.NameNotFoundException dataSourceName_CMP″exception

This problem can occur because:
- When the DataSource resource was configured, container managed persistence was not selected.
  - To confirm this problem, in the administrative console, browse the properties of the data source given in the NameNotFoundException. On the Configuration panel, look for a check box labeled **Container Managed Persistence**.
  - To correct this problem, select the check box for **Container Managed Persistence**.
- If container managed persistence is selected, it is possible that the CMP DataSource could not be bound into the namespace.
  - Look for additional naming warnings or errors in the status bar, and in the hosting application server JVM logs. Check any further naming-exception problems that you find by looking at the topic Cannot look up an object hosted by WebSphere Application Server from a servlet, JSP file, or other client.

Transaction [tran ID] has timed out after 120 seconds accessing an enterprise bean

This error can occur when a client executes a transaction on a CMP or BMP enterprise bean.
- The default timeout value for enterprise bean transactions is 120 seconds. After this time, the transaction times out and the connection closes.
- If the transaction legitimately takes longer than the specified timeout period, go to **Manage Application Servers > *server_name***, select the **Transaction Service properties** page, and look at the property **Total transaction lifetime timeout**. Increase this value if necessary and save the configuration.

Symptom:CNTR0001W: A Stateful SessionBean could not be passivated

This error can occur when a Connection object used in the bean is not closed or nulled out.

To confirm this is the problem, look for an exception stack in the JVM log for the EJB container that hosts the enterprise bean, and looks similar to:

```
[time EDT] <ThreadID> StatefulPassi W CNTR0001W:
A Stateful SessionBean could not be passivated: StatefulBean0
(BeanId(XXX#YYY.jar#ZZZZ, <ThreadID>),
state = PASSIVATING) com.ibm.ejs.container.passivator.StatefulPassivator@<ThreadID>
java.io.NotSerializableException: com.ibm.ws.rsadapter.jdbc.WSJdbcConnection
 at java.io.ObjectOutputStream.outputObject((Compiled Code))
 at java.io.ObjectOutputStream.writeObject(ObjectOutputStream.java(Compiled Code))
 at java.io.ObjectOutputStream.outputClassFields((Compiled Code))
 at java.io.ObjectOutputStream.defaultWriteObject((Compiled Code))
```

```
at java.io.ObjectOutputStream.outputObject((Compiled Code))
at java.io.ObjectOutputStream.writeObject(ObjectOutputStream.java(Compiled Code))
at com.ibm.ejs.container.passivator.StatefulPassivator.passivate((Compiled Code))

at com.ibm.ejs.container.StatefulBeanO.passivate((Compiled Code)
at com.ibm.ejs.container.activator.StatefulASActivationStrategy.atUnitOfWorkEnd
                     ((Compiled Code))
at com.ibm.ejs.container.activator.Activator.unitOfWorkEnd((Compiled Code))
at com.ibm.ejs.container.ContainerAS.afterCompletion((Compiled Code)
```

where *XXX,YYY,ZZZ* is the Bean's name, and *<ThreadID>* is the thread ID for that run.

To correct this problem, the application must close all connections and set the reference to null for all connections. Typically this activity is done in the `ejbPassivate()` method of the bean. See the enterprise bean specification mandating this requirement, specifically section 7.4 in the EJB specification Version 2.1. Also, note that the bean must have code to reacquire these connections when the bean is reactivated. Otherwise, there are NullPointerExceptions when the application tries to reuse the connections.

Symptom: org.omg.CORBA.BAD_PARAM: Servant is not of the expected type. minor code: 4942F21E completed: No

This error can be returned to a client program when the program attempts to execute an EJB method.

Typically this problem is caused by a mismatch between the interface definition and implementation of the client and server installations, respectively.

Another possible cause is when an application server is set up to use a single class loading scheme. If an application is uninstalled while the application server remains active, the classes of the uninstalled application are still loaded in the application server. If you change the application, redeploy and reinstall it on the application server, the previously loaded classes become back level. The back level classes cause a code version mismatch between the client and the server.

To correct this problem:
1. Change the application server class loading scheme to multiple.
2. Stop and restart the application server and try the operation again.
3. Make sure the client and server code version are the same.

Developing enterprise beans

In selecting a tool for developing enterprise beans, there are two basic approaches, with or without an IDE. The steps in this article explain development without an IDE.

Design a J2EE application and the enterprise beans that it needs.
- For general design information, see ″Resources for learning.″
- Before developing entity beans with container-managed persistence (CMP), read ″Concurrency control.″

There are two basic approaches to selecting tools for developing enterprise beans:
- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the enterprise bean code and contain integrated tools for packaging and testing enterprise beans. The IBM WebSphere Application Developer product is the recommended IDE. For more information, see the documentation for that product.
- If you have decided to develop enterprise beans without an IDE, you need at least an ASCII text editor. You can also use a Java development tool that does not support enterprise bean development. You can then use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the beans.

The following steps primarily support the second approach, development without an IDE.

1. If necessary, migrate any pre-existing code to the required version of the Enterprise JavaBeans (EJB) specification.
2. Write and compile the components of the enterprise bean.
   - At a minimum, an EJB 1.1 session bean requires a bean class, a home interface, and a remote interface. An EJB 1.1 entity bean requires a bean class, a primary-key class, a home interface, and a remote interface.
   - At a minimum, an EJB 2.x session bean requires a bean class, a home or local home interface, and a remote or local interface. An EJB 2.x entity bean requires a bean class, a primary-key class, a remote home or local home interface, and a remote or local interface. The types of interfaces go together: If you implement a local interface, you must define a local home interface as well.

     Note: Optionally, the primary-key class can be *unknown*. See unknown primary-key class for more information.
   - A message-driven bean requires only a bean class.
3. For each entity bean, complete work to handle persistence operations.
   - Create a database schema for the entity bean's persistent data.
     - For entity beans with container-managed persistence (CMP), you must store the bean's persistent data in one of the supported databases. The Application Service Toolkit automatically generates SQL code for creating database tables for CMP entity beans. If your CMP beans require complex database mappings, it is recommended that you use the IBM Rational Application Developer product to generate code for the database tables.
     - For entity beans with bean-managed persistence (BMP), you can create the database and database table by using the database tools or use an existing database and database table.

     For more information on creating databases and database tables, consult your database documentation.
   - **(CMP entity beans for EJB 2.x only)** Define finder queries with EJB Query Language (EJB QL).

     With EJB QL, you define finders in terms of CMP fields and container-managed relationships, as follows:
     - *Public* finders are visible in the bean's home interface. Implemented in the bean class, they return only remote interfaces and collection types.
     - *Private* finders, expressed as SELECT statements, are used only within the bean class. They can return both local and remote interfaces, dependent values, other CMP field types, and collection types.
   - **(CMP entity beans for EJB 1.1 only: an IBM extension)** Create a finder helper interface for each CMP entity bean that contains specialized finder methods (other than the findByPrimaryKey method).

     The following logic is required for each finder method (other than the findByPrimaryKey method) contained in the home interface of an entity bean with CMP:
     - The logic must be defined in a public interface named `NameBeanFinderHelper`, where *Name* is the name of the enterprise bean (for example, AccountBeanFinderHelper).
     - The logic must be contained in a String constant named `findMethodName WhereClause`, where *findMethodName* is the name of the finder method. The String constant can contain zero or more question marks (?) that are replaced from left to right with the value of the finder method's arguments when that method is called.

Assemble the beans in one or more EJB modules.

Developing read-only entity beans

In addition to the existing EJB caching options, you can develop read-only entity beans.

You are most likely to want to use it under the following conditions:
- Your application uses data that change relatively infrequently. An example might be a retailing application that uses pricing data that only changes once a week or month.
- Your application can tolerate data that may be stale. The degree of "staleness" that the EJB container allows is configurable by the user.

- The bean is coded in a thread-safe manner, so it can safely be invoked by multiple threads at once.

To use this function, you declare the bean type as *read-only* the same way you currently select the bean caching options, through a selection list within the application assembly tooling (either WebSphere Application Developer or the Application Server Toolkit).

1. Start your assembly tool.

2. Call up the parameter selection list as you normally do.

3. Set the **Activate At** parameter to *ONCE*. This is the same as for standard option A caching.

4. Set the **Load At** parameter to either *INTERVAL*, *DAILY*, or *WEEKLY.*

   INTERVAL
   > causes the bean to be reloaded if a certain time interval has been exceeded since the last time the bean was loaded.

   DAILY causes the bean to be reloaded on the first business method invocation that occurs after a specified time on the host computer's local time-of-day clock.

   WEEKLY
   > is similar to DAILY except it occurs once per week at a specified time.

5. Set the **Reload Interval** parameter to a nonnegative integer value. The meaning of this parameter depends on whether the Load At parameter is INTERVAL, DAILY, or WEEKLY.

   INTERVAL
   > the integer represents the number of minutes that can elapse (since the last time the bean was loaded) before the EJB container reloads the bean's state from persistent storage. A value of 0 is permissible and causes the container to never reload the state of the bean.

   DAILY the integer represents an absolute time each day that the reload is performed after, expressed in what is commonly called the 24-hour clock. That is, a whole number between 0000 and 2359, where 0000 represents midnight, 1200 represents noon, and 2359 represents one minute before midnight. Any leading zeroes on this number are optional. In the case of malformed values (for example, 1285), the resulting clock time is always computed by taking the minutes value from the two least-significant digits and adding that to the hour value taken from the digit or digits to the left of the two least-significant ones. Thus, a value of 1285 will be interpreted as 1325 (85 minutes after 1200). Any values exceeding 2359, as well as negative or nonnumeric values, are interpreted as 0000.

   WEEKLY
   > the integer is encoded in the same manner as daily, except it must be five digits in length, the first digit representing the day of the week. Sunday is encoded as **1** and Saturday is encoded as **7**. If the value is four digits or less, it is treated as if it were five digits long with the first digit being **1**.

   Reloading is performed only in response to a business method invocation on the bean. When a business method is invoked, the EJB container checks to see whether either the reload interval time has expired or the absolute clock time for that day has passed (depending on whether INTERVAL, DAILY, or WEEKLY was used). If so, the container reloads the bean state.

   When a read-only entity bean is invoked within a global transaction and the reload interval expires while the transaction is active, business method calls on the bean during that transaction continue to see the non-reloaded state of the bean for the duration of that transaction. That is, a snapshot of the bean state is effectively taken on the first business method invocation on that bean during a transaction, and that state continues to be in effect for that transaction until it completes. New invocations on that bean performed in a different transaction after the reload see the reloaded state.

Example: read-only entity bean:

A usage scenario and example for writing an EJB application that uses a read-only entity bean.

Usage Scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

Example

The customer's entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it's a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
     (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...      some other processing, etc. in the interim
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:
* ActivateAt = ONCE
* LoadAt = DAILY
* ReloadInterval = 2200

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had prior to any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred prior to 22:00. Thus, the item price and shipping cost used remain in sync with each other.

Migrating enterprise bean code to the supported specification
Support for Version 2.1 of the Enterprise JavaBeans (EJB) specification is added for Version 6 of this product. Migration of enterprise beans deployed in Versions 4 or 5 of this product is not generally necessary; Versions 1.1 and 2.0 of the EJB specification are still supported.

Follow these steps as appropriate for your application deployment.
1. Modify enterprise bean code for changes in the specification.
    * For Version 1.0 beans, migrate at least to Version 1.1.
    * As stated previously, migration from Version 1.1 to Version 2.x of the EJB specification is not required for redeployment on this version of the product. However, if your application requires the capabilities of Version 2.x, migrate your Version 1.1-compliant code.

> **Note:** The EJB Version 2.0 specification mandates that prior to the EJB container's running a
> findBy*Method* query, the state of all enterprise beans enlisted in the current transaction be
> synchronized with the persistent store. (This is so the query is performed against current
> data.) If Version 1.1 beans are reassembled into an EJB 2.x-compliant module, the EJB
> container synchronizes the state of Version 1.1 beans as well as that of Version 2.x beans.
> As a result, you might notice some change in application behavior even though the
> application code for the Version 1.1 beans has not been changed.

2. You might have to modify code for some EJB 1.1-compliant modules that were not migrated to Version
   2.x. Use the following information to help you decide.
   - Some stub classes for deployed enterprise beans have changed in the Java 2 Software
     Development Kit, Version 1.4.1.
   - The task of generating deployment code for enterprise beans changed significantly for EJB
     1.1-compliant modules relative to EJB 1.0-compliant modules.

3. Ensure WebSphere Application Server 32-bit to 64-bit compatibility. For a ″pure″ Java application this
   is not an issue. However, if your application code utilizes the Java Native Interface (JNI) code, you
   should be aware of the following: the JNI allows Java code running in a virtual machine to operate with
   applications and libraries written in other languages, such as C, C++, and assembly. So, if your J2EE
   application uses JNI in a 32-bit environment, your code must be recompiled in the 64-bit environment.
   It is possible that the JNI calls could be different after the compilation, as the JNI specifications can
   change from version to version.

4. Reassemble and redeploy all modules to incorporate migrated code.

Migrating enterprise bean code from Version 1.0 to Version 1.1:

The following information generally applies to any enterprise bean that currently complies with Version 1.0
of the Enterprise JavaBeans (EJB) specification.

For more information about migrating code for beans produced with Rational Application Developer, see
the documentation for that product. For more information about migrating code in general, see ″Resources
for learning.″

1. In session beans, replace all uses of javax.jts.UserTransaction with javax.transaction.UserTransaction.
   Entity beans may no longer use the UserTransaction interface at all.

2. In finder methods for entity beans, include FinderException in the `throws` clause.

3. Remove throws of java.rmi.RemoteException; throw javax.ejb.EJBException instead. However,
   continue to include RemoteException in the `throws` clause of home and remote interfaces as required
   by the use of Remote Method Invocation (RMI).

4. Remove uses of the finalize() method.

5. Replace calls to getCallerIdentity() with calls to getCallerPrincipal(). The use of getCallerIdentity() is
   deprecated.

6. Replace calls to isCallerInRole(Identity) with calls to isCallerinRole (String). The use of
   isCallerInRole(Identity) and java.security.Identity is deprecated.

7. Replace calls to getEnvironment() in favor of JNDI lookup. As an example, change the following code:

   ```
   String homeName =
      aLink.getEntityContext().getEnvironment().getProperty("TARGET_HOME_NAME");
   if (homeName == null) homeName = "TARGET_HOME_NAME";
   ```

   The updated code would look something like the following:

   ```
   Context env = (Context)(new InitialContext()).lookup("java:comp/env");
   String homeName = (String)env.lookup("ejb10-properties/TARGET_HOME_NAME");
   ```

8. In ejbCreate methods for an entity bean with container-managed persistence (CMP), return the bean's
   primary key class instead of `void`.

9. Add the getHomeHandle() method to home interfaces.

   ```
   public javax.ejb.HomeHandle getHomeHandle() {return null;}
   ```

Consider enhancements to match the following changes in the specification:
- Primary keys for entity beans can be of type java.lang.String.
- Finder methods for entity beans return java.util.Collection.
- Check the format of any JNDI names being used. Local name spaces are also supported.
- Security is defined by role, and isolation levels are defined at the method level rather than at the bean level.

Migrating enterprise bean code from Version 1.1 to Version 2.1:

Enterprise JavaBeans (EJB) Version 2.1-compliant beans can be assembled only in an EJB 2.1-compliant module, although an EJB 2.1-compliant module can contain a mixture of Version 1.x and Version 2.1 beans.

The EJB Version 2.1 specification mandates that prior to the EJB container starting a findBy*Method* query, the state of all enterprise beans that are enlisted in the current transaction be synchronized with the persistent store. (This action is so the query is performed against current data.) If Version 1.1 beans are reassembled into an EJB 2.1-compliant module, the EJB container synchronizes the state of Version 1.1 beans as well as that of Version 2.1 beans. As a result, you might notice some change in application behavior even though the application code for the Version 1.1 beans has not been changed.

The following information generally applies to any enterprise bean that currently complies with Version 1.1 of the EJB specification. For more information about migrating code for beans produced with the Rational Application Developer tool, see the documentation for that product. For more information about migrating code in general, see ″Resources for learning.″

1. In beans with container-managed persistence (CMP) version 1.x, replace each CMP field with abstract get and set methods. In doing so, you must make each bean class abstract.
2. In beans with CMP version 1.x, change all occurrences of `this.`*field* `= `*value* to set*Field*(*value*).
3. In each CMP bean, create abstract get and set methods for the primary key.
4. In beans with CMP version 1.x, create an EJB Query Language statement for each finder method.

   Note: EJB Query Language has the following limitations in Application Developer Version 5:
      - EJB Query Language queries involving beans with keys made up of relationships to other beans appear as invalid and cause errors at deployment time.
      - The IBM EJB Query Language support extends the EJB 2.1 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB Query Language queries strictly according to instructions described in Chapter 11 of the EJB 2.1 specification.
5. In finder methods for beans with CMP version 1.x, return java.util.Collection instead of java.util.Enumeration.
6. Update handling of non-application exceptions.
      - To report non-application exceptions, throw javax.ejb.EJBException instead of java.rmi.RemoteException.
      - Modify rollback behavior as needed: In EJB versions 1.1 and 2.1, all non-application exceptions thrown by the bean instance result in the rollback of the transaction in which the instance is running; the instance is discarded. In EJB 1.0, the container does not roll back the transaction or discard the instance if it throws java.rmi.RemoteException.
7. Update rollback behavior as the result of application exceptions.
      - In EJB versions 1.1 and 2.1, an application exception does not cause the EJB container to automatically roll back a transaction.
      - In EJB Version 1.1, the container performs the rollback only if the instance has called setRollbackOnly() on its EJBContext object.
      - In EJB Version 1.0, the container is required to roll back a transaction when an application exception is passed through a transaction boundary started by the container.

8. Update any CMP setting of application-specific default values to be inside ejbCreate (not using global variables, since EJB 1.1 containers set all fields to generic default values before calling ejbCreate, which overwrites any previous application-specific defaults). This approach also works for EJB 1.0 CMPs.

Note: In Application Developer Version 5, there is a J2EE Migration wizard to migrate the EJB beans within an EJB 2.1 project from 1.x into 2.1 (you cannot just migrate individually selected beans). The wizard performs migration steps #1 to #2 above. It also migrates EJB 1.1 (proprietary) relationships into EJB 2.1 (standard) relationships, and maintains EJB inheritance.

Adjusting exception handling for EJB wrappered applications migrating from version 5 to version 6:

Because of a change in the Java APIs for XML based Remote Procedure Call (JAX-RPC) specification, EJB applications that could be wrappered in WebSphere Application Server version 5.1 cannot be wrappered in version 6 unless you modify the code to the exception handling of the base EJB application.

Essentially, the JAX-RPC version 1.1 specification states:

```
a service specific exception declared in a remote method signature must be a
checked exception. It must extend java.lang.Exception either directly or indirectly
but it must not be a RuntimeException.
```

So it is no longer possible to directly use java.lang.Exception or java.lang.Throwable types. You must modify your applications using service specific exceptions to comply with the specification.

1. Modify your applications that use service specific exceptions. For example, say that your existing EJB uses a service specific exception called UserException. Inside of UserException is a field called *ex* that is type java.lang.Exception. To successfully wrapper your application with Web services in WebSphere Application Server version 6, you must change the UserException class . In this example, you could modify UserException to make the type of *ex* to be *java.lang.String* instead of java.lang.Exception.

```
new UserException class:

package irwwbase;

/**
 * Insert the type's description here.
 * Creation date: (9/25/00 2:25:18 PM)
 * @author: Administrator
 */

public class UserException extends java.lang.Exception {

        private java.lang.String _infostring = null;
        private java.lang.String ex;
/**
 * UserException constructor comment.
 */

public UserException() {
        super();
}
/**
 * UserException constructor comment.
 */
public UserException (String infostring)
{
        _infostring = infostring;
} // ctor
/**
 * Insert the method's description here.
 * Creation date: (11/29/2001 9:25:50 AM)
```

```
 * @param msg java.lang.String
 * @param ex java.lang.Exception
 */
public UserException(String msg,String t) {
      super(msg);
      this.setEx(t);

      }
      /**
       * @return
       */
      public java.lang.String get_infostring() {
            return _infostring;
      }

      /**
       * @return
       */
      public java.lang.String getEx() {
            return ex;
      }

      /**
       * @param string
       */
      public void set_infostring(java.lang.String string) {
            _infostring = string;
      }

      /**
       * @param Exception
       */
      public void setEx(java.lang.String exception) {
            ex = exception;
      }

      public void printStackTrace(java.io.PrintWriter s) {
        System.out.println("the exception is :"+ex);
        }

}
```

2. Modify all of the exception handling in the enterprise beans that use it. You must ensure that your enterprise beans are coded to accept the new exceptions. In this example, the code might look like this:

```
new EJB exception handling:

try {
     if (isDistributed()) itemCMPEntity = itemCMPEntityHome.findByPrimaryKey(ckey);
     else itemCMPEntityLocal = itemCMPEntityLocalHome.findByPrimaryKey(ckey);
  } catch (Exception ex) {
       System.out.println("%%%% ERROR: getItemInstance - CMPjdbc " + _className);
       ex.printStackTrace();
       throw new UserException("error on itemCMPEntityHome.findByPrimaryKey(ckey)",ex.getMessage());
   }
```

WebSphere extensions to the Enterprise JavaBeans specification

This article outlines extensions to the Enterprise JavaBeans (EJB) specification that IBM provides with this product.

Inheritance in enterprise beans

In the Java language, *inheritance* is the creation of a new class from an existing class or a new interface from an existing interface. This product supports two forms of inheritance: standard class inheritance and EJB inheritance.

In standard class inheritance, the home interface, remote interface, or enterprise bean class inherits properties and methods from base classes that are not themselves enterprise bean classes or interfaces.

By contrast in enterprise bean inheritance, an enterprise bean inherits properties (such as container-managed persistence (CMP) fields and container-managed relationship (CMR) fields), methods, and method-level control descriptor attributes from another enterprise bean.

For more information, see the documentation for the IBM Rational Application Developer product.

Optimistic concurrency control for container-managed persistence

This product supports optimistic concurrency control of data access. See "Concurrency control" on page 182 for more information.

Access intents for EJB persistence

This product supports the application of named data-access policies.

Sequence grouping for container-managed persistence

By designating CMP sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your EJB application. Within each group you specify the order in which the beans update your relational database tables. See "Setting the run time for CMP sequence groups" on page 200 for instructions.

Performance enhancements

Through the lifetime-in-cache settings, this product provides a way for you to improve performance for beans that are only occasionally updated. For more information, see "Entity bean assembly settings."

Some enterprise beans created with the IBM Rational Application Developer product can utilize read-ahead for loading a bean and its related beans in a single database operation. An entire object graph or any part of the graph can be preloaded by configuring a finder method to use read-ahead.

Assembly and deployment extensions

This product supports IBM extensions of assembly and deployment options.

Best practices for developing enterprise beans

Use the following guidelines when designing and developing enterprise beans.
- Use a stateless session bean to act as the entry point for business logic. For more information about using session facades, see "Resources for learning."
- Entity beans should use container-managed persistence.
- In an Enterprise JavaBeans (EJB) Version 2.x environment, use local interfaces to improve communication between enterprise beans in the same Java virtual machine.

  Local calls avoid the overhead of RMI/IIOP and use pass-by-reference semantics instead of pass-by-value. For each call, the caller and callee beans share the state of arguments. EJB 2.x beans can have both a local and remote interface but more typically have one or the other.
- For communicating with remote clients, provide remote and remote home interfaces. For communicating with local clients like servlets, entity beans, and message-driven beans, provide local and local home interfaces.

Batched commands for container managed persistence:

From JDBC 2.0 on, *PreparedStatement* objects can maintain a list of commands that can be submitted together as a batch. Instead of multiple database round trips, there is only one database round trip for all the batched persistence requests.

You can enable the use of this feature for EJB container managed persistence. When you do, the run time defers *ejbStore/ejbCreate/ejbRemove* or the equivalent database persistence requests (insert/update/delete) until they are needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. When the persistence operation finally happens, run time accumulates the database requests and uses JDBC *PreparedStatement* batch operation to make a single JDBC call for multiple rows of the same operation.

The WebSphere Application Server enables you to make the same settings using the Application Server Toolkit (AST).

Deferred Create for container managed persistence:

The specification for Enterprise JavaBeans (EJB) 2.x states that for Container Managed Persistence (CMP) during the *ejbCreate*, the container can create the representation of the entity in the database immediately, or defer it to a later time.

The WebSphere Application Server versions 5.0.2 and later enable you to take advantage of this specification. You can turn this option on from the EJB CMP side. When you choose this option, the runtime defers *ejbCreate* (or the equivalent database persistence request) until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

The WebSphere Application Server enables you to make the same settings using the Application Server Toolkit (AST).

Partial column updates for container managed persistence:

Previously, the WebSphere Application Server implementation of the Container Managed Persistence (CMP) bean method *ejbStore* always stored all of the persistent attributes of the CMP bean to the database, even if only a subset of persistent attribute fields were changed. This needless performance degradation is eliminated in this release of the product.

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean level persistence option, called *PartialOperation*, in the access intent policy configured for the bean. PartialOperation has two possible values:

NONE Partial update is turned off. All of the persistent attributes of the CMP bean are stored to the database. This is the default value.

UPDATE_ONLY
   Specifies that updates to the database occur only for the persistent attributes of the CMP bean that are changed.

For information on how to set partial update, see "Setting partial update for container-managed persistent beans" on page 169.

Affects on performance

Performing partial updates increases performance in several ways:
* by reducing query execution time, since only a subset of the columns are in the query. Improvement is higher for tables with many columns and indexes. When the table has many indexes only the indexes affected by the updated columns need to be updated by the backend database.
* by reducing network i/o since there is less data to be transmitted.

- by saving any processing time for non-trivially mapped columns (if a column uses converters/composers/transformations), by partially injecting the input record.
- by eliminating unnecessary firing of update triggers. If a CMP bean field is not changed, any trigger depending only on the corresponding column is not fired.

Although partial update improves performance in general, it can adversely affect performance too.
- If you enable partial update for a bean for which your application modifies several different combinations of columns during the same time span, then the prepared statement cache maximum for the connection is reached very quickly. As a result, statement handles are evicted from the cache based on least recent usage. This results in statements being prepared again and again, decreasing performance for all CMP functions (not just limited to ejbStore()).
- Partial update query templates cached in the function set increase memory use. The increase is linear relative to the number of fields in the CMP bean for which the partial update access intent option is turned on.
- The PartialOperation persistent option, when used in combination with the Batch Update persistent option, affects the performance of the batch update because now each partial query is different. There is an execution time cost incurred for generating a partial update query string dynamically. Since query fragments are stored for each column, the execution cost to assemble the query fragments is linear, based on the number of CMP bean fields dirtied.
- There are condition checks for each CMP field (for example to inspect the dirty flags, to execute the preparedStatement setXXX() calls, and so on).

Considerations for using partial update

The performance gains you hope to achieve should be weighed against the possible instances where degradation can occur. You can use the following guidelines to help you make the decision.
- Partial update might not benefit an application that only involves a small table (few columns) with simple data types and no update triggers. The cost to assemble the partial query dynamically would probably outweigh the performance gain.
- Partial update is a benefit if there is a complex data type that is not updated often. An example of a complex data type might be an employee bean with a "photo" CMP attribute mapped to a BLOB OR VARGRAPHIC or similar complex backend type that is typically stored in a different location in the database manager implementation.
- Partial Update might benefit if there are several VARCHAR type columns and only a very few of them are updated typically.
- It is better not to use the partial operation if the application can randomly be updating different combinations of columns and the number of assignable columns (non-key) is higher than five. This generates many different partial queries and fills up the prepared statement cache quickly. But if the bean does not have too many columns (four or less) and it has complex data types, then you might consider turning partial update on, with the option of increasing the statement cache size to allow for the increased number of queries. For information on increasing the statement cache size, refer to Data source settings.
- Partial Update is beneficial when there are update triggers needed on a subset of columns.
- Partial Update is beneficial when the table has many columns and indexes and only a few indexes are touched by a typical update.

Restrictions

By default, batch update of *update queries* is disabled for all CMP beans for which partial update is enabled. In other words, partial update takes precedence over batch update. Batch update of delete and insert queries is not affected.

Batch update performance is affected when both batch update and partial update persistence options are used on the same bean, because each partial query is different. You can use the JVM property *-Dcom.ibm.ws.pm.grouppartialupdate=true* to group the similar partial update queries into a batch update. Grouping of partial updates only helps when there are several partial queries with the same shape in a

transaction. Otherwise, grouping partial updates has the opposite affect on performance. Because this setting is not on a bean level basis, you should be careful when turning it on. Because this affects all beans that have both partial update and batch update on, you must make sure that batch update of partial queries does indeed increase performance when viewed across all the beans for which both updates are on.

So you should determine which situation gives the best performance for your application: batch update only or partial update only or both (with grouppartialupdate flag set to true).

To set the JVM property:

```
1. Open the server.xml file.
2. Change the value of -Dcom.ibm.ws.pm.grouppartialupdate=true to
                       -Dcom.ibm.ws.pm.grouppartialupdate=false.
```

Explicit invalidation in the Persistence Manager cache:

Container managed persistence (CMP) entity beans can be configured as *long-lifetime* beans. A long-lifetime bean is one that is configured with *Lifetime In Cache Usage* equal to a value other than the default **OFF** . A value other than **OFF** means that data for this bean is cached beyond the end of the transaction in which the bean was obtained by a finder or other method. The *Lifetime In Cache Usage* and *Lifetime In Cache* values control the basic length of time the cached data remains valid. When the specified time runs out, the cached data is no longer valid. See the *LifetimeInCache* help sections of the Assembly Service Toolkit (AST) for more details.

However, there is also an API that lets the client application code explicitly invalidate the cached data of a bean on demand, superseding the basic lifetime of the cache data as controlled by the *Lifetime In Cache Usage* and *Lifetime In Cache* settings. This is useful where an application that does not use CMP beans modifies the data that underlies a CMP bean (for example, it updates a database table to which a CMP bean is mapped). Such an application can inform WebSphere Application Server that any cached version of this bean data is **stale** and no longer matches what is in the database. The data should be invalidated (in essence, discarded). For CMP beans that cannot tolerate stale data, this is an important feature.

Because the PM Cache Invalidation mechanism does consume resources in exchange for its benefits, it is not enabled by default. To enable it refer to Setting Persistence Manager Cache Invalidation .

Example: Explicit invalidation in the persistence manager cache:

The usage scenario for this feature begins with configuring one or more bean types to be long-lifetime beans and configuring the necessary Java Message Service (JMS) resources, which is described below. After this is done, the server is started.

Usage Scenario

The scenario continues as follows:
1. Assume that a CMP entity bean of type *Department* has been configured to be a long-lifetime bean.
2. Transaction 1 begins. Application code looks up *Department*'s home and calls a finder method (such as *findByPrimaryKey("dept01")*). As this is the first finder to return *Department dept01*, a trip is made to the database to obtain the data. Transaction 1 ends.
3. Transaction 2 begins. Application code calls *findByPrimaryKey("dept01")* again. Because this is not the first finder to return *Department dept01*, we get a cache hit and no database trip is made. Transaction 2 ends. So far this is current WebSphere Application Server behavior for long-lifetime beans.
4. Another application, which does not use the *Department* CMP bean, is executed. This application might or might not be run on WebSphere Application Server; it could be a legacy application. The application updates the database table that is mapped to the *Department* bean, altering the row for *dept01*. For example, the *budget* column in the table (mapped to a Java double CMP attribute in the *Department* bean) is changed from $10,000.00 to $50,000.00. This application was designed to

cooperate with WebSphere Application Server. After performing the update, the application sends an invalidate request message to invalidate the (now incorrect) cached data for *Department* bean *dept01*.

5. Transaction 3 begins. Application code looks up *Department*'s home and calls a finder method (such as *findByPrimaryKey("dept01")*). Because this is the first finder after *Department dept01* is invalidated, a new database trip is made to obtain the data. Transaction 3 ends.

Persistence Manager cache invalidation API

The PM cache invalidation API is in the form of a JMS message that the client sends to a specially named JMS topic using a connection from a specifically named JMS *TopicConnectionFactory*. The JMS message must be an *ObjectMessage* created by the client. The client code creates a *PMCacheInvalidationRequest* object that describes the bean data to invalidate. Client code places the *PMCacheInvalidationRequest* object in the *ObjectMessage* and publishes the *ObjectMessage* (for further details on the JMS objects and terms used here, please see the Java Message Service documentation).

The public class *PMCacheInvalidationRequest* is central to the API, so we include a portion of its code here for illustration purposes (if you see any differences between this illustration and the actual class, the class is to be considered correct):

```
packagecom.ibm.websphere.ejbpersistence;

/**
*An instance of this class represents a request to invalidate one or more
*CMP beans in the PM cache. When an invalidate occurs, cached data for this
*bean is removed from the cache; the next time an application tries to find
*this bean, a fresh copy of the bean data is obtained from the data store.
*
*The ability to invalidate a bean means that a CMP bean may be configured
*as a long-lifetime bean and thus be cached across transactions for much
*greater performance on future attempts to find this bean. Yet when some
*outside mechanism updates the bean data, sending an invalidation request
*will remove stale data from the PM cache so applications do not behave falsely
*based on stale data.
*/
public class PMCacheInvalidationRequestimplementsSerializable{

. . .

/**
 * Constructor used to invalidate a single bean
 * @param beanHomeJNDIName the JNDI name of the bean home. This is the same value
 * used to look up the bean home prior to calling findByPrimaryKey, for example.
 * @param beanKey the primary key of the bean to be invalidated. The actual
 * object type must be the primary key type for this bean type.
 */
public PMCacheInvalidationRequest(String beanHomeJNDIName, Object beanKey)
 throws IOException {
. . .
}
/**
 * Constructor used to invalidate a Collection of beans
 * @param beanHomeJNDIName java.lang.String the JNDI name of the bean home.
 * This is the same value used to look up the bean home prior to calling
 * findByPrimaryKey, for example.
 * @param beanKeys a Collection of the primary keys of the beans to be
 * invalidated. The actual type of each object in the Collection must be the
 * primary key type for this bean type.
*/
 public PMCacheInvalidationRequest(String beanHomeJNDIName, Collection beanKeys)
 throws IOException {
. . .
}
/**
 * Constructor used to invalidate all beans of a given type
```

```
 * @param beanHomeJNDIName java.lang.String the JNDI name of the bean home.
 * This is the same value used to look up the bean home prior to calling
 * findByPrimaryKey, for example.
 */
public PMCacheInvalidationRequest(String beanHomeJNDIName) {
. . .
}

}
```

If the client wants to perform the invalidation in a synchronous way, it can opt to receive an acknowledgement JMS message when the invalidation is complete. To ask for an acknowledgement (ACK) message, the client sets a *Topic* of its own choosing in the *JMSReplyTo* field of the *ObjectMessage* for the invalidation request (see the Java Message Service documentation for further details). The client then waits (using the *receive()* method of JMS) on receipt of the acknowledgement message before continuing execution.

An ACK message enables the caller to insure there is not even a brief (seconds or less) window during which PM cache data is stale. The sending of an acknowledgement for each request does, of course, take a bit more time and so is recommended to be used only when needed.

The JMS resources used to make an invalidation request--topic connection factory, topic destination (sometimes called just ″topic″), and so forth--must be configured by the user (using the administrative console or other method) if they want to use PM Cache Invalidation. In this way the user can chose whichever JMS provider is preferred (as long as it supports pub-sub). The names that must be used for these resources are defined as part of the API. These names are unique to the WebSphere Application Server namespace to avoid name conflict with customer JMS resources.

The following are the names that must be used when the user configures the JMS resources (shown as Java constants for clarity):

```
// The JNDI name of the topic connection factory
 private static final String topicConnectionFactoryJNDIName = "com.ibm.websphere.ejbpersistence.InvalidateTCF";
// The JNDI name of the topic destination
  private static final String topicDestinationJNDIName = "com.ibm.websphere.ejbpersistence.invalidate";
// The topic name (part of the topic destination)
  private static final String topicString = "com.ibm.websphere.ejbpersistence.invalidate";
```

Other JMS configuration, such as bus name (required if you choose the *default messaging* JMS provider), can use names you define. Also, the bus used by the invalidate JMS resources can be used by other resources; the invalidate mechanism does not require exclusive use of a bus.

Here are examples of how these constants can be used in client code:

```
// Look up the topic connection factory...
InitialContext ic = new InitialContext();
TopicConnectionFactory topicConnectionFactory = (TopicConnectionFactory) ic.lookup(topicConnectionFactoryJNDIName);
...
// Look up the topic
Topic topic = (Topic) ic.lookup(topicDestinationJNDIName);
```

Note that JMS messages can be sent not only from J2EE application code (for example, a SessionBean or BMP entity bean method) but also from non-J2EE applications if your chosen JMS provider allows for this. For example, the IBM MQ Client product installed on a database server, which typically does not have J2EE installed to create a topic connection and topic that are compatible with the topic connection factory and topic destination you configure using the WebSphere Application Server administrative console.

Setting the run time for batched commands with JVM arguments

This article explains how to set the run time for batched commands with JVM arguments.

1. Open the administrative console.

2. Select **Servers**.

3. Select **Application Servers**.

4. Select the server you want to configure.

5. In the Additional Properties area, select **Process Definition**.

6. In the Additional Properties area, select **Java Virtual Machine**.

7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.batch=true*.

Setting the run time for batched commands with the assembly tools

This article explains how to set the run time for batched commands using the Application Server Toolkit.

1. Start an assembly tool. Refer to *Starting WebSphere Application Server Toolkit* in the Application Server Toolkit documentation.

2. On the Project Explorer tab, click **EJB Modules** > *project* > **ejbModule** > **META-INF** > **ejb-jar.xml** The EJB Deployment Descriptor window appears.

3. Select the **Access** tab. The Add Access Intent window appears. There are two areas of the panel that deal with adding access intent:
   - Default Access Intent for Entities 2.x (Bean Level)
   - Access Intent for Entities 2.x (Method Level)

4. Select the Bean or Method level. Another access intent window appears where you can set the properties you wish to use.

5. Use the dropdown list to select the Access intent name.

6. **Optional:** Enter a description.

7. Check the **Persistence Option** box.

8. Check the **Deferred Operation** box.

9. Use the dropdown list to select **All** for deferred operation. You must select All to use the batch option.

10. Check the **Batch** box. This operation uses the JDBC batch command to insert, update, or delete rows in the database backend that this particular enterprise bean is connected to.

11. Select **Finish**.

Setting the run time for deferred create with JVM arguments

The specification for Enterprise JavaBeans (EJB) 2.x states that for Container Managed Persistence (CMP) during the ejbCreate, the container can create the representation of the entity in the database immediately, or defer it to a later time.

When you choose the defer option, the run time defers ejbCreate (or the equivalent database persistence request) until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

1. Open the administrative console.

2. Select **Servers**.

3. Select **Application Servers**.

4. Select the server you want to configure.

5. In the Additional Properties area, select **Process Definition**.

6. In the Additional Properties area, select **Java Virtual Machine**.

7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.deferredcreate=true*.

Setting the run time for deferred commands with the assembly tools

To set the run time for deferred commands using the assembly tools, follow these steps.

1. Start the Application Server Toolkit.

2. On the Project Explorer tab, click **EJB Modules** > *project* > **ejbModule** > **META-INF** > **ejb-jar.xml** The EJB Deployment Descriptor window appears.

3. Select the **Access** tab. The Add Access Intent window appears. There are two areas of the panel that deal with adding access intent:

   - Default Access Intent for Entities 2.x (Bean Level)
   - Access Intent for Entities 2.x (Method Level)

4. Select the Bean or Method level. Another access intent window appears where you can set the properties you wish to use.

5. Use the dropdown list to select the Access intent name.

6. **Optional:** Enter a description.

7. Check the **Persistence Option** box.

8. Check the **Deferred Operation** box.

9. Use the dropdown list to select your choice for deferred operation. You have three options for deferred operation:

   NONE Nothing is deferred.

   CREATE_ONLY
   > Only ejbCreate commands are deferred until the next ejbStore occurs to create row in database.

   ALL All ejbCreate, ejbStore, and ejbRemove commands are deferred until a flush is needed, which is either before a finder method or before transaction completion.

10. Select **Finish**.

Setting partial update for container-managed persistent beans

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean-level persistence option, called *PartialOperation*, in the access intent policy configured for the bean.

1. Start the Application Server Toolkit.

2. Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. Open the Project Explorer view. Click **Window > Show View > Project Explorer**.

4. Open the EJB Deployment Descriptor. Click **EJB Projects > *project* > ejbModule > META-INF > ejb-jar.xml**. The Deployment Descriptor editor opens.

5. In the Deployment Descriptor editor, select the **Access** tab. The access page opens.

6. In the **Default Access Intent for Entities 2.x (Bean Level)** section of the access page, select the bean for which you want to set partial operation. If an access intent has already been configured for this bean, click on the **Edit** button to edit the access intent policy. Otherwise, click on the **Add** button to add an access intent policy to the bean. This opens the **Add access intent** window.

7. Select the **Persistence Option** check box if it is not already checked.

8. Select the **Partial Operation** check box. Use the drop-down list next to the Partial Operation check box to select your preference.
   NONE Partial update is turned off. All of the persistent attributes of the CMP bean are stored to the database. This is the default value.
   UPDATE_ONLY
   > Specifies that updates to the database occur only for the persistent attributes of the CMP bean that are changed.

9. Select **Finish**.

Setting Persistence Manager Cache invalidation

To set Persistence Manager Cache invalidation, follow these steps.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. Select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.ejbpersistence.cacheinvalidation=true*.

Unknown primary-key class

When writing an entity bean for Enterprise JavaBeans Version 2.1, the minimum requirements usually include a primary-key class. However, in some cases you might choose not to specify the primary-key class for an entity bean with container-managed persistence (CMP).

Perhaps there is no obvious primary key, or you want to allow the deployer to select the primary key fields at deployment time. The primary key type is usually derived from the type used by the database system that stores the entity objects, and you might not know what this key is.

So, the *unknown key type* is actually a type chosen at deployment time, making it changeable each time the bean is deployed. Your client code must deal with this key as type *Object*.

Currently, WebSphere Application Server supports top-down mapping and enables the deployer to choose *String* keys generated at the application server. For an example of how to use this function, see the Samples library.

Configuring a Timer Service

To configure a timer service, follow these steps.

1. Open the administrative console.
2. Click **Servers** >**Application Servers** > *servername* > **EJB Container Settings** > **EJB timer service settings**. The Timer Service settings panel is displayed.
3. If you want to use the internal, or pre-configured, scheduler instance, click the **Use internal EJB timer service scheduler instance** radio button. If you choose not to change the default settings, this instance is associated with a Cloudscape database. If you choose to customize the pre-configured instance:
   a. To change the data source (you can use any supported database, such as DB2 or Oracle), enter your **Data source JNDI name**.
   b. Enter your chosen **Data source alias**.
   c. Enter your chosen **Table prefix** if you want to have several server processes use the same database, but different tables.
   d. Enter a **Poll interval** value in milliseconds.
   e. If you want more timers to execute concurrently, enter a new value for **Number of timer threads**.

   For more information about the fields, see "EJB Timer Service settings" on page 172

4. If you want to configure your own scheduler instance instead of using the pre-configured internal one, click the **Use custom scheduler instance** radio button. Some reasons you might want to use your own instance are:
   • to change scheduler service configuration options not available for customization on this panel
   • to keep EJB Timer tasks in the same database tables as your other tasks

- you are running in a Clustered environment and want to have a single scheduler instance handle all of the EJB Timers for the cluster. This way, an *ejbTimer* Task created on one cluster member can execute on a different cluster member.

  To use your own instance, you must:

  a. Configure a scheduler instance through the Scheduler Service graphical user interface. See "Using schedulers" on page 1280 for information on how to do this.

  b. Select your **Scheduler JNDI name** from the list.

5. Click **Apply**.
6. Click **OK**.

Configuring a Timer Service for network deployment:

Use this task to configure the Enterprise JavaBeans (EJB) Timer Service to be used across multiple servers.

This is largely a question of using the same data source. The steps that follow assume that you have already created a database instance (for example, DB2 or Oracle). From there, you must configure the Timer Service to use that database.

There are two ways to configure the Timer Service to share the same database across multiple servers. Choose either step 1 or 2.

1. **Configure a scheduler instance for the cluster, then configure the Timer Service to use that scheduler instance.**

   a. Configure a scheduler instance for the cluster. This creates for you a *custom scheduler instance*. Next you need to configure the Timer Service to use that custom instance.

   b. Open the administrative console.

   c. Click **Servers** >**Application Servers** > *servername* > **EJB Container Settings** > **EJB timer service settings**. The Timer Service settings panel appears.

   d. Select the **Use custom scheduler instance** radio button.

   e. Select your **Scheduler JNDI name** from the dropdown list.

   f. Click **Apply**.

   g. Click **OK**.

2. **Configure the Timer Service default scheduler instance for each server to use the same data source.**

   a. Select the **Use internal EJB timer service scheduler instance** radio button. To customize the pre-configured instance:

   b. To change the data source (you can use any supported database, such as DB2 or Oracle) select your **Data source JNDI name** from the dropdown list. The default database listed cannot be shared, because it is configured to be visible to one server only, and it uses the single server version of Cloudscape, which can only be accessed by one server process at a time.

   c. Enter your chosen **Datasource Alias**.

   d. Enter your chosen **Table Prefix** if you want to have several server processes use the same database, but different tables.

   e. Enter a **Poll Interval** value in milliseconds. For more information about the fields, see "EJB Timer Service settings" on page 172

   f. Click **Apply**.

   g. Click **OK**.

   h. Change all of your server processes to use the same database you chose from the **Data source JNDI name** dropdown list earlier.

Example: Timer Service:

This example shows the implementation of the *ejbTimeout()* method that is called when the scheduled event occurs.

The ejbTimeout method can contain any code normally placed in a business method of the bean. Method-level attributes such as *transaction* or *runAs* can be associated with this method by the application assembler. An instance of the Timer object that causes the method to fire is passed in as an argument to ejbTimeout().

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the EJB container upon Timer expiration.
  public void ejbTimeout(Timer theTimer) {

    // Any code typically placed in an EJB method can be placed here.

     String whyWasICalled = (String) Timer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

In this section, a Timer is created that executes the ejbTimeout() method in 30 seconds. A simple string object is passed in at Timer creation to identify the Timer.

```
// instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

  // save the entity context passed in upon bean creation.
  theEJBContext = theContext;

}

// This business method cause the ejbTimeout method to invoke in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {

  TimerService theTimerService = theEJBContext.getTimerService();
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTinmerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

EJB Timer Service settings:

Use this page to configure and manage the EJB Timer Service for a specific EJB container.

To view this administrative console page, click **Servers** >**Application Servers** > *servername* > **EJB Container Settings** > **EJB Timer Service Settings**.

The two radio buttons that appear on this page offer you choices that are *mutually exclusive*.

Scheduler Type:

Use Internal EJB Timer Service Scheduler Instance:

WebSphere Application Server provides an internal scheduler instance for use by the EJB Timer Service. The internal scheduler instance is pre-configured for basic EJB Timer functionality, and provides limited configuration settings for an EJB Timer Service. Clicking this button specifies that you want to use the internal scheduler instance to manage your tasks. They are persisted to a Cloudscape database associated with the server process. Selecting this choice locks out the *Use Custom Scheduler Instance* option.

This is the default choice.

Use Custom Scheduler Instance:

You can perform a more advanced configuration for the EJB Timer Service by defining a custom scheduler instance. Scheduler configuration provides more configuration options than the internal EJB Timer Service pre-configured scheduler instance. You might want to define a custom scheduler instance when running in a clustered environment, allowing all cluster members to run with a single scheduler instance. This enables EJB Timers created on one cluster member to execute on other cluster members. Providing a custom scheduler instance also enables EJB Timers to be maintained in the same database as other scheduled tasks. Selecting this choice locks out the *Use Internal EJB Timer Service Scheduler Instance* option

Data source JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source where persistent EJB Timers are stored for this EJB container. Any data source available in the name space can be used for EJB Timers. Multiple EJB containers can share a single data source while using different tables by specifying a table prefix.

Data type	String
Default	*jdbc/DefaultEJBTimerDataSource*

Data source alias:

Authentication alias to a user name and password used to access the data source.

Data type	String

Table prefix:

A string prepended to the EJB Timer Service table names (TASK, TREG, LMGR and LMPR). These tables are created during server start if they do not already exist. See help on the Scheduler Service for information about manually creating these tables. Multiple independent EJB Timer Services can share the same database if each instance specifies a different prefix string.

Data type	String
Default	*EJBTIMER_*

Poll interval:

The interval at which the EJB Timer Service daemon polls the database. Each poll operation can be expensive. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources. New Timers set to expire sooner than this interval might not execute until the interval ends. If this value is too large, a potentially large number of timer events might be read into memory, because all the timer events occurring in the next poll interval are read in each time.

Data type	Integer

Units	seconds
Default	300
Range	3 -- 1800

Number of timer threads:

The number of threads used to execute concurrent EJB Timer tasks. Setting the number of Timer Threads to zero disables the EJB Timer Service.

Data type	Integer
Default	1
Range	0 -- 500

Scheduler JNDI name:

This field is only used when the **Use Custom Scheduler Instance** choice is made. It specifies the JNDI name of a custom Scheduler instance to use for managing and persisting EJB Timers. Internal EJB Timer Service Scheduler Instance configuration information is not applied to the specified Scheduler instance.

Data type	String

Developing Enterprise JavaBeans 2.1 for the timer service

In WebSphere Application Server, the **EJB Timer Service** implements EJB Timers as a new kind of Scheduler Service task. By default, an internal (or pre-configured) scheduler instance is used to manage those tasks, and they are persisted to a Cloudscape database associated with the server process.

However, you can perform some basic customization to the internal scheduler instance. For information about how to do this customization, see "Configuring a Timer Service" on page 170.

Creation and cancellation of Timer objects are transactional and persistent. That is, if a Timer object is created within a transaction and that transaction is later rolled back, the Timer object's creation is rolled back as well. Similar rules apply to the cancellation of a Timer object. Timer objects also survive across application server shutdowns and restarts.

1. Write your enterprise bean to implement the *javax.ejb.TimedObject* interface, including the *ejbTimeout()* method. The bean calls the *EJBContext.getTimerService()* method to get an instance of the **TimerService**object. The bean calls the TimerService method to create a Timer. This Timer is now associated with that bean.

2. After you create it, you can pass the Timer instance to other Java code as a *local* object.

   Note: For WebSphere Application Server Version 6, no assembly tooling supports the Enterprise JavaBeans timedObject. To set the ejbTimeout method transaction attribute you must manually enter the attributes in the deployment descriptor. See "EJB Timer Service settings" on page 172 for more information.

Clustered environment considerations for timer service:

In a single server environment, it is clear which server instance should invoke the *ejbTimeout()* method on a given bean. In a multi-server clustered environment there are two possibilities.

- Separate timer service database per server process or cluster member. This is the default configuration. Only the server instance or cluster member that created the Timer can access the Timer and run the *ejbTimeout()* method. If the server instance is unavailable, the Timer does not run at the specified time, and does not run until the server is restarted. Also, if an enterprise bean calls the *findTimers()* method,

only those timers created on the server instance are found. This can cause unexpected behavior if the enterprise bean attempts to cancel all timers associated with it; for example, when the enterprise bean is removed. This configuration is NOT recommended for production level systems.

- Shared or common timer service database for the cluster. Timers can be created and accessed on any server process or cluster member. Timers created in one server process are found by the *findTimers()* method on other server processes in the cluster. When an entity bean is removed, all timers, no matter where created, are cancelled. However, all timers are executed on a single server in the cluster, that is, the *ejbTimeout()* method is run for all timers on a single server. Which server executes the timers varies depending on which server process obtains a lock on the common database tables. If the server executing timers becomes unavailable, then another server or cluster member takes over and begins executing all timers at their scheduled time. This is the recommended configuration for all production level systems.

- **A note about deadlock and access intent:** When using the EJB Timer service in an application using multi-threaded database access, application flow can introduce deadlock problems. To avoid this, use the wsPessimisticUpdate access intent. This access intent causes the finder method in your application to run a *select for update* statement instead of a generic select. This in turn prevents the lock escalation deadlock when multiple threads try to escalate their locks to perform an update.

See "Configuring a Timer Service" on page 170 for information on how to configure the data source (database) to be used for each server process timer service. Note that once the data source for the timer service is changed to point to a different database, the server process automatically attempts to create the required tables in that database on the next server start. If the userid associated with the start of the server process is not authorized to create database tables in the configured timer service database, then the tables must be created manually. For more information, see Creating scheduler tables using DDL files.

Timer service commands:

Information about EJB timers is generally specific to the application that creates the timers, and the timers are not visible outside of the creating application. Therefore, management of EJB timers should be performed by the application that contains the enterprise bean and that creates the EJB timer.

However, you can use the following commands during application development. They provide some basic EJB timer management functions. These commands are not available on *client only* installs.

findEJBTimers

This command displays information about existing EJB timers based on specified filter criteria.

The syntax for this command is:
```
findEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app    application name
           -mod    module name
           -bean   bean name

  options: -host   host name
           -port   portnumber
           -conntype connector type
           -user   userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

where :

server the name of the server process where the EJB timers are located

-all find all EJB timers associated with the server process

timer id
> EJB Timer ID that uniquely identifies the timer

application name
> find all EJB timers associated with the application

module name
> find all EJB timers associated with the module

bean name
> find all EJB timers associated with the enterprise bean

host name
> host name of the server process

portnumber
> port of the server process

connector type
> type of connection. For example, SOAP, RMI, or NONE.

userid user to use when connecting to the server process

password
> password to use when connecting to the server process

quiet disable output

logfile directs output to a file

replacelog
> clears the existing log before executing the command

trace enable trace

help provides command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers created in any of the server processes might be found.

For an example of the findEJBTimers command, see "Example: FindEJBTimers command" on page 177.

cancelEJBTimers

This command cancels and removes from persistent storage EJB timers based on the specified filter criteria.

The syntax for this command is:
```
cancelEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app    application name
           -mod    module name
           -bean   bean name

  options: -host   host name
           -port   portnumber
           -conntype connector type
           -user   userid
```

```
-password password
-quiet
-logfile filename
-replacelog
-trace
-help
```

where :

server the name of the server process where the EJB timers are located

-all find all EJB timers associated with the server process

timer id
EJB Timer ID that uniquely identifies the timer

application name
find all EJB timers associated with the application

module name
find all EJB timers associated with the module

bean name
find all EJB timers associated with the enterprise bean

host name
host name of the server process

portnumber
port of the server process

connector type
type of connection. For example, SOAP, RMI, or NONE.

userid user to use when connecting to the server process

password
password to use when connecting to the server process

quiet disable output

logfile directs output to a file

replacelog
clears the existing log before executing the command

trace enable trace

help provides command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple
servers, then EJB timers created in any of the server processes might be cancelled.

For an example of the cancelEJBTimers command, see "Example: CancelEJBTimers command" on page
178.

Example: FindEJBTimers command:

The following examples illustrate how to use the command to find EJB timers and explain the output
statement.

To use the findEJBTimers command to find *all* Enterprise JavaBeans (EJB) timers on a server called
server1:

```
findEJBTimers server1 -all
```

To find all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
findEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

When EJB timers matching the filter criteria are found, the output appears similar to this:

```
EJB Timer : 25    Expiration: Mon Feb 09 13:36:47 CST 2004    Repeating
 EJB       : DefaultApplication.ear Increment.jar Increment
 EJB Key: 8
 Info : Increment Counter
EJB Timer : 26    Expiration: Mon Feb 09 13:36:47 CST 2004    Single
 EJB       : DefaultApplication.ear Increment.jar Increment
 EJB Key: 8
 Info : Decrement Counter
2 EJB Timers found
```

In this output:

- The *EJB Timer* is the unique identifier of the timer.
- *Expiration* is the next time the timer is expected to execute.
- *Repeating* or *Single* indicates whether the EJB timer is single action or repeating.
- *EJB Key* is the *toString()* method output of the primary key for the Entity enterprise bean (not present for other EJB types).
- *Info* is the *toString()* method output of the object passed by the application when the EJB timer was created.

Only the first 40 bytes of *toString()* output are displayed for the Primary Key and Timer Info. This information is only useful if the application overrides the *toString()* method for these objects.

Increment in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

Example: CancelEJBTimers command:

The following examples illustrate how to use the command to cancel EJB timers.

To use the cancelEJBTimer command to cancel all EJB timers on a server called **server1**:

```
cancelEJBTimers server1 -all
```

To cancel all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
cancelEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

To cancel a specific EJB timer identified through the FindEJBTimers command or from a system log entry indicating a problem or failure:

```
cancelEJBTimers server1 -id 25
```

Increment in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

Web service support

WebSphere Application Server Version 6.0 complies with the Java 2 platform, Enterprise Edition (J2EE) Enterprise JavaBeans (EJB) 2.1 specification by enabling you to expose an EJB stateless session bean as Web service.

You can do this by simply declaring a link between the desired Endpoint name in the Web service deployment descriptor of the EJB module. During deployment and installation of the bean into the Application Server environment, the bean is linked to the specified Web service endpoint.

If you are writing a stateless session bean to implement a preexisting Web Services Description Language (WSDL) interface, you must remember to implement in your bean all of the methods defined on the WSDL interface.

For more information, see "Developing a Web service from an enterprise bean" on page 444.

Binding Web modules to virtual hosts

Web modules must be bound to specific virtual hosts. By associating a Web module to a specific host, you are specifying that all requests that match this virtual host must be handled by the Web application containing the binding.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. In the J2EE view, select the Web module to open its deployment descriptor.
4. On the Overview page, find the WebSphere bindings section.
5. Specify the virtual host name.
6. **Save** the deployment descriptor.

Binding EJB and resource references

Follow these steps to bind an enterprise bean local reference (or nickname) to a Java Naming and Directory Interface (JNDI) name.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. In the J2EE view, select the EJB module to open its deployment descriptor.
4. Switch to the References page.
5. Expand the tree under your chosen bean and select the appropriate reference.
6. In the WebSphere bindings section, specify the JNDI name.
7. Repeat these steps for all the references in the EJB module.
8. **Save** the deployment descriptor.

> **Note:** Reference bindings can be defined or overridden at deployment time in the administrative console for all modules except for application clients. For those, you must use the Application Server Toolkit.

Defining data sources for entity beans

Before an application that is installed on an application server can start, all enterprise bean (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

Create a data source or JDBC resource and give it a Java Naming and Directory Interface (JNDI) name.

For more information, see "Application bindings" on page 1396.

The following steps assume that the entity beans in your application are container-managed persistence (CMP) enterprise beans. The EJB container handles the persistence of the bean attributes in the underlying persistent store. You must specify which data store is used. You do this by binding an EJB module or individual EJB to a data source.

If you bind an EJB *module* to a data source, all beans in that module use the same data source for persistence. If you specify the data source at the bean level, then that data source is used instead.

1. Start the Application Server Toolkit.

2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.

3. In the J2EE view, select the EJB module or individual EJB to open its deployment descriptor.

4. Find the WebSphere bindings section.

5. In the JNDI name field, enter the name of the data source or JDBC resource you want to use.

6. Specify whether the authentication is handled at the container or application level.

7. **Save** the deployment descriptor.

Lightweight local operational mode for entity beans

WebSphere Application Server provides a special operational mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

In lightweight local mode, the container streamlines the processing that it performs before and after every method on the local home interface and local business interface of the bean. This streamlining can result in improved performance when entity bean operations are called locally from within an application. Because some processing is skipped when running in lightweight local mode, this mode can be used in certain scenarios only.

Lightweight local mode is patterned somewhat after the Plain Old Java Object (POJO) entity model introduced in the Enterprise JavaBeans (EJB) 3.0 specification. Using lightweight local mode, you can obtain some of the performance advantages of the POJO entity model without having to convert your existing EJB 2.x application code to the new POJO model. You can apply lightweight local mode to both container-managed persistence (CMP) and bean-managed persistence (BMP) entity types that meet the specific criteria.

For more information about EJB containers, see "Enterprise beans: Resources for learning" on page 148.

When to use the lightweight local mode

Lightweight local mode is designed for entity beans that are created, found, and called using the *Session Facade* pattern. Under this pattern, entity bean local home and local business methods are called from within methods of a stateless session bean or stateful session bean. The session bean methods, which can be called remotely or locally, provide security control and transaction demarcation for the entity beans that are accessed by the session bean.

You can apply lightweight local mode only to an entity bean that meets the following criteria:
• The bean implements an EJB local interface.
• No security authorization is defined on the entity bean local home or local business interface methods.
• No *run-as* security attribute is defined on the local home or local business methods.
• The classes for the calling bean and the called entity bean are loaded by the same Java classloader.
• The entity bean methods do not call the WebSphere Application Server-specific Internationalization Service or Work Area Service.

The first criterion prevents CMP 1.x beans from supporting lightweight local mode, because the 1.x beans cannot have local interfaces.

In addition, lightweight local mode provides its fullest performance benefits only to entity bean methods that do not need to start a global transaction. This condition is true if you ensure that your entity bean also meets the following criteria:
• A global transaction is already in effect when the entity bean home or business method is called. Typically, this transaction is started by the calling session bean.
• The local business interface methods and the local home methods of the entity bean use the following transaction attributes only: REQUIRED, SUPPORTS, or MANDATORY.

If an entity bean method that is running in lightweight local mode must start a global transaction, the bean still functions normally but only a partial performance benefit is realized.

You can mark an entity bean that defines a remote interface or a TimedObject interface, in addition to the local interface, for lightweight local mode. However, the performance benefit is apparent only when the bean is called through its local interface.

Applying lightweight local mode to an entity bean

WebSphere Application Server provides a special operational mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

You can apply lightweight local mode to specific EntityBean types within your application in two ways. You can use application server tooling, or the Marker interface technique.

Using Application Server Tooling:

1. Start the Application Server Toolkit.
2. Select the EJB deployment descriptor of the entity bean that you want to work with.
3. In the **property** pane, select the **WebSphere Extension** tab.
4. Check the box labeled *Use Lightweight Local mode* .
5. Select OK.
6. Save your changes.

Marker interface technique:

Use the marker interface technique when a group of beans within the application is related through a common inheritance hierarchy, and all the beans in the hierarchy are to be marked. For an application with a large number of beans in a hierarchy, this technique is the most efficient.

To use a marker interface, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.LightweightLocal** interface. The bean implementation class does not need to directly implement the interface; any parent class or interface can also implement it. For details, see the **com.ibm.websphere.ejbcontainer** package in the API documentation section of the information center.

Using access intent policies

You can use access intent policies to help the product runtime environment manage various aspects of Enterprise JavaBeans (EJB) persistence.

You apply access intent policies to EJB Version 2.0 (and later) entity beans and their methods by using an application assembly tool. A set of default access intent policies comes with the Application Server Toolkit (AST) .

1. Apply default access intent to CMP entity beans. For more information, see the online help available with the Application Server Toolkit.
2. Apply access intent policies to methods of CMP entity beans.

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. You can set access intents only within EJB Version 2.x-compliant modules for entity beans with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic/update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

transition: Access intent policies are specifically designed to supplant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.x enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling.

Note: Method level access intent has been deprecated for Version 6.

You can use application profiling or method level access intent policies to control access intent more precisely. Method-level access intent policies are named and defined at the module level. A module can have one or many such policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A method-based policy is acted upon by the combination of the EJB container and persistence manager when the method causes the entity to load.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. The top down default mapping excludes nullable fields. You can override this when doing a meet-in-middle mapping. The fields used in overqualified updates are specified in the ejb-rdb mapping. If nullable columns are selected as overqualified columns, then partial update should also be selected.

Note: When using DB2 for z/OS Version 8, nullable OCC columns create no problems. This is true for JDBC and SQLJ deploy options, and partial and full update.

An entity that is configured with a read-only policy that causes a bean to be activated can cause problems if updates are attempted within the same transaction. Those changes are not committed, and the process throws an exception because data integrity might be compromised.

Concurrency control:

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time over which a given resource would be unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately afterwards. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test whether the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

best-practices: Whether or not to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. (A high-penalty transaction is one for which recovery would be risky or resource-intensive.) For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints:

Read-ahead schemes enable applications to minimize the number of database round trips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query. Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that an application most likely needs next. A *read-ahead hint* is a representation of the related beans to read. The hint is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on the container-managed relationships (CMRs) that are defined for the bean. The following example is provided as supplemental information only. Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: `RelB.RelC; RelD`

Interpret the preceding notation as follows:
* Bean type A has a CMR with bean types B and D.
* Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as the order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once (for example, `RelB.RelC;RelB.RelE`), the data columns for a bean occur only once in the result set, at the position the bean first occupies in the hint.

The tokens shown in the notation (*RelB* and so on) must be CMR field names for the relationships, as defined in the deployment descriptor for the bean. In indirect relationships such as `RelB.RelC`, *RelC* is a CMR field name that is defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has an *employees* relationship with the Employee bean and also has a *manager* relationship with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Rational Application Developer product.

Run-time behaviors of read-ahead hints

When developing your read-ahead hints, consider the following tips and limitations:

- Read-ahead hints on long or complex paths can result in a query that is too complex to be useful. Read-ahead hints on root or leaf inheritance mappings need particular care. Add up the number of tables that potentially comprise a read-ahead preload to gauge the complexity of the join operations that are required. Consider if the resulting statement constitutes a reasonable query on your target database.
- Read-ahead hints do not work in the following cases:
  - Preload paths across M:N relationships
  - Preload paths across recursive enterprise bean relationships or recursive fk relationships
  - When a read-head hint applies to a SELECT FOR UPDATE statement that requires a table join in a database that does not support the combination of those two operations.

    Generally, the persistence manager issues a SELECT FOR UPDATE statement for a bean only if the bean has an access intent that enforces strict locking policies. Strict locking policies require SELECT FOR UPDATE statements for database select queries. If the database table design requires a join operation to fulfill the statement, many databases issue exceptions because these databases do not support table joins with SELECT FOR UPDATE statements. In those cases, WebSphere Application Server does not implement a read-ahead hint. If the database does provide that support, Application Server implements the read-ahead hints that you configure.

    DB2 Universal Database V8.2 supports SELECT FOR UPDATE statements with table joins.
  - When a read-ahead hint contains a table join

    Different access intents can result in requiring a SELECT FOR UPDATE statement. Check the matrix on the JDBC driver and SELECT FOR UPDATE support to see if readAhead is enabled.

Database deadlocks caused by lock upgrades:

To avoid databse deadlocks caused by lock upgrades, you can change the access intent policy for entity beans from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate or can use an optimistic locking approach.

When accessing data in a database concurrently, an application must be aware of and prepared for database locking that must occur to insure the integrity of the data.

If an entity bean performs a findByPrimaryKey (which by default obtains a 'Read' lock in the database), and the entity bean is updated within the same transaction, then a lock upgrade (to 'Exclusive') occurs.

If this scenario occurs on multiple threads concurrently, then a deadlock can happen. This is because multiple 'Read' locks can be obtained concurrently, but one 'Exclusive' lock can be obtained only when all other locks have been dropped. Because all transactions are attempting the lock upgrade in this scenario, this one 'Exclusive' lock can never be obtained .

To avoid this problem, you can change the access intent policy for the entity bean from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate. This change in access intent enables the application to inform WebSphere and the database that the transaction will update the enterprise bean, and so an 'Update' lock is obtained immediately on the findByPrimaryKey. This avoids the lock upgrade when the update is performed later.

The preferred technique to define access intent policies is to change the access intent for the entire entity bean. You can change the access intent for the findByPrimaryKey method, but this is deprecated in Version 6.0. (You might want to change the access intent for an individual method if, for example, the entity bean is involved in some transactions that are read only.)

An alternative technique is to use an optimistic approach, where the findByPrimaryKey method does not hold a 'Read' lock, so there is no lock upgrade. However, this requires that the application is coded for this, to handle rollbacks that could occur. Optimistic locking is really intended for applications that do not expect database contention on a regular basis.

To change the access intent policy for an entity bean, you can use the assembly tool to set the ″Default Access Intent for Entities 2.x (Bean Level)″ on the Access tab of the EJB Deployment Descriptor, as described in "Applying access intent policies to beans" on page 187.

Access intent assembly settings:

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

These settings are applicable only for EJB 2.x-compliant entity beans that are packaged in EJB 2.x-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name:

Specifies a name for a mapping between an access intent policy and one or more methods.

Description:

Contains text that describes the mapping.

Methods - Name:

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean's remote and home interfaces.

Methods - Enterprise bean:

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - Type:

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are `Home`, `Remote`,`Local`, `LocalHome` or `Unspecified`

Methods - Parameters:

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent:

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String

Default	wsPessimisticUpdate-WeakestLockAtLoad. With Oracle, this is the same as wsPessimisticUpdate.
Range	Valid settings are wsPessimisticUpdate, wsPessimisticUpdate-NoCollision, wsPessimisticUpdate-Exclusive, wsPessimisticUpdate-WeakestLockAtLoad, wsPessimisticRead, wsOptimisticUpdate, or wsOptimisticRead. Only wsPessimisticRead and wsOptimisticRead are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (*next()*) does not trigger a remote method call to retrieve the next remote reference. Two policies (wsPessimisticUpdate and wsPessimisticUpdate-Exclusive) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

If an entity is not configured with an access intent policy, the run-time environment typically uses wsPessimisticUpdate-WeakestLockAtLoad by default. If, however, the **Lifetime in cache** property is set on the bean, the default value of **Applied access intent** is wsOptimisticRead; updates are not permitted.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
wsPessimisticRead (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate-Exclusive (Note 3)	pessimistic	update	serializable
wsPessimisticUpdate-NoCollision (Note 4)	pessimistic	update	read committed
wsPessimisticUpdate-WeakestLockAtLoad (Note 5)	pessimistic	update	Repeatable read
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:
1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. A plain SELECT query is generated. No locks are held, but updates are permitted. Use cautiously. This intent enables execution without concurrency control.
5. Where supported by the backend, the generated SELECT query does not include FOR UPDATE; locks are escalated by the persistent store at storage time if updates were made. Otherwise, the same as wsPessimisticUpdate.
6. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

   Be sure to review the rules for forming overqualified-update query predicates. Certain column types (for example, BLOB) are ineligible for inclusion in the overqualified-update query predicate and might affect your design.

Access intent for both entity bean types

Container-managed persistence (CMP) developers can use *access intent* to provide hints on how the application server run time should manage the details of persistence without having to explicitly manage any of the persistence logic from within their application.

Using the access intent service is also an option for programmers who develop bean-managed persistence (BMP) entity beans. Because the only meaningful difference between BMP and CMP components is the mechanism that provides the persistence logic, BMP beans leverage access intent hints in the same manner as the EJB container manages accent intent for CMP beans. This ability becomes especially important when BMP entities and CMP entities want to share connections. BMP beans configured with the same concurrency as the CMP beans and implemented to the same isolation level mapping as the CMP can share connections.

Developers can apply access intent policies to BMP entity beans as well as to CMP entity beans. It is expected that BMP developers use only those access intent attributes that are important to a particular BMP bean. The access intent service interface is bound into the *java:comp namespace* for each particular BMP bean. The access intent policy retrieved from the access intent service is current from the time that the *ejbLoad* process is called until the time that the *ejbStore* process completes its invocation.

Applying access intent policies to beans

You can apply an access intent policy to an application's entity beans through the assembly tool.

Note: This is the preferred technique to define access intent policies. Method-level access intent is deprecated in Version 6.0.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:
   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. In the **Access Intent for Entities 2.x (Bean Level)** panel, select the name of the bean.
8. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
9. In the **Access intent name** field, select wsPessimisticUpdate from the drop-down list.
10. **Optional:** Enter a **Description** to help you remember what this policy does.
11. **Optional:** Change the **Persistence Option** setting
12. Click **Finish**. The access intent policy for the entity bean is shown in the **Access Intent for Entities 2.x (Bean Level)** panel

Configuring read-read consistency checking with the assembly tools

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking.

For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using the Application Server Toolkit.

1. Start the Application Server Toolkit.

2. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.

3. Select the **Access** tab. The Add Access Intent window appears. There are two areas of the panel that deal with adding access intent:

   - Default Access Intent for Entities 2.x (Bean Level)

   - Access Intent for Entities 2.x (Method Level)

4. Select the Bean or Method level. Another access intent window appears where you can set the properties you wish to use.

5. Use the dropdown list to select the Access intent name.

6. **Optional:** Enter a description.

7. Check the **Persistence Option** box.

8. Check the **Verify Read Only Data** box.

9. Use the dropdown list to select your choice for read-read consistency checking. You have three options:

   NONE No read-read checking is done.

   AT_TRAN_BEGIN
   During ejbLoad, if the data is from cache, check the database to ensure that the data of the bean (with proper locking based on access intent's concurrency control attribute) has not changed since the last load.

   AT_TRAN_END
   At the end of transaction, if the bean is not changed and did not load by the current transaction, check the database to ensure that the data of the bean has not changed from last load (with proper locking based on access intent's concurrency control attribute.) If the data has changed, fail the transaction.

10. Select **Finish**.

Examples: read-read consistency checking:

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction.

Usage scenario

For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, but it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in ″Ann's″ bank account. In each case, the data store is shared by this EJB CMP application (to calculate the interest) and other applications, such as EJB BMP, JDBC, or legacy applications. Also in each case, the EJB Account is configured as a "long-lifetime" bean.

NONE

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- Calculate Ann's interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- PM performs read-read check on Ann's account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann's data in the cache is refreshed.
- Calculate Ann's interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from database, with balance of $100.
- Calculate Ann's interest.
- During end of transaction 2, PM performs read-read check on Ann's account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is a WebSphere Application Server runtime service that enables you to more precisely manage an application's persistence.

The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a

specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Generally you configure *bean level* access intent for your applications. You can also apply access intent policies to beans within the scope of *application profiles*. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Support for applying access intent policies at the method level is deprecated in WebSphere Application Server Version 6.0. In this practice of configuring access intent, you apply a policy to methods within the scope of an EJB module so that the policy becomes the default access intent for all requests upon those methods.

Access intent with BMP entity beans:

Access intent's declarative functionality provides great power to you as a CMP entity bean developer. You can provide hints on how WebSphere Application Server is to manage the details of persistence without having to explicitly manage any of the persistence logic from within the application.

There are situations, however, in which you might need to develop BMP entity beans. Because the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP entity beans should be able to leverage access intent hints just as WebSphere Application Server does on behalf of CMP entity beans. BMP entity beans that use the access intent service participate in application profiling; that is, the value of the access intent attributes can differ from request to request, allowing the BMP entity bean to seamlessly modify its persistence strategy.

You can apply access intent policies to BMP entity bean methods as well as CMP entity bean methods. Because access intent hints are not contractual in nature, there is no obligation for a BMP entity bean to exploit them. BMP entity beans are expected to use only those access intent attributes that are important to that particular bean.

The current access intent policy is bound into the java:comp namespace for a particular BMP entity bean. That policy is current only for the duration of the method call during which the access intent policy was retrieved. In a typical scenario, you would cache the access type during invocation of the ejbLoad() method so that appropriate actions can be taken during invocation of the ejbStore() method.

Access intent design considerations

Use the access intent service to solve clear performance problems. Identify usage patterns that lead to poor application performance and apply appropriate access intent policies.

best-practices: Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is confusingly configured with multiple access intent policies.

Note: Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles.

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the runtime environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad() method is driven to

open a connection to, and read data from, a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore() method. Read-ahead hints are only used during the execution of a finder for a bean. Finally, the collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that will not use the policy is not an error (only certain attributes of any policy are used, even when the policy is appropriately applied to a method). However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tool.

Note: Method-level access intent is deprecated in Version 6.0.

1. Start the Application Server Toolkit.
2. **Optional:** Open the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other > J2EE**.
3. **Optional:** Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. **Optional:** Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. **Optional:** Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

    Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.
16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.

18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.

19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.

20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of BMP entity bean methods.

1. Look up the current access intent in the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntent ai = ic.lookup("java:comp/websphere/AppProfile/AccessIntent");
```

2. Call the necessary get() methods. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
    && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
      int exclusive = ai.getPessimisticUpdateLockHint();
      // . . .
}
// . . .
```

Note: The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean's method; the reference does not exist during a request on a CMP entity bean. Therefore, access intent object references should not be cached beyond, or used outside of, the scope of the execution of any given BMP method.

AccessIntent interface:

The AccessIntent interface is available to BMP entity beans.

The following JNDI lookup allows BMP entity beans to access the AccessIntent interface:

```
java:comp/websphere/AppProfile/AccessIntent
```

AccessIntent interface

```
package com.ibm.websphere.appprofile.accessintent;

/**
* This interface defines the essential access intents
* available at run time.
*/
public interface AccessIntent {

/**
* Returns the concurrency control intent, which indicates
* the application prefers either pessimistic or optimistic
* concurrency control when accessing the current component
* in the context of the current transaction.
*/
public int getConcurrencyControl();
public final int CONCURRENCY_CONTROL_PESSIMISTIC = 1;
public final int CONCURRENCY_CONTROL_OPTIMISTIC = 2;

/**
* Returns access type intent, which indicates the application
* intends either update or read access of the current component
```

```
* in the context of the current transaction.
*/
public int getAccessType();
public final int ACCESS_TYPE_UPDATE= 1;
public final int ACCESS_TYPE_READ = 2;

/**
* Returns an integer value that indicates that the run time should
* assume that there will be no collision on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/*
* Returns an integer value that indicates that the run time should
* assume that there will be collisions on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/**
* Returns the collection access intent, which indicates the
* application intends to access the objects returned by the
* currently executing finder in either serial or random fashion.
*/
public int getCollectionAccess();
public final int COLLECTION_ACCESS_RANDOM = 1;
public final int COLLECTION_ACCESS_SERIAL = 2;

/**
* Returns the collection scope, which indicates the maximum
* lifespan of a lazy collection.
*/
public int getCollectionScope();
public final int COLLECTION_SCOPE_TRANSACTION = 1;
public final int COLLECTION_SCOPE_ACTIVITYSESSION = 2;
public final int COLLECTION_SCOPE_TIMEOUT = 3;

/**
* Returns the timeout value in seconds when collectionScope is Timeout.
*/
public int getCollectionTimeout();

/**
* Returns the number of elements the application requests be contained
* in each segment of the element collection returned by the currently
* executing finder.
*/
public int getCollectionIncrement();

/**
* Returns the ReadAheadHint requested by the application for the currently
* executing finder.
*/
public ReadAheadHint getReadAheadHint();

/**
* Returns the number of elements the application requests be contained in
* each segment of a query made on a database.
```

```
*/
public int getResourceManagerPreFetchIncrement();

}
```

Access intent exceptions

The exceptions thrown in response to the application of access intent policies are listed.

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

> If the method that drives the ejbLoad() method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation of the ejbStore() method, and the transaction is rolled back. Likewise, the ejbRemove() method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean` *beanName*

> This exception is also thrown if the applied access intent policy cannot be honored because a finder, ejbSelect, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec -` *methodName*

> The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a USE AND KEEP UPDATE LOCKS clause on the SQL SELECT statement to be executed, but a read-only query cannot support USE AND KEEP UPDATE LOCKS. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

> To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.
> - If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
> - If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
> - If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed

> If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a CollectionCannotBeFurtherAccessed exception is thrown.

com.ibm.ws.exception.RuntimeWarning

> If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the verify function. Some examples of misconfiguration include:
> - A method configured with two different access intent policies
> - A method configured with an undefined access intent policy

Access intent best practices

When applying access intent policies to Enterprise JavaBeans (EJB) methods, consider the following issues.
- **Start by configuring the default access intent policy for an entity.** After your application is built and running, you can more finely tune certain access paths in your application using application profiling or method-level access intent.
- **Don't mix access types.** Avoid using both pessimistic and optimistic policies in the same transaction. For most databases, pessimistic and optimistic policies use different isolation levels. This can result in multiple database connections, which prevents you from taking advantage of the performance benefits possible through connection sharing.

- **Take care when applying `wsPessimisticUpdate-NoCollision`.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction will attempt to update persistent store at any given time.

Frequently asked questions: Access intent

The following frequently asked questions involving access intent are answered.

I have not applied any access intent policies at all. My application runs just fine with a DB2 database, but it fails with an Oracle database with the following message: *com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec :FindAllCustomers. The backend datastore does not support the SQLStatement needed by this AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource manager prefetch: 0) (AccessIntentImpl@d23690a)*. Why?

If you have not configured access intent, all of your data is accessed under the default access intent policy (`wsPessimisticUpdate-WeakestLockAtLoad`). On DB2 the weakest lock is share. On Oracle databases, however, the weakest lock is update; this means that the SQL query must contain a FOR UPDATE clause. To avoid this problem, try to apply an access intent policy that supports optimistic concurrency.

I am calling a finder method and I get an InconsistentAccessIntentException at run time. Why?

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean instance with access intent policy X applied; you are now trying to load the second bean again by calling its findByPrimaryKey method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

I have two beans in a container-managed relationship. I call findByPrimaryKey() on the first bean and then call getBean2( ), a CMR accessor method, on the returned instance. At that point, I get an InconsistentAccessIntentException. Why?

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean. However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

I have a bean with a one-to-many relationship to a second bean. The first bean has a pessimistic-update intent policy applied. When I try to add an instance of the second bean to the first bean's collection, I get an UpdateCannotProceedWithIntegrityException. Why?

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. (The second bean contains a foreign key to the first bean, which is modified.)

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

Assembling EJB modules

An enterprise bean is a Java component that can be combined with other resources to create Java 2 Platform, Enterprise Edition (J2EE) applications.

This topic assumes that you have created and unit tested an enterprise bean (EJB file) that you want to assemble in an enterprise application and deploy onto an application server.

Assemble an Enterprise JavaBeans (EJB) module to contain enterprise beans and related code artifacts. Group Web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a standalone application or combine it with other modules into an enterprise application.

Use an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file).
- Create a new EJB module.
- Copy code artifacts (such as entity beans) from one EJB module into a new EJB module.

For information on assembling EJB modules, refer to the online documentation or the information center for your assembly tool. This topic points you to AST documentation. The Application Server Toolkit information center accompanies this WebSphere Application Server information center.

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **J2EE** and **EJB** capabilities are enabled.
3. Migrate enterprise bean (JAR) files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your enterprise bean files to the assembly tool.
4. Create a new EJB module.
5. Copy code artifacts (such as entity beans) from one EJB module into a new EJB module.

An EJB module is migrated or created, reflecting the J2EE folder structure that specifies the location of enterprise bean content files, class files, class paths, the deployment descriptor, and supporting metadata. Files for the EJB module are shown in the Project Explorer view under **Enterprise Applications** and **EJB Projects**.

After you finish assembling your EJB module, you are ready to deploy your module.

You can generate EJB deployment code and deploy the module to a target server in one step. In the Project Explorer view, right-click on the EJB project and click **Deploy**.

Container transactions

Container transaction properties specify how an EJB container is to manage transaction scopes for the enterprise bean's method invocations. A transaction attribute is mapped to one or more methods.

Defining container transactions for EJB modules:

Some container transaction settings are not available for all enterprise beans. Also, some methods are not available for particular transaction settings and beans. These rules have been implemented in the Add Container Transaction wizard based on the EJB 1.1 and EJB 2.x specifications.

To add a container transaction to an enterprise bean:

1. In the Project Explorer view of the J2EE perspective, right-click the Deployment Descriptor for your EJB project and select **Open With** → **Deployment Descriptor Editor** to open the deployment descriptor editor.
2. On the **Assembly** page of the editor, click **Add** in the Container Transactions section.
3. Select one or more enterprise beans from the list of beans found.
4. Select a container transaction type from the following choices:
   - **NotSupported -** Directs the container to invoke bean methods without a transaction context. If a client calls a bean method from within a transaction context, the container suspends the association between the transaction and the current thread before invoking the method on the enterprise bean instance. The container then resumes the suspended association when the method invocation returns. The suspended transaction context is not passed to any enterprise bean objects or resources that are used by this bean method.
   - **Supports -** Directs the container to invoke the bean method within a transaction context if the client calls the bean method within a transaction . If the client calls the bean method without a transaction context, the container calls the bean method without a transaction context. The transaction context is passed to any enterprise bean objects or resources that are used by this bean method.
   - **Required -** Directs the container to invoke the bean method within a transaction context. If a client calls a bean method from within a transaction context, the container calls the bean method within the client transaction context. If a client calls a bean method outside a transaction context, the container creates a new transaction context and calls the bean method from within that context. The transaction context is passed to any enterprise bean objects or resources that are used by this bean method.
   - **RequiresNew -** Directs the container to always invoke the bean method within a new transaction context, regardless of whether the client calls the method within or outside a transaction context. The transaction context is passed to any enterprise bean objects or resources that are used by this bean method.
   - **Mandatory -** Directs the container to always invoke the bean method within the transaction context associated with the client. If the client attempts to invoke the bean method without a transaction context, the container throws the javax.jts.TransactiononRequiredException exception to the client. The transaction context is passed to any EJB object or resource accessed by an enterprise bean method. EJB clients that access these entity beans must do so within an existing transaction . For other enterprise beans, the enterprise bean or bean method must implement the Bean Managed value or use the Required or Requires New value. For non-enterprise bean EJB clients, the client must invoke a transaction by using the javax.transaction.UserTransaction interface.
   - **Never -** Directs the container to invoke bean methods without a transaction context. If the client calls a bean method from within a transaction context, the container throws the java.rmi.RemoteException exception. If the client calls a bean method from outside a transaction context, the container behaves in the same way as if the Not Supported transaction attribute was set. The client must call the method without a transaction context
5. Select one or more methods elements from the list.
6. Click **Finish**.

The container transaction is added and displayed in the Container Transactions section, where the container transactions are listed by container transaction type.

After you define container transactions, you can use the deployment descriptor editor to work with them. Information about the editor can be found in the WebSphere Application Server Express documentation.
- To edit a container transaction, select it from the Container Transactions list and click **Edit**.

- To delete a container transaction, select from the list and click **Remove**.
- To take multiple container transactions that are the same container transaction type and combine them into a single container transaction definition, click **Combine**.

Method extensions

Method extensions are IBM extensions to the standard deployment descriptors for enterprise beans.

Method extension properties are used to define transaction isolation levels for methods, to control the delegation of a principal's credentials, and to define custom finder methods.

Method permissions

A method permission is a mapping between one or more security roles and one or more methods that a member of the role can call.

References

References are logical names used to locate external resources for enterprise applications. References are defined in the application's deployment descriptor file. At deployment, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment.

This product supports the following types of references:
- An EJB reference is a logical name used to locate the home interface of an enterprise bean.
- A resource reference is a logical name used to locate a connection factory object.

These objects define connections to external resources such as databases and messaging systems. The container makes references available in a JNDI naming subcontext. By convention, references are organized as follows:
- EJB references are made available in the java:comp/env/ejb subcontext.
- Resource references are made available as follows:
  - JDBC DataSource references are declared in the java:comp/env/jdbc subcontext.
  - JMS connection factories are declared in the java:comp/env/jms subcontext.
  - JavaMail connection factories are declared in the java:comp/env/mail subcontext.
  - URL connection factories are declared in the java:comp/env/url subcontext.

EJB references:

Use this page to view and modify the Enterprise JavaBeans (EJB) references to the enterprise beans.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **EJB references** .

Module:

Specifies the name of the Enterprise JavaBeans module used by your application.

EJB:

Specifies the name of an enterprise bean that is contained by the module.

URI:

Specifies location of the module relative to the root of the application EAR file.

Reference binding:

Specifies the name of the EJB reference that is used in the enterprise bean, if applicable, and declared in the deployment descriptor of the application module.

Class:

Specifies the name of a Java class associated with this enterprise bean.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Data type	String

EJB JNDI names for beans:

Use this page to view and modify the Java Naming and Directory Interface (JNDI) names of non-message-driven enterprise beans in your application or module.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **EJB JNDI Names** .

EJB module:

Specifies the name of the Enterprise Javabeans module used by your application.

EJB:

Specifies the name of an enterprise bean that is contained by the module.

URI:

The Uniform Resource Identifier (URI) specifies the location of the module archive relative to the root of the application EAR.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Data type	String

Sequence grouping for container-managed persistence

After assembling an Enterprise JavaBeans (EJB) module that contains container-managed persistence (CMP) beans, you can prevent certain types of database-related exceptions from occurring during application run time. Using *sequence grouping*, you can specify the order in which entity beans update relational database tables.

Eliminate exceptions resulting from referential integrity (RI) violations

Sequence grouping is particularly useful for preventing violations of database *referential integrity* (RI). A database RI policy prescribes rules for how data is written to and deleted from the database tables to

maintain relational consistency. Run-time requirements for managing bean persistence, however, can cause an EJB application to violate RI rules, which can cause database exceptions. These run-time requirements mandate that:

- Entity bean create and remove operations correlate to the database immediately upon method invocation.
- Entity bean changes are cached by the EJB container until either a finder method is called, or the transaction ends.

Consequently, the order in which entity beans update the database is unpredictable. That randomness translates into high risk of the application violating database RI. Although caching the operations for batch processing overrides these run-time requirements, it does not guarantee a bean persistence sequence that follows any given RI policy.

The only way to guarantee a persistence sequence that honors database RI is to designate the sequence, which you do in the EJB deployment descriptor editor of the assembly tool. Through the sequence grouping feature, you assign beans to CMP groups. Within each group you specify the order in which the persistence manager inserts bean data into the database to accomplish updates without violating RI.

See the "Setting the run time for CMP sequence groups" topic for detailed instructions on designating sequence groups. Consult your database administrator about the RI policy with which you need to synchronize.

Minimize exception risk for optimistic concurrency control schemes

Sequence grouping can also reduce the risk of transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. In these concurrency control schemes, database locks are held for minimal amounts of time so that a maximum number of transactions consistently have access to the data. The relatively unrestricted state of the database can lead to transaction rollback exceptions for two common reasons:

- When concurrent transactions attempt to lock the same table row, database deadlock occurs.
- Transactions can occur in an order that violates application logic.

Use the sequence grouping feature to order bean persistence so that these scenarios are less likely to occur.

Setting the run time for CMP sequence groups

By designating CMP sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your EJB application. Within each group you specify the order in which the beans update your relational database tables.

When you define a sequence group, you designate it as one of two types:

- RI_INSERT, for setting a bean persistence sequence to prevent database referential integrity (RI) violations
- UPDATE_LOCK, for setting a bean persistence sequence to minimize exceptions resulting from optimistic concurrency control

Both types of sequence groups must be created after you have assembled the beans into an EJB module, prior to installing your application on the product. If you need to edit sequence groups, you must uninstall the application, make your changes using the following steps as a guide, and then reinstall your application.

Note: If you already selected or plan to use top-down mapping for mapping your enterprise beans to back end data, you do not need to create a sequence group with an RI_INSERT type. The product does not generate an RI policy for the database schema that it creates when you select top-down mapping.

1. Start an assembly tool. Refer to *Starting WebSphere Application Server Toolkit* in the Application Server Toolkit documentation.
2. Open the J2EE perspective. Click **Window > Open perspective > J2EE**.
3. In a J2EE hierarchy view (**Window > Show view > J2EE hierarchy**), right-click the EJB module containing beans that require sequence grouping, and click **Open with > EJB deployment descriptor editor**. The EJB deployment descriptor editor for the module is displayed in a view.
4. Click the **Overview** tab.
5. In the **EJB CMP sequence groups** section, click **Add**. The **EJB CMP Sequence Group** wizard panel is displayed.
6. Type a name for your sequence group.
7. Type your group type designation in all capital letters: RI_INSERT or UPDATE_LOCK
8. In the **Available Beans** list, highlight the first bean that you want to place in the group. Click the arrow pointing toward the **Selected beans** list. The bean name is removed from the Available beans list and is displayed in the Selected beans list.
9. Repeat the previous step until you complete your sequence group. You must add each bean in the order that you want the persistence manager to handle it. In the case of delete operations for an RI_INSERT group, the persistence manager reverses the order that you designate and deletes the beans and their corresponding database rows accordingly. If you need to alter the sequence of your group, select a bean and click the arrow to move the bean one position vertically.
10. Save your changes to the deployment descriptor.
    a. Close the EJB deployment descriptor editor.
    b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.

    You also can save changes to deployment descriptors at any time by pressing Ctrl+S.

You are now ready to deploy your EJB module or combine it with other modules into a J2EE application.

Deploying EJB modules

When you deploy an EJB module, you install that module on a server that has been configured to support deployed modules.

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application.
1. Prepare the deployment environment.
2. Update the configuration for each EJB module as needed for the deployment environment. See the AST information center for more information about modifying deployment descriptors.
3. Deploy the application.

If you specify that EJB deploy be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input JAR or EAR file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module.

Troubleshooting tips for EJBDEPLOY relationships
This article provides troubleshooting information for EJBDEPLOY problems.

The converter that is defined for the primary key is not invoked on its foreign key value

The mapping for primary key fields to database columns may use a converter to transform the key values. If a container-managed persistence (CMP) bean uses a converter to map its primary key, and that bean has a relationship where the bean at the other end holds a foreign key, the mapping for the foreign key will not use the converter.

The following errors might occur, indicating that the converter defined for the primary key is not invoked on its foreign key value. During the run of the ejbDeploy command , you receive the following message:

```
No type mapping defined for Java datatype1 to Database datatype2
```

During run time, the application does not find the CMP bean at the other end of the relationship.

To work around this limitation, define your own foreign key in the database table, and create a mapping that uses the same converter as defined for the primary key on the enterprise beans at the other end of its relationship.

EJB module settings
Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications > Enterprise Applications >** *applicationName* **> Manage Modules >** *moduleName*.

URI:

Specifies location of the module relative to the root of the application EAR file. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate deployment descriptor:

Specifies an alternate deployment descriptor for the module as defined in the application deployment descriptor according to the J2EE specification.

Starting weight:

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

EJB deployment tool
Before you can successfully run your enterprise beans on either a test or production server, you need to generate deployment code for the enterprise beans. The EJB deployment tool provides a command-line interface that you can use to generate enterprise bean deployment code. The tool employs this command-line environment that enables you to run a build process overnight and have the deployment tool automatically invoked to generate your deployment code in batch mode.

The EJB deployment tool is invoked from the command line using the ejbdeploy command, which accepts an input EJB JAR or EAR file that contains one or more enterprise beans. It then generates an output, deployed JAR file or EAR file that contains deployment code in the form of .class files.

For a complete description of all of the options available to the ejbdeploy, see the related reference The ejbdeploy command.

The EJB deployment tool supports EJB single and multiple table inheritance. It supports the use of converters, which translate a database representation to a Java™ object type, and composers, which are used to map a single, complex bean field to multiple database columns. The EJB deployment tool supports the following levels of access intent (where AccessIntent is a WebSphere® extension):

1. wsPessimisticUpdateWeakestLockAtLoad
2. wsPessimisticUpdate
3. wsPessimisticUpdate-NoCollision
4. wsPessimisticUpdate-Exclusive
5. wsPessimisticRead
6. wsOptimisticUpdate
7. wsOptimisticRead

For more information on these access intents, see the related topic *Access intent and isolation level*.

In addition to these values, an access intent can also contain an optional *read ahead* hint.

Note: The *read ahead* hint indicates how deeply to read ahead in an EJB relationship graph.

2.0 EJB projects only: Mapping to multiple back-end databases is also supported. The schemas and the generated data definition language (DDL) file are stored in the following directory of the JAR or EAR file:

META-INF\backends*backend_id**databasename*.dbm

META-INF\backends*backend_id*\Table.ddl

If multiple backends exist and you did not set the current back-end ID in the EJB deployment descriptor, the EJB deployment tool will default to the first back-end ID that appears as a folder in the respective META-INF\backends directory as described earlier. If you map to a single backend database, then the generated DDL file will appear both in the directory as described above and also in the META-INF folder.

You can perform the following tasks with the EJB deployment tool:
- Generating deployment code for enterprise beans from the command line
- Implementing finders for CMP entity beans

Also refer to Message format for EJB validation to understand the format used for messages generated by the EJB validator.

Generating deployment code for enterprise beans from the command line:

The EJB deployment tool provides a command-line interface that you can use to generate enterprise bean deployment code. Before you can successfully run your enterprise beans on either a test or production server, you need to generate deployment code for the enterprise beans.

You generate EJB deployment code by running the `ejbdeploy` command.

Running the EJB deployment tool from the command line:
1. Open a command prompt.
2. Type the following at the prompt:

> ▶ Windows ◀ `ejbdeploy in.ear tmp out.ear`

> **UNIX** > **z/OS** > **400** `ejbdeploy.sh in.ear tmp out.ear`

This generates a EAR file called `out.ear`.

The following activities occur when you run the `ejbdeploy` command:

1. Code is imported from the input JAR or EAR file.
2. A top-down mapping is created if one does not exist.
3. Deployment code is generated.
4. The deployment code is compiled.
5. Remote Method Invocation Compiler (RMIC) is run.
6. Code is exported to the output JAR or EAR file.

Note: For CMP entity beans, a data definition language (DDL) file is generated that can be used to create corresponding database tables that are mapped to CMP fields. The DDL file is contained within the META-INF\backends*backend_id* directory and entitled Table.ddl

The ejbdeploy command:

Before you can successfully run your enterprise beans on either a test or production server, you need to generate deployment code for the enterprise beans. This reference topic describes what is the syntax, expected behavior, and descriptions of each of the parameters for running the ejbdeploy command from a command line.

Syntax

Use the following command and the optional parameters, when the schema and map are provided in the input EAR or JAR file:

```
ejbdeploy input_EAR_name|input_JAR_name working_directory output_EAR_name|output_JAR_name
[-bindear "options"] [-cp classpath] [-codegen] [-debug] [-keep] [-ignoreErrors] [-quiet]
[-nowarn] [-noinform] [-rmic "options"][-trace] [-sqlj] [-outer] [-complianceLevel "1.4"|"5.0"]
```

Use the following command and the optional parameters, when the schema and map are not available in the input EAR or JAR file, and a top-down mapping approach is needed:

```
ejbdeploy input_EAR_name|input_JAR_name working_directory output_EAR_name|output_JAR_name
[-bindear "options"] [-cp classpath] [-codegen] [-dbname "name"] [-dbschema "name"] [-dbvendor
name] [-debug] [-keep] [-ignoreErrors] [-quiet] [-nowarn] [-noinform] [-rmic "options"][-trace]
[-sqlj][-OCCColumn] [-outer] [-complianceLevel "1.4"|"5.0"]
```

The -dbschema, -dbname, -dbvendor, and -OCCColumn options are only used when creating a database definition in the top-down mode of operation. The database information is then saved in the schema document in the JAR or EAR file, which means that the options do not need to be specified again. It also means that when a JAR or EAR is generated, the correct database must be defined at that point because it cannot be changed later.

Behaviour

If your input JAR or EAR file contains CMP beans, the EJB deployment tool looks for an existing schema and map to use when generating deployment code. If no existing schema and map are found, a schema and map are created using top-down mapping rules.

In the top-down mapping approach, you already have existing enterprise beans and their design determines the database design. The generated schema contains one table for each CMP entity bean. In these tables, each column corresponds to a CMP field of the enterprise bean, and the generated mapping maps the field to the column.

If the -dbvendor option is not set, the default database backend is **DB2UDB_V82**. If you want to set a different database backend, use the -dbname, -dbschema, and -dbvendor options to specify your choice. A data definition language (DDL) file, Table.ddl, is created for the database backend set in the -dbvendor option, when you run the ejbdeploy command. However, you can specify only one backend at a time using the -dbvendor option.

If the -dbvendor option is specified for mapped jars, for example the JAR file already contains a DB2® backend and you specify -dbvendor ORACLE on the command line; in previous releases of the product, rather than getting a second backend, the database vendor specification was ignored. Starting in WebSphere Application Server v6.0.2, the following changes were made for the scenario where the -dbvendor option is specified for a mapped jar:

For 2.x CMP beans where multiple mappings to different database vendors are supported:
- If the value for the -dbvendor option is different from the existing maps, then a new top-down map is generated, and that becomes the current backend.
- If the value for the -dbvendor option is the same as one of the existing maps, then that map becomes the current backend, and the following message is issued:

  ```
  A mapping to the database vendor, database_vendor, already exists. Setting the current
  backend id to backend_id.
  ```

For 1.1 CMP beans that can only be mapped once:
- If the value for the -dbvendor option is the same as the existing map, then the following message is issued and deployment continues:

  ```
  A mapping to the database vendor, database_vendor, already exists.  Using the existing map to continue
  ```

- If the value for the -dbvendor option is different as the existing map, the following exception is thrown and deployment stops:

  ```
  A mapping already exists for a different database vendor.
  Action: If you want to generate deployment code against this existing map, for the -dbvendor argument
  ```

Another general behavior of the ejbdeploy command is if the abstract fields or bean name for CMP entity beans use any SQL reserved keywords, the top-down mapping adds a numeric suffix to the column name when generating the data definition language file (Table.ddl). This is to avoid SQL command conflicts when SQL reserved words are used as column names. For a list of SQL reserved words, see the topic SQL reserved keywords.

Parameters

ejbdeploy
    The command to generate deployment code. If run without any arguments, the `ejbdeploy` command displays a list of arguments that can be run with the command.

input_JAR_name **or** *input_EAR_name*
    The fully qualified name of the input JAR or EAR file that contains the enterprise beans for which you want to generate deployment code; for example, c:\ejb\inputJARs\myEJBs.jar. (This argument is required.)

    The ejbdeploy command no longer uses what is specified on the system class path. Instead, the dependent classes need to be contained in a JAR file or included in the command processing using the -cp option. You must ensure that the .class files of each enterprise bean's home and remote classes are packaged in the input JAR or EAR file.

You should not include source files in the input JAR or EAR file. If there are source files in the input JAR or EAR file, the EJBDeploy tools runs a rebuild before generating the deployment code. **Recommendation**: Either remove the source files, or include all dependent classes and resource files on the class path. Otherwise, this might cause problems during rebuild of your application on the server.

working_directory
> The name of the directory where temporary files that are required for code generation are stored. (This argument is required.) If the working directory that you specify already exists prior to running the `ejbdeploy` command, the temporary files are generated into the working directory (as an Eclipse workspace). However, if the working directory does not already exist prior to running the command, the directory is created and the Eclipse workspace is generated into it. In both cases, the workspace and all of its files are automatically removed when the deployment code generation is complete unless you specify the `-keep` option. (Retaining the workspace is useful for problem determination.)

output_JAR_name **or** *output_EAR_name*
> The fully qualified name of the output JAR or EAR file that is created by the ejbdeploy command and that contains the generated classes required for deployment; for example: c:\ejb\outputJARs\ myEJBs.jar. (This argument is required.) The directories specified in the fully-qualified name must already exist before you run the ejbdeploy command. (Note that when you specify a name for the output JAR or EAR file and then run the ejbdeploy command, any existing output JAR or EAR file of the same name will be overwritten without warning.)

-cp *classpath*
> If you intend to run the ejbdeploy command against JAR or EAR files that have dependencies on other zipped or JAR files, you can use the -cp option to specify the class path of the other JAR or zipped files. Using the -cp option, you can specify multiple zipped and JAR files as arguments. However, the zipped and JAR file names must be fully qualified, separated by semicolons, and enclosed in double quotation marks. For example: `-cp "path\myJar1.jar;path\myJar2.jar; path\myJar3.jar"`

> **Tip:** If you specfied the -sqlj option, you need to specify the location of the SQLJ translator classes, sqlj.zip. The default path for this file is *x*:\java, where *x* is the installation directory of DB2, for example, d:\sqllib\java\sqlj.zip on Windows®.

-codegen
> Restricts the ejbdeploy command to just (a) importing code from the input JAR or EAR file (b) generating the deployment code, and (c) exporting code to the output JAR or EAR file. It will not compile the generated deployment code or run remote method invocation compiler (RMIC). Since Java source code is not usually exported in the output EAR or JAR, this is the only way to save the generated code.

-bindear *"options"*
> Enables you to populate an EAR file with bindings. This argument applies only to EAR files. You can also use this command without specifying any options. The options must be separated by a space and enclosed in double quotation marks. For example: `-bindear "xx yy zz"` For more information on these options, see the WebSphere Application Server documentation.

-dbname *"name"*
> The name of the database you want to define in the data definition language (DDL) file that gets generated. If the name of the database contains any spaces, the entire name must be enclosed in double quotes. For example: `-dbname "my database"`

-dbschema *"name"*
> The name of the schema you want to create. If the name of the schema contains any spaces, the entire name must be enclosed in double quotes. For example: `-dbschema "my schema"`

-dbvendor *name*
> The name of the database vendor, which is used to determine database column types, mapping information, Table.ddl, and other information. The valid database vendor names are:

DB2UDB_V81
DB2 Universal database V8.1 for Linux®, UNIX®, and Windows

DB2UDB_V82
DB2 Universal database V8.2 for Linux, UNIX, and Windows

DB2UDBOS390_V7
DB2 Universal Database™ for z/OS®, V7

DB2UDBOS390_V8
DB2 Universal Database for z/OS, V8

DB2UDBOS390_NEWFN_V8
DB2 Universal Database for z/OS, V8

Additional to the DB2UDBOS390_V8 option, this option includes the generated data model that has all the new catalog features of DB2 Universal Database for z/OS v8 specified in the new function mode. Use this option if you plan to work with the generated data model available in the WebSphere Application Server Toolkit or IBM® Rational® Software Development Platform products.

DB2UDBISERIES_V53
DB2 Universal Database for iSeries™, V5R3

DB2UDBISERIES_V54
DB2 Universal Database for iSeries, V5R4

DERBY_V10
IBM Cloudscape™, V10.1

ORACLE_V9I
Oracle, V9i

ORACLE_V10G
Oracle, V10g

INFORMIX_V93
Informix® Dynamic Server, V9.3

INFORMIX_V94
Informix Dynamic Server, V9.4

INFORMIX_V100
Informix Dynamic Server, V10.0

SYBASE_V1250
Sybase Adaptive Server Enterprise, V12.5

SYBASE_V15
Sybase Adaptive Server Enterprise, V15.0

MSSQLSERVER_2000
Microsoft® SQL Server 2000

MSSQLSERVER_2005
Microsoft SQL Server 2005

The following backend ids are deprecated:

SQL92 (1992 SQL Standard)

SQL99 (1999 SQL Standard)

Although SQL92 and SQL99 are deprecated, the SQL92 and SQL99 options remain available. If you choose to use the deprecated SQL92 or SQL99 backend id, see the topic EJB query to SQL syntax to help determine what backend you should use, in the near future, when the deprecated SQL92 and SQL99 backends are no longer available.

If you want to use an unsupported database, see the topic EJB query to SQL syntax to help choose a valid database vendor backend id that matches closely to your unsupported deployment environment.

Note:
- The default is **DB2UDB_V82** (DB2 for Windows, V8.2 and UNIX)
- If -sqlj is specified, it supports **DB2UDB_V82** (DB2 for Windows, V8.2 and UNIX), **DB2UDB_V81** (DB2 for Windows, V8.1 and UNIX), **DB2UDBOS390_V8** (DB2 for z/OS, V8) and **DB2UDBOS390_V7**(DB2 for z/OS, V7).

-debug
Specifies that deployment code will be compiled with debug information.

-keep
Controls the disposition of the temporary files that are created (that is, the Eclipse workspace) when the `ejbdeploy` command has run. Without this option, the Eclipse workspace is deleted when the command has completed.

-ignoreErrors
Specifies that processing should continue even if validation errors are detected.

-quiet
During validation, suppresses status messages (but does not suppress error messages).

-nowarn
During validation, suppresses warning and informational messages.

-noinform
During validation, suppresses informational messages.

-rmic *"options"*
Enables you to pass RMIC options to RMIC. The options, which are described in Sun's RMI Tools documentation, must be separated by a space and enclosed in double quotation marks. For example: `-rmic "-nowarn -verbose"`

-trace
Generates additional progress messages to the console.

-sqlj

Note: This option is valid only on enterprise beans compliant with the 2.0 specification.

Enables you to use SQLJ instead of JDBC to make calls to a DB2 database. With the **-sqlj** option specified, the EJB deployment tool generates SQLJ code for your CMP beans to use SQLJ to access the database. It also automatically invokes the SQLJ translator to translate the SQLJ source files. Finally, an Ant script will be created by the EJB deployment tool to help you to customize the SQLJ profiles easily. You can run the Ant script against the profile to produce a DB2 package. These DB2 packages can be used at runtime to avoid extensive runtime checking. Once you have generated the deployment code for SQLJ using the EJB deployment tool, you will need to run the DB2 SQLJ profile customizer, `db2sqljcustomize`, against the generated .ser file, which is found in the subfolder of the *websphere_deploy* folder associated with the DB2 backend. Consult the DB2 documentation for more information on running the DB2 SQLJ profile customizer, or visit www7b.boulder.ibm.com/dmdd/zones/java/bigpicture.html (section *SQLJ support*).

-OCCColumn

Note: This option is valid only on EJB 2.x CMP entity beans when generating top-down mapping. Enables you to add a column to your relational database table for collision detection. The *collision detection column* is the additional database column reserved to determine if a record has been updated. Adding a column for collision detection is an alternative optimistic concurrency control scheme of including attributes in a predicate for optimistic access intents. To manage the collision

detection column, you will need to provide your own database trigger implementation. The following are the result of adding a column for collision detection:

- The data type of the collision detection column is a 64 bit integer.
- The naming convention of the collision detection column has the following format: **OCC**_*bean_name*
- The top-down mapping generates an extra relational column. This column can not be mapped to the enterprise bean.

-outer
> This is an optional parameter and is only supported for deploying J2EE 1.3 applications. It specifies to use `OUTER` semantics for path expressions in EJB query language queries. If this parameter is not specified, the default setting is `INNER` semantics.

> **Note:** If you specify this parameter for deploying a J2EE 1.4 application, this option is ignored because the specification for J2EE 1.4 defines the `INNER` semantics be used for J2EE 1.4 applications.

-complianceLevel ″**1.4** ″ | ″**5.0**″
> Specify the Java Development Kit (JDK) compiler compliance level to either 1.4 or 5.0, if you have included application source files for compilation. If this parameter is not specified, the default setting is JDK v1.4. If your application is using new functionality defined in JDK v5.0 or you have included source files (which is not recommended) then you must specify the parameter value as ″5.0″.

Example

ejbdeploy AceEmp.ear d:\deploydir AceEmp_sqlj.ear -dbvendor DB2UDB_V82 -keep -sqlj -cp "e:\sqllib\java\ssqlj.zip"

Explanation:

We have DB2 Universal database (version 8.2 for Windows and UNIX) installed in e:\sqllib.

The ejbdeploy command takes the AceEmp.ear file (which has enterprise beans that are compliant with the EJB 2.0 specification) as input and produces the AceEmp_sqlj.ear as output. Since the -sqlj option is used, SQLJ is used instead of JDBC in the generated code to make calls to DB2.

When ejbdeploy runs, it creates an Eclipse workspace in the directory that you specify as the working directory: d:*deploydir*. When it has completed running, it deletes this workspace. However, the -keep option causes ejbdeploy to end without deleting the workspace.

Implementing query methods in home interfaces for CMP entity beans:

EJB 2.x provides a query syntax called EJB QL for both finder and select methods of CMP entity beans.

Finder methods obtain one or more entity bean instances from a database, and are defined in the home interface. Select methods are defined on the abstract bean class and can return entity beans (any entity bean type defined in the EJB JAR file) or CMP field values.

The <query> element is used to define the query for the finder method in the deployment descriptor, for every finder method except findByPrimaryKey(key). Queries specified in the deployment descriptor are translated into SQL during deployment. The query statement is contained in the <ejb-ql> element of the <query> element:

```
<query>
<query-method>
<method-name>findAll</method-name>
<method-params>
<method-param></method-param>
</method-params>
```

```
</query-method>
<result-type-mapping></result-type-mapping>
<ejb-ql>select object(o) from Employee o</ejb-ql>
</query>
```

Where to find additional information about the EJB query language

Detailed information on how to structure EJB queries is found in Chapter 11 of the EJB 2.x specification available at java.sun.com/products/ejb/docs.html. However, the WebSphere documentation contains Sun's information along with the WebSphere extensions.

Client applications

Using application clients

An application client module is a Java Archive (JAR) file that contains a client for accessing a Java application.

Complete the following steps for developing different types of application clients.

1. Decide on a type of application client.
2. Develop the application client code.
   a. Develop ActiveX application client code.
   b. Develop J2EE application client code.
   c. Develop pluggable application client code.
   d. Develop thin application client code.
3. Assemble the application client using the Application Server Toolkit.
4. Deploy the application client.

   Deploy the application client on Windows systems.
5. Run the application client.

View the Application Clients Samples Gallery for more information. To access these samples, install Application Clients, and retrieve the samples from your local file system as the following command indicates:

`<app_server_root>/samples/index.html`

Application Client for WebSphere Application Server

In a traditional client-server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client runtime environment.

WebSphere Application Server Version 6.1 supports the pluggable client.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server Version 6 (Application Client) consists of the following client applications:
- J2EE application client application (Uses services provided by the J2EE Client Container)
- Thin application client application (Does not use services provided by the J2EE Client Container)
- Applet application client application
- ActiveX to EJB Bridge application client application (Windows only)

The Application Client is packaged with the following components:
- Java Runtime Environment (JRE) (or an optional full Software Development Kit) that IBM provides.

- WebSphere Application Server run time for J2EE application client applications or Thin application client applications
- ▶ Windows ◀ An ActiveX to EJB Bridge run time for ActiveX to EJB Bridge application client applications (Windows only)
- ▶ Windows ◀ IBM plug-in for Java platforms for Applet client applications (Windows only)

> **Note:** The Pluggable application client is a kind of Thin application client. However, the Pluggable application client uses a Sun JRE and Software Development Kit instead of the JRE and Software Development Kit that IBM provides.

The *ActiveX application client* model, uses the Java Native Interface (JNI) architecture to programmatically access the Java virtual machine (JVM) API. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or Active Server Pages (ASP) files) and remains attached to the process until that process terminates.

In the *Applet client* model, a Java applet embeds in a HyperText Markup Language (HTML) document residing on a remote client machine from the WebSphere Application Server. With this type of client, the user accesses an enterprise bean in the WebSphere Application Server through the Java applet in the HTML document.

The *J2EE application client* is a Java application program that accesses enterprise beans, Java DataBase Connectivity (JDBC) APIs, and Java Message Service message queues. The J2EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the J2EE application client depends on the Application Client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The *Pluggable and Thin application clients* provide a lightweight Java client programming model. These clients are useful in situations where a Java client application exists but the application needs enhancements to use enterprise beans, or where the client application requires a thinner, more lightweight environment than the one offered by the J2EE application client. The difference between the Thin application client and the Pluggable application client is that the Thin application client includes a Java virtual machine (JVM) API, and the Pluggable application client requires the user to provide this code. The Pluggable application client uses the Sun Java Development Kit, and the Thin application client uses the IBM Developer Kit for the Java platform.

The J2EE application client programming model provides the benefits of the J2EE platform for the Java client application. Use the J2EE application client to develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application remains the same.

The Application Client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The Application Client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The J2EE platform supports the Application Client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also

eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the Application Client can require redeployment.

The Application Client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Application Client run time also provides support for security authentication to enterprise beans and local resources.

The Application Client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

View the Samples gallery for more information about the Application Client.

Application client functions:

This topic provides information about available functions in the different types of clients.

Use the following table to identify the available functions in the different types of clients.

Available functions	ActiveX client	Applet client	J2EE client	Pluggable client	Thin client
Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No
Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. **Note:** Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes
Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans	Yes	Limited	Yes	Yes	Yes

Supports security authentication to local resources	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes
Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes
Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No
Supports JMS connections to the default messaging provider	No	No	Yes	Yes	Yes

ActiveX application clients:

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:
- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ActiveX to EJB bridge, initializing JVM code.

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ActiveX to EJB bridge, using Java proxy objects. For more information about calling methods and access fields, see ActiveX to EJB bridge, calling Java methods and ActiveX to EJB bridge, accessing Java fields.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between

native automation types and Java types. All other types are handled automatically by the proxy objects For more information about data type conversion, see ActiveX to EJB bridge, converting data types.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ActiveX to EJB bridge, handling errors.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ActiveX to EJB bridge, using threading.

Applet clients:

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA objects, and bundling these pieces together to install or download to the client machine. The Java applet client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine.

Generate client-side bindings using an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

J2EE application clients:

The J2EE application client programming model provides the benefits of the Java 2 Platform for WebSphere Application Server Enterprise product.

The J2EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the J2EE platform, you can put the client application code from one J2EE platform implementation to another. The client application package can require redeployment using each J2EE platform deployment tool, but the code that comprises the client application does not change.

The J2EE application client run time supplies a container that provides access to system services for the application client code. The J2EE application client code must contain a main method. The J2EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the J2EE platform. These deployment descriptors identify enterprise beans or local resources (JDBC data sources, J2C connection factories, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

The J2EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The J2EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The J2EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the J2EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the J2EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients:

The Pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

The Pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the Pluggable application client, and the Thin application client are similar.

Note: The Pluggable application client is only available on the Windows platform.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The Pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The Pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The Pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Pluggable application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the Pluggable application client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The Pluggable application client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a J2EE application client:

```
        java.lang.Object ejbHome =  initialContext.lookup("java:/comp/env/ejb/MyEJBHome"
);
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

However, you need more explicit code in a Pluggable application client for Java:

```
        java.lang.Object ejbHome =  initialContext.lookup("the/fully/qualified
/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,
MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The Pluggable application client is a traditional Java application that contains a *main* function. The WebSphere Pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA-based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Pluggable application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Pluggable application client run time.

Thin application clients:

The thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

WebSphere Application Server Version 6.1 supports the pluggable client.

The thin client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the J2EE platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The thin application client provides the necessary runtime to support the communication needs between the client and the server.

The thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the J2EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client

does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The thin application client offers access to most of the available client services in the J2EE application client. However, you cannot access the services in the thin client as easily as you can in the J2EE application client. The J2EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a J2EE application client:

```
    java.lang.Object ejbHome = initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

However, you need more explicit code in a Java thin application client:

```
    java.lang.Object ejbHome =
initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
    MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

In this example, the J2EE application client accesses a logical name from the `java:/comp` name space. The J2EE client run time resolves that name to the physical location and returns the reference to the client application. The thin client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the lookup() statement.

In the J2EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The thin application client is a traditional Java application that contains a *main* function. The WebSphere thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services (security, Workload Management (WLM), and others). This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The thin application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the thin application client run time.

Application client troubleshooting tips

This topic provides debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide.

Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing.

Error: java.lang.NoClassDefFoundError

Explanation	This exception is thrown when Java code cannot load the specified class.
Possible causes	• Invalid or non-existent class • Class path problem • Manifest problem
Recommended response	Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:
1. Open your EAR file with the Application Server Toolkit or the Rational Web Developer assembly tool, and select the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CCclasspath option and the class paths configured with the Application Client Resource Configuration Tool. Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the `.ear` file. Remove entries from the classpaths, or include the `.jar` files and classes in the `.ear` file instead of referencing them from the file system.

If you use the -CCclasspath parameter or resource classpaths in the Application Client Resource Configuration Tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field, these class path fields use platform-specific separator characters, usually a colon (on operating systems such as AIX or Linux) or a semi-colon (on Windows systems).
Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the -CCBootstrapHost parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Application Server Toolkit to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: ″iiop://[invalidhostname]″. Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getIPAddress(), InetAddress.getByName[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the -CCBootstrapHost parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of "localhost" and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation	This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the launchClient tool. The default behavior is for the launchClient tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.
Possible causes	• Incorrect host server invoked • Invalid host server name • Invalid reference to `localhost` • Application server is not started • Invalid bootstrap port
Recommended response	If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context "java:"

Explanation	This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.
Possible causes	• No binding information for the specified name • Binding information for the specified name is incorrect • Wrong class loader was used to load one of the program classes • A resource reference does not include any client configuration information • A client container on the deployment manager is trying to use enterprise extensions (not supported)
Recommended response	Open the EAR file with the Application Server Toolkit, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)

Explanation	This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.
Possible causes	• The files, *_Stub.class and _Tie.class, are not in the EJB .jar file • Class loader could not find the classes
Recommended response	Look at the EJB .jar file located in the .ear file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in _Stub and _Tie. If the binding classes are in the EJB .jar file, then you might have a class loader error.

Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found. com.ibm.websphere.client.applicationclient.ClientContainerException: com.ibm.etools.archive.exception.OpenFailureException

Explanation	This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.
Possible causes	The most likely cause of this error is that the system cannot find the EAR file cannot be found in the path specified on the launchClient command.
Recommended response	Verify that the path and file name specified on the launchclient command are correct. If you are running on the Windows operating system and the path and file name are correct, use a short version of the path and file name (8 character file name and 3 character extension).

The launchClient command appears to hang and does not return to the command line when the client application has finished.

Explanation	When running your application client using the launchClient command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until System.exit is called.
Possible causes	The JVM code does not end because there is an AWT thread. Java code requires that System.exit() be called to end AWT threads.
Recommended response	• Modify your application to call System.exit(0) as the last statement. • Use the -CCexitVM=true parameter when you call the launchClient command.

The applet client application client fails to launch an HTML browser in Internet Explorer

Explanation

Applet client applications run only on Windows systems. When the applet client application runs, the application output data is displayed in a browser window. If you are using Internet Explorer with the Windows XP operating system for Service Pack 2 , then you might get errors when trying to display output data.

Possible causes

The Windows XP operating system for Service Pack 2 has a security feature that blocks pop-up browser windows from appearing.

Recommended response

- Locate the information bar found under the URL Address bar in the Internet Explorer pop-up browser that has been blocked.
- Click the Information Bar to display options that disable the operating system security feature.
- Select **Allow blocked content**. You are prompted with a security window asking you to confirm your selection to allow blocked content.
- Click **Yes**.
- The applet client application runs successfully, and the browser information is displayed appropriately.

Installing the Developer Kit feature downgrades the JRE files from Version 6.0.1 or Version 6.0.2 to Version 6.0

Explanation

If you select the Developer Kit feature on the Application Client Version 6.0.0 installer, all the files are installed under the *<client_install_root>*/java directory, instead of leaving the Java Runtime Environment (JRE) files intact. The JRE files are unexpectedly downgraded to the Version 6.0.0 level.

Possible causes

Selecting the **Developer Kit** feature on the Application Client 6.0.0 installer will actually install all files under the *<client_install_root>*/java directory rather than leave the JRE files intact. Therefore, the JRE files are unexpected downgraded to the 6.0.0 level in the above installation scenario.

Recommended response

Complete the following installation steps to prevent unexpected downgrading of the JRE files.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/software/webservers/appserv/was/support/

Developing application clients

This topic provides the steps for programming application clients to access resource objects defined on the server.

To use application clients to access a remote object on the server, develop your application clients as described in the following steps:

1. Create an instance of the object that you want to access from the remote server.
2. Specify the user ID and password on the connection method, when you create a connection to the server. Security must be enabled.

3. Assemble the application client `.ear` file using an assembly tool, such as the Application Server Toolkit (AST) or Rational Application Developer. Assemble the application client `.ear` file on any development machine where the assembly tool is installed.

4. Add the resource to the client deployment descriptor by completing the binding JNDI name for the resource object on the server.

5. Distribute the configured `.ear` file to the client machines.

6. Deploy the application client.

7. Configure the application client resources.

After you develop the application client code, run the application client.

Developing ActiveX application client code

This topic provides an outline for developing an ActiveX Windows program, such as Visual Basic, VBScript, and Active Server Pages, to use the WebSphere ActiveX to EJB bridge to access enterprise beans.

This topic assumes that you are familiar with ActiveX programming and developing on the Windows platform. Consider the information given in ActiveX to EJB bridge as good programming guidelines.

To use the ActiveX to EJB bridge to access a Java class, develop your ActiveX program to complete the following steps:

1. Create an instance of the XJB.JClassFactory object.

2. Create Java virtual machine (JVM) code within the ActiveX program process, by calling the XJBInit() method of the XJB.JClassFactory object. After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM code is initialized and ready for use.

3. Create a proxy object for the Java class, by using the XJB.JClassFactory FindClass() and NewInstance() methods. The ActiveX program can use the proxy object to access the Java class, object fields, and methods.

4. Call methods on the Java class, using the Java method invocation syntax, and access Java fields as required.

5. Use the helper functions to do the conversion in cases where automatic conversion is not possible. You can convert between the following data types:
   - Java Byte and Visual Basic Byte
   - Visual Basic Currency types and Java 64-bit

6. Implement methods to handle any errors returned from the Java class. In Visual Basic or VBScript, use the **Err.Number** and **Err.Description** fields to determine the actual Java error.

After you develop the ActiveX client code, start the ActiveX application.

Starting an ActiveX application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

To perform the required configuration, complete one or more of the following tasks:

1. Start an ActiveX application and configure service programs.

2. Start an ActiveX application and configuring non-service programs

Starting an ActiveX application and configuring service programs:

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, some initial configuration (to set appropriate environment variables

and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time) is necessary. This configuration sets up the environment within which the ActiveX service program can run.

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java virtual machine (JVM) version available on a machine using ASP.

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following task.

On Windows 2000 systems, complete the following steps:
1. Open the Control Panel, then double-click the **System** icon.
2. Click the **Advanced** tab on the System Properties window.
3. Click **Environment Variables**.
4. Edit the Path variable in the System Variables window.
5. Add the following information to the beginning of the path that is displayed in the Variable Value field:

`C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

> where `C:\WebSphere\AppClient` is the directory in which you installed the Java client in the WebSphere product.
6. Click **OK** in the Edit System Variable window to apply the changes.
7. Click **OK** in the Environment Variables window.
8. Click **OK** in the System Properties window.
9. Restart Windows 2000.

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

Starting an ActiveX application and configuring non-service programs:

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

To perform the required configuration, complete the following steps:
1. Edit the `setupCmdLineXJB.bat` file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java virtual machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
   - Use the `launchClientXJB.bat` file to start the application. For example:

     `launchClientXJB MyApplication.exe parm1 parm2`

     or

     `launchClientXJB MyApplication.vbp`
   - Use the `setupCmdLineXJB.bat` file to create an environment in which to run the application, then start the application from within that environment.

setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files:

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise JavaBeans (EJB) bridge to find its `XJB.JAR` file and the Java run-time environment.

Location

The include file is located in the `was_client_home`\aspIncludes directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<-- #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called `WSASPIncludes` that points to the `was_client_home`\aspIncludes directory.

Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- **setupCmdLineXJB.bat**

  Sets the client environment variables.

- **launchClientXJB.bat**

  Calls the `setupCmdLineXJB.bat` file and launches the application you specify as its arguments; for example:

  ```
  launchClientXJB.bat myapp.exe parm1 parm2
  ```

  or

  ```
  launchClientXJB MyApplication.vbp
  ```

- **Active Server Pages (ASP) include file**

  An include file is provided for ASP users to automatically set the following page-level (local) environment variables:

  - **com_ibm_websphere_javahome**. Path to the Java run-time directory installed with the WebSphere advanced server client.
  - **com_ibm_websphere_washome**. Path to the WebSphere advanced server client directory.
  - **com_ibm_websphere_namingfactory**. Sets the Java java.naming.factory.initial system property.
  - **com_ibm_websphere_computername**. (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.

- **System settings**

  To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

  ```
  was_client_home\java\jre\bin;was_client_home\java\jre\bin\classic
  ```

  Where *was_client_home* is the name of the directory where you installed the WebSphere Application Server client (for example, `C:\WebSphere\AppClient`).

  Note: This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

JClassProxy and JObjectProxy classes

The majority of tasks for accessing your Java classes and objects are handled with the JClassProxy and JObjectProxy objects. This topic provides reference information about the object classes of the ActiveX to Enterprise Java Beans (EJB) bridge.

JClassFactory is the object used to access the majority of Java Virtual Machine (JVM) features. This object handles JVM initialization, accesses classes and creates class instances (objects). Use the JClassProxy and JObjectProxy objects to access the majority of your Java classes and objects:

- XJBInit(String astrJavaParameterArray())

  Initializes the JVM environment using an array of strings that represent the command line parameters you normally send to the `java.exe` file.

  If you have invalid parameters in the XJBInit() string array, the following error is displayed:

  ```
  Error: 0x6002 "XJBJNI::Init() Failed to create VM" when calling XJBInit()
  ```

  If you have C++ logging enabled, the activity log displays the invalid parameter.

- JClassProxy FindClass(String strClassName)

  Uses the current thread class loader to load the specified fully qualified class name and returns a JClassProxy object representing the Java Class object.

- JObjectProxy NewInstance()

  Creates a Class instance for the specified JClassProxy object using the parameters supplied to call the Class constructor. For more information about using the JMethodArgs method, see ActiveX to EJB bridge, calling Java methods.

```
JObjectProxy NewInstance(JClassFactory obj, Variant vArg1, Variant vArg2, Variant vArg3, ...)
JObjectProxy NewInstance(JClassFactory obj, JMethodArgs args)
```

- JMethodArgs GetArgsContainer()

  Returns a JMethodArgs object (Class instance).

  You can create a JClassProxy object from the JClassFactory.FindClass() method and from any Java method call that normally return a Java Class object. You can use this object as if you had direct access to the Java Class object. All of the class static methods and fields are accessible as are the java.lang.Class methods. In case of a clash between static method names of the reflected user class and those of the java.lang.Class (for example, getName()), the reflected static methods would execute first.

  For example, the following is a static method called getName(). The java.lang.Class object also has a method called getName():

  – In Java:

    ```
    class foo{
     foo(){};
     public static String getName(){return "abcdef";}
     public static String getName2(){return "ghijkl";}
     public String toString2(){return "xyz";}
    }
    ```

  – In Visual Basic:

    ```
    ...
    Dim clsFoo as Object
    set clsFoo = oXJB.FindClass("foo")
    clsFoo.getName()  ' Returns "abcdef" from the static foo class
    clsFoo.getName2() ' Returns "ghijkl" from the static foo class
    clsFoo.toString() ' Returns "class foo" from the java.lang.Class object.
    oFoo = oXJB.NewInstance(clsFoo)
    oFoo.toString() ' Returns some text from the java.lang.Object's
                    ' toString() method which foo inherits from.
    oFoo.toString2() ' Returns "xyz" from the foo class instance
    ```

  You can create a JObjectProxy object from the JClassFactory.NewInstance() method, and can be created from any Java method call that normally returns a Class instance object. You can use this object as if you had direct access to the Java object and can access all the static methods and fields of the object. All of object instance methods and fields are accessible (including those accessible through inheritance).

  The JMethodArgs object is created from the JClassFactory.GetArgsContainer() method. Use this object as a container for method and constructor arguments. You must use this object when

overriding the object type when calling a method (for example, when sending a java.lang.String JProxyObject type to a constructor that normally takes a java.lang.Object type).

You can use two groups of methods to add arguments to the collection: Add and Set. You can use Add to add arguments in the order that they are declared. Alternatively, you can use Set to set an argument based on its position in the argument list (where the first argument is in position 1).

For example, if you had a Java Object Foo that took a constructor of Foo (int, String, Object), you could use a JMethodArgs object as shown in the following code extract:

```
...
Dim oArgs as Object
set oArgs = oXJB.GetArgsContainer()

oArgs.AddInt(CLng(12345))
oArgs.AddString("Apples")
oArgs.AddObject("java.lang.Object", oSomeJObjectProxy)

Dim clsFoo as Object
Dim oFoo as Object
set clsFoo = oXJB.FindClass("com.mypackage.foo")
set oFoo = oXJB.NewInstance(clsFoo, oArgs)

' To reuse the oArgs object, just clear it and use the add method
' again, or alternatively, use the Set method to reset the parameters
' Here, we will use Set
oArgs.SetInt(1, CLng(22222))
oArgs.SetString(2, "Bananas")
oArgs.SetObject(3, "java.lang.Object", oSomeOtherJObjectProxy)

Dim oFoo2 as Object
set oFoo2 = oXJB.NewInstance(clsFoo, oArgs)
```

- AddObject (String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the next available position, casting the object to the class name specified in the first parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  AddObject("java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  AddObject("int[]", oMyArrayOfInts)
  ```

- AddByte (Byte byteArg)

  Adds a primitive byte value to the argument container in the next available position.

- AddBoolean (Boolean bArg)

  Adds a primitive boolean value to the argument container in the next available position.

- AddShort (Integer iArg)

  Adds a primitive short value to the argument container in the next available position.

- AddInt (Long lArg)

  Adds a primitive int value to the argument container in the next available position.

- AddLong (Currency cyArg)

  Adds a primitive long value to the argument container in the next available position.

- AddFloat (Single fArg)

  Adds a primitive float value to the argument container in the next available position.

- AddDouble (Double dArg)

  Adds a primitive double value to the argument container in the next available position.

- AddChar (String strArg)

  Adds a primitive char value to the argument container in the next available position.

- AddString (String strArg)

  Adds the argument in string form to the argument container in the next available position.

- SetObject (Integer iArgPosition, String strObjectTypeName, Object oArg)

Adds an arbitrary object to the argument container in the specified position casting it to the class name or primitive type name specified in the second parameter. Arrays are specified using the traditional [] syntax; for example:

```
SetObject(1, "java.lang.Object[][]", oMy2DArrayOfFooObjects)
```

or

```
SetObject(2, "int[]", MyArrayOfInts)
```

- SetByte (Integer iArgPosition, Byte byteArg)

  Sets a primitive byte value to the argument container in the position specified.
- SetBoolean (Integer iArgPosition, Boolean bArg)

  Sets a primitive boolean value to the argument container in the position specified.
- SetShort (Integer iArgPosition, Integer iArg)

  Sets a primitive short value to the argument container in the position specified.
- SetInt (Integer iArgPosition, Long lArg)

  Sets a primitive int value to the argument container in the position specified.
- SetLong (Integer iArgPosition, Currency cyArg)

  Sets a primitive long value to the argument container in the position specified.
- SetFloat (Integer iArgPosition, Single fArg)

  Sets a primitive float value to the argument container in the position specified.
- SetDouble (Integer iArgPosition, Double dArg)

  Sets a primitive double value to the argument container in the position specified.
- SetChar (Integer iArgPosition, String strArg)

  Sets a primitive char value to the argument container in the position specified.
- SetString (Integer iArgPosition, String strArg)

  Sets a java.lang.String value to the argument container in the position specified.
- Object Item(Integer iArgPosition)

  Returns the value of an argument at a specific argument position.
- Clear()

  Removes all arguments from the container and resets the next available position to one.
- Long Count()

  Returns the number of arguments in the container.

Java virtual machine initialization tips

Initialize the Java virtual machine (JVM) code with the ActiveX to Enterprise Java Beans (EJB) bridge. For an ActiveX client program (Visual Basic, VBScript, or ASP) to access Java classes or objects, the first step that the program must do is to create Java virtual machine (JVM) code within its process.

To create JVM code, the ActiveX program calls the XJBInit() method of the XJB.JClassFactory object. When an XJB.JClassFactory object is created and the XJBInit() method called, the JVM is initialized and ready to use.

- To enable the XJB.JClassFactory to find the Java run-time description definition language (DLL) when initializing, the Java Runtime Environment (JRE) bin and `bin\classic` directories must exist in the system path environment variable.
- The XJBInit() method accepts only one parameter: an array of strings. Each string in the array represents a command line argument that for a Java program you would normally specify on the `Java.exe` command line. This string interface is used to set the class path, stack size, heap size and debug settings. You can get a listing of these parameters by typing `java -?` from the command line.
- If you set a parameter incorrectly, you receive a `0x6002 "Failed to initialize VM"` error message.
- Due to the current limitations of Java Native Interface (JNI), you cannot unload or reinitialize the JVM code after it has loaded. Therefore, after the XJBInit() method has been called once, subsequent calls have no effect other than to create a duplicate JClassFactory object for you to access. It is best to store your XJB.JClassFactory object globally and continue to reuse that object.
- The following Visual Basic extract shows an example of initializing JVM code:

```
Dim oXJB as Object
set oXJB = CreateObject("XJB.JClassFactory")
Dim astrJavaInitProps(0) as String
astrJavaInitProps(0) = _
    "-Djava.class.path=.;c:\myjavaclasses;c:\myjars\myjar.jar"
oXJB.XJBInit(astrJavaInitProps)
```

Example: Developing an ActiveX application client to enterprise beans

This reference topic provides an example of using Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge.

To use Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge:
- After an ActiveX client program (Visual Basic, VBScript, or Active Server Pages (ASP)) has initialized the XJB.JClassFactory object and thereby, the Java virtual machine (JVM), the client program can access Java classes and initialize Java objects. To complete this action, the client program uses the XJB.JClassFactory FindClass() and NewInstance() methods.
- In Java programming, two ways exists to access Java classes: direct invocation through the Java compiler and through the Java Reflection interface. Because the ActiveX to Java bridge needs no compilation and is a complete run-time interface to the Java code, the bridge depends on the latter Reflection interface to access its classes, objects, methods and fields. The XJB.JClassFactory FindClass() and NewInstance() methods behave very similarly to the Java Class.forName() and the Method.invoke() and Field.invoke() methods.
- XJB.JClassFactory.FindClass() takes the fully qualified class name as its only parameter and returns a Proxy Object (JClassProxy). You can use the returned Proxy object like a normal Java Class object and call static methods and access static fields. You can also create a Class Instance (or object), as described below. For example, the following Visual Basic code extract returns a Proxy object for the java.lang.Integer Java class:

```
...
Dim clsMyString as Object
Set clsMyString = oXJB.FindClass("java.lang.Integer")
```
- After the proxy is created, you can access its static information directly. For example, you can use the following code extract to convert a decimal integer to its hexadecimal representation:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```
- The equivalent Java syntax is: `static String toHexString(int i)`. Because ints units in Java programming are really 32-bit (which translates to Long in Visual Basic), the CLng() function converts the value from the default int to a long. Also, even though the toHexString() function returns a java.lang.String, the code extract does not return an Object proxy. Instead, the returned java.lang.String is automatically converted to a native Visual Basic string.

  To create an object from a class, you use the JClassFactory.NewInstance() method. This method creates an Object instance and takes whatever parameters your class constructor needs. Once the object is created, you have access to all of its public instance methods and fields. For example, you can use the following Visual Basic code extract to create an instance of the java.lang.Integer string:

```
...
Dim oMyInteger as Object
set oMyInteger = oXJB.NewInstance(CLng(255))

Dim strMyInteger as String
strMyInteger = oMyInteger.toString
```

Example: Calling Java methods in the ActiveX to enterprise beans

In the ActiveX to Enterprise Java Beans (EJB) bridge, methods are called using the native language method invocation syntax.

The following differences between Java invocation and ActiveX Automation invocation exist:

- Unlike Java methods, ActiveX does not support method (and constructor) polymorphism; that is, you cannot have two methods in the same class with the same name.
- Java methods are case-sensitive, but ActiveX Automation is not case-sensitive.
- To compensate for Java polymorphic behavior, give the exact parameter types to the method call. The parameter types determine the correct method to invoke. For a listing of correct types to use, see ActiveX to EJB bridge, converting data types.
- For example, the following Visual Basic code fails if the CLng() method was not present or the toHexString syntax was incorrectly typed as ToHexString:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```

- Sometimes it is difficult to force some development environments to leave the case of your method calls unchanged. For example, in Visual Basic if you want to call a method `close()` (lowercase), the Visual Basic code capitalizes it `"Close()"`. In Visual Basic, the only way to effectively work around this behavior is to use the CallByName() method. For example:

```
o.Close(123)                                'Incorrect...
CallByName(o, "close", vbMethod, 123)       'Correct...
```

or in VBScript, use the `Eval` function:

```
o.Close(123)                                'Incorrect...
Eval("o.Close(123)")                        'Correct...
```

- The return value of a function is always converted dynamically to the correct type. However, you must take care to use the set keyword in Visual Basic. If you expect a non-primitive data type to return, you must use set. (If you expect a primitive data type to return, you do not need to use set.) See the following example for more explanation:

```
Set oMyObject = o.getObject
iMyInt = o.getInt
```

- In some cases, you might not know the type of object returning from a method call, because wrapper classes are converted automatically to primitives (for example, java.lang.Integer returns an ActiveX Automation Long). In such cases, you might need to use your language built-in exception handling techniques to try to coerce the returned type (for example, On Error and Err.Number in Visual Basic).
- Methods with character arguments

  Because ActiveX Automation does not natively support character types supported by Java methods, the ActiveX to EJB bridge uses strings (byte or VT_I1 do not work because characters have multiple bytes in Java code). If you try to call a method that takes a char or java.lang.Character type you must use the JMethodArgs argument container to pass character values to methods or constructors. For more information about how this argument container is used, see Methods with ″Object″ Type as Argument and Abstract Arguments.
- Methods with ″Object″ Type as Argument and Abstract Arguments

  Because of the polymorphic nature of Java programming, the ActiveX to Java bridge uses direct argument type mapping to find a method. This method works well in most cases, but sometimes methods are declared with a Parent or Abstract class as an argument type (for example, java.lang.Object). You need the ability to send an object of arbitrary type to a method. To acquire this ability, you must use the XJB.JMethodArgs object to coerce your parameters to match the parameters on your method. You can get a JMethodArgs instance by using the JClassFactory.GetArgsContainer() method.

  The JMethodArgs object is a container for method parameters or arguments. This container enables you to add parameters to it one-by-one and then you can send the JMethodArgs object to your method call. The JClassProxy and JObjectProxy objects recognize the JMethodArgs object and attempt to find the correct method and let the Java language coerce your parameters appropriately.

  For example, to add an element to a Hashtable object the method syntax is `Object put(Object key, Object value)`. In Visual Basic, the method usage looks like the following example code:

```
Dim oMyHashtable as Object
Set oMyHashtable = _
    oXJB.NewInstance(oXJB.FindClass("java.utility.Hashtable"))
```

```
' This line will not work. The ActiveX to EJB bridge cannot find a method
' called "put" that has a short and String as a parameter:
oMyHashtable.put 100, "Dogs"
oMyHashtable.put 200, "Cats"

' You must use a XJB.JMethodArgs object instead:
Dim oMyHashtableArgs as Object
Set oMyHashtableArgs = oXJB.GetArgsContainer
oMyHashtableArgs.AddObject("java.lang.Object", 100)
oMyHashtableArgs.AddObject("java.lang.Object", "Dogs")

oMyHashtable.put oMyHashTableArgs
' Reuse the same JMethodArgs object by clearing it.
oMyHashtableArgs.Clear
oMyHashtableArgs.AddObject("java.lang.Object", 200)
oMyHashtableArgs.AddObject("java.lang.Object", "Cats")

oMyHashtable.put oMyHashTableArgs
```

Java field programming tips

Using the ActiveX to Enterprise JavaBeans (EJB) bridge to access Java fields has the same case
sensitivity issue that it has when invoking methods. Field names must use the same case as the Java field
syntax.

Visual Basic code has the same problem with unsolicited case changing on fields as it does with methods.
(For more information about this problem, see ActiveX to EJB bridge, calling Java methods). You might
use the CallByName() function to set a field in the same way that you call a method in some cases. For
fields, use VBLet for primitive types and VBSet for objects. For example:

```
o.MyField = 123                         'Incorrect...
CallByName(o, "MyField", vbLet, 123)    'Correct...
```

or in VBScript:

```
o.MyField = 123                         'Incorrect...
Eval("o.myField = 123")                 'Correct...
```

ActiveX to Java primitive data type conversion values

All primitive Java data types are automatically converted to native ActiveX Automation types. However, not
all Automation data types are converted to Java types (for example, VT_DATE). Variant data types are
used for data conversion.

Variant data types are a requirement of any Automation interface, and are used automatically by Visual
Basic and VBScript. The tables below provide details about how primitive data types are converted
between Automation types and Java types.

Table 7. ActiveX to Java primitive data type conversion

Visual Basic Type	Variant Type	Java Type	Notes
Byte	VT_I1	byte	Byte in Visual Basic is unsigned, but is signed in Java data type.
Boolean	VT_BOOL	boolean	
Integer	VT_I2	short	
Long	VT_I4	int	
Currency	VT_CY	long	
Single	VT_R4	float	
Double	VT_R8	double	

Table 7. ActiveX to Java primitive data type conversion (continued)

Visual Basic Type	Variant Type	Java Type	Notes
String	VT_BSTR	java.lang.String	
String	VT_BSTR	char	
Date	VT_DATE	n/a	

Example: Using helper methods for data type conversion:

Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible:

- Byte helper function

  Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
     GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

  Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, "HOWTO: Do 64-bit Arithmetic in VBA", on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
```

```
      If L < 4 Then
          TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                              Right$("0000" & Value, 4))
      Else
          TextToCurr = CCur(IIf(Negative, "-", "") & _
                              Left$(Value, L - 4) & "." & Right$(Value, 4))
      End If
  End Function

  ' Java Long as Currency Usage Example
  Dim LC As MungeCurr
  Dim L2 As Munge2Long

  ' Assign a Currency Value (really a Java Long)
  ' to the MungeCurr type variable
  LC.Value = cyTestIn

  ' Coerce the value to the Munge2Long type variable
  LSet L2 = LC

  ' Perform some operation on the value, now that we
  ' have it available in two 32-bit chunks
  L2.LoValue = L2.LoValue + 1

  ' Coerce the Munge value back into a currency value
  LSet LC = L2
  cyTestIn = LC.Value
```

Array tips for ActiveX application clients

Arrays are very similar between Java and Automation containers like Visual Basic and VBScript. This topic provides some important points to consider when passing arrays back and forth between these containers.

Here are some important points to consider when passing arrays back and forth between these containers:

- Java arrays cannot mix types. All Java arrays contain a single type, so when passing arrays of variants to a Java array, you must make sure that all of the elements in the variant array are of the same base type. For example, in Visual Basic code:

```
...
Dim VariantArray(1) as Variant
VariantArray(0) = CLng(123)
VariantArray(1) = CDbl(123.4)
oMyJavaObject.foo(VariantArray) '      Illegal!

VariantArray(0) = CLng(123)
VariantArray(1) = CLng(1234)
oMyJavaObject.foo(VariantArray) '      This works
```

- Arrays of primitive types are converted using the rules defined in primitive data type conversion.
- Arrays of Java objects are handled through arrays of JObjectProxy objects.
- Arrays of JObjectProxy objects must be fully initialized and of the correct associated Java type. When initializing an array in Visual Basic (for example, Dim oJavaObjects(1) as Object), you must set each object to a JObjectProxy object before you send the array to a Java object. The bridge is unable to determine the type of null or empty object values.
- When receiving an array from a Java method, the lower-bound is always zero. Java methods only support zero-based arrays.
- Nested or multidimensional arrays are treated as zero-based multidimensional arrays in Visual Basic and VBScript containers.
- Uninitialized arrays or Array Types are unsupported. When calling a Java method that takes an array of objects as a parameter, you must fully initialize the array of JObjectProxy objects.

Error handling codes for ActiveX application clients

All exceptions thrown in Java code are encapsulated and thrown again as a COM error through the ISupportErrorInfo interface and the EXCEPINFO structure of IDispatch::Invoke(), the Err object in Visual Basic and VBScript. Because there are no error numbers associated with Java exceptions, whenever a Java exception is thrown, the entire stack trace is stored in the error description text and the error number assigned is 0x6003.

In Visual Basic or VBScript, you need to use the **Err.Number** and **Err.Description** fields to determine the actual Java error. Non-Java errors are thrown as you would expect via the IDispatch interface; for example, if a method cannot be found, then error 438 ″Object doesn't support this property or method″ is thrown.

Error number	Description
0x6001	Java Native Interface (JNI) error
0x6002	Initialization error
0x6003	Java exception. Error description is the Java Stack Trace.
0x6FFF	General Internal Failure

Threading tips

The ActiveX to Enterprise JavaBeans (EJB) bridge supports both free-threaded and apartment-threaded access and implements the Free Threaded Marshaler to work in a hybrid environment such as Active Server Pages (ASP). Each thread created in the ActiveX process is mirrored in the Java environment when the thread communicates through the ActiveX to EJB bridge.

Once all references to Java objects (there are no JObjectProxy or JClassProxy objects) are loaded in an ActiveX thread, the ActiveX to EJB bridge detaches the thread from the Java virtual machine (JVM) code. Therefore, you must be careful that any Java code that you access from a multithreaded Windows application is thread safe. Visual Basic code and VBScript applications are both essentially single threaded. Therefore, Visual Basic and VBScript applications do not have threading issues in the Java programs they access. Active Server Pages and multithreaded C and C++ programs can have issues.

Consider the following scenario:
1. A multithreaded Windows Automation Container (our ActiveX Process) starts. It exists on Thread A.
2. The ActiveX Process initializes the ActiveX to EJB bridge, which starts the JVM code. The JVM attaches to the same thread and internally calls it Thread 1.
3. The ActiveX Process starts two threads: B and C.
4. Thread B in the ActiveX Process uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM attaches to thread B and calls it Thread 2.
5. Thread C in the ActiveX Process never talks to the JVM code, so the JVM never needs to attach to it. This is a case where the JVM code does not have a one-to-one relationship between ActiveX threads and Java threads.
6. Thread B later releases all of the JObjectProxy and JClassProxy objects that it used. The Java Thread 2 is detached.
7. Thread B again uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM code attaches again to the thread and calls it Thread 3.

ActiveX process	JVM access by ActiveX process
Thread A - Created in 1	Thread 1 - Attached in 2
Thread B - Created in 4	Thread 2 - Attached in 4, detached in 6 Thread 3 - Attached in 7
Thread C - Created in 4	

Threads and Active Server Pages

Active Server Pages (ASP) in Microsoft Internet Information Server is a multithreaded environment. When you create the XJB.JClassFactory object, you can store it in the Application collection as an Application-global object. All threads within your ASP environment can now access the same ActiveX to EJB bridge object. Active Server Pages by default creates 10 Apartment Threads per ASP process per CPU. This means that when your ActiveX to EJB bridge object is initialized any of the 10 threads can call this object, not just the thread that created it.

If you need to simulate single-apartment behavior, you can create a Single-Apartment Threaded ActiveX dynamic link library (DLL) in Visual Basic code and encapsulate the ActiveX to the EJB bridge object. This encapsulation guarantees that all access to the JVM object is on the same thread. You need to use the <OBJECT> tag to assign the XJB.JClassFactory to an Application object and must be aware of the consequences of introducing single-threaded behavior to a Web application.

The Microsoft KnowlegeBase has several articles about ASP and threads, including:
- Q243543 INFO: Do Not Store STA Objects in Session or Application
- Q243544 INFO: Component Threading Model Summary Under Active Server Pages
- Q243548 INFO: Design Guidelines for VB Components Under ASP

Example: Viewing a System.out message

The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

This example redirects output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```
- To view the System.out messages when running a Service program such as Active Server Pages, you need to override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs

' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

Example: Enabling logging and tracing for application clients

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.
- Windows Event Log

  The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining XJBInit() errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

  To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to XJBInit(). If more than one parameter is set, they will be processed in the order in which

they appear in the input string array to the `XJBInit()` method. Once the `XJBInit()` method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java `java.lang.System.setProperty()` to set these values also has no effect.

- `-Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled`

  Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.

- `-Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled`

  Enables or disables event level messages from appearing in the Windows operating system event log.

- `-Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled`

  Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

Viewing the Windows application event log with the event viewer:

To open the event viewer in the Windows operating system:

1. Click **Start** > **Settings** > **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Event Viewer**.

All ActiveX to EJB bridge events display the text `WebSphere XJB` in the source column and in the application log. For information about using Event Viewer, click the **Action** menu in Event Viewer, and then click **Help**.

To open the even viewer in the Windows operating system, click **Start** > **Programs** > **Administrative Tools** > **Event Viewer**. All ActiveX to EJB bridge events have the text `WebSphere XJB` in the source column and display in the application log. For information about using Event Viewer, click the **Help** menu in Event Viewer.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Since the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

  ```
  "-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
  "-DtraceFile=C:\MyTrace.txt"
  ```

ActiveX client programming best practices

The best way to access Java components is to use the Java language. It is recommended that you do as much programming as possible in the Java language and use a small simple interface between your COM Automation container (for example, Visual Basic) and the Java code. This interface avoids any overhead and performance problems that can occur when moving across the interface.

best-practices: The following topics are covered:
- Visual Basic guidelines
- CScript and Windows Scripting Host
- Active Server Pages guidelines
- J2EE guidelines

Visual Basic guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with Visual Basic:
- Launch the Visual Basic replication through the `launchClientXJB.bat` file. If you want to run your Visual Basic application through the Visual Basic debugger, run the Visual Basic integrated development

environment (IDE) within the ActiveX to EJB bridge environment. After you create your Visual Basic project, you can launch it from a command line; for example, `launchClientXJB MyApplication.vbp`. You can also launch the Visual Basic application alone in the ActiveX to EJB environment, by changing the Visual Basic shortcut on the Windows Start menu so that the `launchClientXJB.bat` file precedes the call to the `VB6.EXE` file.

- Exit the Visual Basic IDE before debugging programs.

  Because the Java virtual machine (JVM) code attaches to the running process, you must exit the Visual Basic editor before debugging your program. If you run the process, then exit your program within the Visual Basic IDE, the JVM code continues to run and you reattach the same JVM code when XJBInit() is called by the debugger. This causes problems if you try to update XJBInit() arguments (for example, classpath) because the changes are not be applied until you restart the Visual Basic program.

- Store the XJB.JClassFactory object globally.

  Because you cannot unload or reinitialize the JVM code, cache the resulting XJB.JClassFactory object as a global variable. The overhead of treating this object as a global variable or passing a single reference around is much less than recreating a new XJB.JClassFactory object and calling the XJBInit() argument more than once.

CScript and Windows Scripting Host

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with CScript and Windows Scripting Host (WSH):

- Launch in ActiveX to EJB environment.

  Launch the VBScript files in the ActiveX to EJB bridge environment, to run VBScript files in `.vbs` files. Two common ways exist to launch your script:
  - `launchClientXJB MyScript.vbs`
  - `launchClientXJB cscript MyScript.vbs`

Active Server Pages guidelines

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with Active Server Pages software:

- Use the ActiveX to EJB Helper functions from the Active Server Pages Application.

  Because Active Server Pages (ASP) code typically use VBScript, you can use the included helper functions in any VBScript environment with minor changes. For more information about these helper functions, see Helper functions for data type conversion. To run outside of the ASP environment, remove or change all references to the Server, Request, Response, Application and Session objects; for example, change `Server.CreateObject` to `CreateObject`.

- Set JRE path globally in system.

  The XJB.JClassFactory object must be able to find the Java run time dynamic link library (DLL) when initializing. In Internet Information Server, you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. You can only have a single JVM version available on a machine using the ASP application. Also, remember that after you change the system PATH variable you must reboot the Internet Information Server machine so that the Internet Information Server can see the change.

- Set the system TEMP environment variable.

  If the system TEMP environment variable is not set, Internet Information Server stores all temporary files in the `WINNT` directory, which is usually not desired.

- Use high isolation or an isolated process.

  When using the ActiveX to Java bridge with Active Server Pages software, creating your Web application in its own process is recommended. You can only load one JVM instruction in a single process and if you want to have more than one application running with different JVM environment options (for example, different classpaths), then you need to have separate processes.

- Use the Application Unload option.

When debugging your application, use **Unload** when viewing your ASP application properties in the Internet Information Server administration console to unload the process from memory and thereby unload the JVM code.

- Run one process per application.

  Use only one ASP application per J2EE application or JVM environment, in your ASP environment. If you need separate class paths or JVM settings, you need separate ASP applications (virtual directories with high isolation or an isolated process).

- Store the XJB.JClassFactory object in application scope.

  Because of the one-to-one relationship required between a JVM instruction and a process, and because the JVM code can never detach or shut down from a process independently, cache the XJB.JClassFactory object at application scope and call the XJBInit() method only once.

  Because the ActiveX to EJB bridge employs a free-threaded marshaler, take advantage of the multi-threaded nature of Internet Information Server and the ASP environment. If you choose to reinitialize the XJB.JClassFactory object at Page scope (local variables), then the XJBInit() method can only initialize your local XJB.JClassFactory variable. It is more efficient to use the XJBInit() method once.

- Use VBScript conversion functions.

  Because VBScript code only supports variant data types, use the CStr(), CByte(), CBool(), CCur(), CInt(), CLng(), CSng() and CDbl() functions to tell the activeX to EJB bridge which data type you are using; for example `oMyObject.Foo(CDbl(1.234))`.

J2EE guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with the J2EE environment;

- Store client container objects globally.

  Because you can only have one JVM instruction per process, and a single J2EE client container (com.ibm.websphere.client.applicationclient.launchClient) per JVM instruction, initialize your J2EE client container only once and reuse it. For ASP applications, store the J2EE client container in an application level variable and initialize it only once (either on the Application_OnStart() event in the `global.asa` file or by checking to see if it IsEmpty()).

  A side effect to storing the client container object globally is that you cannot change the client container parameters without destroying the object and creating a new one. These parameters include the EAR file, BootstrapHost, class path, and so on. If you run a Visual Basic application and want to change the client container parameters, you must end the application and restart it. If you run an Active Server Pages application, you must first unload the application from Internet Information Server (see ″Use the Application Unload Button″ under Active Server Pages guidelines). Then load the Active Server Pages application with the different client container parameters. The parameters set the first time the Active Server Pages application loads. Since the client container is stored on the Internet Information Server, all the browser clients share the parameters using the Active Server Pages application. This behavior is normal for Active Server Pages code, but can be confusing when you try to run to different WebSphere Application Servers using the same Active Server Pages application, which is not supported.

- Reuse custom temporary directory for EAR file extraction.

  By default, the client container launches and extracts the application `.ear` file to your `temp` directory and then sets up the thread class loader to use the extracted EAR file directory and the JAR files included in the client JAR manifest. This process is time consuming and because of some limitations with JVM shutdown through Java Native Interface (JNI) and file locking, these files are never cleaned up.

  Specifically, each time the client container launch() method is called, it extracts the EAR file to a random directory name in your temporary directory on your hard drive. The current Java thread class loader is then changed to point to this extracted directory which in turn locks the files within. In a normal J2EE Java client, these files automatically clean up after the application exits. This cleanup occurs when the client container shutdown hook is called (which never happens in the ActiveX to EJB bridge), which leaves the temporary directory there.

To avoid these problems, you can specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property before calling the client container launch() method. If the directory does not exist or is empty, you extract the EAR file normally. If the EAR file was previously extracted, the directory is reused. This feature is particularly important for server processes (for example, ASP), which can stop and restart, potentially calling the launchClient() method several times.

If you need to update your EAR file, delete the temporary directory first. The next time you create the client container object, it extracts the new EAR file to the temporary directory. If you do not delete the temporary directory or change the system property value to point to a different temporary directory, the client container reuses the currently extracted EAR file, and does not use your changed EAR file.

Note: When specifying the com.ibm.websphere.client.applicationclient.archivedir property, ensure that the directory you specify *is unique* for each EAR file you use. For example, do not point `MyEar1.ear` and `MyEar2.ear` files to the same directory.

If you choose not to use this system property, go regularly to your Windows `temp` directory and delete the WSTMP* subdirectories. Over a relatively short period of time, these subdirectories can waste a significant amount of space on the hard drive.

Developing applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

Applet clients have the following setup requirements:
- These clients are available on the Windows platforms. Check the prerequisites page for information on platform support and product prerequisites.
- The browser installation precedes the client code installation.

Unlike typical applets that reside on either Web servers or WebSphere Application Servers and can only communicate using the HTTP protocol, applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

1. Install the Application Client for WebSphere Application Server.

2. Select the applet client feature.

3. From the IBM Control Panel for Java, enter the following code:

```
-Djava.security.policy=<app_client_root>\properties\client.policy
-Dwas.install.root=<app_client_root>
-Djava.ext.dirs=<app_client_root>\java\jre\lib\ext;
<app_client_root>\lib;
<app_client_root>\plugins;
<app_client_root>\lib\ext;
<app_client_root>\lib\WMQ\java\lib"
-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props
-classpath <app_client_root>\properties
```

   Note: The previous entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client. If this sample is being run by a user other than the person who installed the client, the user must enter the entries.
- The Java **Run-Time Parameters** field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.
- Access the IBM Control Panel for Java from the **Start** menu. Click **Start** > **Control panel** > select the IBM Control Panel for Java.
- The applet container is the Web browser and the Java plug-in combination. You must first install the Applet client feature from the Application Client for WebSphere Application Server so that the browser recognizes the IBM product Java plug-in.

View the Samples gallery for more information about application clients.

Accessing secure resources using SSL and applet clients

By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use secure sockets layer (SSL) when needed.

If you decide that the security requirements for the applet differ from other application client types, then create a new version of the `sas.client.props` and `ssl.client.props` files.

1. Make a copy of the following files so that you can use them for an applet:
   - `<app_client_root>\properties\sas.client.props`
   - `<app_client_root>\properties\ssl.client.props`

2. Edit the copies of the `sas.client.props` and `ssl.client.props` files that you made with your changes.

3. Click **Start** > **Control panel** > select the product Java plug-in to open the Java control panel. To use the files you created in step 1, modify the following values:
   - `-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props`
   - `-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props`

   For more information on the `sas.client.props` and `ssl.client.props` files and WebSphere Application Server security, see the Security section of the information center.

Applet client security requirements:

When code is loaded, it is assigned permissions based on the security policy in effect. This policy specifies the permissions that are available for code from various locations. You can initialize this policy from an external policy file.

By default, the client uses the `<app_server_root>/properties/client.policy` file. You must update this file with the following permission:

SocketPermission grants permission to open a port and make a connection to a host machine, which is your WebSphere Application Server. In the following example, `yourserver.yourcompany.com` is the complete host name of your WebSphere Application Server:

```
permission java.util.PropertyPermission "*", "read";
permission java.net.SocketPermission "yourserver.yourcompany.com ,"connect";
```

Applet client tag requirements

Standard applets require the HTML `<APPLET>` tag to identify the applet to the browser. The `<APPLET>` tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by `<OBJECT>` and `<EMBED>` tags.

The following code example illustrates the applet code using the `<APPLET>` tag.

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the `<OBJECT>` and `<EMBED>` tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
```

```
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

Note: The `classid` and `type` values changed from WebSphere Application Server version 6.0.2 for version 6.1. Prior to version 6.1, the `classid` value was `clsid:8AE2D840-EC04-11D4-AC77-006094334AA9` and the `type` value was `application/x-websphere-client`. In order to successfully invoke the applet client in WebSphere Application Server version 6.1, these values need to be changed to those in the preceding example.

For more information about the applet client tag, see the Sun Microsystems article, http://java.sun.com/j2se/1.5.0/docs/guide/plugin/developer_guide/using_tags.html.

Applet client code requirements

The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called `java.naming.applet`. This property informs the `InitialContext` and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet.

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the highlighted third line to your code. That highlighted line identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY,     "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

Developing J2EE application client code

This topic provides the steps required to develop J2EE application client code.

A *J2EE application client* program operates similarly to a standard J2EE program in that it runs its own Java virtual machine (JVM) code and is invoked at its main method.

The Java Virtual Machine application client program differs from a standard Java program because it uses the Java Naming and Directory Interface (JNDI) namespace to access resources. In a standard Java program, the resource information is coded in the program.

Storing the resource information separately from the client application program makes the client application program portable and more flexible.

1. Write the client application program. Write the J2EE application client program on any development machine. At this stage, you do not require access to the WebSphere Application Server.

   Using the `javax.naming.InitialContext` class, the client application program uses the look-up operation to access the Java Naming and Directory Interface (JNDI) namespace. The `InitialContext` class provides the `lookup` method to locate resources.

   The following example illustrates how a client application program uses the `InitialContext` class:

```
import javax.naming.*

public class myAppClient
{
    public static void main(String argv[])
    {
```

```
      InitialContext initCtx = new InitialContext();
      Object homeObject = initCtx.lookup("java:comp/env/ejb/BasicCalculator");
      BasicCalculatorHome bcHome = (BasicCalculatorHome)
      javax.rmi.PortableRemoteObject.narrow(homeObject, BasicCalculatorHome.class);
      BasicCalculatorHome bc = bcHome.create();                      ...
   }
}
```

In this example, the program looks up an enterprise bean called `BasicCalculator`. The `BasicCalculator` EJB reference is located in the client JNDI namespace at `java:comp/env/ejb/BasicCalculator` . Since the actual Enterprise Java Bean run on the server, the application client run time returns a reference to the `BasicCalculator` home interface.

If the client application program lookup was for a resource reference or an environment entry, then the look up function returns an instance of the configured type as defined by the client application deployment descriptor. For example, if the program lookup was a JDBC data source, the lookup would return an instance of `javax.sql.DataSource`. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

2. Assemble the application client using an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer.

   The JNDI namespace knows what to return on a lookup because of the information assembled by the assembly tool.

   Assemble the J2EE application client on any development machine with the assembly tool installed.

   When you assemble your application client, provide the application client run time with the required information to initialize the execution environment for your client application program. Refer to the Application Server Toolkit (AST) or Rational Application Developer for implementation details.

   Remember following when you configure resources used by your client application program:
   • Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look-up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local J2EE resource. The J2EE specification does not specify a particular implementation of a resource. The following table contains supported resource types and identifies the resources to which the WebSphere Application Server provides a client implementation.

Resource Type	Client Configuration Notes	Client implementation provided by WebSphere Application Server
javax.sql.DataSource	Supports specification of any data source implementation class	No
java.net.URL	Supports specification of custom protocol handlers	Provided by Java Runtime Environment files
javax.mail.Session	Supports custom protocol configuration	Yes - POP3, SMTP, IMAP
javax.jms.QueueConnectionFactory, javax.jms.TopicConnectionFactory, javax.jms.Queue, javax.jms.Topic	Supports configuration of WebSphere embedded messaging, IBM MQ Series and other JMS providers	Yes - WebSphere embedded messaging

3. Assemble the Enterprise Archive (EAR) file.

   The application is contained in an enterprise archive or `.ear` file. The `.ear` file is composed of:
   • Enterprise bean, application client, and user-defined modules or `.jar` files
   • Web applications or `.war` files
   • Metadata describing the applications or application `.xml` files

   You must assemble the `.ear` file on the server machine.

4. Distribute the EAR file.

   The client machines configured to run this client must have access to the `.ear` file.

   If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, and then distribute the configured `.ear` file to the other machines.

   If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.

   You can either distribute the `.ear` files to the correct client machines, or make them available on a network drive.

   Distributing the `.ear` files is the responsibility of the system and network administrator.

5. Deploy the application client.

6. Configure the application client resources.

   If the client application defines the local resources, run the ACRCT (`clientConfig` command) on the local machine to reconfigure the `.ear` file. Use the ACRCT to change the configuration. For example, the `.ear` file can contain a DB2 resource, configured as `C:\DB2`. If, however, you installed DB2 in the `D:\Program Files\DB2` directory, use the ACRCT to create a local version of the `.ear` file.

After developing the J2EE application client code, launch the application client.

J2EE application client class loading

When you run your J2EE application client, a hierarchy of class loaders is created to load classes used by your application.

The following list describes the hierarchy of class loaders:
- The Application Client for WebSphere Application Server (Application Client) run time sets this value to the `WAS_LOGGING` environment variable.
- The *extensions class loader* class loader is a child to the bootstrap class loader. This class loader contains JAR files in the `java/jre/lib/ext` directory or those JAR files defined by the `-Djava.ext.dirs` parameter on the Java command. The Application Client client run time does not set `-Djava.ext.dirs` parameters. So it uses the JAR files in the `java/jre/lib/ext` directory.
- The *system class loader* class loader contains JAR files and classes that are defined by the `-classpath` parameter on the Java command. The Application Client run time sets this parameter to the `WAS_CLASSPATH` environment variable.
- The *WebSphere class loader* class loader loads the Application Client client run time and any classes placed in the Application Client user directories. The directories used by this class loader are defined by the `WAS_EXT_DIRS` environment variable. The `WAS_BOOTCLASSPATH`, `WAS_CLASSPATH`, and the `WAS_EXT_DIRS` environment variables are set in the *app_server_root*/bin/setupCmdLine script for WebSphere Application Server installations, or in the *app_server_root*/bin/setupClient script for client installations.

As the J2EE application client run time initializes, additional class loaders are created as children of the WebSphere class loader. If your client application uses resources such as Java DataBase Connectivity (JDBC) API, Java Message Service (JMS) API, or Uniform Resource Locator (URL), a different class loader is created to load each of those resources. Finally, the Application Client run time sets the WebSphere class loader to load classes within the `.ear` file by processing the client JAR manifest repeatedly. The system class path, defined by the CLASSPATH environment variable is never used and is not part of the hierarchy of class loaders.

To package your client application correctly, you must understand which class loader loads your classes. When the Java code loads a class, the class loader used to load that class is assigned to it. Any classes subsequently loaded by that class will use that class loader or any of its parents, but it will not use children class loaders.

In some cases the Application Client run time can detect when your client application class is loaded by a different class loader from the one created for it by the Application Client run time. When this detection occurs, you see the following message:

`WSCL0205W: The incorrect class loader was used to load [0]`

This message occurs when your client application class is loaded by one of the parent class loaders in the hierarchy. This situation is typically caused by having the same classes in the `.ear` file and on the hard drive. If one of the parent class loaders locates a class, that class loader loads it before the Application Client run time class loader. In some cases, your client application still functions correctly. In most cases, however, you receive ″class not found″ exceptions.

Configuring the classpath fields

When packaging your J2EE client application, you must configure various class path fields. Ideally, you should package everything required by your application into your `.ear` file. This is the easiest way to distribute your J2EE client application to your clients. However, you should not package such resources as JDBC APIs, JMS APIs, or URLs. In the case of these resources, use class path references to access those classes on the hard drive. You might also have other classes installed on your client machines that you do not need to redistribute. In this case, you also want to use classpath references to access the classes on the hard drive, as described below.

Referencing classes within the EAR file

WebSphere product J2EE applications do not use the system class path. Use the MANIFEST Class path entry to refer to other JAR files within the `.ear` file. Configure these values using an assembly tool such as the Application Server Toolkit (AST) or Rational Application Developer. For example, if your client application needs to access the path of the EJB JAR file, add the deployed enterprise bean module name to your application client class path. The format of the Class path field for each of the different modules (Application Client, EJB, Web) is the same:

- The values must refer to `.jar` and `.class` files that are contained within the `.ear` file.
- The values must be relative to the root of the `.ear` file.
- The values cannot refer to absolute paths in the file systems.
- Multiple values must be separated by spaces, not colons or semicolons.

Note: This is the Java method for allowing applications to function platform independent.
Typically, you add modules (`.jar` files) to the root of the `.ear` file. In this case, you only need to specify the name of the module (`.jar` file) in the Class path field. If you choose to add a module with a path, you need to specify the path relative to the root of the `.ear` file.

For referencing `.class` files, you must specify the directory relative to the root of the `.ear` file. With the Application Server Toolkit (AST) or Rational Web Developer, you can add individual class files to the `.ear` file. It is recommended that these additional class files are packaged in a `.jar` file. Add this `.jar` file to the module Class path fields. If you add `.class` files to the root of the `.ear` file, add **./** to the module Class path fields.

Consider the following example directory structure in which the file myapp.ear contains an application client JAR file named `myclient.jar` and a `mybeans.jar` EJB module. Additional classes reside in class1.jar and utility/class2.zip files. A class named `xyz.class` is not packaged in a JAR file but is in the root of the EAR file. Specify **./ mybeans.jar utility/class2.zip class1.jar** as the value of the Classpath property. The search order is: `myapp.ear/myclient.jar myapp.ear/xyz.class myapp.ear/mybeans.jar myapp.ear/utility/class2.zip myapp.ear/class1.jar`

Referencing classes that are not in the EAR file

Use the launchClient -CCclasspath parameter. This parameter is specified at run time and takes platform-specific class path values, which means multiple values are separated by semi-colons or colons. The client and the server are similar in this respect.

Resource class paths

When you configure resources used by your client application using the Application Client Resource Configuration Tool, you can specify class paths that are required by the resource. For example, if your application is using a JDBC to a DB2 database, add db2java.zip to the class path field of the database provider. These class path values are platform-specific and require semi-colons or colons to separate multiple values.

On WebSphere Application Server for i5/OS, if you use the IBM Developer Kit for Java JDBC provider to access DB2/400, you do not have to add the db2_classes.jar file to the class path. However, if you use the IBM Toolbox for Java JDBC provider, specify the location of the jt400.jar file.

Using the launchClient API

If you use the launchClient command, the WebSphere class loader hierarchy is created for you. However, if you use the launchClient API, you must perform this setup yourself. Copy the launchClient shell command in defining the Java system properties.

Assembling application clients

Application client projects contain programs that run on networked client systems. An application client project is deployed as a JAR file.

Assemble a client module to contain application client code. Group enterprise beans, Web components, and resource adapter code in separate modules.

Use an Application Server Toolkit (AST) or Rational Application Developer assembly tool to assemble an application client module in any of the following ways:
- Import an existing application client JAR file.
- Create a new application client module.
1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **J2EE** capability is enabled.
3. Migrate application client JAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your application client JAR files to the assembly tool.
4. Create a new application client.
5. Verify the contents of the new application client in either of the following ways:
   - In the Project Explorer view, expand **Application Client Projects** and view the new module.
   - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

After you finish assembling all of your application's modules, you are ready to deploy your application.

▶ Windows   To deploy your application on Windows, refer to "Deploying J2EE application clients on workstation platforms" on page 249.

For more information, see the online help for the assembly tool. Similar information is in the **Application Server Toolkit** information center available with this information center. Click **Application Server Toolkit > J2EE applications >** *application_clients_topic*.

Developing Pluggable application client code

This topic provides steps to install and use the Pluggable application client.

WebSphere Application Server Version 6.1 supports the pluggable client.

As you prepare to install the pluggable application client, remember that pluggable clients are only available on Windows systems.

Both J2EE application clients and thin application clients can access JMS resources provided by the default messaging provider.

1. Install the pluggable application client by selecting option **Pluggable Application Client** from the **Custom client installation** panel.
2. Set the Java application pluggable client environment by using the **setupClient** shell, located in:

   app_client_root\AppClient\bin\setupClient.bat
3. Add your specific Java client application JAR files to the CLASSPATH and start your Java client application from this environment, after setting the environment variables.
4. Run a Java command to invoke your client application.

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING% -Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
-classpath "%WAS_CLASSPATH%;<list of your application jars and classes>
-Djava.ext.dirs="%JAVA_JRE%\lib\ext;%WAS_EXT_DIRS%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
-Djava.naming.provider.url=iiop://<your WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Djava.endorsed.dirs="%WAS_ENDORSED_DIRS%"
%SERVER_ROOT% %CLIENTSAS% %CLIENTSSL% <fully qualified class name to run>
```

View the Samples Gallery for more information about the Application Client.

Developing Thin application client code

You can develop and run Java thin client applications on machines installed with either a client or a server. The client provides a setup command shell which sets up your environment for either a thin client application or a J2EE client application. The server provides a command shell which sets up your environment for J2EE application clients only.

Both J2EE application clients and thin application clients can access JMS resources provided by the default messaging provider.

WebSphere Application Server Version 6.1 supports the pluggable client.

Note: Thin clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 6.1 thin client is not packaged with Cloudscape version 10.1 classes. Likewise, the version 6.02 thin client is not packaged with Cloudscape Version 5.1 or Cloudscape Version 10.0 classes. Therefore, to utilize the JDBC provider classes (such as Cloudscape, Oracle, DB2, Informix, or Sybase) on a thin client, you must:

1. Add the classes to your thin client environment.
2. Make the classes visible to the thin client application. To do this, add the path to the classes in the client classpath within the script that launched the client program.

   Otherwise, any attempt to load a database class (such as through the JNDI lookup of a datasource) results in a ClassNotFoundException.

The Java invocation to run a thin application client varies between a client and a server. If your thin client application needs to run on both a client installation and a server installation, follow the steps for developing thin application clients on a server machine.

1. Install the Java application thin client by selecting option **J2EE and Thin application client** from the Application Client for WebSphere Application Server installation.
2. Perform one of the following:
   - Develop Thin application client code for a client machine.
   - Develop Thin application client code for a server machine.

View the Samples gallery for more information about the Application Client.

Developing Thin application client code on a client machine

This topic provides the steps necessary to develop Thin application client code on a client machine.

You must install the Thin application client from the Application Client for WebSphere Application Server installation before performing this task. For more information, see Developing thin application client code.

1. Set the Java application thin client environment.

   Use the setupClient shell.

   ► Windows

   ```
   app_client_root\AppClient\bin\setupClient.bat
   ```

2. Compile your client application.

   ► Windows   Run the following Java compilation command.

   ```
   "%JAVA_HOME%\bin\javac" -classpath "%WAS_CLASSPATH%;
   <list of your application jars and classes> " -extdirs %WAS_EXT_DIRS%
   <your application class>.java
   ```

3. Invoke your client application.

   Run the following Java command: ► Windows

   ```
   "%JAVA_HOME%\bin\java" %WAS_LOGGING% -Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
   -classpath "%WAS_CLASSPATH%;<list of your application jars and classes>"
   -Djava.ext.dirs="%JAVA_JRE%\lib\ext;%WAS_EXT_DIRS%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
   -Djava.naming.provider.url=iiop://<your WebSphere server machine name>
   -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
   "%SERVER_ROOT%" "%CLIENTSAS%" "%CLISENTSSL%" <fully qualified class name to run>
   ```

   For more information on IIOP and `corbaloc` URLs, see Developing applications that use JNDI.

View the Samples gallery for more information about the Application Client.

Developing Thin application client code on a server machine

This topic provides the steps necessary to develop Thin application client code on a server machine.

You must install WebSphere Application Server before performing this task.

1. Set up the Thin application client environment.

   Use the **setupCmdLine** shell, located in: ► Windows

   ```
   profile_root\bin\setupCmdLine.bat
   ```

2. Compile your client application.

   ► Windows

   ```
   "%JAVA_HOME%\bin\javac" -classpath "%WAS_CLASSPATH%;
   <list of your application jars and classes> " -extdirs %WAS_EXT_DIRS%
   <your application class>.java
   ```

3. Run the application client. Perform one of the following methods.
   - Use Java code to call your main class directly:

     ► Windows

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING%"
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
-Djava.ext.dirs="%JAVA_HOME%\jre\lib\ext;%WAS_EXT_DIRS%%;%WAS_HOME%\plugins;%WAS_HOME%\lib\WMQ\java\lib"
-Djava.naming.provider.url=<an IIOP URL or a corbaloc URL to your
WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="%WAS_HOME%" "%CLIENTSAS%" "%CLIENTSSL%" %USER_INSTALL_PROP%
-classpath "%WAS_CLASSPATH%;<list of your application jars and classes>"
<fully qualified class name to run><your application parameters>
```
  - Use the WebSphere Application Server launcher.

    > Windows ◄ Enter:

```
"%JAVA_HOME%\bin\java" %WAS_LOGGING%
-Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf"
-classpath "%WAS_CLASSPATH%;<list of your application jars and classes>
-Djava.ext.dirs="%WAS_EXT_DIRS%;%WAS_HOME%\plugins"
-Djava.endorsed.dirs="%WAS_ENDORSED_DIRS%
-Djava.naming.provider.url=iiop://<your WebSphere server machine name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
%SERVER_ROOT% %CLIENTSAS% %CLISENTSSL% <fully qualified class name to run>
```

For more information on IIOP and `corbaloc` URLs, see Developing applications that use JNDI.

View the Samples gallery for more information about the Application Client.

Deploying J2EE application clients on workstation platforms

You can deploy the J2EE application clients on workstation platforms using the methods described in this topic.

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the client `.jar` file within the application `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging resources.
6. Configure new environment entries.
7. (Optional) Remove application client resources.
8. Save the EAR file.

Resource Adapters for the client

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

The resource adapter support for the J2EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory

interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running J2EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Configuring resource adapters

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the **Resource Adapters** folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

clientRAR tool:

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.
```

```
<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

On the Windows operating systems:

- clientRAR add c:\rars\myrar.rar
- clientRAR delete myrar.rar

On the UNIX operating systems:

- ./clientRAR add /usr/rars/myrar.rar
- ./clientRAR delete myrar.rar

Configuring new connection factories for resource adapters:

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters.

Complete this task to configure new connection factories for resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the **Connection Factories** folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type   String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type   String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type   String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type   String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type   String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type   String

Configuring administered objects:

252   Developing and deploying applications

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the .ear file, using the Application Client Resource Configuration Tool (ACRCT) tool.

Complete this task to configure new administered objects for installed resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type   String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type   String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type   String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type   String

Resource adapter settings

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type   String

Description:

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type   String

Class Path:

Any additional class path. The path to the resource adapter directory is automatically added.

Data type   String
Default   The path to your Resource Adapter directory.

Native Path:

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type   String

Resource Adapter Name:

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

| **Data type** | String |

Installed Resource Adapter Path:

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type	String
Default	${CONNECTOR_INSTALL_ROOT}

Starting the Application Client Resource Configuration Tool and opening an EAR file

You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

Note: This task only applies to J2EE application clients.

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

1. Open a command prompt and change to the *app_server_root*\bin directory.
2. Run the `clientConfig.bat` file for a Windows system or the `clientConfig.sh` file for a UNIX system.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   - Click **File** > **Open**.
   - Select the file and click **Open**.
4. Save your changes to the file and close the tool:
   - Click **File** > **Save**.
   - Click **File** > **Exit**.

Data sources for the Application Client

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a J2EE application client. If your application client accesses a database directly, you must provide the database drivers on the client machine.

You can contact your database vendor to acquire client database driver code and licenses. In addition, data sources configured on the server and looked up on the client do not participate in global transactions. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine, since the database access is handled by the enterprise bean running on WebSphere Application Server. For a current list of providers that are supported on WebSphere Application Server visit the Supported hardware, software, and APIs Web site:

Data source properties for application clients

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Data type   String

Description:

Specifies a text description of the data source.

Data type   String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data source providers (JDBC providers) for application clients

You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT) .

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

Use this task to connect application clients to relational databases.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example: Configuring data source provider and data source settings:

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.
- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg=="/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type	String

Description:

Specifies a text description for the resource.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type	String
Default	Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

You can edit the configurations of JavaMail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of JavaMail sessions and providers for your application clients to use.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the JavaMail objects in the tree that displays. For example, if your file contains JavaMail sessions, expand **Resources** > **application**.jar > **Mail Providers** > **java_mail_provider_instance** > **Mail Sessions**.

   In this example, **java_mail_provider_instance** is a particular JavaMail provider.

The JavaMail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients:

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: TRANSPORT or STORE.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients:

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or ″domain″) name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JavaMail provider and JavaMail session settings for application clients:

You can configure JavaMail provider and JavaMail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you configure JavaMail provider and JavaMail session settings.
- Required fields:
  - JavaMail Provider Properties page: name, and at least one protocol provider
  - JavaMail Session Properties page: name, jndiName, mail transport protocol, mail store protocol
- Special cases:
  - The password is encrypted when using the ACRCT tool. Without the tool, you cannot encrypt this field.
- Example:

```
<resources.mail:MailProvider xmi:id="MailProvider_1" name="Default Mail Provider"
description="IBM JavaMail Implementation">
<classpath>mailProvider:classpath</classpath>
<factories xmi:type="resources.mail:MailSession" xmi:id="MailSession_1"
name="mailSession:name" jndiName="mailSession:jndiName"
description="mailSession:description" mailTransportHost="mailSession:mailTransportHost"
```

```
mailTransportUser="mailSession:mailTransportUser"
mailTransportPassword="{xor}Mj42Mww6LCw2MDFlMT4yOg=="
mailFrom="mailSession:mailFrom" mailStoreHost="mailSession:mailStoreHost"
mailStoreUser="mailSession:mailStoreUser"
mailStorePassword="{xor}Mj42Mww6LCw2MDFlMT4yOg==" debug="true"
mailTransportProtocol="ProtocolProvider_1" mailStoreProvider="ProtocolProvider_1">
<propertySet xmi:id="J2EEResourcePropertySet_1">
<resourceProperties xmi:id="J2EEResourceProperty_1"
name="mailSession:customName" value="mailSession:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_2">
<resourceProperties xmi:id="J2EEResourceProperty_2" name="mailProvider:customName"
value="mailProvider:customValue"/>
</propertySet>
<protocolProviders xmi:id="ProtocolProvider_1" protocol="smtp"
className="smtp:className"/>
<protocolProviders xmi:id="ProtocolProvider_2" protocol="pop3"
className="pop3:className"/>
<protocolProviders xmi:id="ProtocolProvider_3" protocol="imap"
className="imap:className"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.

2. Select the JAR file in which you want to configure the new JavaMail session.

3. Expand the JAR file to view its contents.

4. Click **Mail Providers** > **Mail Provider** > **Mail Sessions**. Complete one of the following actions:
   - Right click the **Mail Sessions** folder and select **New Factory**.
   - Click **Edit** > **New** on the menu bar.

5. Configure the Mail Session properties in the displayed fields.

6. Click **OK**.

7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www-4.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit** > **New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool:

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> ***application*.jar** -> **URL Providers** -> ***url_provider_instance***
   where ***url_provider_instance*** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients:

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.
- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

During this task, you create URLs for your client application.
1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.

4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File** > **Save** in the menu bar to save your changes.

Asynchronous messaging in WebSphere Application Server using JMS

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for Publisher and Subscriber messaging. A J2EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a J2EE application, without the application having to explicitly poll JMS destinations.

Java Message Service (JMS) providers for clients

This topic describes the different ways that client applications can use JMS providers with WebSphere Application Server. A JMS provider enables use of the Java Message Service (JMS) and other message resources in WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
    Provided for use with supported versions of WebSphere MQ.

Generic

Provided for use with any 3rd party messaging system which supports ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

The service integration bus also provides access to a default messaging provider. This is a J2EE 1.4 compliant JMS messaging provider which is fully integrated with WebSphere Application Server. You can use it in multiple server configurations for messaging interactions with a WebSphere MQ network.

Configuring Java messaging client resources

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Note: When completing this task, you can either create a new messaging provider, or you can use an existing one.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool:

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of J2EE resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients:

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String

Description:

A description of the JMS provider, for administrative purposes.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type	String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type   String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type   String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type   String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type   String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type   String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type   String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type   String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type   String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default   ReliablePersistent

Range

None   There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default   ReliablePersistent

Range

None	There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type	String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type	Selection list
Default	In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`merlin:7276:BootstrapBasicMessaging,Gandalf:`
	`5557:BootstrapSecureMessaging`
	
	where
	
	`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type	String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type	String

Description:

A description of this queue connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type	String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type	String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default   ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

| **Default** | Default |
| **Range** | Default, AlwaysOn and AlwaysOff |

Target:

The name of the Workload Manager target group containing the messaging engine.

| **Data type** | String |

Target Type:

The type of Workload Manager target group that contains the messaging engine.

| **Default** | BusMember |
| **Range** | BusMember, Custom, Destination, ME |

Target Significance:

The priority of significance for the target specified.

| **Default** | Preferred |
| **Range** | Preferred, Required |

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging`
	where
	`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value.
	• If the port number is not specified, then `7276` is used as a default value.
	• If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus, Cluster, Server
Range	Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type	String

Default Provider topic connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Data type String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent
Range	
	None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.
	Best effort nonpersistent Messages are never written to disk, and are thrown away if memory cache overruns.
	Express nonpersistent Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.
	Reliable nonpersistent Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.
	Reliable persistent Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.
	Assured persistent Highest degree of reliability where assured message delivery is supported.
	As Bus destination Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default	ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type   String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type   Selection list
Default   In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default   Default
Range   Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type   String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default   BusMember
Range   BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default   Preferred
Range   Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type   String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example   `localhost:7777:BootstrapBasicMessaging`

                                               where

                                               `BootstrapBasicMessaging` corresponds to the remote
                                               protocol InboundBasicMessaging (JFAP-TCP/IP).
Default   • If the host name is not specified, then the default
                                                 `localhost` is used as a default value.
                                               • If the port number is not specified, then `7276` is used as
                                                 a default value.
                                               • If the chain name is not specified, a predefined chain,
                                                 such as `BootstrapBasicMessaging`, is used as a default
                                                 value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default   Bus
Range   Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type   String

Default Provider queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type   String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type   String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type   String

Queue Name:

The name of the queue.

Data type   String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type   String
Range   Application, Persistent or NonPersistent

Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Default Provider topic destination settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type	String

Description:

A description of the entry.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

| **Data type** | String |

Topic Space:

The name of the topic space. This field is required.

| **Data type** | String |
| **Default** | DEFAULT_TOPIC_SPACE |

Topic Name:

The name of the topic. This field is required.

| **Data type** | String |

Delivery Mode:

The default mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

| **Data type** | Long |
| **Units** | Milliseconds |

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

| **Data type** | Integer |
| **Range** | 0 to 9 with **0** as the lowest priority and **9** as the highest priority |

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Version 5 Default Provider queue connection factory settings for application clients:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A Version 5 Default Provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type   String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A Version 5 Default Provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type   String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type   String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Range	Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Default	QUEUED

Range

             QUEUED

                The listener port used for full-function JMS compliant, publish or subscribe support.

             DIRECT

                The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

             The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type   String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A Version 5 Default Provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type   String

Description:

A description of the queue, for administrative purposes.

Data type   String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	Messages on the destination have their persistence defined by the application that put them onto the queue.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Persistent
	Messages on the destination are persistent.
	Nonpersistent
	Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The priority of messages on this destination is defined by the application that put them onto the destination.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Specified
	The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The expiry timeout for messages in this queue is defined by the application that put them onto the queue.
	Specified
	The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.
	Unlimited
	Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0
	• 0 indicates that messages never timeout.
	• Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A Version 5 Default Provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type	String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type   String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type   String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	Messages on the destination have their persistence defined by the application that put them onto the queue.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Persistent
	Messages on the destination are persistent.
	Nonpersistent
	Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The priority of messages on this destination is defined by the application that put them onto the destination.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Specified
	The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
	Specified
	The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*
	Unlimited
	Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0
	• 0 indicates that messages never time out.
	• Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book, located in the WebSphere MQ Family library.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the userid and password to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type   String
Default   Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type   String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type   String
Default   Null
Range   A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type   Integer
Default   Null
Range   A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type   String
Default   Null
Range   1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	**BINDINGS**
	JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles.
	CLIENT
	WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.
	DIRECT
	For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.
	QUEUED
	QUEUED is a standard TCP protocol.
Recommended	**Queue connection factory transport type**
	BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.
	Topic connection factory transport type
	DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
 -e default -o DynamicSubscriptionEngine -n
 maxClientQueueSize -v 0 -x executionGroupUUID
```

    where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Note: The WebSphere MQ 5.3 JMS cannot be used within WAS 6.1 because WAS 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WAS 6.1.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type	String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www-3.ibm.com/ software/ts/mqseries/library/manualsa/manuals/platspecific.html, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type	Enum
Units	Not applicable
Default	Cleared
Range	**Selected**
	Unwanted messages are left on the queue.
	Cleared
	Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type	String
Range	1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type	String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type	Check box
Default	Selected

Local Server Address:

Specifies the local server address.

Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section "Working with Certificate Revocation Lists" in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

MA0C broker: When creating a WebSphere Application Server v6 topic connection factory for the MA0C broker, you should consider the following attribute values:

BrokerControlQueue
> This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

BrokerVersion
> Set this value to BASIC for the MA0C broker.

ClientID
> Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

XA Enabled

> Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you will probably want to set this to 'true' most of the time).

BrokerMessage Selection

> This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

Direct Broker Authorization Type

> This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
Units	En_US ASCII characters
Range	1 through 45 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type   String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type   String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type   String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type   String
Range   A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type   Integer
Range   A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type   String
Range   1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type	Enum
Default	BINDINGS
Range	**CLIENT**
	WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
	BINDINGS
	JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type	String

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type	String

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

Data type	Enum	
Default	Advanced	
Range	**Advanced**	The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe).
	Basic	The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

Specifies the level of clean up provided by the publish or subscribe cleanup utility.

Data type	Enum
Default	SAFE
Range	**ASPROP**
	NONE
	STRONG

Cleanup interval:

Specifies the interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type	Integer

Units	Milliseconds
Default	6000

Message selection:

Specifies where broker message selection is performed.

Data type	Enum
Default	BROKER
Range	
	BROKER
	Message selection is done at the broker location.
	Message CLIENT
	Message selection is done at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type	Integer
Default	25

Sparse subscriptions:

Enables sparse subscriptions.

Data type	Check box
Default	Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh publish or subscribe status.

Data type	Integer
Default	6000

Subscription store:

Specifies where WebSphere MQ stores data relating to active JMS subscriptions.

Data type	Enum
Default	MIGRATE
Range	
	MIGRATE
	QUEUE
	BROKER

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type	Enum
Default	NOT USED
Range	

NOT USED
This connection factory does not use multicast transport.

ENABLED
This connection factory always uses multicast transport.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport.

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if available.

Direct authentication:

Specifies whether to use direct broker authorization.

Data type	Enum
Default	NONE
Range	**NONE** Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificates.

Proxy Host Name:

Specifies the host name of a proxy to be used for communication with WebSphere MQ.

Data type	String

Proxy Port:

Specifies the port number of a proxy to be used for communication with WebSphere MQ.

Data type	Integer
Default	0

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type	Check box
Default	Selected

Local Server Address:

Specifies the local server address.

Data type   String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type   Integer
Units   Milliseconds
Default   5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type   Integer
Units   Milliseconds
Default   5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section "Working with Certificate Revocation Lists" in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:
  - The property values that you specify must match the values that you specified when configuring WebSphere MQ product for JMS resources. For more information about configuring WebSphere MQ product for JMS resources, see the WebSphere MQ *Using Java* book.
  - In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type	String

Description:

A description of the queue, for administrative purposes.

Data type	String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	Messages on the destination have their persistence defined by the application that put them onto the queue.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Persistent
	Messages on the destination are persistent.
	Nonpersistent
	Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	**Application defined**
	The priority of messages on this destination is defined by the application that put them onto the destination.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Specified
	The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	**Application defined**
	The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
	Specified
	The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.
	Unlimited
	Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0
	• 0 indicates that messages never time out
	• Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type	String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type	String

Units	En_US ASCII characters
Range	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type	String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type	Enum
Default	NORMAL
Range	**NORMAL**
	Normal integer encoding is used.
	REVERSED
	Reversed integer encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type	Enum
Default	NORMAL
Range	**NORMAL**
	Normal decimal encoding is used.
	REVERSED
	Reversed decimal encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type	Enum
Default	IEEENORMAL
Range	**IEEENORMAL**
	IEEE normal floating point encoding is used.
	IEEEREVERSED
	IEEE reversed floating point encoding is used.
	S390 S390 floating point encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type	Enum
Default	Cleared
Range	**Cleared**
	Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
	Selected
	Native encoding is used (to provide appropriate encoding values for the Java platform).
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application.

Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ**
	The target is a traditional WebSphere MQ application that does not support JMS.
	JMS The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:
- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type	String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	Messages on the destination have their persistence defined by the application that put them in the queue.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Persistent
	Messages on the destination are persistent.
	Nonpersistent
	Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The priority of messages on this destination is defined by the application that put them in the destination.
	Queue defined
	[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
	Specified
	The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined**
	The expiry timeout for messages on this queue is defined by the application that put them in the queue.
	Specified
	The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.
	Unlimited
	Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0
	• 0 indicates that messages never time out.
	• Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type	String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type	String

| Units | Integer |
| Range | 1 through 65535 |

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type	Enum
Default	NORMAL
Range	**NORMAL**
	Normal integer encoding is used.
	REVERSED
	Reversed integer encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type	Enum
Default	NORMAL
Range	**NORMAL**
	Normal decimal encoding is used.
	REVERSED
	Reversed decimal encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type	Enum
Default	IEEENORMAL
Range	**IEEENORMAL**
	IEEE normal floating point encoding is used.
	IEEEREVERSED
	IEEE reversed floating point encoding is used.
	S390 S/390 floating point encoding is used.
	For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

| Data type | Enum |
| Default | Cleared |

Range	**Cleared**
	Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.
	Selected
	Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ**
	The target is a traditional WebSphere MQ application that does not support JMS.
	JMS The target is a JMS compliant application.

Multicast:

Specifies whether this connection factory uses multicast transport.

| **Data type** | Enum |
| **Default** | AS_CF |

Range

AS_CF This connection factory uses multicast transport.

DISABLED
This connection factory does not use multicast transport.

NOT_RELIABLE
This connection factory always uses multicast transport.

RELIABLE
This connection factory uses multicast transport when the topic destination is not reliable.

ENABLED
This connection factory uses reliable multicast transport.

Generic JMS connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type   String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type   String
Default   Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type   String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
Queue
        A JMS queue destination for point-to-point messaging.
Topic   A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type   String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type   String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:
Queue
        A JMS queue destination for point-to-point messaging.
Topic   A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients:

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.
- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.

4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new Java Message Service destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new resource environment providers for application clients

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

During this task, you create new resource environment provider configurations for your application client.

To configure a new resource environment provider, perform the following steps:

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

During this task, you create new resource environment entries for your client application.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   * Configure a new resource environment provider.
4. Expand the resource environment provider to view the **Resource Environment Entries** folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   * Right-click the folder and select **New**.
   * Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Managing application clients

You can manage J2EE application clients using the Application Client Resource Configuration Tool (ACRCT).

Perform the following tasks after deploying application clients. This task only applies to J2EE application clients.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool:

You can update the configuration of an existing data source or data source provider using the Application Client Resource Configuration Tool (ACRCT).

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Data source provider properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients:

You can update URLs and URL provider configurations for application clients using the Application Client Resource Configuration Tool (ACRCT).

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File** > **Save** on the menu bar to save your changes.

Updating mail session configurations for application clients:

You can update the configuration of an existing JavaMail session using the Application Client Resource Configuration Tool (ACRCT).

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit** > **Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File** > **Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients:

You can update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination using the Application Client Resource Configuration Tool (ACRCT).

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   • Right-click the provider, and click **Properties**.
   • Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   • JMS provider properties
   • WebSphere Application Server Queue connection factory properties

- WebSphere Application Server Topic connection factory properties
- WebSphere Application Server Queue destination properties
- WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients:

You can update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients:

You can update the configuration of an existing resource environment entry or resource environment provider using the Application Client Resource Configuration Tool (ACRCT).

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.
2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties

5. Click **OK** when you finish.

6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings:

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients:

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources:

You can remove J2EE application client resources using the Application Client Resource Configuration Tool (ACRCT).

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to J2EE application clients.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File** > **Save** to save your work before preceding to delete an object.

2. Locate the object that you want to remove in the tree.

3. Right-click the object, and click **Delete**.
4. Click **File** > **Save**.

Installing Application Client for WebSphere Application Server

This topic describes how to install the Application Client for WebSphere Application Server using the installation image on the product CD-ROM.

Running client applications that communicate with a WebSphere Application Server requires that elements of the Application Server are installed on the system on which the client applications run. However, if the system does not have the Application Server installed, you can install Application Client, which provides a stand-alone client run-time environment for your client applications. See the Supported Prerequisites page for more information on supported product platforms.

The steps that follow provide enough detail to guide you through preparing for, choosing, and installing the variety of options and features provided. To prepare for installation and to make yourself familiar with installation options, complete the steps in this article and read the related topics, before you start to use the installation tools. Specifically, read these topics before installing the product:

*   Installing silently
*   Best practices for installing

As a general rule, if you launch an installation and there is a problem such as not having enough temporary space or not having the right packages on your Linux or UNIX systems, then cancel the installation, and make the required changes. Restart the installation to initiate your changes.

You can install this product by a non-root user on a UNIX operating system and non-administrator user on a Windows operating system. However, the following functions are not enabled on Windows if the product is installed by a non-administrator user:

*   ActiveX to EJB bridge
*   Applet Client
*   Launching Java Web Start from browser

In Version 6.x, the Application Client for WebSphere Application Server is installable on a machine with a previous version of Application Clients. However, you cannot install a Version 6.x Application Client on top of a previous version of the Application Client. For example, if a Version 5 Application Clients install under the `C:\WebSphere\AppClient` directory, you can not choose the same install location for your V6.x

Note: For Application Clients to coexist, there is a limitation on Applet client and ActiveX client on Windows that can not be coexisted with V5.0.x and V4.x of the clients. For example, the Applet client feature in Version 6.x cannot coexist with the Applet client feature in any previous release. This coexistence is not available because the installation of Applet client feature in Version 6.x sets the browser default Java Virtual Machine (JVM) using the Java Runtime Environment (JRE) from the Version 6.x installation, which is Java Runtime Environment Version 1.4.2. Similarly, the ActiveX to EJB Bridge feature in Version 6.x sets the Windows system path to use the JRE from the Version 6.x installation.

1. Install Application Client for WebSphere Application Server using the launchpad.

   See Install Application Client for WebSphere Application Server using the launchpad.

   ▶ **Linux**   The launchpad program is available on the root directory of the product CD in the program, `launchpad.sh`.

   ▶ **Windows**   The launchpad program is available on the root directory of the product CD in the program `launchpad.bat`.

Note: The free download Application Client installation is not packaged with the launchPad program.

a. Click **Launch the installation wizard for Application Client for WebSphere Application Server** from the launchpad tool to launch the InstallShield for MultiPlatforms installation wizard. This action launches the installation wizard.

The Readme documentation to which the launchpad links is the `readme.html` file in the CD root directory. The readme directory off the root of the CD has more detailed Readme files. The Installation Guide is in the `/docs` directory of the CD root directory.

Note: Readme file names are based on product offerings.

When you install application clients, the current working directory must be the directory where the installer binary program is located. This placement is important because the resolution of the class files location is done in the current working directory. For example:

```
cd /install_root/AppClient

./install
```

or

```
 cd <CD mount point>/AppClient

    ./install
```

Failing to use the correct working directory can cause ISMP errors that abort the installation.

The installation wizard does not upgrade or remove previous Application Clients installation automatically. Application Client V6.1 can be installed together with previously installed Application Clients if their versions are lower than 6.1. However, only one instance of Application Client V6.1 can be installed on the same system. When the installer is launched, it will detect any existing installation of Application Client V6.1 and direct the install flow to the feature panels so that additional features can be added on top of the existing installation.

b. As indicated in the previous example, you can start the installation wizard from the product CD-ROM, using the command line.

On other Linux platforms and UNIX-based platforms, run the `./install` command.

On Windows platforms, run the `Install.exe` command.

c. You can also perform a silent installation using the `-options responsefile -silent` parameter, which causes the installation wizard to read your responses from the options response file, instead of from the interactive graphical user interface. Customize the response file before installing silently. After customizing the file, issue the command to silently install. Silent installation is particularly useful if you install the product often.

The rest of this procedure assumes that you are using the installation wizard. There are corresponding entries in the response file for every prompt that is described as part of the wizard. Review the description of the response file for more information. Comments in the file describe how to customize its options.

2. Click **Next** to continue when the Welcome panel is displayed.

a. Click the radio button beside the **I accept the terms in the license agreement** message if you agree to the license agreement, and click **Next** to continue.

3. The installation wizard checks the system for prerequisites. Click **Next** if you see a success message on the wizard panel. If a warning message is displayed on the panel, click **Cancel** to exit the installation wizard and install the proper prerequisites to the system. **Note:** Application Client may be fully functional even if some prerequisites are not installed on the system, however it is recommended you update your system to the required level.

4. Specify a destination directory. Click **Next** to continue.

a. Ensure that there is adequate space available in the target directory.

b. Specify a target directory for the Application Client product.

c. Enter the required target directory to proceed to the next panel. Deleting the default target location and leaving an installation directory field empty prevents you from continuing the installation process.

5. Choose a type of installation, and click **Next**.

If you use the GUI you can choose a Typical installation type, which installs J2EE and Thin application client, Samples and IBM Developer Kit, Java 2 Technology Edition, or you can choose the custom installation type. For Windows, there are two custom installation types: Custom J2EE/Thin Client and Custom Pluggable Client. For other platforms, there is only one custom installation type.

▶ Windows Custom J2EE/Thin Client

- If you select the **ActiveX to EJB Bridge** feature, then the following is displayed in a dialog box: Do you want to add Java runtime to the system path and make it the default JRE? If you answer Yes, then the Java run time is added to the beginning of the system path. If you answer No, then the ActiveX to EJB Bridge does not function from the Active Server Pages (ASP), unless you add the Java run time to the path. To add the Java run time later, see the topic ActiveX application clients or reinstall the Application Client.

- If you select the **Applet client** feature, then the following message might be displayed: An existing JDK or JRE has been detected on your computer. You chose to install the Applet Client, which will overwrite the registry entries for this JDK or JRE. Do you want to continue and install the Applet Client? If you select Yes, the installation overrides the registry on your machine. If you select No, the Applet client feature is not installed, and you are directed back feature dialog box.

- Install the Software Developer Kit feature, if you need to use any of the utilities that it provides, such as the javaccompiler, the jarutility or the jarsigner utility. The Java 2 Development Kit that IBM provides has two components, Java Runtime Environment (JRE) and a complete Software Developer Kit (SDK). The JRE sub feature is selected by default for the Custom J2EE/Thin Client installation type. The SDK component is optional; however, you must install the SDK component to compile the sample.

- Install the Administration Thin Client, if you need a runtime jar that is customed to enable client applications to perform WebSphere administration tasks. The Administration Thin Client is installed into *<install_root>/runtimes*.

- Install the Web Services Thin Client, if you need a runtime jar that is customed to enable client applications to communicate with the Application Server through Web Services. The Web Services Thin Client is installed into *<install_root>/runtimes*.

▶ Windows Custom Pluggable Client

- Install the Pluggable Client samples if you want to make use of the Pluggable Client applications.

▶ Linux Custom

- Install the Software Developer Kit feature, if you need to use any of the utilities that it provides, such as the *javaccompiler*, the *jarutility* or the *jarsigner* utility. The Java 2 Development Kit that IBM provides has two components, Java Runtime Environment (JRE) and a complete Software Developer Kit (SDK). The JRE sub feature is selected by default for the Custom J2EE/Thin Client installation type. The SDK component is optional; however, you must install the SDK component to compile the sample.

- Install the Administration Thin Client, if you need a runtime jar that is customized to enable client applications to perform WebSphere administration tasks. The Administration Thin Client is installed into *<install_root>/runtimes*.

- Install the Web Services Thin Client, if you need a runtime jar that is customed to enable client applications to communicate with the Application Server through Web Services. The Web Services Thin Client is installed into *<install_root>/runtimes*.

6. (Pluggable Client installation type only) Click **Next** to accept the detected Sun JRE, or click Browse to select the location of the installed Sun JRE. The Sun Software Development Kit installation location is optional. However, if the installation location is not provided, the installed Samples do not compile.

- If Sun JRE has not been installed, the installation cannot be continued. Click **Cancel** to exit the installation. Install the Sun JRE, and restart the Pluggable Custom installation. The Sun JRE panel is displayed with the JRE path detected, and the Pluggable application client installation continues.

7. Enter the host name of the WebSphere Application Server machine. Click **Next** to continue. The default port number is 2809.

8. Review the summary information, and click **Next** to install the product code or you might also click **Back** to change your specifications.

9. Click **Finish** to exit the wizard, after the Application Client installs.

10. Verify the success of the installer program by examining the Completion panel and the `<install_root>`/logs/install/log.txt file for installation status. The installer program records the following indicators of success in the logs:

   - `INSTCONFSUCCESS` indicates that the installation is successful and that no further log analysis is required.
   - `INSTCONFFAILED` indicates an installation failure that you cannot retry or recover from without reinstalling.

You successfully installed the Application Client for WebSphere Application Server and the features you selected.

Use the installation verification utility to verify a successful installation. If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Best practices for installing Application Client for WebSphere Application Server

This topic provides tips for installing Application Client on multiple platforms.

The following table offers tips for installing Application Client on multiple platforms.

Operating environment	Tip
Linux and UNIX systems	Spaces are not supported in the name of the installation directory on Linux and UNIX platforms.
UNIX systems	When the application client installations are successful, the return code **0** is issued from the UNIX shell where you issued the /install command. Other return codes include: • **1** -- Failure • **2** -- Partial success Any other return code indicates an unsuccessful installation.
Solaris systems	Double-byte character set (DBCS) characters are not supported in the name of the installation directory on Solaris systems.
All platforms	Reserve at least 4 to 5MB free space in the target platform temporary directory.

All platforms	When specifying a different temporary directory while installing Application Client, the following message is displayed if the target platform default temporary directory does not have enough free space to install Application Client:
| | ```
Error writing file =  There may not be enough
temporary disk space.
Try using -is:tempdir to use a temporary
directory on a partition with more disk
space.
``` |
| | Use the `-is:tempdir` installation option to specify a different temporary directory. For example, the following command uses `/swap` as a temporary directory during installation: |
| | ```
./install -is:tempdir /swap
``` |
| All platforms | After the installation, when changing the installation settings for the WebSphere Application Server host name and the port number, edit the `setupClient.bat` for Windows or `setupClient.sh` for UNIX. Change the `DEFAULTSERVERNAME` and `SERVERPORTNUMBER` to the new WebSphere Application Server host name and port number, respectively. If the `SERVERPORTNUMBER` is not set, then the default is 2809. Review the following example: |
| | ```
set DEFAULTSERVERNAME=NDServerName
set SERVERPORTNUMBER=9810
``` |
| | The `setupClient.bat` file or `setupClient.sh` file is located in the `bin` sub-directory under the Application Client installation destination. |

Installing Application Client for WebSphere Application Server silently

This topic provides the steps necessary to use the installation wizard and perform a silent installation.

Use these steps to perform a silent installation, which uses the installation wizard to install the product. Instead of displaying a user interface, the silent installation provides interaction between you and the wizard by reading all of your responses from a file that you must customize.

1. Verify that the user ID that you are using to run the silent installation has sufficient authority to perform the task.
2. Customize the option response file.
   a. Locate the sample options response file. The file name is `setup.response` in the operating system platform directory on the product CD-ROM.
   b. Make a copy to preserve the original response file. For example, copy the file as `myoptionsfile`.
   c. Edit the copy in your flat file editor of choice, on the target operating system. Read the directions within the response file to choose appropriate values.

      Note: To prepare the file for a silent installation on AIX, use UNIX line-end characters (0x0D0A) to terminate each line of the options response file.
   d. Make a non-commented option to have a silent install.
   e. Include custom option responses that reflect parameters for your system.
   f. Follow the instructions in the response file to choose appropriate values.
   g. Save the file.
3. Issue a command to use your custom response file: `Install.exe -options myoptionsfile -silent` for Windows platforms and `install -options ./myoptionsfile -silent` for Linux and UNIX platforms.

   The sample options response file is located in the `AppClient` directory on the product CD-ROM.
   a. Issue the following command from a command prompt to update your response file: `-OPT silentInstallLicenseAcceptance="true'` .

Issuing this command indicates that you accept all IBM license terms associated with this product, which is necessary for installing application clients.

4. **Optional:** Restart your machine in response to the prompt that appears on Windows platforms when the installation is complete.

You installed application clients silently by using the response file.

To verify the silent install, look for the string `INSTCONFSUCCESS` in the log.txt file for successful installation and `INSTCONFFAILED` for a failed installation. For UNIX platforms, the install command returns a return code of **0** to indicate a successful installation, **1** to indicate failure and **2** to indicate partial success. Any other return code means that the installation failed.

When the InstallShield for MultiPlatforms (ISMP) fails and the log.txt file is not created, the error log file might have been created in one of the following directories:

- *<system_temp_dir>*/niflogs
- *<user_home>*/cltlogs

Uninstalling Application Client for WebSphere Application Server

This task describes using the uninstall program to uninstall the Application Client for WebSphere Application Server.

If you want to uninstall IBM Application Client for WebSphere Application Server manually, see the topic, Manually uninstalling on a Windows system.

1. Stop any browsers and any Java processes related to Application Client products.

   See Uninstalling the product.

2. Change directories to the `uninstall` directory before issuing the command to uninstall the application client. The command file is located in the *install_root*/`uninstall` directory on a Linux or z/OS platform, and in the *install_root*\\`product`\\`uninstall` directory on a Windows system.

   For example, to change directories before uninstalling the product from a Linux platform, issue this command if your installation root is `/opt/IBM/WebSphere/AppClient`:

   `cd /opt/IBM/WebSphere/AppClient/uninstall`

3. Issue the command to uninstall the product.

   Use the **uninstall** command.

   ▶ Linux   The command file is named `uninstall`.

   ▶ Windows   The command file is named `uninstall.exe`.

   ▶ Linux   On Linux and z/OS platforms, issue the **uninstall** command from the *install_root*/`uninstall` directory:

   `./uninstall`

   ▶ Windows   On Windows platforms, call the **uninstall.exe** command:

   install_root\\`uninstall`\\`uninstall.exe`

   ▶ Windows   Call the program directly from the *install_root*\\`uninstall` directory. For example, if the installation root is `C:\IBM\WebSphere\AppClient`, issue the following command:

   `C:\IBM\WebSphere\AppClient\uninstall> uninstall.exe`

   The Uninstall wizard begins and displays the Welcome panel.

4. Click **Next** to begin uninstalling the product. The Uninstall wizard displays a Confirmation panel that lists the product and features that you are uninstalling.

5. Click **Next** to continue uninstalling the product. The Uninstall wizard deletes existing profiles first.

   After deleting profiles, the Uninstall wizard deletes core product files by component.

6. Click **Finish** to close the wizard after the wizard removes the product.

Application Client for WebSphere Application Server is uninstalled.

Verify the uninstall procedure by viewing the *install_root*/`logs/uninstall/log.txt` file for errors. Look for the `INSTCONFSUCCESS`, indicating a successful uninstall in the log file:

```
Uninstall, com.ibm.ws.install.ni.ismp.actions.ISMPLogSuccessMessageAction, msg1,
    INSTCONFSUCCESS
```

Running application clients

The J2EE specification requires support for a client container that runs stand-alone Java applications (known as J2EE application clients) and provides J2EE services to the applications. J2EE services include naming, security, and resource connections.

You are ready to run your application client using this tool after you have:
1. Written the application client program.
2. Assembled and installed an application module (`.ear` file) in the application server run time.
3. Deployed the application using the Application Client Resource Configuration Tool (ACRCT) on Windows .

This task only applies to J2EE application clients. To launch J2EE application clients using the launchClient script, perform the following steps:

1.

   On the CL command line, enter the following command to start the Qshell environment:

   `STRQSH`

   a. Enter the following command to launch J2EE application clients:

      app_server_root/`bin/launchClient`

2. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   `launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]`

   where

   - *userapp.ear* is the path and the name of the EAR file that contains the application client.

   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.

   - *app args* are arguments that pass to the application client.

   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation. The default is **default_profile**.

   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.

   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

3. Specify the server name.

   By default, the **launchClient** command uses the localhost for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=c:\mydir\util.jar;c:\mydir\harness.jar;c:\production\G19
\global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=c:\WebSphere\mylog.txt
```

launchClient tool

This topic describes the Java 2 Platform Enterprise Edition (J2EE) command line syntax for the launchClient tool for WebSphere Application Server.

You can use the `launchClient` command from a node within a Network Deployment environment. **However, do not attempt to use the `launchClient` command from the Deployment Manager.**

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp.ear* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

   The default is **default_profile**.
- *-JVMOptions* is a valid Java standard or nonstandard option string. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *<userapp>* parameter. The J2EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
> Specifies the host name of the server from which configuration information is retrieved.
>
> The default is the value of the `-CCBootstrapHost` parameter or the value, `localhost`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
> Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
> Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
> Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required. The SOAP connector does not prompt for authentication.

-CCadminConnectorPassword
> The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
> The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
> The name of the host server you want to connect to initially. The format is:
> *your_server_of_choice.com*

-CCBootstrapPort
> The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCclassLoaderMode
> Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:
> * Classes defined for the J2EE application client
> * Resources defined in the J2EE application
> * Classes specified on the manifest of the J2EE client JAR file
> * Classes specified using the -CCclasspath option
>
> If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
> A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
> Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the `-CCD`. For example:

-CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>. For example, -CCDI18NService.enable=true.

-CCdumpJavaNameSpace
Prints out the Java portion of the Java Naming and Directory Interface (JNDI) name space for WebSphere Application Server. The true value uses the short format that prints out the binding name and the type of the object bound at that location. The long value uses the long format that prints out the binding name, bound object type, local object, type and string representation of the local object, for example, IORs and string values. The default value is false.

-CCexitVM
Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is false.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the -CC prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: verbose=true.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the -CCBootstrapHost and -CCBootstrapPort parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809

This value is mapped to the java.naming.provider.url system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is disable.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is *<app_server_root>*/ properties/client.policy.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace

Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the topic ″Enabling trace.″

-CCtracefile

Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode

Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

For more information on basic and advanced trace formatting, see Interpreting trace output.

-CCverbose

This option displays additional information messages. The default is `false`.

The following examples demonstrate correct syntax.

▶ Windows

```
launchClient c:\earfiles\myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.

2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java 2 client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a Web browser.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using

Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the J2EE infrastructure, the technology inherits the complete security architecture of the J2EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Base on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server, Version 6 as a dependent resource, using Java Web Start.

The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are three JNLP descriptor files:
• Client application JNLP descriptor (application-desc in the diagram)
• Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)
• Application Clients run-time library component JNLP descriptor (component-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from J2SE Java Runtime Environment 5.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported with the exception Linux on Power and OS400 platforms.

You can use any of the following:

- Java Web Start on the Java 2 Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server, Version 6.1
- Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 5.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java 2 Platform Standard Edition, version 5, which you can download from the HP Web site

Using Java Web Start

This topic provides the steps and prerequisites necessary to use Java Web start.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:
- "Java Web Start architecture for deploying application clients" on page 336
- "Client application Java Network Launcher Protocol deployment descriptor file" on page 339
- "ClientLauncher class" on page 343

Note: You can use any of the following:
- Java Web Start on Java 2 Standard Edition Developer Kits that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 6.1
- Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 5.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java 2 Platform Standard Edition, version 5.0, which you can download from the HP Web site.

1. Prepare the Application Clients run-time dependency component for JWS.
2. Prepare the Application Clients run-time library component for JWS.
3. Installing JWS.
4. **Optional:** Run the Java Web Start sample.

   Problem: When you run Web services clients from Java Web Start using a Mozilla browser, you might get errors if the client argument contains quotations in the jnlp.jsp file. For example, the following argument results in an error:

   ```
   <argument>-url="wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm/wssvt/tc
   /pli/ejb/WSMultiProtocolHome&"</argument>
   ```

   Error: The following errors display in the Java Web Start console:

   If using the EJB protocol, the following error is displayed:

   ```
   Client caught exception getting the InsuranceWebServicesPort
   using the URL
   "wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm/wssvt/tc
   /pli/ejb/WSMultiProtocolHome&"
   java.net.MalformedURLException: no protocol:
   "wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm/wssvt/tc
   /pli/ejb/WSMultiProtocolHome&"
    at java.net.URL.<init>(URL.java(Compiled Code))
    at java.net.URL.<init>(URL.java(Compiled Code))
    at java.net.URL.<init>(URL.java:411)
    at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient
   .getInsuranceServicesClientURL(InsuranceWebServicesClient.java:231)
    at com.ibm.wssvt.tc.pli.webservice.InsuranceWebServicesClient
   .main(InsuranceWebServicesClient.java:748)
    at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
    at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:85)
    at sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:58)
   ```

```
 at sun.reflect.DelegatingMethodAccessorImpl.invoke(DelegatingMethodAccessorImpl.java:60)
 at java.lang.reflect.Method.invoke(Method.java:391)
 at com.ibm.websphere.client.applicationclient.launchClient.
createContainerAndLaunchApp(launchClient.java:649)
```

If using the HTTP protocol, the following error is displayed:

```
Client caught exception getting the InsruanceWebServicesPort
using the URL
"http://svtlnx1:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol"
java.net.MalformedURLException: no protocol:
"http://svtlnx1:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol"
```

If using the JMS protocol, the following error is displayed:

```
Client caught exception getting the InsruanceWebServicesPort
using the URL
"jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=jms/InsuranceServices_Q

CF&targetService=WSMultiProtocolJMS&jndiProviderURL=IIOP://svtlnx1.austin.ibm.com:981
1"
java.net.MalformedURLException: no protocol:
"jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=jms/InsuranceServices_Q

CF&targetService=WSMultiProtocolJMS&jndiProviderURL=IIOP://svtlnx1.austin.ibm.com:981
1"
        at java.net.URL.<init> (URL.java(Compiled Code))
Making calls to methods in WSMultiprotocolWebServicesBean ...
```

Solution: To resolve the problem, update the jnlp.jsp file to remove the quotations (″ ″) from the argument. When a jnlp.jsp file has statements or expressions that begin with ″${″ and the statement is not to be interpreted as an expression, then add a backward slash ″\″, as shown in the following example:

```
<argument>-CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/DummyClientKeyFile.jks</argument>
<argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/DummyClientTrustFile.jks</argument>
```

For the EJB protocol, use the following example argument to correct the errors:

```
<argument>-url=wsejb:/com.ibm.wssvt.tc.pli.ejb.WSMultiProtocolHome?jndiName=com/ibm/wssvt/tc
/pli/ejb/WSMultiProtocolHome&</argument>
```

For the HTTP protocol, use the following argument to correct the errors:

```
<argument>-url=http://svtaix23:9081/WebSvcsInsSession20EJB/services/WSMultiProtocol</argument>
```

For the JMS protocol, use the following argument to correct the errors:

```
<argument>-url=jms:/queue?destination=jms/MultiProtocol_Q&connectionFactory=
jms/InsuranceServices_QCF&targetService=
WSMultiProtocolJMS&jndiProviderURL=IIOP://svtaix23.austin.ibm.com:9811</argument>
```

Now, rerun the client from Java Web Start.

Client application Java Network Launcher Protocol deployment descriptor file:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients run-time dependency that provides the following:
- Java 2 Runtime Environment from IBM
- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file.

```
<j2se version="WASclient6.1.0"
href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJre/AppClientRT.jsp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a J2EE Application client application (that is the resources for the application contain an EAR file with a client application), then the launcher class starts a second Java Virtual Machine (JVM) using the JRE provided by the Application Clients run-time dependency and launches the J2EE Application client application that is packaged in the EAR file.

  The EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See "JNLP descriptor file for a J2EE Application client application" on page 341 for an example.

- If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

  The Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See "JNLP descriptor file for a Thin Application client application" on page 342 for an example.

  Unlike the J2EE Application client application, the Thin Application client application is not loading the Application Clients run-time library JAR files from the Application Clients run-time dependency. It is downloaded from the server directly as it is for the Thin Application client application JAR file. An Application Clients run-time library component JNLP descriptor is used for specifying the Application Clients run-time library JAR files resources, as shown in the following example:

```
<extension name="WAS Thin EJB Client Library"
              href="/WebSphereClientRuntimeWeb/Runtime/WebSphereJars/AppClientLib.jnlp"/>
```

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

If any of the default settings in the `sas.client.props` and `ssl.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

```
<argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
```

Note: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

```
<argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
<argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
```

JNLP descriptor file for a J2EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a J2EE Application client application (that is the resources for the application contain an EAR file with a client application), then the launcher class starts a second Java Virtual Machine (JVM) using the JRE provided by the Application Clients run-time dependency and launches the J2EE Application client application that is packaged in the EAR file.

Here is an example of the client application JNLP descriptor file for a J2EE Application client application.

```

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a Web browser.

This client is packaged in the WebSphereClientLauncher.jar file that is located in a WebSphere Application Server clients installation under the *<app_server_root>*/ JWS directory.

This launcher class configures the run-time environment for J2EE application clients and thin client applications (not J2EE application clients).

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
        If the client application is a Thin Application client, then this property should be specified. It
        specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear

> If the client application is a J2EE Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Launcher tool:

The launcher configures the run-time environment for J2EE application clients and thin client applications (not J2EE application clients). The launcher utility is located in the main entry point of the Java Network Launching Protocol (JNLP) application client. The main class launcher name is com.ibm.websphere.client.launcher.ClientLauncher and is located in the `WebSphereClientLauncher.jar` file.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main

> If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides.

com.ibm.websphere.client.launcher.ear

> If the client that is to run is the J2EE client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main although only one of the two properties should be specified.

com.ibm.websphere.client.launcher.classpath.* (required for J2EE client applications only)

> There can be a set of properties that are prefixed with com.ibm.websphere.client.launcher.classpath. Each property specifies a JAR file that is to be added to the class path of the application. This JAR file is a JAR file that is already defined as a resource for the application. This file is needed so that the correct elements of the class path of the Java Virtual Machine (JVM) starting the client launcher can be retrieved and added to the class path of the (JVM) that is to be spawned for the application client.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

Preparing the Application Client run-time dependency component for Java Web Start:

For a J2EE application client application and or Thin application client application to be launched using Java Web Start (JWS), an Java Runtime Environment that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. This article provides the steps to build the Application Client run-time dependency component from an Application Client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Client run-time dependency component must be built separately for each platform that client application supports.

For example, if the client application deploys to both the Windows platform and Linux platform, follows the steps for this task to build the Application Client run-time dependency component for Windows on a Windows platform machine with the Application Client for WebSphere Application Server for Windows installed. Now, repeat the steps for this task to build the Application Client run-time dependency component for Linux on a Linux platform machine with the Application Client for WebSphere Application Server for Linux installed.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems. Install Application Client in the `C:\Program Files\IBM\WebSphere\AppClient` directory.

2. Change the directory to the installation bin directory. See the following example for help:

   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```

3. Run the buildClientRuntime tool to generate the Application Client run-time JAR file in a temporary directory which contains the Java 2 Runtime Environment, Application Client run-time properties, the SSL KeyStore and TrustStore file, and the Application Client run-time library JAR files. See the following example for help:

   ```
   buildClientRuntime C:\WebApp1\runtime\WASClient6.1_windows.jar
   ```

   If you are building an Application Client run-time JAR file only for serving Thin application client applications and not for J2EE application client applications, you can reduce the size of the generated JAR file by not including the Application Client run-time library JAR files. An extra parameter is passed to the buildClientRuntime tool, as the following example shows:

   ```
   buildClientRuntime C:\WebApp1\runtime\WASClient6.1_windows.jar
                      buildThin
   ```

4. Copy the `WebSphereClientRuntimeInstaller.jar` file to the same location of the JAR file generated in the previous step. This JAR file is located in the JWS directory of the WebSphere Application Server clients installation. See the following example for help:

   ```
   copy ..\JWS\WebSphereClientRuntimeInstaller.jar   C:\WebApp1\runtime
   ```

5. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility, as the following example shows:

   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
               WASClient6.1_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
               WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

   a. This step also requires you to create a keystore file, such as `myKeystore`.

   b. You must also create a self-signed certificate for the `myKeystore` file.

   Note: When running the JAR signer tool on HP platforms, add the `-J″-Xmx256m″` flag to the jarsigner command to increase the available heap size and prevent the error, `OutOfMemoryError`. See the following example for help:

   ```
   jarsigner -J"-Xmx256m" -keystore myKeystore -storepass myPassword
               WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

6. Create an Application Client run-time installer JNLP descriptor file or a JavaServer Pages (JSP) file if it is generated dynamically in the same temporary directory as previous step. See the sample JNLP file shown in the Example section of this topic.

7. Package the two signed JAR files and the Application Client run-time installer JNLP descriptor file into a WAR file. This WAR file is packaged into an EAR file that can be deployed to an Application Server.

Your Web application is ready to serve the Application Client run time and the JRE environment.

```
<!-- This sample program is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run-time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.
4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run-time dependency component. This version is registered to the JNLP client.
6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run-time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

Preparing Application Client run-time library component for Java Web Start.

buildClientRuntime tool:

For a J2EE application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a Web browser. .

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java 2 Runtime Environment (JRE) that IBM provides
- Application Clients run-time properties and configuration
- SSL KeyStore and TrustStore files
- Run-time library JAR files

In the case of building an Application Clients run-time JAR file only for serving Thin Application client applications and not for J2EE Application client applications, the run-time library JAR files and the Application Clients run-time properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a Web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime .bat  jar_file  [type]
Unix Usage:       buildClientRuntime.sh   jar_file  [type]
Where:
      jar_file
Specifies the target jar file name.

Range:
                  buildJ2EE - Default value that builds a Application Clients
                          run-time library for J2EE application.
                  buildThin - Builds a Application Clients run-time library
                          for Thin application.
```

ClientRuntimeInstaller class: This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the `<app_server_root>`/JWS directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
> Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
> Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="java\jre\bin\javaw.exe"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="WASclient6.1"/>
```

Preparing Application Clients run-time library component for Java Web Start:

The Java Web Start client is used with platforms that support a Web browser. For a Thin Application client application to be launched using Java Web Start (JWS), you also need to create a Java Network Launching Protocol (JNLP) component to serve the Application Clients run-time library JAR files from the Application server. This JNLP component is referenced in the client application JNLP file with the <extension> tag. This article provides the steps to build the Application Clients run-time library component from an Application Clients installation. It is packaged as its own Web Archive Resource (WAR) file or to the same WAR file that contains the Application Clients run-time dependency component, and can be installed in an Application server.

Install the Application Client for WebSphere Application Server for the platform to which client applications deploy.
1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Change the directory to the installation bin directory. For example:

   `CD C:\Program files\IBM\WebSphere\AppClient\bin`
3. Run `buildClientLibJars` to copy the Application Clients run-time library JAR files from the Application Clients installation to a temporary directory. All the JAR files in the temporary directory are signed, as shown in the following example:

   ```
   buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                    myKeystore myPassword myKeyAliasName
   ```
   a. This step also requires you to create a keystroke file, such as `myKeystore`.
   b. You must also create a self-signed certificate for the `myKeystore` file.
4. Create an Application Clients run-time installer JNLP descriptor file in the same temporary directory as the previous step. See the sample JNLP file shown in the Example section of this topic.
5. Package these JAR files and the Application Clients run-time library component JNLP descriptor file into a WAR file. You can also package both Application Clients run-time library component and

Application Clients run-time dependency component in the same WAR file. This WAR file is packaged into an EAR file that can deployed to an Application server.

```

buildClientLibJars tool:

For a J2EE application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server

must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a Web browser.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass` and `alias` to sign all the JAR files in the specified location.

```
Windows Usage: buildClientLibJars.bat  target_dir keystore  storepass  alias
Unix Usage:       buildClientLibJars.sh  target_dir keystore  storepass  alias
Where:
    target_dir        Specifies the target directory where the Application
                        Clients library JAR files copied to.
    keystore          Specifies a keystore file.
    storepass         Specifies the keystore password.
    alias               Specifies an alias for the key object in the key file.
```

Using the Java Web Start sample:

The EAR file, `WebSphereClientRuntime.ear`, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

Install the Application Client for WebSphere Application Server for the platform to which the client application deploys. If there is a requirement to deploy the client application to multiple platforms, the Application Clients run-time dependency component must be built separately for each platform that the client application supports.

1. Install the Application Clients on the client application supported operating system. For example, install Application Clients in the `C:\Program Files\IBM\WebSphere\AppClient` directory.
2. Create the following temporary working directories:
   ```
   MKDIR C:\WebApp1
   MKDIR C:\WebApp1\runtime
   MKDIR C:\WebApp1\runtime\Widnows
   MKDIR C:\WebApp1\runtime\WebSphereJars
   ```
3. Change directory to the installation bin directory. See the following example for help:
   ```
   CD C:\Program files\IBM\WebSphere\AppClient\bin
   ```
4. Run the buildClientRuntime tool to generate the Application Clients run-time JAR file in a temporary directory that contains the Java 2 Runtime Environment that IBM provides, Application Clients run-time properties, the SSL KeyStore and TrustStore files, and the Application Clients run-time library JAR files. See the following example for details:
   ```
   buildClientRuntime C:\WebApp1\runtime\windows\WASClient6.1.0_Windows.jar
   ```
5. Copy the `WebSphereClientRuntimeInstaller.jar` file to the same location of the JAR file generated in the previous step. This JAR file is located in the `JWS` directory of the Application Client for WebSphere Application Server installation. For example, copy the `..\JWS\WebSphereClientRuntimeInstaller.jar` file to the `C:\WebApp1\runtime` directory.
6. Sign the JAR files created from the previous steps, using the Java 2 SDK jarsigner utility. See the following example for details:
   ```
   cd C:\WebApp1\runtime

   jarsigner -keystore myKeystore -storepass myPassword
               WASClient6.1_windows.jar myKeyAliasName

   jarsigner -keystore myKeystore -storepass myPassword
               WebSphereClientRuntimeInstaller.jar myKeyAliasName
   ```

a. This step also requires you to create a keystore file, such as `myKeystore`.

b. You must also create a self-signed certificate for the `myKeystore` file.

7. Run buildClientLibJars to copy the Application Clients run-time library JAR files from the Application Client for WebSphere Application Server installation to a temporary directory. All the JAR files in the temporary directory are signed. See the following example for details:

```
buildClientLibJars C:\WebApp1\runtime\WebSphereJars
                    myKeystore myPassword myKeyAliasName
```

a. This step also requires you to create a keystroke file, such as `myKeystore`.

b. You must also create a self-signed certificate for the `myKeystore` file.

8. Add all the JAR files created in the previous steps in the `C:\WebApp1` directory to the WAR file within the `WebSphereClientRuntime.ear` file. The contents of the WAR file are shown in the following example:

```
The root of the WAR
├───META-INF
                MANIFEST.MF

├───Runtime
│   ├───WebSpherejars
│   │       AppClientLib.jnlp
│   │       com.ibm.ws.runtime_6.1.0.jar
│   │       com.ibm.ws.j2ee.client_6.1.0.jar
│   │       com.ibm.ws.wccm_6.1.0.jar
│   │                :
│   │       (all the jars created in step 7 under
│   │       c:\WebApp1\Runtime\WebSphereJars)
│   └───WebSphereJre
│           AppClientRT.jsp
│           WASClient6.1.0_Windows.jar
│           WebSphereClientLauncher.jar

└───WEB-INF
        ibm-web-bnd.xmi
        ibm-web-ext.xmi
        web.xml
```

9. Install the `WebSphereClientRuntime.ear` file to an Application Server. You have just created an Application Clients run-time dependency component and Application Clients run-time libraries for serving J2EE Application client applications and Thin Application client applications using Java Network Launching Protocol (JNLP) or Java Web Start (JWS).

Installing Java Web Start:

This topic provides the steps necessary to install JWS on the AIX platform.

Before you begin this task, see the following topics to understand Java Web Start (JWS) technology and its components:

- Prepare the Application Clients run-time dependency component for JWS
- Prepare the Application Clients run-time library component for JWS

Note: You can use Java Web Start on Java 2 Standard Edition Developer Kits that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 6; Java Web Start on Sun Microsystems J2SE Software Development Kit or J2SE Java Runtime Environment 1.4.2, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP SDK or RTE for Java 2 version 1.4.2, which you can download from the HP Web site.

Use the following steps to install JWS on the AIX platform.

1. Install IBM Application Client for WebSphere Application Server.

2. Change your directory to the `client_install_root/java/jre` path.

3. Run `sh bin/webstart_install_sdk.sh`.

4. When prompted for the Java path, enter your JRE path. Use the following example:
   `client_install_root/java/jre`.

5. You should see the following messages, which indicate that JWS installs successfully:
   - Obtaining version...
   - You appear to be running 1.4.2
   - Extracting...
   - Updating ~/.mailcap...
   - Updating ~/.mime.types...

6. Change your path to the JWS installed path. For example, enter `client_install_root/java/jre/javaws/`.

7. Run `./javaws` from the path mentioned in the previous step.

Java Web Start for Application client best practices:

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers. To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
        <display-name>
        WAS Client runtime for Java Web Start</display-name>
        <welcome-file-list>
                <welcome-file>index.html</welcome-file>
                <welcome-file>index.htm</welcome-file>
                <welcome-file>index.jsp</welcome-file>
                <welcome-file>default.html</welcome-file>
                <welcome-file>default.htm</welcome-file>
                <welcome-file>default.jsp</welcome-file>
        </welcome-file-list>
        <mime-mapping>
        <extension>jnlp</extension>
        <mime-type>application/x-java-jnlp-file</mime-type>
        </mime-mapping>
</web-app>
```

Writing command interfaces

The base interface for all commands is the Command interface.

To write a command interface, you extend one or more of the three interfaces included in the command package. The command interface provides only the client-side interface for generic commands and declares three basic methods:

- isReadyToCallExecute

  This method is called on the client side before the command is passed to the server for execution.

- execute

  This method passes the command to the target and returns any data.

- reset

  This method reverts any output properties to the values they had before the execute method was called so that the object can be reused.

The implementation class for your interface must contain implementations for the isReadyToCallExecute and reset methods. The execute method is implemented for you elsewhere; for more information, see "Implementing command interfaces" on page 356. Most commands do not extend the Command interface directly but use one of the provided extensions: the "TargetableCommand interface" and the "CompensableCommand interface" on page 354.

TargetableCommand interface

The TargetableCommand interface extends the Command interface and provides for remote execution of commands.

Most commands will be targetable commands. The TargetableCommand interface declares several additional methods:

- setCommandTarget

  This method allows you to specify the target object to a command.

- setCommandTargetName

  This method allows you to specify the target by name to a command

- getCommandTarget

  This method returns the target object of the command.

- getCommandTargetName

  This method returns the name of the target object of the command.

- hasOutputProperties

  This method indicates whether the command has output that must be copied back to the client. (The implementation class also provides a method, setHasOutputProperties, for setting the output of this method. By default, hasOutputProperties returns true.)

- setOutputProperties

  This method saves output values from the command for return to the client.

- performExecute

  This method encapsulates the application-specific work. It is called for you by the execute method declared in the Command interface.

With the exception of the performExecute method, which you must implement, all of these methods are implemented in the TargetableCommandImpl class. This class also implements the execute method declared in the Command interface.

Command interface example application:

ModifyCheckingAccountCmd command interface

This example uses an entity bean with container-managed persistence (CMP), called CheckingAccountBean, which enables a client to deposit money, withdraw money, set a balance, get a balance, and retrieve the name on the account. This entity bean also accepts commands from the client. The code examples illustrate the command-related programming. For a servlet-based example, see "Writing a command target (client-side adapter)" on page 365

This command is both targetable and compensable, so the interface extends both TargetableCommand and CompensableCommand interfaces.

```
...
import com.ibm.websphere.exception.*;
import com.ibm.websphere.command.*;
public interface ModifyCheckingAccountCmd
extends TargetableCommand, CompensableCommand {
float getAmount();
float getBalance();
float getOldBalance(); // Used for compensating
```

```
float setBalance(float amount);
float setBalance(int amount);
CheckingAccount getCheckingAccount();
void setCheckingAccount(CheckingAccount newCheckingAccount);
TargetPolicy getCmdTargetPolicy();
...
}
```

CompensableCommand interface

The CompensableCommand interface extends the Command interface.

A compensable command is one that has another command (a compensator) associated with it, so that the work of the first can be undone by the compensator. For example, a command that attempts to make an airline reservation followed by a hotel reservation can offer a compensating command that allows the user to cancel the airline reservation if the hotel reservation cannot be made.

The CompensableCommand interface declares one method:

*   getCompensatingCommand

    This method returns the command that can be used to undo the effects of the original command.

To create a compensable command, you write an interface that extends the CompensableCommand interface. Such interfaces typically extend the TargetableCommand interface as well. You must implement the getCompensatingCommand method in the implementation class for your interface. You must also implement the compensating command.

Overview of the command package

The command package can be used by distributed applications to reduce the number of remote invocations that a client makes.

Distributed applications are defined by the ability to utilize remote resources as if they were local, but this remote work affects the performance of distributed applications. Distributed applications can improve performance by using remote calls sparingly. For example, if a server does several tasks for a client, the application can run more quickly if the client bundles requests together, reducing the number of individual remote calls. The command package provides a mechanism for collecting sets of requests to be submitted as a unit.

In addition, the command package provides a generic way of making requests. A client instantiates the command, sets its input data, and tells it to run. The command infrastructure determines the target server and passes a copy of the command to it. The server runs the command, sets any output data, and copies it back to the client. The package provides a common way to issue a command, locally or remotely, and independently of the server's implementation. Any server (an enterprise bean, a Java Database Connectivity (JDBC) server, a servlet, and so on) can be a target of a command if the server supports Java access to its resources and provides a way to copy the command between the client's Java Virtual Machine (JVM) and its own JVM.

The command facility is implemented in the com.ibm.websphere.command Java package. The classes and interfaces in the command package fall into four general categories:

*   Interfaces for creating commands
*   Classes and interfaces for implementing commands
*   Classes and interfaces for determining where the command is run
*   Classes defining package-specific exceptions

Interfaces for creating commands:

The Command interface specifies the most basic aspects of a command. This interface is extended by both the TargetableCommand interface and the CompensableCommand interface, which offer additional features.

To create commands for applications, you must:

- Define an interface that extends one or more of interfaces in the command package.
- Provide an implementation class for your interface.

In practice, most commands implement the TargetableCommand interface, which allows the command to be executed remotely. The following example shows the structure of a command interface for a targetable command:

```
... import com.ibm.websphere.command.*;
public interface MySimpleCommand extends TargetableCommand { // Declare application
methods here }
```

The CompensableCommand interface enables the association of one command with another that can undo the work of the first. Compensable commands also typically implement the TargetableCommand interface. The following example shows the structure of a command interface for a targetable, compensable command:

```
... import com.ibm.websphere.command.*;
public interface MyCommand extends TargetableCommand, CompensableCommand {
// Declare application methods here }
```

Facilities for implementing commands:

Commands are implemented by extending the class TargetableCommandImpl, which implements the TargetableCommand interface. The TargetableCommandImpl class is an abstract class that provides some implementations for some of the methods in the TargetableCommand interface (for example, setting return values) and declares additional methods that the application itself must implement (for example, how to execute the command).

You implement your command interface by writing a class that extends the TargetableCommandImpl class and implements your command interface. This class contains the code for the methods in your interface, the methods inherited from extended interfaces (the TargetableCommand and CompensableCommand interfaces), and the required (abstract) methods in the TargetableCommandImpl class. You can also override the default implementations of other methods provided in the TargetableCommandImpl class. The following example shows the structure of an implementation class for an interface:

```
... import java.lang.reflect.*; import com.ibm.websphere.command.*;
public class MyCommandImpl extends TargetableCommandImpl implements MyCommand
{ // Set instance variables here ... // Implement methods in the MyCommand
interface ... // Implement methods in the CompensableCommand interface ...
// Implement abstract methods in the TargetableCommandImpl class ... }
```

Facilities for setting and determining targets:

The object that is the target of a TargetableCommand must implement the CommandTarget interface. This object can be an actual server-side object, such as an entity bean, or it can be a client-side adapter for a server.

The implementor of the CommandTarget interface is responsible for ensuring the proper execution of a command in the desired target server environment. This typically requires the following steps:

1. Copying the command to the target server by using a server-specific protocol.
2. Running the command in the server.
3. Copying the executed command from the target server to the client by using a server-specific protocol.

Exceptions in the command package:

The command package defines a set of exception classes.

The CommandException class extends the DistributedException class and acts as the base class for the additional command-related exceptions:

* UnauthorizedAccessException
* UnsetInputPropertiesException
* UnavailableCompensableCommandException

Applications can extend the CommandException class to define additional exceptions.

Although the CommandException class extends the DistributedException class, you do not have to import the distributed-exception package, com.ibm.websphere.exception, unless you need to use the features of the DistributedException class in your application.

Implementing command interfaces

The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

* To implement an application command interface, write a class that extends the TargetableCommandImpl class and implements your command interface. The structure of the ModifyCheckingAccountCmdImpl class is as follows:

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
...
// Methods
...
}
```

* The class must declare any variables and implement the following methods:
    – Any methods you defined in your command interface.
    – The isReadyToCallExecute and reset methods from the Command interface.
    – The performExecute method from the TargetableCommand interface.
    – The getCompensatingCommand method from the CompensableCommand interface, if your command is compensable. You must also implement the compensating command.

    You can also override the nonfinal implementations provided in the TargetableCommandImpl class. The most likely candidate for reimplementation is the setOutputProperties method, since the default implementation does not save final, transient, or static fields.

Instance and class variables:

The ModifyCheckingAccountCmdImpl class declares the variables used by the methods in the class, including the remote interface of the CheckingAccount entity bean, the variables used to capture operations on the checking account (balances and amounts), and a compensating command.

Variables that are used by the ModifyCheckingAccountCmd command

The following code example shows the variables in the ModifyCheckingAccountCmdImpl class:

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
public float balance;
public float amount;
public float oldBalance;
public CheckingAccount checkingAccount;
```

```
public ModifyCheckingAccountCompensatorCmd
modifyCheckingAccountCompensatorCmd;
...
}
```

Command-specific methods:

The ModifyCheckingAccountCmd interface defines several command-specific methods in addition to extending other interfaces in the command package. These command-specific methods are implemented in the ModifyCheckingAccountCmdImpl class.

Code example: Constructors in the ModifyCheckingAccountCmdImpl class

You must provide a way to instantiate the command. The command package does not specify the mechanism, so you can choose the technique most appropriate for your application. The fastest and most efficient technique is to use constructors. The most flexible technique is to use a factory. Also, since commands are implemented internally as JavaBeans components, you can use the standard Beans.instantiate method. The ModifyCheckingAccountCmd command uses constructors.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
...
// Constructors
// First constructor: relies on the default target policy
public ModifyCheckingAccountCmdImpl(CommandTarget target,
float newAmount)
{
amount = newAmount;
checkingAccount = (CheckingAccount)target;
setCommandTarget(target);
}
// Second constructor: allows you to specify a custom target policy
public ModifyCheckingAccountCmdImpl(CommandTarget target,
float newAmount,
TargetPolicy targetPolicy)
{
setTargetPolicy(targetPolicy);
amount = newAmount;
checkingAccount = (CheckingAccount)target;
setCommandTarget(target);
}
...
}
```

This code example shows the two constructors for the command. The difference between them is that the first uses the default target policy for determining the target of the command and the second allows you to specify a custom policy. For more information on targets and target policies, see "Targets and target policies".

Both constructors take a CommandTarget object as an argument and cast it to the CheckingAccount type. The CheckingAccount interface extends both the CommandTarget interface and the EJBObject (see Figure 80 on page 160). The resulting checkingAccount object routes the command to the desired server by using the bean's remote interface. (For more information on CommandTarget objects, see "Writing a command target (server)" on page 159.)

Code example: Command-specific methods in the ModifyCheckingAccountCmdImpl class

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
```

```
{
// Variables
...
// Constructors
...
// Methods in ModifyCheckingAccountCmd interface
public float getAmount() {
return amount;
}
public float getBalance() {
return balance;
}
public float getOldBalance() {
return oldBalance;
}
public float setBalance(float amount) {
balance = balance + amount;
return balance;
}
public float setBalance(int amount) {
balance += amount ;
return balance;
}
public TargetPolicy getCmdTargetPolicy() {
return getTargetPolicy();
}
public void setCheckingAccount(CheckingAccount newCheckingAccount) {
if (checkingAccount == null) {
checkingAccount = newCheckingAccount;
}
else
System.out.println("Incorrect Checking Account (" +
newCheckingAccount + ") specified");
}
public CheckingAccount getCheckingAccount() {
return checkingAccount;
}
...
}
```

This code example shows the implementation of the following command-specific methods:

- setBalance - sets the balance of the account.
- getAmount - returns the amount of a deposit or withdrawal.
- getOldBalance, getBalance - capture the balance before and after an operation.
- getCmdTargetPolicy - retrieves the current target policy.
- setCheckingAccount, getCheckingAccount - set and retrieve the current checking account.

The ModifyCheckingAccountCmd command operates on a checking account. Because commands are implemented as JavaBeans components, you manage input and output properties of commands using the standard JavaBeans techniques. For example, initialize input properties with set methods (like setCheckingAccount) and retrieve output properties with get methods (like getCheckingAccount). The get methods do not work until after the execute method for the command has been called.

Implementing methods from the TargetableCommand interface:

The TargetableCommand interface declares one method, performExecute, that application programmer must implement.

Methods from the TargetableCommand interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementations for the **ModifyCheckingAccountCmd** command. The implementation of the **performExecute** method is as follows:

- Saves the current balance (so the command can be undone by a compensator command)
- Calculates the new balance
- Sets the current balance to the new balance
- Ensures that the hasOutputProperties method returns true so that the values are returned to the client

In addition, the ModifyCheckingAccountCmdImpl class overrides the default implementation of the setOutputProperties method.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Method from the TargetableCommand interface
public void performExecute() throws Exception {
CheckingAccount checkingAccount = getCheckingAccount();
oldBalance = checkingAccount.getBalance();
balance = oldBalance+amount;
checkingAccount.setBalance(balance);
setHasOutputProperties(true);
}
public void setOutputProperties(TargetableCommand fromCommand) {
try {
if (fromCommand != null) {
ModifyCheckingAccountCmd modifyCheckingAccountCmd =
(ModifyCheckingAccountCmd) fromCommand;
this.oldBalance = modifyCheckingAccountCmd.getOldBalance();
this.balance = modifyCheckingAccountCmd.getBalance();
this.checkingAccount =
modifyCheckingAccountCmd.getCheckingAccount();
this.amount = modifyCheckingAccountCmd.getAmount();
}
}
catch (Exception ex) {
System.out.println("Error in setOutputProperties.");
}
}
...
}
```

Implementing methods from the Command interface:

The Command interface declares two methods, isReadyToCallExecute and reset, that the application programmer must implement.

Methods from the Command interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementations for the **ModifyCheckingAccountCmd** command. The implementation of the **isReadyToCallExecute** method ensures that the checkingAccount variable is set. The **reset** method sets all of the variables back to starting values.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Methods from the Command interface
public boolean isReadyToCallExecute() {
if (checkingAccount != null)
return true;
```

```
else
return false;
}
public void reset() {
amount = 0;
balance = 0;
oldBalance = 0;
checkingAccount = null;
targetPolicy = new TargetPolicyDefault();
}
...
}
```

Implementing methods from the Compensable interface:

The CompensableCommand interface declares the **getCompensatingCommand** method that the
application programmer must implement.

Method from the CompensableCommand interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementation for the **ModifyCheckingAccountCmd** command.
The implementation simply returns an instance of the **ModifyCheckingAccountCompensatorCmd**
command that is associated with the current command.

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Method from CompensableCommand interface
public Command getCompensatingCommand() throws CommandException {
modifyCheckingAccountCompensatorCmd =
new ModifyCheckingAccountCompensatorCmd(this);
return (Command)modifyCheckingAccountCompensatorCmd;
}
}
```

Writing the compensating command

An application that uses a compensable command requires two separate commands: the primary
command (declared as a CompensableCommand) and the compensating command. In the example
application, the primary command is declared in the ModifyCheckingAccountCmd interface and
implemented in the ModifyCheckingAccountCmdImpl class. Because this command is also a compensable
command, there is a second command associated with it that is designed to undo its work. When you
create a compensable command, you also have to write the compensating command.

Writing a compensating command can require exactly the same steps as writing the original command:
writing the interface and providing an implementation class. In some cases, it may be simpler. For
example, the command to compensate for the ModifyCheckingAccountCmd does not require any methods
beyond those defined for the original command, so it does not need an interface. The compensating
command, called ModifyCheckingAccountCompensatorCmd, simply needs to be implemented in a class
that extends the TargetableCommandImpl class. This class must:

- Provide a way to instantiate the command; the example uses a constructor.
- Implement the three required methods: isReadyToCallExecute and reset—both from the Command
  interface and performExecute—from the TargetableCommand interface.

The following code example shows the structure of the implementation class, its variables (references to
the original command and to the relevant checking account), and the constructor. The constructor simply
instantiates the references to the primary command and account.

```
...
public class ModifyCheckingAccountCompensatorCmd extends TargetableCommandImpl
{
public ModifyCheckingAccountCmdImpl modifyCheckingAccountCmdImpl;
public CheckingAccount checkingAccount;
public ModifyCheckingAccountCompensatorCmd(
ModifyCheckingAccountCmdImpl originalCmd)
{
// Get an instance of the original command
modifyCheckingAccountCmdImpl = originalCmd;
// Get the relevant account
checkingAccount = originalCmd.getCheckingAccount();
}
// Methods from the Command and Targetable Command interfaces
....
}
```

The performExecute method verifies that the actual checking-account balance is consistent with what the original command returns. If so, it replaces the current balance with the previously stored balance by using the ModifyCheckingAccountCmd command. Finally, it saves the most-recent balances in case the compensating command needs to be undone. The reset method has no work to do.

The following code example shows the implementation of the inherited methods. The implementation of the isReadyToCallExecute method ensures that the checkingAccount variable has been instantiated.

```
...
public class ModifyCheckingAccountCompensatorCmd extends TargetableCommandImpl
{
// Variables and constructor
....
// Methods from the Command and TargetableCommand interfaces
public boolean isReadyToCallExecute() {
if (checkingAccount != null)
return true;
else
return false;
}
public void performExecute() throws CommandException
{
try {
ModifyCheckingAccountCmdImpl originalCmd =
modifyCheckingAccountCmdImpl;
// Retrieve the checking account modified by the original command
CheckingAccount checkingAccount = originalCmd.getCheckingAccount();
if (modifyCheckingAccountCmdImpl.balance ==
checkingAccount.getBalance()) {
// Reset the values on the original command
checkingAccount.setBalance(originalCmd.oldBalance);
float temp = modifyCheckingAccountCmdImpl.balance;
originalCmd.balance = originalCmd.oldBalance;
originalCmd.oldBalance = temp;
}
else {
// Balances are inconsistent, so we cannot compensate
throw new CommandException(
"Object modified since this command ran.");
}
}
catch (Exception e) {
System.out.println(e.getMessage());
}
}
public void reset() {}
}
```

Using a command

To use a command, the client creates an instance of the command and calls the execute method for the command. Depending on the command, calling other methods can be necessary. The specifics will vary with the application.

In the example application, the server is the CheckingAccountBean, an entity enterprise bean. In order to use this enterprise bean, the client gets a reference to the bean's home interface. The client then uses the reference to the home interface and one of the finder methods for the bean to obtain a reference to the remote interface for the bean. If there is no appropriate bean, the client can create one using a create method on the home interface.

The following code example illustrates the use of the **ModifyCheckingAccountCmd** command. This work takes place after an appropriate CheckingAccount bean has been found or created. The code instantiates a command, setting the input values by using one of the constructors defined for the command. The null argument indicates that the command should look up the server using the default target policy, and 1000 is the amount the command attempts to add to the balance of the checking account. After the command is instantiated, the code calls the setCheckingAccount method to identify the account to be modified. Finally, the execute method on the command is called.

```
{
...
CheckingAccount checkingAccount
...
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Compensating command example:

To use a compensating command, you must retrieve the compensator that is associated with the primary command and call its execute method.

ModifyCheckingAccountCompensator command

The following code example shows the code used to run the original command and to give the user the option of undoing the work by running the compensating command.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
...
System.out.println("Would you like to undo this work? Enter Y or N");
try {
// Retrieve and validate user's response
...
}
...
if (answer.equalsIgnoreCase(Y)) {
Command compensatingCommand = cmd.getCompensatingCommand();
```

```
      compensatingCommand.execute();
      }
      }
      catch (Exception e) {
      System.out.println(e.getMessage());
      }
      ...
      }
```

Using the WebSphere Application Server EJBCommandTarget bean as a command target:

WebSphere Application Server ships a CommandTarget enterprise bean to enable administrators to run a command in a designated server without providing their own implementation of CommandTarget. The EJBCommandTarget class, along with the EJBCommandTarget bean (CommandServerSessionBean), are located in the `EJBCommandTarget.jar` file in the `lib` directory under the WebSphere Application Server installation directory. This is a deployed jar file. You can use this JAR file in a new application or add it into an existing application.

The EJBCommandTarget class serves as a wrapper for a CommandTarget bean. CommandServerSessionBean is the WebSphere Application Server implementation of this CommandTarget bean. A command developer can set this EJBCommandTarget object into the Command. The following is a code example of the EJBCommandTarget bean:

```
EJBCommandTarget target = new EJBCommandTarget();
MyCommand cmd = new MyCommandImpl(Arguments...);
cmd.setCommandTarget(target);
cmd.execute();
```

In the code example, the client creates a MyCommand object. It is then executed in the application server. When the execute method is run, the target (EJBCommandTarget) looks up the CommandServerSessionHome from the InitialContext and executes the executeCommand method on the CommandServerSessionBean. The EJBCommandTarget object ensures that there is only one CommandServerSessionBean per object to avoid extra naming lookup.

An EJBCommandTarget object can be created using four different constructors:
- EJBCommandTarget(△MyNamingServerName△, △PortNumber△, △JNDIName△)
- EJBCommandTarget(InitialContext,△JNDIName△)
- EJBCommandTarget(△JNDIName△)
- EJBCommandTarget()

The first constructor enables the application to specify the naming server name and the port. The JNDI name of the CommandServerSessionBean can also be specified. The EJBCommandTarget constructs a `iiop://MyNamingServerName:PortNumber` provider URL and looks up the CommandServerSessionBean with the given JNDI name. If null values are passed in for any of the parameters, WebSphere Application Server defaults for server and port and a default JNDI name of CommandServerSession are used.

The second constructor enables the application to specify its own initial context. The EJBCommandTarget object then uses this initial context to look up the CommandServerSession bean with the specified JNDI name.

The third constructor enables the application to set up the naming server (the provider URL) in property files.

The default constructor uses the default values for the provider URL and default JNDI name for the CommandServerSession bean (CommandServerSession).

You do not need to use the EJBCommandTarget class. You can instead create your own custom target policy that uses the EJBCommandTarget bean (CommandServerSessionBean). The EJBCommandTarget object is a convenience class and attempts to address most usage scenarios.

Writing a command target (server):

A server must implement the CommandTarget interface and its single method, executeCommand, to accept commands.

The example application implements the CommandTarget interface in an enterprise bean. The target enterprise bean can be a session bean or an entity bean. You can write a target enterprise bean that forwards commands to a specific server, such as another entity bean. In this case, all commands directed at a specific target go through the target enterprise bean. You can also write a target enterprise bean that does the work of the command locally.

Make an enterprise bean the target of a command, as follows:
- Extending the CommandTarget interface when you define the remote interface for the bean, which must also extend the EJBObject interface.
- Implementing the CommandTarget interface when you implement the bean class, which must also implement either the SessionBean or EntityBean interface. The target of the example application is an enterprise bean called CheckingAccountBean. The remote interface for the bean, CheckingAccount, extends the CommandTarget interface in addition to the EJBObject interface. The methods that are declared in the remote interface are independent of those that are used by the command. The executeCommand is declared in neither the home for the bean, nor remote interfaces. "Writing a command target (server)" shows the CheckingAccount interface.

```
...
import com.ibm.websphere.command.*;
import javax.ejb.EJBObject;
import java.rmi.RemoteException;
public interface CheckingAccount extends CommandTarget, EJBObject {
float deposit (float amount) throws RemoteException;
float deposit (int amount) throws RemoteException;
String getAccountName() throws RemoteException;
float getBalance() throws RemoteException;
float setBalance(float amount) throws RemoteException;
float withdrawal (float amount) throws RemoteException, Exception;
float withdrawal (int amount) throws RemoteException, Exception;
}
```

The enterprise bean class, CheckingAccountBean, implements the EntityBean interface as well as the CommandTarget interface. The class contains the business logic for the methods in the remote interface, the necessary life-cycle methods (ejbActivate, ejbStore, and so on), and the executeCommand declared by the CommandTarget interface. The executeCommand method is the only command-specific code in the enterprise bean class. It attempts to run the performExecute method on the command and throws a CommandException if an error occurs. If the performExecute method runs successfully, the executeCommand method uses the hasOutputProperties method to determine if there are output properties that must be returned. If the command has output properties, the method returns the command object to the client. "Writing a command target (server)" shows the relevant parts of the CheckingAccountBean class.

```
...
public class CheckingAccountBean implements EntityBean, CommandTarget {
// Bean variables
...
// Business methods from remote interface
...
// Life-cycle methods for CMP entity beans
...
// Method from the CommandTarget interface
public TargetableCommand executeCommand(TargetableCommand command)
throws RemoteException, CommandException
```

```
{
try {
command.performExecute();
}
catch (Exception ex) {
if (ex instanceof RemoteException) {
RemoveException remoteException = (RemoteException)ex;
if (remoteException.detail != null) {
throw new CommandException(remoteException.detail);
}
throw new CommandException(ex);
}
}
if (command.hasOutputProperties()) {
return command;
}
return null;
}
}
```

Writing a command target (client-side adapter):

Commands can be used with any Java application, but the means of sending the command from the client to the server varies. The example in this topic shows how you can send a command to a servlet over the HTTP protocol. The client implements the CommandTarget interface locally.

The structure of a client-side adapter for a target

This example shows the structure of the client-side class; it implements the CommandTarget interface by implementing the executeCommand method.

```
...
import java.io.*;
import java.rmi.*;
import com.ibm.websphere.command.*;
public class ServletCommandTarget implements CommandTarget, Serializable
{
protected String hostName = "localhost";
public static void main(String args[]) throws Exception
{
....
}
public TargetableCommand executeCommand(TargetableCommand command)
throws CommandException
{
....
}
public static final byte[] serialize(Serializable serializable)
throws IOException {
... }
public String getHostName() {
... }
public void setHostName(String hostName) {
... }
private static void showHelp() {
... }
}
```

Instantiating the client-side adapter

The main method in the client-side adapter constructs and intializes the CommandTarget object, as follows:

```
public static void main(String args[]) throws Exception
{
String hostName = InetAddress.getLocalHost().getHostName();
String fileName = "MyServletCommandTarget.ser";
// Parse the command line
...
// Create and initialize the client-side CommandTarget adapter
ServletCommandTarget servletCommandTarget = new ServletCommandTarget();
servletCommandTarget.setHostName(hostName);
...
// Flush and close output streams
...
}
```

Implementing a client-side adapter:

The CommandTarget interface declares one method, executeCommand, which the client implements. The executeCommand method takes a TargetableCommand object as input; it also returns a TargetableCommand.

A client-side implementation of the executeCommand method

This example shows the implementation of the method used in the client-side adapter. This implementation does the following:

- Serializes the command it receives
- Creates an HTTP connection to the servlet
- Creates input and output streams, to handle the command as it is sent to the server and returned
- Places the command on the output stream
- Sends the command to the server
- Retrieves the returned command from the input stream
- Returns the returned command to the caller of the executeCommand method

```
public TargetableCommand executeCommand(TargetableCommand command)
throws CommandException
{
try {
// Serialize the command
byte[] array = serialize(command);
// Create a connection to the servlet
URL url = new URL
("http://" + hostName +
"/servlet/com.ibm.websphere.command.servlet.CommandServlet");
HttpURLConnection httpURLConnection =
(HttpURLConnection) url.openConnection();
// Set the properties of the connection
...
// Put the serialized command on the output stream
OutputStream outputStream = httpURLConnection.getOutputStream();
outputStream.write(array);
// Create a return stream
InputStream inputStream = httpURLConnection.getInputStream();
// Send the command to the servlet
httpURLConnection.connect();
ObjectInputStream objectInputStream =
new ObjectInputStream(inputStream);
// Retrieve the command returned from the servlet
Object object = objectInputStream.readObject();
if (object instanceof CommandException) {
throw ((CommandException) object);
}
// Pass the returned command back to the calling method
return (TargetableCommand) object;
```

```
}
// Handle exceptions
....
}
```

Running the command in the servlet:

The CommandTarget interface declares one method, executeCommand, which the client implements. The executeCommand method takes a TargetableCommand object as input; it also returns a TargetableCommand.

Running the command in the servlet

The servlet that runs the command is shown in the following example. The service method retrieves the command from the input stream and runs the performExecute method on the command. The resulting object, with any output properties that must be returned to the client, is placed on the output stream and sent back to the client.

```
...
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
import com.ibm.websphere.command.*;
public class CommandServlet extends HttpServlet {
...
public void service(HttpServletRequest request,
HttpServletResponse response)
throws ServletException, IOException
{
try {
...
// Create input and output streams
InputStream inputStream = request.getInputStream();
OutputStream outputStream = response.getOutputStream();
// Retrieve the command from the input stream
ObjectInputStream objectInputStream =
new ObjectInputStream(inputStream);
TargetableCommand command = (TargetableCommand)
objectInputStream.readObject();
// Create the command for the return stream
Object returnObject = command;
// Try to run the command's performExecute method
try {
command.performExecute();
}
// Handle exceptions from the performExecute method
...
// Return the command with any output properties
ObjectOutputStream objectOutputStream =
new ObjectOutputStream(outputStream);
objectOutputStream.writeObject(returnObject);
// Flush and close output streams
...
}
catch (Exception ex) {
ex.printStackTrace();
}
}
}
```

The target invokes the performExecute method on the command, but this is not always necessary. In some applications, it can be preferable to implement the work of the command locally. For example, the command can be used only to send input data, so that the target retrieves the data from the command

and runs a local database procedure based on the input. You must decide the appropriate way to use commands in your application.

Targets and target policies

A targetable command extends the TargetableCommand interface, which allows the client to direct a command to a particular server. The TargetableCommand interface (and the TargetableCommandImpl class) provide two ways for a client to specify a target: the setCommandTarget and setCommandTargetName methods.

The setCommandTarget methods allows the client to set the target object directly on the command. The setCommandTargetName method allows the client to refer to the server by name; this approach is useful when the client is not directly aware of server objects. A targetable command also has corresponding getCommandTarget and getCommandTargetName methods.

The command package needs to be able to identify the target of a command. Because there is more than one way to specify the target and because different applications can have different requirements, the command package does not specify a selection algorithm. Instead, it provides a TargetPolicy interface with one method, getCommandTarget, and a default implementation. This enables applications to devise custom algorithms for determining the target of a command when appropriate.

The default target policy:

The command package provides a default implementation of the TargetPolicy interface in the TargetPolicyDefault class.

Relevant variables and the methods in the TargetPolicyDefault class

If you use this default implementation, the command determines the target by looking through an ordered sequence of four options:
- The CommandTarget value
- The CommandTargetName value
- A registered mapping of a target for a specific command
- A defined default target

If the command finds no target, it returns null.

The TargetPolicyDefault class provides methods for managing the assignment of commands with targets (registerCommand, unregisterCommand, and listMappings), and a method for setting a default name for the target (setDefaultTargetName). The default target name is com.ibm.websphere.command.LocalTarget, where LocalTarget is a class that runs the command's performExecute method locally.

```
...
public class TargetPolicyDefault implements TargetPolicy, Serializable
{
...
protected String defaultTargetName = "com.ibm.websphere.command.LocalTarget";
public CommandTarget getCommandTarget(TargetableCommand command) {
... }
public Dictionary listMappings() {
... }
public void registerCommand(String commandName, String targetName) {
... }
public void unregisterCommand(String commandName) {
... }
public void seDefaultTargetName(String defaultTargetName) {
... }
}
```

Setting the command target:

The ModifyCheckingAccountImpl class provides two command constructors. One of them takes a command target as an argument and implicitly uses the default target policy to locate the target. The constructor passes a null target, so that the default target policy traverses its choices and eventually finds the default target name, LocalTarget.

Identifying a target with CommandTarget

If you use this default implementation, the command determines the target by looking through an ordered sequence of four options:
- The CommandTarget value
- The CommandTargetName value
- A registered mapping of a target for a specific command
- A defined default target

If the command finds no target, it returns null.

This example uses the same constructor to set the target explicitly. This example differs from the example in "Using a command" on page 362 as follows:
- The command target is set to the checking account rather than null. The default target policy starts to traverse its choices and finds the target in the first place it looks.
- It does not have to call the setCheckingAccount method to indicate the account on which the command should operate; the constructor uses the target variable as both the target and the account.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(checkingAccount, 1000);
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Setting the command target name:

If a client needs to set the target of the command by name, it can use the setCommandTargetName method for the command.

Identifying a target with CommandTargetName

This example compares with the example in "Using a command" on page 362 as follows:
- Both explicitly set the command target in the constructor to null.
- Both use the setCheckingAccount method to indicate the account on which the command should operate.
- This example sets the target name explicitly by using the setCommandTargetName method. When the default target policy traverses its choices, it finds a null for the first choice and a name for the second.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
```

```
cmd.setCheckingAccount(checkingAccount);
cmd.setCommandTargetName("com.ibm.sfc.cmd.test.CheckingAccountBean");
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Mapping the command to a target name:

The default target policy also permits commands to be registered with targets. Mapping a command to a target is an administrative task that most appropriately done through a configuration tool.

Mapping a command to a target in an external application

The WebSphere Application Server administrative console does not yet support the configuration of mappings between commands and targets. Applications that require support for the registration of commands with targets must supply the tools to manage the mappings. These tools can be visual interfaces or command-line tools.

The following example shows the registration of a command with a target. The names of the command class and the target are explicit in the code, but in practice, these values would come from fields in a user interface or arguments to a command-line tool. If a program creates a command as shown in the example in "Using a command" on page 362, with a null for the target, when the default target policy traverses its choices, it finds a null for the first and second choices and a mapping for the third.

```
{
...
targetPolicy.registerCommand(
"com.ibm.sfc.cmd.test.ModifyCheckingAccountImpl",
"com.ibm.sfc.cmd.test.CheckingAccountBean");
...
}
```

Customizing target policies:

You can define custom target policies by implementing the TargetPolicy interface and providing a getCommandTarget method appropriate for your application. The TargetableCommandImpl class provides setTargetPolicy and getTargetPolicy methods for managing custom target policies.

Custom target policy example

So far, the target of all the commands has been a checking-account entity bean. Suppose that someone introduces a session enterprise bean (MySessionBean) that can also act as a command target. The following code example shows a simple custom policy that sets the target of every command to MySessionBean.

```
import java.io.*;
import java.util.*;
import java.beans.*;
import com.ibm.websphere.command.*;
public class CustomTargetPolicy implements TargetPolicy, Serializable {
public CustomTargetPolicy {
super();
}
public CommandTarget getCommandTarget(TargetableCommand command) {
CommandTarget = null;
try {
target = (CommandTarget)Beans.instantiate(null,
"com.ibm.sfc.cmd.test.MySessionBean");
```

```
}
catch (Exception e) {
e.printStackTrace();
}
}
}
```

Because commands are implemented as JavaBeans components, using custom target policies requires importing the java.beans package and writing some elementary JavaBeans code. Also, your custom target-policy class must also implement the java.io.Serializable interface.

Using a custom target policy:

The ModifyCheckingAccountImpl class provides two command constructors. One of them implicitly uses the default target policy; the other takes a target policy object as an argument, which enables you to use a custom target policy.

Custom target policy example

The following example uses the second constructor, passing a null target and a custom target policy, so that the custom policy is used to determine the target. After the command is executed, the code uses the reset method to return the target policy to the default.

```
{
...
CheckingAccount checkingAccount
....
try {
CustomTargetPolicy customPolicy = new CustomTargetPolicy();
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000, customPolicy);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
cmd.reset();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
}
```

Web services

Implementing Web services applications

This topic introduces you to using Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. WebSphere Application Server supports Web services that are developed and implemented based on Web Services for J2EE. Use Web services when operating across a variety of platforms, including the J2EE 1.4 and non-J2EE platforms.

Decide if a Web service implementation benefits your business process.

Implementing Web services applications is an easy way to integrate application systems together within or outside your company's infrastructure that otherwise function as a standalone systems. For example, your customer information database is a standalone application, but you want your accounting application to be able to access the customer data. You can create a Web service for the customer database and then enable the accounting application as a Web service client. The accounting application can now access the customer information. By implementing a Web service, these two applications can share information in an efficient manner.

Because Web services are easily applied to existing applications and information technology assets, new solutions can be deployed quickly and recomposed to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

You can use Web services applications with WebSphere Application Server by following the steps provided:

1. Plan to use Web services. Review the Universal Description, Discovery, and Integration (UDDI) and Web services enablement of the service integration bus (SIBWS) concepts to learn how these components can make your Web services plan more robust.

2. (Optional) Migrate existing Web services.

   If you have used Web services based on Apache SOAP and now want to develop and implement Web services based on the Web Services for J2EE specification, you need to migrate client applications developed with all versions of 4.0, and versions of 5.0 prior to 5.0.2.

3. Develop Web services.

   This topic is a good starting point in learning about how to develop a J2EE Web service.

4. Configure Web services deployment descriptors.

   You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.

5. Assemble Web services.

   This topic presents what you need to assemble a Web service and in what order you should assemble the parts, for example an enterprise archive (EAR) file.

6. Deploy Web services.

   This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

7. Configure Web service client bindings. This topic explains how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.

8. Publish the WSDL file.

   After installing a Web services application, and optionally modifying the endpoint information, you might need Web Services Description Language (WSDL) files containing the updated endpoint information. This topic presents the steps necessary to publish the WSDL files so that this information is available.

9. Develop Web services clients.

   This topic explains how to develop a Web services client based on the Web Services for J2EE specification.

10. Secure Web services.

    This topic presents the methods used to integrate message-level security into a WebSphere Application Server environment. If you are using V5.x, refer to Securing Web services for version 5.x applications based on WS-Security. If you are using V6.x, refer to Securing Web services for version 6 applications based on WS-Security

11. Monitoring the performance of Web services applications.

    This topic includes information to help you use the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests.

12. Troubleshoot Web services.

    You can use this topic to learn more about troubleshooting different processes used to develop, implement and use Web services, including command-line tools, Java compiling errors, client runtime errors and exceptions, serialization and deserialization errors, and authentication challenges and authorization failures with Web services security.

The following example illustrates how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. This owner starts the process by finding wholesale flower suppliers, pricing the product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers. One way to find new suppliers is to use a Universal Description, Discovery and Integration (UDDI) registry to search for potential suppliers. When the suppliers are chosen, the registry sends back information on how to contact the flower distributors that meet the flower shop owner's criteria.

The flower shop owner can request price lists from each of the suppliers by obtaining a WSDL file for each potential supplier. The WSDL can be downloaded from the supplier's Web page, received through e-mail, or retrieved from the supplier's UDDI registry entry.

The WSDL describes the procedure call. When using WebSphere Application Server, the procedure call is a Java API for XML-based remote procedure call (JAX-RPC), which retrieves price lists. The WSDL file also specifies the Universal Resource Locator (URL) where the request is sent.

The flower shop owner now has to compare the prices received back from each supplier, decide which suppliers to do business with, and make arrangements for future orders to fill. The flower shop can now sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need publishing to the Web site and a mechanism is needed for customers to order flowers.

The Web services clients of the flower supplier are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through JAX-RPC. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of all the suppliers. If the supplier ships directly to the customer, the order tracking inquiries can pass directly to the supplier's order tracking system. The supplier can also use Web services to send invoices for orders and by the flower shop to pay the supplier's invoices. Processes that previously required forms to fill manually, and fax or mail, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. No merchandise maintenance overhead exists, but the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or money invested into additional product.

For a more detailed scenario, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how they incorporated the Web services concept.

Web Services for J2EE specification

The *Web services for Java 2 Platform, Enterprise Edition (J2EE)* specification defines the programming model and run-time architecture for implementing Web services based on the Java language. Another name for the Web Services for J2EE specification is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

The Web Services for J2EE specification focuses on Extensible Markup Language (XML) remote procedure call (RPC) and the Java language, including representing XML-based interface definitions in the Java language; Java language definitions in XML-based definition languages, such as SOAP, and assembling.

The J2EE technology can be integrated with Web services in a variety of ways. J2EE components, for example, JavaBeans and enterprise beans, can be exposed as Web services. These services can be accessed by clients written in Java code or by existing Web service clients that are not written in Java code. J2EE components can also act as Web service clients.

The Web Services for J2EE specification is the preferred platform for Web-based programming because it provides open standards allowing different types of languages, operating systems and software to communicate seamlessly through the Internet.

For a Java application to act as Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification.

You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request.

This entire process encompassed is based on the Web Services for J2EE specification.

The specification brings with it the `webservices.xml` deployment descriptor specifically for Web services. You are responsible for providing various elements to the deployment descriptor, including:
- Port name
- Port service implementation
- Port service endpoint interface
- Port WSDL definition
- Port QName
- JAX-RPC mapping
- Handlers (optional)
- Servlet mapping (optional)

The Enterprise JavaBeans (EJB) 2.1 specification also states that for a Web service developed from a session bean, the EJB deployment descriptor, `ejb-jar.xml`, must contain the service-endpoint element. The service-endpoint value must be the same as that stated in the webservices.xml deployment descriptor. To learn more about the EJB 2.1 specification see Enterprise beans: Resources for learning.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

JAX-RPC

The *Java API for XML-based RPC (JAX-RPC)* specification enables you to develop SOAP-based interoperable and portable Web services and Web service clients. JAX-RPC 1.1 provides core APIs for developing and deploying Web services on a Java platform and is a required part of the J2EE 1.4 platform. The J2EE 1.4 platform allows you to develop portable Web services. Web services can also be developed and deployed on J2EE 1.3 containers.

WebSphere Application Server implements JAX-RPC 1.1 standards.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language. JAX-RPC simplifies development of Web services by shielding you from the underlying complexity of SOAP communication.

On the surface, JAX-RPC looks like another instantiation of remote method invocation (RMI). Essentially, JAX-RPC allows clients to access a Web service as if the Web service was a local object mapped into the client's address space even though the Web service provider is located in another part of the world. The JAX-RPC is done by using the XML-based protocol SOAP, which typically rides on top of HTTP.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and Extensible Markup Language (XML) schema types.

A JAX-RPC Web service can be created from a JavaBean or a enterprise bean implementation. You can specify the remote procedures by defining remote methods in a Java interface. You only need to code one or more classes that implement the methods. The remaining classes and other artifacts are generated by the Web service vendor's tools. The following is an example of a Web service interface:

```
package com.ibm.mybank.ejb;
import java.rmi.RemoteException;
import com.ibm.mybank.exception.InsufficientFundsException;
/**
 * Remote interface for Enterprise Bean: Transfer
 */
public interface Transfer_SEI extends java.rmi.Remote {
   public void transferFunds(int fromAcctId, int toAcctId, float amount)
      throws java.rmi.RemoteException;

}
```

The interface definition in JAX-RPC must follow specific rules:

- The interface must extend `java.rmi.Remote` just like RMI.
- Methods must throw `java.rmi.RemoteException`.
- Method parameters cannot be remote references.
- Method parameter must be one of the parameters supported by the JAX-RPC specification. The following list are examples of method parameters that are supported. For a complete list of method parameters see the JAX-RPC specification.
  - Primitive types: `boolean`, `byte`, `double`, `float`, `short`, `int` and `long`
  - Object wrappers of primitive types: `java.lang.Boolean`, `java.lang.Byte`, `java.lang.Double`, `java.lang.Float`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Short`
  - `java.lang.String`
  - `java.lang.BigDecimal`
  - `java.lang.BigInteger`
  - `java.lang.Calendar`
  - `java.lang.Date`
- Methods can take value objects which consist of a composite of the types previously listed, in addition to aggregate value objects.

A client creates a stub and invokes methods on it. The stub acts like a proxy for the Web service. From the client code perspective, it seems like a local method invocation. However, each method invocation gets marshaled to the remote server. Marshaling includes encoding the method invocation in XML as prescribed by the SOAP protocol.

The following are key classes and interfaces needed to write Web services and Web service clients:

- **Service interface**: A factory for stubs or dynamic invocation and proxy objects used to invoke methods
- **ServiceFactory class**: A factory for Services.
- `loadService`

  The `loadService` method is provided in WebSphere Application Server Version 6.0 to generate the service locator which is required by a JAX-RPC implementation. If you recall, in previous versions there was no specific way to acquire a generated service locator. For managed clients you used a JNDI method to get the service locator and for non-managed clients, you were required to instantiate IBM's specific service locator `ServiceLocator service=new ServiceLocator(...);` which does not offer portability. The `loadService` parameters include:

  - `wsdlDocumentLocation`: A URL for the WSDL document location for the service or null.

- **serviceName**: A qualified name for the service
- **properties**: A set of implementation-specific properties to help locate the generated service implementation class.

- **isUserInRole**

  The isUserInRole method returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical role.

  - **role**: The role parameter is a String specifying the name of the role.

- **Service**
- **Call interface**: Used for dynamic invocation
- **Stub interface**: Base interface for stubs

If you are using a stub to access the Web service provider, most of the JAX-RPC API details are hidden from you. The client creates a ServiceFactory (java.xml.rpc.ServiceFactory). The client instantiates a Service (java.xml.rpc.Service) from the ServiceFactory. The service is a factory object that creates the port. The port is the remote service endpoint interface to the Web service. In the case of DII, the Service object is used to create Call objects, which you can configure to call methods on the Web service's port.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

SOAP

SOAP is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

WebSphere Application Server follows the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the Extensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus. This protocol consists of three parts:

- An *envelope* that defines a framework for describing message content and processing instructions.
- A set of *encoding rules* for expressing instances of application-defined data types.
- A *convention* for representing remote procedure calls and responses.

SOAP is a protocol-independent transport and can be used in combination with a variety of protocols. In Web services that are developed and implemented with WebSphere Application Server, SOAP is used in combination with HTTP, HTTP extension framework, and Java Message Service (JMS). SOAP is also operating-system independent and not tied to any programming language or component technology.

As long as the client can issue XML messages, it does not matter what technology is used to implement the client. Similarly, the service can be implemented in any language, as long as the service can process SOAP messages. Also, both server and client sides can reside on any suitable platform.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

SOAP with Attachments API for Java interface

SOAP with Attachments API for Java (SAAJ) interface is used for SOAP messaging that works behind the scenes in the Java API for XML-based RPC (JAX-RPC) implementation. You can map XML to Java types with standards supported by the JAX-RPC specification, but there are limited XML schema types, therefore you can use the SOAPElement interface to create a *custom data binder*.

Web services use XML messages to exchange messages. These messages conform to XML schema and when developing We services applications, there are limited XML APIs to work with, for example, Document Object Model (DOM). It is more efficient to manipulate the Java objects and have the serialization and deserialization completed during run time. To manipulate the XML schema types, you need to map the XML schema types to Java types with a *custom data binder*.

Web services uses SOAP messages to represent remote procedure calls between the client and the server. In normal JAX-RPC flows, the SOAP message is deserialized into a series of Java value-type business objects that represent the parameters and return values. In addition, JAX-RPC provides APIs that support applications and handlers to manipulate the SOAP message directly. Because there are a limited number of XML schema types that are supported by JAX-RPC, the specification provides the SAAJ data model as an extension to manipulate the message.

The primary interface in the SAAJ model is javax.xml.soap.SOAPElement, also referred to as SOAPElement. Using this model, applications can process an SAAJ model that uses pre-existing DOM code. It is also easier to convert pre-existing DOM objects to SAAJ objects.

Messages created using SAAJ follow SOAP standards. A SOAP message is represented in the SAAJ model as a javax.xml.soap.SOAPMessage object. The XML content of the message is represented by a javax.xml.soap.SOAPPart object. Each SOAP part has a SOAP envelope. This envelope is represented by the SAAJ javax.xml.SOAPEnvelope object. The SOAP specification defines various elements that reside in the SOAP envelope; SAAJ defines objects for the various elements in the SOAP envelope.

The SOAP message can also contain non-XML data that is called attachments. These attachments are represented by SAAJ AttachmentPart objects that are accessible from the SOAPMessage object.

A number of reasons exist as to why handlers and applications use the generic SOAPElement API instead of a tightly bound mapping:
- The Web service might be a conduit to another Web service. In this case, the SOAP message is only forwarded.
- The Web service might manipulate the message using a different data model, for example a Service Data Object (SDO). It is easier to convert the message from a SAAJ Document Object Model (DOM) to a different data model.
- A handler, for example, a digital signature validation handler, might want to manipulate the message generically.

You might need to go a step further to map your XML schema types, because the SOAPElement interface is not always the best alternative for legacy systems. In this case you might want to use a generic programming model, such as Service Data Object (SDO), which is more appropriate for data-centric applications.

The XML schema can be configured to include a custom data binding that pairs the SDO or data object with the Java object. For example, the run time renders an incoming SOAP message into a SOAPElement interface and passes it to the customer data binder for more processing. If the incoming message contains an SDO, the run time recognizes the data object code, queries its type mapping to locate a custom binder, and builds the SOAPElement interface that represents the SDO code. The SOAPElement is passed to the SDOCustomBinder.

See Custom data binders for more information about the process of developing applications with SOAPElement, SDO and custom binders.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

Web services SOAP/JMS protocol

The Web services engine supports the use of a Java Message Service (JMS)-compliant messaging transport as an alternative to HTTP for communicating SOAP messages between clients and servers.

You can use SOAP/JMS if you need to provide implementations for the client or server components, and need to make sure that the implementations are interoperable with the client and server components provided by the Web services engine in WebSphere Application Server.

Client responsibilities

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use either a JMS TextMessage, for example, javax.jms.TextMessage, or a BytesMessage, for example, javax.jms.BytesMessage, to transmit the SOAP request message to the server. If the request message contains attachments, a BytesMessage must be used. If the request message does not contain attachments, the client can use a TextMessage or a BytesMessage. The WebSphere product client implementation uses only a BytesMessage for the request message due to the potential need to transmit attachments.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **contentType** - This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, is written as follows:

    ```
    text/xml; charset="UTF-8"
    ```

    The **contentType** property in a SOAP request message that contains attachments must be set as follows:

    ```
    multipart/related; type="text/xml"; start="<...content-id of first part...>"
    ```

    This example represents a multi-part message, where the first part is of type ″text/xml″ that contains the SOAP message. The other parts of the multi-part message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.
  - **targetService** - This property must be set to the targetService property value that is found in the JMS-style endpoint location URL for the request. This value is used by the server component to determine the port component in the target when dispatching the request.
  - **endpointURL** - This property must be set to the JMS endpoint URL associated with the request.
  - **transportVersion** - This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).
- If the SOAP request message represents a two-way request, the client component must set the JMS message's **replyTo** property to specify the queue that is used for the reply message. The JMS message's setJMSReplyTo method is used for this.
- If the SOAP request message represents a one-way request, the client component must not set the JMS message's **replyTo** property.
- The client component must be prepared to handle a reply message that is a BytesMessage or a TextMessage, regardless of the type of JMS message used to transmit the SOAP request. The WebSphere product implementation of the server component responds with the same type of JMS message that is received from the client, unless the response contains attachments and a BytesMessage must be used.
- The client component can assume that the reply message **correlation ID** matches the original request **message ID**.

Server responsibilities

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages while adhering to the following protocol constraints:

- The server must be prepared to receive a TextMessage or a BytesMessage. If the request contains attachments, a ByteMessage must be used. The WebSphere product implementation of the server component responds in kind when sending the reply message back to the client, unless the response contains attachments and a BytesMessage is used.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's **replyTo** property is set.
- The server component must set the following properties in the JMS reply message before sending the message to the replyTo queue:
  - **contentType** - See the description for this property in the client responsibilities section in this article.
  - The **correlation ID** of the JMS reply message should be set to the **message ID** of the original JMS request message. This is done by calling the JMS message's `setJMSCorrelationID` method.
  - **transportVersion** - This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).

Example: SOAP request without attachments

The following example displays the results from calling the JMS message's `toString` method for a request message without attachments:

```
JMSMessage class: jms_bytes
JMSType:         null
JMSDeliveryMode: 2
JMSExpiration:   0
JMSPriority:     4
JMSMessageID:    ID:d438eebf04cb124aa25c5821110a134f0000000000000001
JMSTimestamp:    1092110476167
JMSCorrelationID: null
JMSDestination:  topic://NewsGroupTopic?topicSpace=FvtTopicSpace
JMSReplyTo:      null
JMSRedelivered:  false

Web Services-Interoperability Basic Profile

The *Web Services-Interoperability (WS-I) Basic Profile* is a set of non-proprietary Web services specifications that promote interoperability.

WebSphere Application Server conforms to the WS-I Basic Profile 1.1.

The WS-I Basic Profile is governed by a consortium of industry-leading corporations, including IBM, under direction of the WS-I Organization. The profile consists of a set of principles that relate to bringing about open standards for Web services technology. All organizations that are interested in promoting interoperability among Web services are encouraged to become members of the Web Services Interoperability Organization.

Several technology components are used in the composition and implementation of Web services, including messaging, description, discovery, and security. Each of these components are supported by specifications and standards, including SOAP 1.1, Extensible Markup Language (XML) 1.0, HTTP 1.1, Web Services Description Language (WSDL) 1.1, and Universal Description, Discovery and Integration (UDDI). The WS-I Basic Profile specifies how these technology components are used together to achieve interoperability, and mandates specific use of each of the technologies when appropriate. You can read more about the WS-I Basic Profile at the WS-I Organization Web site.

Each of the technology components have requirements that you can read about in more detail at the WS-I Organization Web site. For example, support for Universal Transformation Format (UTF)-16 encoding is required by WS-I Basic Profile. UTF-16 is a kind of Unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet; UTF-16 encoding is typically used for Java and Windows product applications; and UTF-32 is used by various Linux and Unix systems. Unlike UTF-8, UTF-16 has issues with big-endian and little-endian, and often involves Byte Order Mark (BOM) to indicate the endian. BOM is mandatory for UTF-16 encoding and it can be used in UTF-8.

See how to modify your encoding from UTF-8 to UTF-16 if you need to change from UTF-8 to UTF-16.

The following table summarizes some of the properties of each UTF:

Bytes	Encoding form
EF BB BF	UTF-8
FF FE	UTF-16, little-endian
FE FF	UTF-16, big-endian
00 00 FE FF	UTF-32, big-endian
FF FE 00 00	UTF-32, little-endian

BOM is written prior to the XML text, and it indicates to the parser how the XML is encoded. The XML declaration contains the encoding, for example: `<?xml version=xxx encoding="utf-xxx"?>`. BOM is used with the encoding to determine how to interpret the XML. Here is an example of a SOAP message and how BOM and UTF encoding are used:

```
POST http://www.whitemesa.net/soap12/add-test-rpc HTTP/1.1
Content-Type: application/soap+xml; charset=utf-16; action=""
SOAPAction:
Host: localhost: 8080
Content-Length: 562

0xFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
 xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString soap:encodingStyle="http://example.org/unknownEncoding"
   xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

In the example code, 0xFF0xFE represents the byte codes, while the *<?xml>* declaration is the textual representation.

RMI-IIOP using JAX-RPC

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can use protocols with the transport such as SOAP and Remote Method Invocation (RMI). You can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings.

Using RMI-IIOP with JAX-RPC, enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard J2EE programming model. When a enterprise JavaBeans implementation is used to invoke a Web service, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients. Learn more about this by reviewing Using enterprise bean bindings to invoke an EJB from a Web services client.

Benefits of using the RMI/IIOP protocol instead of a SOAP- based protocol are:
* XML processing is not required to send and receive messages; Java serialization is used instead.
* The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

WS-I Attachments Profile

The *Web Services-Interoperability (WS-I) Attachments Profile* is a set of non-proprietary Web services specifications that promote interoperability. This profile compliments the WS-I Basic Profile 1.1 to add support for interoperable SOAP messages with attachments-based Web services.

WebSphere Application Server conforms to the WS-I Attachments Profile 1.0.

Attachments are typically used to send binary data, for example, data that is mapped in Java code to java.awt.Image and javax.activation.DataHandler. The raw data can be sent in the SOAP message, however, this approach is inefficient because an XML parser has to scan the data as it parses the message.

The WS-I Attachments Profile provides a solution to the limitations that are presented by Web Services Description Language (WSDL) 1.1. Because WSDL 1.1 attachments are not part of the XML schema type space, they can be message parts only. As message parts, the attachments cannot be arrays or properties of Java beans. The profile defines the wsi:swaRef XML schema type.Use the wsi:swaRef XML schema type to overcome the limitations of WSDL 1.1 attachments.

The wsi:swaRef type is an extension of the xsd:anyURI type, where its value contains the content-ID of the attachment.

Web services: Resources for learning

This topic provides relevant supplemental information about Web services-related topics.

The following topics provide extended reference information about Web services:
- Web services overview
- Developing Web services:

  This topic includes information about developing Web services that based on the Java 2 Platform, Enterprise Edition (J2EE) and Java API for XML-based remote procedure call (JAX-RPC) specifications.
- Performance

  Review this topic for information about key Web sites that discuss performance best practices.
- Universal Description Discovery and Integration (UDDI)

  This topic is an overview about UDDI and information about the UDDI Java API.
- The Web Services Invocation Framework (WSIF)

  This topic includes a look into the Apache Software Foundation and its maintenance of WSIF.
- Web Services-Interoperability (WS-I) Basic Profile

  This topic is an overview about the WS-I Basic Profile.
- SOAP

  This topic is an overview about SOAP, information about the SOAP syntax and processing rules.
- Security

  This topic provides a roadmap to security, the WS-Security specification, best practices, a profile of the OASIS Security Assertion Markup Language (SAML) and more.
- Samples

  This topic is the Samples Gallery for WebSphere Application Server and Samples Central for UDDI and WSIF.

The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to an IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links

are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Web services overview

*   WebSphere Version 6 Web Services Handbook

    This IBM Redbook describes the new concept of Web services from various perspectives. It presents the major building blocks on which Web services rely. Well-defined standards and new concepts are presented and discussed.
*   Web services (r)evolution, Part 1

    This article focuses on the benefits and challenges of building Web services applications. Web services might be an evolutionary step in designing distributed applications, however, the technology is not without problems. Outlined are the difficulties developers face in creating a truly workable distributed system of Web services. This article also outlines author Graham Glass's plan for building peer-to-peer Web applications.

Developing Web services

*   Java Web Services: SOAP with Attachments API for Java (SAAJ)

    This document describes the SOAP with Attachments API for Java (SAAJ) and how this API provides a standard way to send XML documents over the Internet from the Java platform.
*   JSR 109: Implementing Enterprise Web services

    This document describes the J2EE specification.
*   JAX-RPC: Core Web services API in the Java platform

    This document reviews the JAX-RPC specification which enables Java technology developers to develop SOAP-based interoperable and portable Web services.
*   A developer introduction to the JAX-RPC specification, Part 1: Learn the ins and outs of the JAX-RPC type-mapping system. The JAX-RPC specification is an important step forward in the quest for Web services interoperability. This DeveloperWorks WebSphere article explains the mapping between WSDL and XML types and Java types. It explains how the JAX-RPC standard defines this feature and some of the important points on designing an interoperable type system.
*   A developer introduction to JAX-RPC, Part 2: Mine the JAX-RPC specification to improve Web service interoperability. This DeveloperWorks WebSphere article explains how you can achieve the next level of Web service interoperability using the JAX-RPC standard client and server side interface definitions and message processing model. It includes information on developing JAX-RPC handlers and handler chains.
*   Getting Started with JAX-RPC. This article explains the basic JAX-RPC programming concepts. It describes the JAX-RPC client and server programming models and illustrates simple examples. The article is intended to give developers a good grasp of how to use the JAX-RPC specification to develop or use Web services.
*   Web Services Description Language

    This article is a detailed overview of Web Services Description Language (WSDL), which includes programming specifications.

Performance

*   Web services programming tips and tricks: Using SOAP headers with JAX-RPC
*   Web services programming tips and tricks: Extend JAX-RPC Web services using SOAP headers
*   Web services programming tips and tricks: Roundtrip issues in Java coding conventions

UDDI

- Universal Description, Discovery and Integration

  This article is a detailed overview of the UDDI registry.

- A new approach to UDDI and WSDL: Introduction to the new OASIS UDDI WSDL Technical Note

  This article is about using WSDL with UDDI. Although it is based on the UDDI Registry in WebSphere Application Server Version 5, it remains a useful description of the recommended approach for use of WSDL with UDDI.

- UDDI Version 3 Features List

  This article is an introduction to the new features in UDDI Version 3.

WSIF

- The Apache Software Foundation. The Apache Software Foundation provides support for the Apache community of open-source software projects. Of particular interest is the Apache Web services project. The WSIF source code is donated by IBM to the Apache Software Foundation, and is maintained here as an Apache project.

WS-I Basic Profile

- Web Services Interoperability Organization This Web site offers resources and guidelines for Web services interoperability. You can also view the latest specification documents for WS-I Basic Profile from the documentation link on the home page.

- UTF and BOM Frequently Asked Questions. This Web site offers general information about UTF-8, UTF-16, UTF-32, along with Byte Order Mark (BOM) in a question and answer format.

SOAP

- SOAP

  This article is a detailed overview of SOAP, which includes the programming specifications.

- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 Envelope

Security

- Security in a Web Services World: A Proposed Architecture and Roadmap

  This document describes a proposed model for addressing security within a Web service environment. It defines a comprehensive Web services security model that supports, integrates, and unifies several popular security models, mechanisms, and technologies, including both symmetric and public key technologies. You can enable a variety of systems to securely interoperate in a platform and language-neutral manner. It also describes a set of specifications and scenarios that show how these specifications can be used together.

- Web Services Security (WS-Security)

  The Web Services Security (WS-Security) specifications describe enhancements to SOAP messaging to provide the quality of protection through message integrity, message confidentiality, and single message authentication. Use these mechanisms to accommodate a wide variety of security models and encryption technologies. The WS-Security specification also provides a general-purpose mechanism for associating security tokens with messages. Additionally, the specification describes how to encode binary security tokens. Specifically, the specification describes how to encode X.509 certificates and Kerberos tickets, as well as how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the credentials that are included with a message.

- SOAP Security Extensions: Digital Signature

  This document specifies the syntax and processing rules of a SOAP header entry to carry digital signature information within a SOAP 1.1 envelope

- Web Services Security Addendum

This document describes clarifications, enhancements, best practices, and errata of the WS-Security specification.

- WS-Security Profile of the OASIS Security Assertion Markup Language (SAML) Working Draft 04, 10 September 2002

    This document proposes a set of standards for SOAP extensions that are used to increase message confidentiality.
- Web Services Security: SOAP Message Security Working Draft 12, Monday 21 April 2003

    This document describes the support for multiple token formats, trust domains, signature formats, and encyrption technologies.
- JSR 55:Certification Path API

    This document provides a short description of the Certification Path API.
- XML-Signature Syntax and Processing

    This document specifies XML digital signature processing rules and syntax. XML signatures provide integrity, message authentication, or signer authentication services for data of any type, whether it is located within the XML that includes the signature or elsewhere.
- Canonical XML Version 1.0

    This specification describes a method for generating a physical representation or the canonical form of an XML document that accounts for the permissible changes.
- Exclusive XML Canonicalization Version 1.0

    Canonical XML [XML-C14N] specifies a standard serialization of XML that, when applied to a subdocument, includes the subdocument ancestor context including all of the namespace declarations and attributes in the ″xml:″namespace.
- XML Encryption Syntax and Processing

    This document specifies a process for encrypting data and representing the result in XML.
- Decryption Transform for XML Signature

    This document specifies an XML Signature decryption transform that enables XML Signature applications to distinguish between those XML encryption structures that are encrypted before signing, and must not be decrypted, and those that are encrypted after signing, and must be decrypted, for the signature to validate.
- WS-Security

    This document specifies resources for the April 2002 WS-Security specification. The following addenda and drafts are available:
    - http://schemas.xmlsoap.org/ws/2002/07/secext/
    - http://schemas.xmlsoap.org/ws/2002/07/utility/
    - OASIS draft 12 for secext
    - OASIS draft 12 for utility
- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002
- XML Encryption Syntax and Processing W3C Recommendation 10 December 2002
- XML-Signature Syntax and Processing W3C Recommendation 12 February 2002

Samples
- Samples Gallery
- Samples Central. Samples and associated documentation for the following Web services components are available through the Samples Central page of the DeveloperWorks WebSphere Web site:
    - The IBM WebSphere UDDI Registry.
    - The Web Services Invocation Framework (WSIF).

Developing Web services applications

This topic explains how to develop a Web service based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. Web services are structured in a service-oriented architecture (SOA) that makes integrating your business and e-commerce systems more flexible.

Before you develop the Web services you need to Set up a Web services development and unmanaged client execution environment . You do not have to set up a development environment if you are using Rational Application Developer.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

WebSphere Application Server uses Web services standards developed for the Java language under the Java Community Process (JCP). WebSphere Application Server follows these standards:
- SOAP Version 1.1
- WSDL Version 1.1
- Web Services for J2EE (JSR-109) Version 1.1
- Java API for XML-based remote procedure call (JAX-RPC) (JSR 101) Version 1.1
- SOAP with Attachments API for Java (SAAJ) Version 1.2

WebSphere Application Server provides extensions to the JSR-101 and JSR-109 programming models. See "Extensions to the JAX-RPC and Web Services for J2EE programming models" on page 399 for more information.

You can also use the Rational Application Developer graphical user interface development tools to develop Web services that integrate with WebSphere Application Server.

You can develop Web services in one of four ways:
1. Develop Web services using JavaBeans implementation.
2. Develop Web services using a stateless session enterprise bean.
3. Develop Web services with an existing WSDL file using JavaBeans implementation.
4. Develop Web services with an existing WSDL file using a stateless session enterprise bean.

You have developed a Web service.

Assemble the Web service.

This topic presents what you need to assemble a Web service and in what order you should assemble the parts, for example an enterprise archive (EAR) file.

Example: Developing a Web service from an EJB or JavaBeans implementation

This example takes you through the steps to develop a Web service from an Enterprise JavaBeans (EJB) or JavaBeans implementation. The development process is based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

1. **Select the enterprise bean or JavaBeans implementation that you want to enable as a Web service.**

   The implementation must meet the following Web Services for J2EE specification requirements:
   - It must have methods that can be mapped to a service endpoint interface. See step 2 for more information.

- It must be a stateless session EJB implementation or a JavaBeans implementation without client-specific state, because the implementation bean might be selected to process a request from any client. If a client-specific state is required, a client identifier must be passed as a parameter of the Web service operation.

  The selected methods of an enterprise bean must not have a transaction attribute of mandatory, because no standard currently exists, for these Web services transactions.

  A JavaBeans implementation in a Web container requires the following contents:
  - A public default constructor
  - Exposed public methods
  - It must not save a client-specific state between method calls
  - It must be a public, non-final, and non-abstract class
  - It must not define a finalize method

2. **Develop a service endpoint interface**.

   Developing a Web service requires a service endpoint interface.

   If you are using an EJB implementation, develop a service endpoint interface from an EJB remote interface.

   If you are using a JavaBeans implementation, develop a service endpoint interface for a JavaBeans implementation.

3. Develop a Web Services Description Language (WSDL) file.

4. **Develop deployment descriptor templates**.

   If you are using an EJB implementation, develop Web services deployment descriptor templates from an EJB implementation.

   If you are using a JavaBeans implementation, develop Web services deployment descriptor templates for a JavaBeans implementation.

5. **Configure the deployment descriptors.**

   By setting the `ejb-link` or `servlet-link` values of the service-impl-bean elements you can link to the enterprise bean or JavaBeans implementation that implement the service.

   Configure the `webservices.xml` deployment descriptor.

   Configure the `ibm-webservices-bnd.xmi` deployment descriptor.

6. Assemble an enterprise archive (EAR) file from a JAR file or assemble an EAR file from a WAR file.

7. Enable the Web service-enabled EAR file.

   This step only applies if you are using an EJB implementation.

8. Deploy the Web service application.

9. Publish the WSDL file.

Review the API Documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

Artifacts used to develop Web services

With *development artifacts* you can develop an enterprise bean or a Java bean module into a Web service. This topic describes artifacts used to develop Web services that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

To create a Web service from an enterprise bean or a Java bean module, the following files are added to the respective Java archive (JAR) file or Web archive (WAR) modules at assembly time:

- **Web Services Description Language (WSDL) Extensible Markup Language (XML) file**

  The WSDL XML file describes the Web service that is implemented.

- **Service Endpoint Interface**

  A Service Endpoint Interface is the Java interface corresponding to the Web service port type implemented. The Service Endpoint Interface is defined by the WSDL 1.1 World-Wide Web Consortium (W3C) Note.

- **webservices.xml**

  The webservices.xml file contains the J2EE deployment descriptor of the Web servicespecifying how the Web service is implemented. The webservices.xml file is defined in the Web Services for J2EE specification available through Web services: Resources for learning

- **ibm-webservices-bnd.xmi**

  This file contains WebSphere product-specific deployment information and is defined in ibm-webservices-bnd.xmi assembly properties.
- **Java API for XML-based remote procedure call (JAX-RPC) mapping file**

  The JAX-RPC mapping deployment descriptor specifies how Java elements are mapped to and from WSDL file elements.

The following files are added to an application client, enterprise beans or Web module to permit J2EE client access to Web services:
- **WSDL file**

  The WSDL file is provided by the Web service implementer.
- **Java interfaces for the Web service**

  The Java interfaces are generated from the WSDL file as specified by the JAX-RPC specification. These bindings are the Service Endpoint Interface based on the WSDL port type, or the service interface, which is based on the WSDL service.
- **ibm-webservicesclient-bnd.xmi**

  This file contains WebSphere product-specific deployment information, such as security information.
- **Other JAX-RPC binding files**

  Additional JAX-RPC binding files that support the client application in mapping SOAP to the Java language are generated from WSDL by the **WSDL2Java** command tool.

Mapping between Java language, WSDL and XML

This topic contains the mappings between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP, supported by WebSphere Application Server. Most of these mappings are specified by the Java API for XML-based Remote Procedure Call (JAX-RPC) specification. Some mappings that are optional or unspecified in JAX-RPC are also supported.

References to the JAX-RPC specification throughout this topic. Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

Notational conventions

The following table specifies the namespace prefixes and corresponding namespace used.

Namespace prefix	Namespace
xsd	`http://www.w3.org/2001/XMLSchema`
xsi	`http://www.w3.org/2001/XMLSchema-instance`
soapenc	`http://schemas.xmlsoap.org/soap/encoding/`
wsdl	`http://schemas.xmlsoap.org/wsdl/`
wsdlsoap	`http://schemas.xmlsoap.org/wsdl/soap/`
ns	user-defined namespace
apache	`http://xml.apache.org/xml-soap`
wasws	`http://websphere.ibm.com/webservices/`

Detailed mapping information

The following sections identify the supported mappings, including:
- Java-to-WSDL mapping
- WSDL-to-Java mapping

- Mapping between WSDL and SOAP messages

Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the **Java2WSDL** command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the Web service. The generated WSDL file can require additional manual editing for the following reasons:
- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a java.lang.String class can map to either an xsd:string or soapenc:string construct. The **Java2WSDL** command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.
- Multiple ways exist to generate WSDL constructs. For example, you can generate the wsdl:part in wsdl:message with a type or element attribute. The **Java2WSDL** command makes an informed choice based on the -style and -use option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the **Java2WSDL** command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the wsdl:import construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point.

General issues
- **Package to namespace mapping**

  The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, com.ibm.webservice, is mapped to the XML namespace `http://webservice.ibm.com`.

  You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.
- **Identifier mapping**

  Java identifiers are mapped directly to WSDL and XML identifiers.

  Java bean property names are mapped to XML identifiers. For example, a Java bean, with getInfo and setInfo methods, maps to an XML construct with the name, `info`.

  The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the WSDL2Java command -implClass option for more details.
- **WSDL construction summary**

  The following table summarizes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Service endpoint interface	wsdl:portType
Method	wsdl:operation
Parameters	wsdl:input, wsdl:message, wsdl:part
Return	wsdl:output, wsdl:message, wsdl:part
Throws	wsdl:fault, wsdl:message, wsdl:part

Primitive types	xsd and soapenc simple types
Java beans	xsd:complexType
Java bean properties	Nested xsd:elements of xsd:complexType
Arrays	JAX-RPC defined xsd:complexType or xsd:element with a maxOccurs=″unbounded″ attribute
User defined exceptions	`xsd:complexType`

- **Binding** and **service** construction

  A wsdl:binding that conforms to the generated wsdl:portType is generated. A wsdl:service containing a port that references the generated wsdl:binding is generated. The names of the binding and service are controlled by the **Java2WSDL** command.

- **Style** and **use**

  Use the -style and -use options to generate different kinds of WSDL files. The four supported combinations are:
  - -style DOCUMENT -use LITERAL
  - -style RPC -use LITERAL
  - -style DOCUMENT -use LITERAL -wrapped false
  - -style RPC -use ENCODED

  The following is a brief description of each combination.
  - **DOCUMENT LITERAL**

    The **Java2WSDL** command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The wsdl:binding is generated with embedded style=″document″ and use=″literal″ attributes. An xsd:element is generated for each service endpoint interface method to describe the request message. A similar xsd:element is generated for each service endpoint interface method to describe the response message.
  - **RPC LITERAL**

    The **Java2WSDL** command generates a WS-I compliant rpc-literal WSDL file. The wsdl:binding is generated with embedded style=″rpc″ and use=″literal″ attributes. The wsdl:message constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the wsdl:message constructs.
  - **DOCUMENT LITERAL not wrapped**

    The **Java2WSDL** command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of wsdl:message constructs to define the request and response messages.
  - **RPC ENCODED**

    The **Java2WSDL** command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The wsdl:binding is generated with embedded style=″rpc″ and use=″encoded″ attributes. Certain soapenc mappings are used to represent types and arrays.

Mapping of standard XML types from Java types

Many Java types map directly to standard XML types. For example, a java.lang.String maps to an xsd:string. These mappings are described in the JAX-RPC specification.

Generation of wsdl:types

Java types that cannot be mapped directly to standard XML types are generated in the `wsdl:types` section. A Java class that matches the Java bean pattern is mapped to an `xsd:complexType`. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

Java:

```
public abstract class Base {
```

```
    public Base() {}
    public int a;                          // mapped
    private int b;                         // mapped via setter/getter
    private int c;                         // not mapped
    private int[] d;                       // mapped via indexed setter/getter

    public int getB() { return b;}         // map property b
    public void setB(int b) {this.b = b;}

    public int[] getD() { return d;}       // map indexed property d
    public void setD(int[] d) {this.d = d;}
    public int getD(int index) { return d[index];}
    public void setB(int index, int value) {this.d[index] = value;}

    public void someMethod() {...}         // not mapped
  }

  public class Derived extends Base {
    public int x;                          // mapped
    private int y;                         // not mapped
  }
```

Mapped to:

```
<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
  <xsd:element name="a" type="xsd:int"/>
  <xsd:element name="b" type="xsd:int"/>
  <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
  <xsd:extension base="ns:Base">
   <xsd:sequence>
    <xsd:element name="x" type="xsd:int"/>
   </xsd:sequence>
  </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>
```

- **Unsupported classes**

  If a class cannot be mapped to an XML type, the **Java2WSDL** command issues a message and an xsd:anyType reference is generated in the WSDL file. In these situations, modify the Web service implementation to use the JAX-RPC compliant classes.

WSDL-to-Java mapping

The **WSDL2Java** command generates Java classes using information described in the WSDL file.

General issues

- **Mapping of a namespace to a package**

  JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name com.ibm.websphere.

  The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the

com.ibm.websphere Java package. You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.

Identifier mapping

XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- **Java construction summary**

  The following table summarizes the Java-to-XML construction. See the JAX-RPC specification for a description of these mappings.

WSDL and XML construction	Java construction
xsd:complexType	Java bean class, Java exception class, or Java array
nested xsd:element/xsd:attribute	Java bean property
xsd:simpleType (enumeration)	JAX-RPC enumeration class
wsdl:message The method parameter signature typically is determined by the wsdl:message.	Service endpoint interface method signature
wsdl:portType	Service endpoint interface
wsdl:operation	Service endpoint interface method
wsdl:binding	Stub
wsdl:service	Service interface
wsdl:port	Port accessor method in Service interface

- **Mapping standard XML types**
  - **JAX-RPC simple XML types mapping**

    Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

    Mapping the XML types defined in the wsdl:types section

    The **WSDL2Java** command generates Java types for the XML schema constructs that are defined in the wsdl:types section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The **WSDL2Java** command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The **WSDL2Java** command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an xsd:element is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, javax.xml.soap.SOAPElement.

    The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The xsd:complexType defines the type. The nested xsd:elements within the xsd:sequence or xsd:all groups are mapped to Java bean properties. For example:

    XML:

    ```
    <xsd:complexType name="Sample">
      <xsd:sequence>
      <xsd:element name="a" type="xsd:string"/>
      <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
     </xsd:sequence>
    </xsd:complexType>
    ```

    Java:

```
public class Sample {
    // ..
    public Sample() {}

    // Bean Property a
    public String getA()           {...}
    public void   setA(String value) {...}

    // Indexed Bean Property b
    public String[] getB()         {...}
    public String   getB(int index) {...}
    public void     setB(String[] values) {...}
    public void     setB(int index, String value) {...}

}
```

– **Mapping of the wsdl:portType construct**

The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.

– **Mapping of the wsdl:operation construct**

A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

- **Effect of document literal wrapped format**

If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The document literal wrapped and literal format is automatically detected by the **WSDL2Java** command. The following criteria must be met:
  - The WSDL file must have style=″document″ in its wsdl:binding construct.
  - The input and output constructs of the operations within the wsdl:binding must contain soap:body elements that contain use=″literal″.
  - The wsdl:message referenced by the wsdl:operation input construct must have a single part.
  - The part must use the element attribute to reference an xsd:element.
  - The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
  - The wrapper element must not contain any xsd:attributes.

In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

WSDL:

```
<xsd:element name="myMethod">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="param1" type="xsd:string"/>
   <xsd:element name="param2" type="xsd:int"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
 <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
```

```
  <input name="input" message="request"/>
  <output name="output" message="response"/>
 </wsdl:operation>
```

Java:

```
void myMethod(String param1, int param2) ...
```

- **Parameter mapping**

  If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

  Each parameter is defined by a wsdl:message part referenced from the input and output elements.
  - A wsdl:part in the request wsdl:message is mapped to an input parameter.
  - A wsdl:part in the response wsdl:message is mapped to the return value. If multiple wsdl:parts exist in the response message, they are mapped to output parameters.
    – A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
  - A wsdl:part that is both the request and response wsdl:message is mapped to an inout parameter.
    – A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
    – The wsdl:operation parameterOrder attribute defines the order of the parameters.

  XML:

```
<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
 <part name="param2" type="xsd:int"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>

  Java:

  void myMethod(String param1, int param2) ...
```

- **Mapping of wsdl:binding**

  The **WSDL2Java** command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the Web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

  - **MIME attachments**

    For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

    XML:
```
<wsdl:types>
 <schema ...>
  <complexType name="ArrayOfBinary">
   <restriction base="soapenc:Array">
     <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]"/>
   </restriction>
  </complexType>
 </schema>
</wsdl:types>
```

```
<wsdl:message name="request">
 <part name="param1" type="ns:ArrayOfBinary"/>
<wsdl:message name="response"/>

<wsdl:message name="response"/>
 ...

 <wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
 </wsdl:operation>
   ...

<binding ...
 <wsdl:operation name="myMethod">
  <input>
   <mime:multipartRelated>
    <mime:part>
     <mime:content part="param1" type="image/jpeg"/>
    </mime:part>
   </mime:multipartRelated>
  </input>
   ...
 </wsdl:operation>
```

Java:

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

MIME type	Java type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
multipart/*	javax.mail.internet.MimeMultipart
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source

– **Mapping of wsdl:service**

The wsdl:service element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the wsdl:service element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

In addition, the wsdl:service element is mapped to the implementation-specific ServiceLocator class, which is an implementation of the generated service interface.

Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The **WSDL2Java** command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

DOCUMENT versus RPC, LITERAL versus ENCODED

If a wsdl:binding element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a wsdl:binding element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the wsdl:part element is defined using the type attribute, the name and type of the part are used in the message. If the wsdl:part element is defined using the element attribute, the name and type of the element are used in the message. The element attribute is not supported by the JAX-RPC specification when use=″encoded″.

If a wsdl:binding element indicates that a message is encoded, the values in the message are sent with xsi:type information. If a wsdl:binding element indicates that a message is literal, the values in the message are typically not sent with xsi:type information. For example:

DOCUMENT/LITERAL
WSDL:

```
<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="a" type="xsd:string"/>
   <xsd:element ref="ns:c"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
  <wsdl:message name="request">
    <part name="parameters" element="ns:method"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
  <input message="request"/>
 ...
```

Message:
```
<soap:body>
  <ns:method>
   <a>ABC</a>
   <c>123</a>
  <ns:method>
</soap:body>
```

RPC/ENCODED
WSDL:
```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>
 ...
```

Message:
```
<soap:body>
  <ns:method>
   <a xsi:type="xsd:string">ABC</a>
   <element attribute is not allowed in rpc/encoded mode>
  </ns:method>
 </soap:body>
```

DOCUMENT/LITERAL   not wrapped
WSDL:
```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
```

```
    </wsdl:message>
 ...
 <wsdl:operation name="method">
     <input message="request"/>

...

Message:
<soap:body>
   <a>ABC</a>
   <c>123</c>
</soap:body>
```

Extensions to the JAX-RPC and Web Services for J2EE programming models

WebSphere Application Server provides extensions to the Java API for XML-based RPC (JAX-RPC) and Web Services for Java 2 Platform, Enterprise Edition (J2EE) client programming models.

These extensions are defined as follows:

- The **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties can be added to a JAX-RPC client Stub to enable a Web services client to send or retrieve implicit SOAP headers. An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.

  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  To learn how to modify your client code to send or retrieve transport headers see Sending values from implicit SOAP headers or Receiving values from implicit SOAP headers.

- The **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties can be added to a JAX-RPC client Stub to enable a Web services client to send or retrieve HTTP transport headers.

  To learn how to modify your client code to send or retrieve transport headers see Sending HTTP transport headers or Receiving HTTP transport headers. To learn more about these properties, see HTTP transport header properties best practices.

- Implementation-specific support for javax.xml.rpc.ServiceFactory.loadService() as described by the JAX-RPC specification. The loadService methods create an instance of the generated service implementation class in an implementation-specific manner. The loadService methods are new for JAX-RPC 1.1 and include three signatures:

  – **public.javax.xml.rpc.Service loadService (Class serviceInterface)**

    As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. You can review the JAX-RPC specification through Web services: Resources for learning.

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

    This method behaves like the loadService (Class serviceInterface) because the following parameters are ignored:

    - wsdlDocumentLocation

    - properties

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

    This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

- - wsdlDocumentLocation - ignored
  - serviceName - QName (namespace, localpart) of the service
  - properties - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

    If the properties argument contains an entry with a key (namespace) that matches the namespace portion of the QName serviceName argument, the entry value (`javaPackage`) is used as the package name when trying to locate the service implementation.

- **CustomBinder interface**

WebSphere Application Server defines a CustomBinder interface that you can implement to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods:
- QName for the XML schema type
- QName scope
- Java type

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the run time system and interacts with the Web services runtime using a SOAPElement. They are added to the run time by using custom binding providers. See the related links to learn more about the topics associated with the CustomBinder interface.

See the related links to learn more about the topics associated with these programming model extensions.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

Review the specifications for the standards and APIs used in developing Web services.

Custom data binders:

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the run time system and interacts with the Web services runtime using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the run time system processes as follows:

1. The run time system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example SDOCustomBinder.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the SDOCustomBinder.

Within the deserialized method, the SDOCustomBinder extracts the content from the SOAPElement and builds a concrete DataGraph object with a `commonj.sdo.DataGraph` type. The figure displays the Web services runtime flow and a custom data binder.

When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```xsd
<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
  <xsd:complexContent>
    <xsd:extension base="sdo:BaseDataGraphType">
      <xsd:sequence>
        <xsd:any minOccurs="0" maxOccurs="1"
                 namespace="##other" processContents="lax"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
  <xsd:sequence>
    <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
    <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
    <xsd:element name="changeSummary"

```

```
    <xsd:attribute name="delete" type="xsd:string"/>
  </xsd:complexType>

</xsd:schema>
```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, see Custom binding providers. The topic Usage patterns for deploying custom data binders provides usage patterns and roles for deploying the custom data binders.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

You can also review the specifications for the standards and APIs used in developing Web services.

Custom binding providers:

A *custom binding provider* is the packaging of custom data binder classes with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

You can review information in Custom data binders to learn more about custom data binders and CustomBinder interface, which is the API included in WebSphere Application Server to define the custom data binders. After you have reviewed these articles you are ready to deploy the custom binder package. To learn how to deploy this package, see Usage patterns for deploying custom data binders.

The declarative metadata file, `CustomBindingProvider.xml`, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the `/META-INF/services/directory`. After a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the **WSDL2Java** command-line tool and the run time system.

The following example is the XML schema for the `CustomBindingProvider.xml` file. The top level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in CustomBinder interface. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
    targetNamespace=
      "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:customdatabinding=
      "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified" attributeFormDefault="qualified">
```

```
    <xsd:element name="provider" type="customdatabinding:providerType"/>

  <xsd:complexType name="providerType">
  <xsd:sequence>
    <xsd:element name="description" type="xsd:string" minOccurs="0"/>
    <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
     <xsd:complexType>
       <xsd:sequence>
         <xsd:element name="description" type="xsd:string" minOccurs="0"/>
         <xsd:element name="xmlQName" type="xsd:QName"/>
         <xsd:element name="javaName" type="xsd:string"/>
         <xsd:element name="qnameScope"
                      type="customdatabinding:qnameScopeType"/>
         <xsd:element name="binder" type="xsd:string"/>
       </xsd:sequence>
      /xsd:complexType>
     </xsd:element>
      <xsd:attribute name="scope"
            type="customdatabinding:ProviderScopeType" default="module"/>
       </xsd:sequence>
  </xsd:complexType

 <xsd:simpleType name="qnameScopeType">
    <xsd:restriction base="xsd:string">
       <xsd:enumeration value="simpleType"/>
       <xsd:enumeration value="complexType"/>
       <xsd:enumeration value="element"/>
    </xsd:restriction>
 </xsd:simpleType>

 <xsd:simpleType name="ProviderScopeType">
    <xsd:restriction base="xsd:string">
       <xsd:enumeration value="server"/>
       <xsd:enumeration value="application"/>
       <xsd:enumeration value="module"/>
    </xsd:restriction>
 </xsd:simpleType>
</xsd:schema>
```

The following is an example of the `CustomBindingProvider.xml` file for the SDO DataGraph schema that
was introduced in CustomBinder interface. The example displays the mapping between a schema type,
DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is
called `test.sdo.SDODataGraphBinder`.

```
<cdb:provider
 xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
   xmlns:sdo="commonj.sdo">
   <cdb:mapping>
     <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
     <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
     <cdb:qnameScope>complexType</cdb:qnameScope>
     <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
   </cdb:mapping>
</cdb:provider>
```

You need to import your custom data binders into the **WSDL2Java** command-line tool for development
purposes. The custom data binders affect how the development artifacts, including the Service Endpoint
Interface and the JSR 109 mapping data, are generated from the Web Services Description Language
(WSDL) file. The **WSDL2Java** command-line tool ships with WebSphere Application Server and uses the
custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in
the CustomBinder interface topic.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
    xmlns:impl="http://sdo.test"
    xmlns:intf="http://sdo.test"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:sdo="commonj.sdo">

 <wsdl:types>
  <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
       xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
   <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
  </schema>
 </wsdl:types>

 <wsdl:message name="echoResponse">
  <wsdl:part element="sdo:datagraph" name="return"/>
 </wsdl:message>

 <wsdl:message name="echoRequest">
   <wsdl:part element="sdo:datagraph" name="parameter"/>
 </wsdl:message>

 <wsdl:portType name="EchoService">
   <wsdl:operation name="echo">
     <wsdl:input message="impl:echoRequest" name="echoRequest"/>
     <wsdl:output message="impl:echoResponse" name="echoResponse"/>
   </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
   <wsdlsoap:binding style="document"
                     transport="http://schemas.xmlsoap.org/soap/http"/>
     <wsdl:operation name="echo">
       <wsdlsoap:operation soapAction=""/>
       <wsdl:input name="echoRequest">
        <wsdlsoap:body use="literal"/>
       </wsdl:input>

       <wsdl:output name="echoResponse">
          <wsdlsoap:body use="literal"/>
       </wsdl:output>
     </wsdl:operation>
  </wsdl:binding>

 <wsdl:service name="EchoServiceService">
    <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
      <wsdlsoap:address location="http://<uri>"/>
    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>
```

If you run the **WSDL2Java** command without the custom data binding package, the following Service
Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```
public interface EchoService extends java.rmi.Remote {
  public javax.xml.soap.SOAPElement
   echo(javax.xml.soap.SOAPElement parameter)
    throws java.rmi.RemoteException;
}
```

When you run the **WSDL2Java** command with the custom data binding package, the custom data binders
are used to generate the parameter types. To apply the custom data binders, use the -classpath option on
the WSDL2Java tool. The tool searches its classpath to locate all the files with the same file path of

/META-INF/services/CustomBindingProvider.xml. The following is an example how you would use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.Datagraph`:

```
WSDL2Java -role develop-server -container web classpath sdobinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```
public interface EchoService extends java.rmi.Remote {
  public commonj.sdo.DataGraph
   echo(commonj.sdo.DataGraph parameter)
    throws java.rmi.RemoteException;
}
```

The custom binder packaged JAR file has to be made available at runtime to make sure the Web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

You can also review the specifications for the standards and APIs used in developing Web services.

CustomBinder interface:

WebSphere Application Server defines a CustomBinder interface that you can implement to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods. These properties are QName for the XML schema type, the QName scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

getQName

The getQName method returns the QName of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the getQName method returns the QName of the containing element.

For named types, the getQName method returns the QName of the complexType or the simpleType.

getQNameScope

The getQNameScope method returns the binder qnameScope property that indicates whether the schema type is a named type or an anonymous type. The qnameScope property value can be *complexType* for an `<xsd:complexType>`, *simpleType* for an `<xsd:simpleType>` or *element* for an <xsd:element> that is defined with an anonymous type.

In the following schema, data1 is an element that is defined with an anonymous type. The element, data2, is defined using the named type, data2Type.

```
<xsd:element name="data1">
 <xsd:complexType>
  ...
 </xsd:complexType>
</xsd:element>

<xsd:element name= "data2" type="data2Type"/>
<xsd:complexType name="data2Type">
 ...
</xsd:complexType>
```

The anonymous type, data1, has a qNameScope of element and a qName of data1. The type, data2Type, has a qNameScope of complexType and a qName of data2Type.

The element, data2, is not represented in the custom data binder. The custom data binder only processes types and not elements.

getJavaName

The getJavaName method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from the deserialize method has a type that is compatible with the Java type that is returned by the getJavaName method.

serialize

The serialize method returns the SOAPElement that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the getJavaName method. The SOAPElement parameter does not have child elements, but it does have a valid QName. This parameter is a reference for the binder to create the final SOAPElement.

In most cases, the binder implementation appends the child elements to the root SOAPElement. The run time system guarantees that the SOAPElement QName is correct. Therefore, the custom data binder for named types keeps the QName of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the QName in the returned SOAPElement that matches the defined schema type. WebSphere Application Server does not have concrete methods in the CustomBindingContext parameter.

deserialize

The deserialize method returns a Java object that the custom data binder builds from the passed root SOAPElement. The object type of the returned Java object must match what is returned from the getJavaName method. Unlike the parameter serialize method, the passed SOAPElement contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO DataGraph binder, where the convertToSDO and convertToSAAJ utility methods convert between SOAPElement and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
 public QName getQName() {
   return new QName("commonj.sdo", "DataGraphyType");
}
public String getJavaName() {
 return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
}
public String getJavaName() {
 return commonj.sdo.DataGraph.class.getName();
}
public javax.xml.soap.SOAPElement serialize(
  Object bean,
  SOAPElement rootNode,
  CustomBindingContext context)
  throws javax,xml.soap.SOAPException {
 // convertToSAAJ is a utility method to convert
```

```
 // the SDO DataGraph to the SOAPElement
 return convertToSAAJ(bean, rootNode);

public Object deserialize(
  SOAPElement source,
  CustomBindingContext context)
  throws javax.xml.soap.SOAPException {
  // convertToSDO is a utility method to convert
  // the SOAPElement to the SDO DataGraph
  return convertToSDO(source);
 }
}
```

To learn more about custom data binders, see "Custom data binders" on page 400. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, see Custom binder providers.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

You can also review the specifications for the standards and APIs used in developing Web services.

Usage patterns for deploying custom data binders:

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Java 2 Enterprise Edition (J2EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

You can learn about the CustomBinder API in the topic CustomBinder interface. The topic Custom data binders includes general information about custom binders and the topic Custom binding providers reviews how they are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the J2EE specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a `CustomBindingProvider.xml` file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.
- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the Web services deployment tools after the application is installed.

Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

*   **Deploy the custom data binders at the server level**

    This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

    This type of situation occurs frequently for new Web services specifications that define new schema types. For example, the WS-Addressing specification defines an EndpointReferenceType schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.

*   **Deploy the custom binders for one or more application**

    Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.

*   **Deploy the custom binders for a specific Web module within an application**

    Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

*   **Server level deployment**

    If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as `server`. Setting the value to *server* guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath see Java virtual machine settings.

*   **Deploying custom data binders for one or more applications**

    To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as `application`. Setting the value to application guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path see Managing shared libraries.

*   **Deploy the custom data binders for a specific Web module within an application**

    To deploy custom data binders for a specific Web module within an application, set the scope attribute of the declared custom binding provider to the value `module`. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the Web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

You can also review the specifications for the standards and APIs used in developing Web services.

Implicit SOAP Header property code example:

WebSphere Application Server provides extensions to the Java API for XML-based RPC (JAX-RPC) and Web Services for Java 2 Platform, Enterprise Edition (J2EE) client programming models, including the REQUEST_SOAP_HEADERS and RESPONSE_SOAP_HEADERS Stub properties. This is an example of how these two properties are used.

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a Web services request and response:

```
1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUuid1" and "AtmUuid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid1"),
7   "<AtmUuid1 xmlns=\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid2"),
9  ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10   "x:AtmUuid2 xmlns:x=\"com.rotbank.security\"><x:uuid>ROTB-0A01254385FCA09
    </x:uuid><x:AtmUuid2>"));
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS.requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS.responseHeaders);
20
21 //Call the operationon the Stub.
22 stub.foo(parm2, parm2);
23
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26   (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
    </y:uuid></y:ServerUuid.");
```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the Web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the Web services engine.

To review the documentation used for APIs and SPIs, see Reference: Generated API documentation. Follow the instructions in this topic that lead you to the API and SPI interfaces.

Review the specifications for the standards and APIs used in developing Web services.

Sending values in implicit SOAP headers:

This task explains how to enable an existing Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing Web service request.

To complete this task, you need a Web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:
- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers. You can modify the client code as follows:
1. Create a java.util.HashMap.
2. Add an entry to the HashMap for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is either an SAAJ SOAPElement object or a String that contains the XML text of the entire SOAP header element.
3. Set the HashMap as a property on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Stub or Call object. The headers within the HashMap are sent in the outgoing message.

   A `JAXRPCException` can occur if any of the following are true:
   - The HashMap contains a key that is not a QName or if the HashMap contains a value that is not a String or a SOAPElement.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

You have a Web service client that is configured to send implicit SOAP headers.

Receiving values from implicit SOAP headers:

This task explains how to enable an existing Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming Web service response.

To complete this task, you need a Web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers. You can modify the client code as follows:

1. Create a java.util.HashMap.
2. Add an entry to the HashMap for each implicit SOAP header that the client wants to receive. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is `null`.
3. Set the HashMap entry on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue remote method calls against the Stub or Call object. The Web services engine extracts the specified response headers from the Web services response message and inserts them into the HashMap. After the remote method returns, the response headers are accessible from the HashMap.

   A `JAXRPCException` can occur if any of the following are true:
   - The HashMap contains a key that is not a QName.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

You have a Web service client that is able to receive values from implicit SOAP headers.

HTTP transport header properties best practices: The REQUEST_TRANSPORT_PROPERTIES property and RESPONSE_TRANSPORT_PROPERTIES property can be set on a Java API for XML-based RPC (JAX-RPC) client Stub to enable a Web services client to send or retrieve HTTP transport headers.

REQUEST_TRANSPORT_PROPERTIES best practices

Header values format

The header values format must be written in the following way:
- Each name=value pair must be separated by a semi-colon (;).
- Each *name* and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:
```
name1=value1;name2=value2;name3=value3
```

HashMap values

The HashMap values might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the HashMap. The header values in the HashMap are parsed into individual name=value components. A semi-colon (;) separates the components, for example, name1=value1;name2=value2. Each name=value is appended to the outgoing header unless:
- **The outgoing request header contains a *name* value**.

In this case, the name=value from the HashMap is silently ignored, preventing a client from overwriting or modifying values for the *name* value that are already set in the outgoing request header by either the server or the Web services engine.

- **The HashMap header value contains multiple *name* values**.

  When the HashMap header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the HashMap header value contains name1=value1;name2=value2;name1=value3, where there are two occurrences of name1, the first value, name1=value1, is used. The other value, name1=value3, is silently ignored.

RESPONSE_TRANSPORT_PROPERTIES best practices

HashMap values

Only the HashMap keys are used; the HashMap values are ignored. The values are filled in this HashMap by retrieving the HTTP headers, which correspond to the HashMap keys from the incoming HTTP response. An empty HashMap causes all of the HTTP headers and the associated values to be retrieved from the incoming HTTP response

HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through REQUEST_TRANSPORT_PROPERTIES overrides the values set any other way.

Header	Send request	Retrieve response
Transfer-encoding	- The transfer-encoding header is ignored for HTTP 1.0. - When using HTTP 1.1, the transfer-encoding header is set to `chunked` if the value is `chunked`.	There is no special processing.
Connection	- The connection header is ignored for HTTP 1.0. - When using HTTP 1.1, the following values are set: - The connection header is set to ″close″ if the value is set to ″close″. - The connection header is set to ″keep-alive″ if the value is set to ″keep-alive″. - All other value settings are ignored.	There is no special processing.

Expect	• The expect header is ignored for HTTP 1.0.
	• When using HTTP 1.1, the following values are set:
	  – The connection header is set to ″100-continue″ if the value is set to ″100-continue″.
	  – All other value settings are ignored.
		There is no special processing.

Host	Ignored	There is no special processing.
Content-type	Ignored	There is no special processing.
SOAPAction	Ignored	There is no special processing.
Content-length	Ignored	There is no special processing.
Cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE	The value is sent on the header if it is structured correctly. See the information in this article for Header value format and HashMap values.	There is no special processing.
Cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE2	See the information in the ″Cookie″ entry.	There is no special processing.
Authorization	Ignored	There is no special processing.
Proxy-authorization	Ignored	There is no special processing.
Set-cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.
Set-cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE2	There is no special processing.	If the property MAINTAIN_SESSION is set to true, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.

Example client code

The following is an example of how a Web service a Web services client can be coded to send and retrieve HTTP transport header values:

```
HashMap sendTransportHeaders=new HashMap();
sendTransportHeaders.put("Cookie","ClientAuthenticationToken=FFEEBCC");
sendTransportHeaders.put("MyRequestHeader","MyRequestHeaderValue");
((Stub) portType)._setProperty(Constants.REQUEST_TRANSPORT_PROPERTIES, sendTransportHeaders);

HashMap receiveTransportHeaders=new HashMap();
receiveTransportHeaders.put("Set-Cookie", null);
receiveTransportHeaders.put("MyResponseHeader", null);
```

```
((Stub) portType)._setProperty(Constants.RESPONSE_TRANSPORT_PROPERTIES,
 receiveTransportHeaders);

resultString=portType.echoString("Foo");
```

Sending HTTP transport headers:

This task explains how to enable an existing Web services client to send values in HTTP transport headers. By modifying your client code to send transport headers, you can send specific information within the HTTP transport headers of outgoing requests.

You need a Web services client that you can enable to send HTTP transport headers.

Sending transport headers is supported by Web services clients only, and over the HTTP transport only. The Web services client must call the Java API for XML-based RPC (JAX-RPC) APIs directly and not through any intermediary layers, such as a gateway-like function. Sending and retrieving HTTP transport headers on the Web services server-side is done through non-Web services APIs.

The client must set a property on the Stub to send values in HTTP transport headers. Once the property is set, the values are set in all the HTTP requests for subsequent remote method invocations against the Stub until the associated property is set to `null` or the Stub is discarded. To send values in the HTTP transport headers on outbound requests, modify the client code as follows:

1. Create a java.util.HashMap that contains the HTTP header identifiers.
2. Add an entry to the HashMap for each header that you want the client to send.
   a. Set the HashMap entry key to a string that exactly matches the HTTP header identifier. The header identifier can be one that is defined for HTTP, such as Cookie, or it can be user-defined, such as MyHTTPHeader. Certain header identifiers are processed in a special manner, but no other checks are made as to the header identifier value. To learn more about the header identifiers that have special consideration, see HTTP transport header properties best practices.

      Common header identifier string constants, such as HTTP_HEADER_SET_COOKIE can be found in the com.ibm.websphere.webservices.Constants class. The HashMap entry value does not need to be set; it is ignored. An empty HashMap (one that is non-null, but does not contain keys), causes values from all headers in the HTTP response to be received.
   b. Set the HashMap value to a string that contains the header value to send in the HTTP header.
3. Set the HashMap on the Stub by using the property com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about the HTTP transport header properties see HTTP transport header properties best practices.
4. Issue the remote method calls against the Stub. The headers and the associated values from the HashMap are added to the outgoing HTTP request for each method invocation.

   A `JAXRPCException` can occur if the property is not set correctly. The following requirements must be met:
   - The property value set on the Stub must be a HashMap object or `null`.
   - The HashMap must not be empty.
   - Each key in the HashMap must be a String object.
   - Each value in the HashMap must be a String object.

You have a Web service client that is configured to send HTTP transport headers.

Retrieving HTTP transport headers:

This task explains how to enable an existing Web services client to retrieve values from HTTP transport headers. By modifying your client code, you can retrieve information from incoming HTTP headers responses

You need a Web services client that you can enable to retrieve HTTP transport headers.

Retrieving transport headers is supported only by Web services clients, and only over the HTTP transport. The Web services client must call the Java API for XML-based RPC (JAX-RPC) APIs directly and not through any intermediary layers, such as a gateway-like function. Sending and retrieving HTTP transport headers on the Web services server-side is done through non-Web services APIs.

The client must set a property on the Stub in order to retrieve values from the HTTP transport headers. Once the property is set, values are read from HTTP responses for the subsequent method invocations against that Stub until the associated property is set to `null` or the Stub is discarded. To retrieve values from the HTTP transport headers on inbound responses, modify the client code as follows:

1. Create a java.util.HashMap that contains the HTTP header identifier values to retrieve and the values for those headers on responses.
2. Add an entry to the HashMap for each header that you want the client to retrieve a value from.
   a. Set the HashMap entry key to a string that exactly matches the HTTP header identifier. The header identifier can be defined for HTTP, such as Cookie, or it can be user-defined, such as MyHTTPHeader. Certain header identifiers are processed in a special manner, but no other checks are made to confirm the header identifier value. To learn more about the header identifiers that have special consideration, see HTTP transport header properties best practices. Common header identifier string constants, such as HTTP_HEADER_SET_COOKIE can be found in the com.ibm.websphere.webservices.Constants class. The HashMap entry value is ignored and does not need to be set. An empty HashMap, for example, one that is non-null, but does not contain keys, causes values from all headers in the HTTP response to be received.
3. Set the HashMap entry on the Stub using the `com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES` property. When the HashMap is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to `null`, no headers are retrieved from the response. To learn more about the properties used, see HTTP transport header properties.
4. Issue remote method calls against the Stub. The values from the HTTP response headers are placed in the HashMap.

   You might experience API usage errors that result in a JAXRPCException. The following items are checked for during invocation and cause an exception to be thrown if there is an error:
   - The property value that is set on the Stub is either `null` or a HashMap.
   - All the HashMap keys are not non-null and an instance of a String.

You have a Web service that is able to receive HTTP transport headers.

Java2WSDL command
The **Java2WSDL** command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification. The **Java2WSDL** command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the **Java2WSDL** command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The **Java2WSDL** command is protocol independent; when you run the **Java2WSDL** command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the **Java2WSDL** command has a binding generator to generate the WSDL for that binding.

Command line syntax and arguments

The command line syntax is:
```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

Required arguments
- class

  Represents the fully qualified name of one of the following Java classes:
  - Stateless session Enterprise JavaBeans (EJB) remote interface that extends the javax.ejb.EJBObject class
  - Service endpoint interface that extends the java.rmi.Remote class
  - Java beans

  The **Java2WSDL** command locates the class in the CLASSPATH variable.

Important arguments
- -location *location*

  Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the Web service is deployed.

  The name after the last backslash is the name of the service port, unless the name is overridden by the -servicePortName argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the -location option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the -x flag.

  The following example illustrates how to produce both SOAP over HTTP, and SOAP over Java Message Service (JMS) bindings :
  ```
  java2wsdl -bindingTypes http,jms \
    -x http.location=http://your.server.name:9080/StockQuoteService/services/StockQuote \
    -x jms.location= \
   jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&targetService=StockQuote
  ```

  Use the -location option to determine which port the -location option value applies, by requiring the endpoint URLs to be specified through the binding-specific property values.
- -output *wsdl-uri*

  Indicates the path and file name of the output WSDL file. If not specified, the default `class`.wsdl file is written into the current directory.
- -input *wsdl-uri*

  Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.
- -bindingTypes

  Specifies the list of binding types write to the output WSDL file. Each binding generator in the **Java2WSDL** command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the my.pkg.MySEI Service Endpoint Interface and the my.pkg.MyEJBClass implementation class :
  ```
  java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
  ```

  The following command is an example of using the -bindingTypes option to generate SOAP over HTTP and SOAP over JMS bindings:
  ```
  java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
  ```
- -style RPC | DOCUMENT

Specifies the WSDL style to use in the generated WSDL file. For more information about styles, see Mapping between Java, WSDL and XML. This argument is used with the -use argument.

If RPC is specified with -use ENCODED, a `style=rpc/use=encoded` WSDL file is generated. If RPC is specified with the -use LITERAL option, a `style=rpc/use=literal` WSDL file is generated. If DOCUMENT is specified with the -use LITERAL option, a `style=document/use=literal` WSDL file is generated.

- -use LITERAL | ENCODED

   Specifies which style and use combinations are generated into the WSDL file when used with the -style argument. The combinations are rpc and encoded, rpc and literal, or doc and literal. This setting applies to all SOAP bindings. For more information, see the Mapping between Java language, WSDL and XML.

- -transport http | jms

   Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

   This option is deprecated. The -bindingTypes option replaces the -transport option, so that you can generate bindings that are non-SOAP specific.

- -portTypeName *name*

   Specifies the name to use for the portType element. If not specified, the binding name is the port type name.

- -bindingName *name*

   Specifies the name to use for the binding element. If not specified, the binding name is the port type name.

- -serviceElementName *name*

   Specifies the name of the service element.

- -servicePortName *name*

   Specifies the name of the service. If not specified, the service name is derived from the -location argument.

- -namespace *targetNamespace*

   Indicates the target namespace for the WSDL file being generated. See Mapping between Java code, WSDL and XML for the algorithm that is used to obtain the default namespace.

- -PkgtoNS *package namespace*

   Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the **Java2WSDL** command generates a namespace name. You can repeat the -PkgtoNS argument to specify mappings for multiple packages.

- -extraClasses *classes*

   Specifies other classes that are represented in the WSDL file.

- -implClass *impl-class*

   The **Java2WSDL** command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the -implClass argument to provide an alternative class from which to obtain method parameter names. The impl-class does not need to implement the class if the class is an interface, but it must implement the same methods as the class.

- -verbose

   Displays verbose messages.

- -help

   Displays the help message.

- -helpX

   Displays the help message for extended options and for various options that are supported by binding generators.

Other arguments

- -wrapped *boolean*

  Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if `use` is literal only. The option defaults to `true`.

- -stopClasses *parent* [, *parent*]

  The **Java2WSDL** command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the -all argument is specified.

  The **Java2WSDL** command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the -stopClasses argument to define additional classes that cause the search to stop.

- -methods *argument*

  Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.

- -soapAction

  Valid arguments are:
  - DEFAULT

    Sets the soapAction field according to the deployment information.
  - NONE

    Sets the soapAction field to double quotes (″″).
  - OPERATION

    Sets the soapAction field to the operation name.

- -outputImpl *impl-wsdl*

  Specifies if you want an interface and implementation WSDL file emitted.

- -locationImport *location-uri*

  Specifies the location of the interface WSDL file if you use the -outputImpl argument.

- -namespaceImpl *namespace*

  Specifies the target namespace for the implementation WSDL file, if you use the -outputImpl argument.

- -MIMEStyle *<style>*

  Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (wsi:swaRef) for the binding element.

  <style> can be one of the following:
  - WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.
  - AXIS: Map MIME types using AXIS standards, for example image becomes axis:image.
  - swaRef: Map MIME types using WSDL 1.1 standards with two caveats:
    - DataHandler maps to the wsi:swaRef element instead of an application and octet-stream
    - If mapping is illegal through WSDL 1.1, map to the wsi:swaRef element

- -propertiesFile *argument*

  Sets existing options, such as -extraClasses, with a properties file instead of with a command line. The following example illustrates the use of this argument:

  `extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3`

- -voidReturn

  Valid arguments are:
  - ONEWAY

    Methods with void returns are one-way. This argument is the default for a JMS transport.
  - TWOWAY

    Methods with void returns are two-way. This argument is the default for an HTTP transport.

- -debug

    Displays debug messages.

- -property or -x

    You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the **Java2WSDL** command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

    ```
    java2wsdl -x prop1=value1 -x prop2=value2
    ```

    is equivalent to:

    ```
    java2wsdl -x prop1=value1,prop2=value2
    ```

    The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

WSDL2Java command

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the Web service. The Web Services for Java 2 Platform, Enterprise Edition (J2EE) 1.1 specification defines deployment descriptors that deploy a Web service in a J2EE environment. The **WSDL2Java** command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

Required arguments

- WSDL-URI

    Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

Important arguments

- -role *j2ee role*

    Specifies the J2EE development role that identifies which files to generate. Valid arguments include:
    – client

        A combination of the develop-client and deploy-client arguments.
    – deploy-client

        Generates binding files for client deployment.
    – deploy-server

        Generates binding files for server deployment.
    – develop-client (default)

        Generates files for client development.
    – develop-server

        Generates files for server development.

- server

    A combination of the develop-server and deploy-server arguments.
- -container *j2ee-container*

    Indicates the J2EE container to use. Valid arguments include:
    - client

        Indicates client container.
    - ejb

        Indicates an Enterprise JavaBeans (EJB) container.
    - none

        Indicates no container.
    - web

        Indicates a Web container.

    For client roles (see the -role option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.
- -output *directory*

    Sets the root directory for emitted files.
- -inputMappingFile mapping file

    Specifies the file name of the Web Services for J2EE 1.1 mapping file.
- -introspect

    Uses existing Java beans with a new Web service API.

    In some scenarios, it is good to use existing Java classes instead of generating new classes. The -introspect option directs the **WSDL2Java** command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

    Suppose you have an existing Java bean

    ```
    public class Bean {
     public Date x;
    }
    ```

    The WSDL file defines *x* as xsd:dateTime. Without the -introspect option, the **WSDL2Java** command generates a Java bean that is similar to the following example:

    ```
    public class Bean {
     private Calendar x;
     public void setx(Calendar value) (x=value;)
     public Calendar getX() { return x;)
    }
    ```

    The **WSDL2Java** command uses the -introspect option to examine the original Java bean and to generate classes that are compatible with existing Java beans.
- -classpath *paths*

    Defines an alternative class path to search for Java classes.
- -noDataBinding

    Disables the binding of XML types to Java types. Instead, each XML type is mapped to a javax.xml.soap.SOAPElement interface defined by the SOAP with Attachments API for Java (SAAJ) 1.2 specification.

    The JAX-RPC specification defines Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the **WSDL2Java** command maps the type to an SAAJ SOAPElement. A SAAJ SOAPElement is a generic representation of the element in the message. The methods on the SOAPElement can be used to examine the element and its children.

    In some scenarios, it might be more appropriate to use the generic SOAPElement mapping exclusively. To read more about the use of SOAPElement see SOAP with Attachments API for Java and Custom data binders.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

- -help

  Displays a help message and exits.
- -helpX

  Displays a help message for extended options. The options include:
- -verbose

  Displays processing information, including the names of the generated files.
- -NStoPkg *namespace=package*

  By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form *http://x.y.com* or *urn:x.y.com*, the corresponding package is *com.y.x*.

  You can provide your own mapping by using the -NStoPkg argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the samples.addr package, provide the -NStoPkg ″http://urn:AddressFetcher2/″=samples.addr argument to the **WSDL2Java** command.
- -timeout *seconds*

  Specifies how long the **WSDL2Java** command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; -1 disables the timeout.
- -genResolver

  Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future **WSDL2Java** command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named _AbsoluteImportResolver.java. Compile and package this class with the other Java classes that are generated by the **WSDL2Java** command.
- -useResolver *resolver-class*

  Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the **WSDL2Java** command that uses the -genResolver option. The class must be available in the CLASSPATH variable.
- -deployScope *argument*

  Indicates how to deploy the server implementation. Valid arguments include:
  - Application

    Uses one instance of the implementation class for all requests.
  - Request

    Creates a new instance of the implementation class for each request.
  - Session

    Creates a new instance of the implementation class for each session.

Other arguments

- -user *id*

  Specifies the login user name to access the WSDL URI.
- -password *password*

  Specifies the login user password to access the WSDL URI.
- -all

  Generates Java files for all types, even those that are not referenced.
- -debug

  Prints debugging information.
- -genJava *argument*

Generates Java files. Valid arguments include:
– IfNotExists, default
– Overwrite
– No

- -javaSearch *argument*

  The -javaSearch option is used with the -genJava option. If the -genJava IfNotExists, use the -javaSearch option to determine how file existence is detected.

    – File (default): Looks for a file in the output directory

    – Classpath: Looks for a class in the CLASSPATH variable

    – Both: Looks for a file in the output directory or in a class in the CLASSPATH variable

- -genXML *argument*

  Generates the `.xml` and `.xmi` files. Valid arguments are:
  – IfNotExists, default
  – Overwrite
  – No

- -genImplSer *true or false*

  Indicates that each generated Java bean implements the java.io.Serializable. The default is `false`.

- -genEquals *true or false*

  Indicates that each generated Java bean have `equals` and `hashCode` methods. The default is false.

- -noWrappedOperations

  Disables wrapped operations detection. Java beans for the request and response messages are generated.

- -noWrappedArrays

  Disables wrapped array detection.

- -fileNStoPkg *file name*

  Specifies the file of the namespace to package mappings. The default is NStoPKG.properties.

- service *wsdl service name*

  Generates files for the installed WSDL service only.

- -testCase

  Generates the template for a JUnit test case for testing Web services. JUnit is a simple framework to write repeatable tests.

Using HTTP to transport Web services requests

This task leads you into developing an HTTP accessible Web service when you already have a JavaBean object to enable as a Web service.

Run the **Java2WSDL** command to create a Web Services Description Language (WSDL) file. When you run the **Java2WSDL** command, use the -bindingsTypes option, along with `http`, to set the HTTP transport bindings. For example:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

WebSphere Application Server supports the use of HTTP to transport Web services client requests. With HTTP, your Web services clients and servers can communicate through SOAP messages. SOAP is the underlying communication protocol that is used in Web services that support the Web Services for Java 2 platform Enterprise Edition (J2EE) and the Java API for XML-based remote procedure call (JAX-RPC) specifications.

HTTP is the most commonly used transport for Web services.

To develop an HTTP-accessible Web service from an existing an existing JavaBean object:

1. Add an HTTP binding and a SOAP address to the WSDL file.

   The WSDL file of a Web service must include an HTTP binding and a SOAP address, which specifies an HTTP endpoint URL string, to be accessible on the HTTP transport. An HTTP binding is a wsdl:binding element that contains a wsdlsoap:binding element with a transport attribute that ends in `soap/http`.

   In addition to the HTTP binding, a wsdl:port element that references the HTTP binding must be included in the wsdl:service element within the WSDL file. The wsdl:port element contains a wsdlsoap:address element with a location attribute that specifies an HTTP endpoint URL string.

   When you develop the Web service, a placeholder such as `file:unspecified_location` can be used for the endpoint URL string.

2. Add the HTTP endpoints to your enterprise archive (EAR) file using the **endptEnabler** command, if your application includes enterprise beans.

   By default, the **endptEnabler** command adds only HTTP endpoints.

3. Deploy the Web services application.

4. Configure security for the HTTP connection.

   For a secure HTTP connection, add the basicAuth assembly property to the `ibm-webservicesclient-bnd.xmi` deployment descriptor file. Set the user ID and the password attributes.

5. Configure the endpoint URL information for HTTP bindings.

   The WSDL publisher uses this partial URL string to produce the actual HTTP URL for each port component defined in the EAR file. The published WSDL file can be used by clients, that need to invoke the Web service.

You have a JavaBean object that uses HTTP to transport Web services client requests.

Publish the WSDL file.

Configuring HTTP outbound transport level security with the administrative console

This topic explains how to configure HTTP outbound transport level security with the administrative console.

This task is one of several ways that you can configure the HTTP outbound transport level security for a Web service acting as a client to another Web service server. You can also configure the HTTP outbound transport level security with an assembly tool or by using the Java properties. If you do not configure the HTTP outbound transport level security, the Web services runtime defers to the Java 2 Platform, Enterprise Edition (J2EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the J2EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

If you choose to configure the HTTP outbound transport level security with the administrative console or an assembly tool, the Web services security binding information is modified. You can use the administrative console to configure the Web services client security bindings if you have deployed or installed the Web services application into WebSphere Application Server. If you have not installed the Web services application, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have deployed the Web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the J2EE security programming model , or that are associated the Dynamic selection, have higher precedence.

Review the topic Secure communications using Secure Sockets Layer for more information.

Configure the HTTP outbound transport level security with the following steps provided in this task section.

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web Services Client Security Bindings**.
3. Click **HTTP SSL Configuration** to access the HTTP SSL configuration panel. Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration that is based on the current context. Select the **Specific to this Web service port** radio button if you want to choose the SSL configuration in the HTTP SSL configuration drop down box.

You have configured the HTTP outbound transport level security for a Web service acting as a client to another Web service with the administrative console.

HTTP SSL Configuration collection:

Use this page to configure transport-level Secure Sockets Layer (SSL) security. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable HTTP SSL (or HTTPS). Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:
1. Click **Applications > Enterprise Applications >** *application_instance*.
2. Click **Manage modules >** *URI_file_name* **> Web Services: Client Security Bindings**.
3. Under HTTP SSL Configuration, click **Edit**.

SSL configuration: Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration that is based on the current context. Select the **Specific to this Web service port** radio button if you want to choose the SSL configuration in the **HTTP SSL configuration** drop down box.

HTTP SSL configuration: The **HTTP SSL configuration** drop down box lists the SSL configurations used with the HTTP transport for a port. Use this drop down box if you want to select the SSL configuration rather than using the SSL configuration that the runtime automatically selects. To use the drop down box, select the **Specific to the Web service port** radio button that is located in the **SSL configuration** field. After you select the radio button, you can click the drop down box to view and select an SSL configuration.

Configuring HTTP outbound transport level security with an assembly tool
This topic explains how to configure the HTTP outbound transport level security with an assembly tool.

You can configure HTTP outbound transport level security with assembly tools provided with WebSphere Application Server.

This task is one of several ways that you can configure the HTTP outbound transport level security for a Web Service acting as a client to another Web service server. You can also configure the HTTP outbound transport level security with the administrative console or by using the Java properties. If you do not configure the HTTP outbound transport level security, the Web services runtime defers to the Java 2 Platform, Enterprise Edition (J2EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the J2EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

If you configure the HTTP outbound transport level security with assembly tool or with the administrative console, the Web services security binding information is modified. If you have not yet installed the Web services application into WebSphere Application Server, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have not deployed the Web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration that is specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the J2EE security programming model, or are associated with the Dynamic selection, have a higher precedence.

Review the topic Secure communications using Secure Sockets Layer for more information.

Configure the HTTP outbound transport level security with the following steps provided in this task section.

1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.

2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.

3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.

4. Configure the HTTP outbound transport level security. See ″Enabling Web service endpoints″ in the Application Server Toolkit documentation for more information.

You have configured the HTTP outbound transport level security for a Web Service acting as a client to another Web service with an assembly tool.

Configuring HTTP outbound transport-level security using Java properties

This topic explains how to configure the HTTP outbound transport level security for a Web service using Java properties

This task is one of three ways that you can configure HTTP outbound transport-level security for a Web service that is acting as a client to another Web service. You can also configure the HTTP outbound transport level security with the administrative console or an assembly tool. However, you can also use this task to configure the HTTP outbound transport-level security for a Web service client.

If you choose to configure the HTTP outbound transport-level security with the administrative console or an assembly tool, the Web services security binding information is modified.

If you configure the HTTP outbound transport-level security using Java properties, the properties are configured as system properties. However, the configuration specified in the binding takes precedence over the Java properties.

You can configure the HTTP outbound transport-level security using WebSphere SSL properties or JSSE SSL properties. However, the WebSphere SSL properties take precedence over the JSSE SSL properties.

Configure the HTTP outbound transport-level security with the following steps provided in this task section.

1. Create a property file that includes the following properties:
```
com.ibm.ssl.protocol
com.ibm.ssl.keyStoreType
com.ibm.ssl.keyStore
com.ibm.ssl.keyStorePassword
com.ibm.ssl.trustStoreType
com.ibm.ssl.trustStore
com.ibm.ssl.trustStorePassword
```

2. Set the `com.ibm.webservices.sslConfigURL` Java system property to the absolute path of the created property file. If no WebSphere SSL properties are defined, the JSSE SSL properties are used. Set the JSSE SSL properties as JVM custom properties. See "Secure transports with JSSE and JCE programming interfaces" on page 964 for more information about setting the JSSE SSL properties.

You have configured the HTTP outbound transport-level security for a Web service acting as a client to another Web service.

Transport level security

Transport level security is based on Secure Sockets Layer (SSL) or Transport Layer Security (TLS) that runs beneath HTTP.

Transport level security can be used to secure Web services messages. However, transport-level security functionality is independent from functionality that is provided by WS-Security or HTTP Basic Authentication.

SSL and TLS provide security features including authentication, data protection, and cryptographic token support for secure HTTP connections. To run with HTTPS, the service port address must be in the form `https://`.

The integrity and confidentiality of transport data, including SOAP messages and HTTP basic authentication, is confirmed when you use SSL and TLS.

Web services applications can also use Federal Information Processing Standard (FIPS) approved ciphers for more secure TLS connections.

WebSphere Application Server uses the Java Secure Sockets Extension (JSSE) package to support SSL and TLS.

HTTP basic authentication

HTTP basic authentication uses a user name and password to authenticate a service client to a secure endpoint.

WebSphere Application Server can have several resources, including Web services, protected by a Java 2 Platform, Enterprise Edition (J2EE) security model.

HTTP basic authentication is orthogonal to the security support provided by WS-Security or HTTP Secure Sockets Layer (SSL) configuration.

A simple way to provide authentication data for the service client is to authenticate to the protected service endpoint using HTTP basic authentication. The basic authentication is encoded in the HTTP request that carries the SOAP message. When the application server receives the HTTP request, the user name and password are retrieved and verified using the authentication mechanism specific to the server.

Although the basic authentication data is base64-encoded, sending data over HTTPS is recommended. The integrity and confidentiality of the data can be protected by the SSL protocol.

In some cases, a firewall is present using a pass-thru HTTP proxy server. The HTTP proxy server forwards the basic authentication data into the J2EE application server. The proxy server can also be protected. Applications can specify the proxy data by setting properties in a stub object.

Configuring HTTP basic authentication with the administrative console

This topic explains how to configure HTTP basic authentication with the administrative console.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or by modifying the HTTP properties programmatically.

If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web services security binding information is modified. You can use the administrative console to configure HTTP basic authentication if you have deployed or installed the Web services application into

WebSphere Application Server. If you have not installed the Web services application, then you can configure the security bindings with an assembly tool. This task assumes that you have deployed the Web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding. However, you only can programmatically configure HTTP proxy authentication.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication with the following steps provided in this task section.

Open the administrative console.
1. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services: Client security bindings**.
2. Click **HTTP Basic Authentication** to access the HTTP basic authentication panel. Enter the values in the HTTP Basic Authentication panel.

You have configured the HTTP basic authentication.

HTTP basic authentication collection:

Use this page to specify a user name and password for transport-level basic authentication security for this port. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable basic authentication. Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:
1. Click **Applications > Enterprise Applications >** *application_instance*.
2. Click **Manage modules >** *URI_file_name* **> Web Services: Client Security Bindings**.
3. Under HTTP basic authentication, click **Edit**.

Basic authentication ID:

The user name for the HTTP basic authentication for this port is set in this field.

Basic authentication password:

The password for the HTTP basic authentication for this port is set in this field.

Configuring HTTP basic authentication with an assembly tool
This topic explains how to configure HTTP basic authentication with an assembly tool.

You can configure HTTP basic authentication with assembly tools provided with WebSphere Application Server.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with the administrative console or by modifying the HTTP properties programmatically.

If you choose to configure the HTTP basic authentication with an assembly tool or with the administrative console , the Web services security binding information is modified. You can use an assembly tool to configure HTTP basic authentication before you deploy or install the Web services application into WebSphere Application Server. This task assumes that you have not deployed the Web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding. However, you only can programmatically configure HTTP proxy authentication.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

To configure HTTP basic authentication, use the WebSphere Application Server tools to modify the binding information.
1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.
4. Configure the HTTP basic authentication in the Web Services Client Port Binding page for a Web service or a Web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file.

Configuring HTTP basic authentication programmatically

This topic explains how to configure HTTP basic authentication by programmatically modifying HTTP properties.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or with the administrative console.

If you programmatically configure HTTP basic authentication, the properties are configured in the Stub or Call instance. If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web services security binding information is modified. The values that are set programmatically take precedence over the values defined in the binding. However, you can only configure HTTP proxy authentication programmatically.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication programmatically with the following steps provided in this task section.
1. Set the properties in the Stub or Call instance for a Web service or a Web service client You can set the following properties:
   ```
   javax.xml.rpc.Call.USERNAME_PROPERTY
   javax.xml.rpc.Call.PASSWORD_PROPERTY
   javax.xml.rpc.Stub.USERNAME_PROPERTY
   javax.xml.rpc.Stub.PASSWORD_PROPERTY
   ```
2. Set the properties in the Stub or Call instance to configure the HTTP proxy authentication.

a. You can set the following properties for HTTP:

```
com.ibm.wsspi.webservices.HTTP_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.HTTP_PROXYPASSWORD_PROPERTY
```

3. You can set the following properties for HTTPS:

```
com.ibm.wsspi.webservices.HTTPS_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.HTTPS_PROXYPASSWORD_PROPERTY
```

Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console

This topic explains how to configure additional HTTP transport properties with the JVM custom properties panel in the administrative console.

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configure the properties with an assembly tool
- Configure the properties using the **wsadmin** command-line tool

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- com.ibm.websphere.webservices.http.requestContentEncoding
- com.ibm.websphere.webservices.http.responseContentEncoding
- com.ibm.websphere.webservices.http.connectionKeepAlive
- com.ibm.websphere.webservices.http.requestResendEnabled
- http.proxyHost
- http.proxyPort
- https.proxyHost
- https.proxyPort

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with the administrative console with the following steps provided in this task section:

1. Open the administrative console.
   a. Click **Servers** > **Application Servers** > *server* > **Java and Process Management** > **Process Definition** > **Java Virtual Machine** > **Custom Properties**.
2. (Optional) If the property is not listed, create a new property name.
3. Enter the name and value.
4. (Optional) Accept the redirection of the HTTP request to a different URI in HTTPS.

A redirection of the HTTP request to a different URI in HTTPS can occur if the transport guarantee of CONFIDENTIAL or INTEGRAL is configured in the application. To accept the redirection, you can do either of the following tasks:

- Set the `com.ibm.ws.webservices.HttpRedirectEnabled` Java system property to `true`.
- Programmatically set the `com.ibm.wsspi.webservices.Constants.HTTP_REDIRECT_ENABLED` property to `true` in the stub or call object before invoking the service.

You have configured HTTP transport properties for a Web services application.

Configuring additional HTTP transport properties with an assembly tool

This topic explains how to configure additional HTTP transport properties with an assembly tool. The assembly tool is used to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor binding file.

You can configure additional HTTP transport properties with assembly tools provided with WebSphere Application Server.

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console
- Configure the properties using the **wsadmin** command-line tool.

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- com.ibm.websphere.webservices.http.requestContentEncoding
- com.ibm.websphere.webservices.http.responseContentEncoding
- com.ibm.websphere.webservices.http.connectionKeepAlive
- com.ibm.websphere.webservices.http.requestResendEnabled
- http.proxyHost
- http.proxyPort
- https.proxyHost
- https.proxyPort

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with an assembly tool with the following steps provided in this task section:

1. The assembly tools, Application Server Toolkit (AST) and Rational Web Developer, provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2, 1.3 or 1.4 compliant deployment descriptors.
2. Start an assembly tool. See "Starting WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.

3. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.

4. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.

5. Configure the additional HTTP transport properties. Create and specify the name/value pair in the **Web Services Client Port Binding** page for a Web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file.

You have configured additional HTTP transport properties for a Web services application.

Configuring additional HTTP transport properties using the wsadmin command-line tool

This topic explains how to configure additional HTTP transport properties with the **wsadmin** command-line tool.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages. For more information about the wsadmin tool options, review Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configure the properties with an assembly tool
- Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- com.ibm.websphere.webservices.http.requestContentEncoding
- com.ibm.websphere.webservices.http.responseContentEncoding
- com.ibm.websphere.webservices.http.connectionKeepAlive
- com.ibm.websphere.webservices.http.requestResendEnabled
- http.proxyHost
- http.proxyPort
- https.proxyHost
- https.proxyPort

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with the wsadmin tool by following steps provided in this task section:

1. Launch a scripting command.

2. At the **wsadmin** command prompt, enter the command syntax. You can use install, installInteractive, edit, editInteractive, update, and updateInteractive commands.

3. If you are configuring the `com.ibm.websphere.webservices.http.responseContentEncoding` property, use the **WebServicesServerCustomProperty** command option.

4. Configure all other properties using the **WebServicesClientCustomProperty** command option.

5. Save the configuration changes with the **$AdminConfig save** command.

You have configured HTTP transport properties for a Web services application.

The following illustrates an example of the Jython script syntax:

```
AdminApp.edit ( 'PlantsByWebSphere', '[ -WebServicesClientCustomProperty [[PlantsByWebSphere.war ""
service/FrontGate_SEIService FrontGate http.proxyHost+http.proxyPort myhost+80]]]')
AdminConfig.save()

AdminApp.edit ( 'WebServicesSamples', '[ -WebServicesServerCustomProperty
[[AddressBookW2JE.jarAddressBookService AddressBook http.proxyHost+http.proxyPort myhost+80]]]')
AdminConfig.save()
```

The following illustrates an example of the Jacly script syntax:

```
$AdminApp edit PlantsByWebSphere {  -WebServicesClientCustomProperty {{PlantsByWebSphere.war {}
service/FrontGate_SEIService FrontGate  http.proxyHost+http.proxyPort myhost+80 }}}
$AdminConfig save

$AdminApp edit WebServicesSamples {-WebServicesServerCustomProperty {{AddressBookW2JE.jar
AddressBookService AddressBook http.proxyHost+http.proxyPort myhost+80}}}
$AdminConfig save
```

To convert these examples from **edit** to **install**, add `.ear` to form a file name, and add any extra keywords for deployment, like `-usedefaultbindings` and `-deployejb`.

Additional HTTP transport properties for Web services applications

This topic defines additional HTTP transport properties for Web services applications. The additional properties can be used to manage the connection pool for HTTP outbound connections, configure the content encoding of the HTTP message, enable HTTP persistent connection, and resend the HTTP request when a timeout occurs.

Properties that manage the connection pool for Web services HTTP outbound connections

For information about how to configure these properties see Configuring additional HTTP transport properties using the administrative console.

Note: These properties can only be configured as JVM custom properties.

Establishing a connection is an expensive operation. Connection pooling improves performance by avoiding the overhead of creating and disconnecting connections. When an application invokes a Web service over an HTTP transport, the HTTP outbound connector for the Web service locates and uses an existing connection from a pool of connections. When the response is received, the connector returns the connection to the connection pool for reuse. The overhead to create and disconnect the connection is avoided.

The following properties are only configured as JVM custom properties that manage the connection pool for HTTP outbound connections for Web services applications:

- **com.ibm.websphere.webservices.http.connectionTimeout**

  This property specifies the interval, in seconds, that a connection request times-out and the `WebServicesFault( "Connection timed out" )` error occurs. You can configure the property only as a JVM custom property. The value affects all of the HTTP connection requests made by the HTTP outbound connector. The wait time is needed when the maximum number of connections in the connection pool is reached. For example, if the property is set to 300 and the maximum number of connections is reached, the connector waits for 300 seconds until a connection is available. After 300 seconds, the `WebServicesFault( "Connection timed out" )` error occurs if a connection is not available. If the property is set to 0 (zero), the connector waits until a connection is available.

  If the `WebServicesFault( "Connection timed out")` error occurs in the application, set the com.ibm.websphere.webservices.http.connectionTimeout property value higher. Also, review the application usage. If the com.ibm.websphere.webservices.http.maxConnection property value is set to 0 (zero), and is enabled for an unlimited number of connections, the com.ibm.websphere.webservices.http.connectionTimeout property value is ignored.

Data type	Integer
Units	Seconds
Default	300
Range	0 (zero) to the maximum integer

- **com.ibm.websphere.webservices.http.maxConnection**

  This property specifies the maximum number of connections that are created in the HTTP outbound connector connection pool. You can configure the property only as a JVM custom property. It affects all of the Web services HTTP connections that are made within one JVM. When the maximum number of connections is reached, no new connection are created and the HTTP connector waits for a current connection to return to the connection pool. If the HTTP connector does not wait for a current connection because of a connection request timeout, the `WebServicesFault( "Connection timed out" )` error occurs. For example, if the property is set to 5, and there are 5 connections in use, the HTTP connector waits for the specified time set in the com.ibm.websphere.webservices.http.connectionTimeout property for a connection to become available.

  If the property is set to 0 (zero), the com.ibm.websphere.webservices.http.connectionTimeout property is ignored. The connector attempts to create as many connections allowed by the system.

Data type	Integer
Default	50
Range	0 (zero) to the maximum integer

- **com.ibm.websphere.webservices.http.connectionPoolCleanUp**

  This property specifies the interval, in seconds, between runs of the connection pool maintenance thread. You can configure the property only as a JVM custom property. This property affects all HTTP connections for Web Services made within one JVM. For example, if the property is set to 180, the pool maintenance thread runs every 180 seconds. When the pool maintenance thread runs, the connector discards any connections remaining idle for longer than the time set in the com.ibm.websphere.webservices.http.connectionIdleTimeout property.

Data type	Integer
Units	Seconds
Default	180
Range	0 (zero) to the maximum integer

- **com.ibm.websphere.webservices.http.connectionIdleTimeout**

  This property specifies the interval, in seconds, after an idle connection is discarded. You can configure the property only as a JVM custom property. For example, if the property is set to 120, the pool

maintenance thread discards any connection that remains idle for 2 minutes. This property affects all Web services HTTP connections made within one JVM.

Data type	Integer
Units	Seconds
Default	5
Range	0 (zero) to the maximum integer

Additional HTTP transport properties

Additional HTTP transport properties can also be configured for Web services applications.

For more information about how to configure these properties see Configuring additional HTTP transport properties using wsadmin, and Configuring additional HTTP transport properties using an assembly tool.

The following are additional HTTP transport properties that can be configured:

* **com.ibm.websphere.webservices.http.requestContentEncoding**

   This property specifies the type of encoding to use in the message of each HTTP outbound request. Supported encoding formats follow the HTTP 1.1 protocol specification including gzip, x-gzip, and deflate. If this property is configured, the headers ″Content-Encoding″ and ″Accept-Encoding″ in the HTTP request are also set to the same value. For example, if the property is set to gzip, the headers become Content-Encoding: gzip and Accept-Encoding: gzip. However, if the property is not set, the HTTP request message is not encoded. The default is no encoding.

   You should check if the target Web server is capable of decoding the configured coding format. For example, if the property is set to gzip, the target Web server must also support the gzip encoding. Otherwise, a failure can occur and a status code of `415 Unsupported Media Type` might display.

   The compress encoding format is not supported and x-gzip encoding is equivalent to gzip encoding.

Data type	String
Valid values	gzip, x-gzip, and deflate

* **com.ibm.websphere.webservices.http.responseContentEncoding**

   This property specifies the type of encoding to be used in the message of each HTTP response. Supported encoding formats follow the HTTP 1.1 protocol specification including gzip, x-gzip, and deflate. If this property is configured, the headers ″Content-Encoding″ in the HTTP response is set to the same value. If the property is not set, the HTTP response message content is not encoded. The default value is `no encoding`.

   If the property is set, the request client must also support the same encoding. Otherwise, a failure can occur and a `WebServicesFault()` error displays.

   The compress encoding format is not supported and x-gzip encoding is equivalent to gzip encoding.

*

Data type	String
Valid values	gzip, x-gzip, or deflate

* **com.ibm.websphere.webservices.http.connectionKeepAlive**

   This property specifies whether the connector should maintain a live or persistent HTTP connection. If the property is set to `true`, the connector keeps the connection in the connection pool and reuses the connection for subsequent HTTP requests. However, the connection is closed if syncTimeout(Read timeout) is reached or the server has dropped the connection. Also, an idle connection is closed by the pool maintenance thread if the idle time has passed the connection idle time-out. If the property is set to `false`, the connection is closed after the HTTP request is sent. If a new request is ready to send and

the connection does not exist, the HTTP connector creates one.

Data type	String
Default	True
Valid values	True, false

- **com.ibm.websphere.webservices.http.requestResendEnabled**

  This property tells the HTTP connector to resend the SOAP message over HTTP request after a `java.net.ConnectException: read timed out` error is logged. The `java.net.ConnectException` is caused by a socket time-out, or when a server shuts down while the request is being sent. If the property is enabled, the connector tries to reconnect one time only and resends the same SOAP message over HTTP. Otherwise, the connector stops sending the SOAP message and a `WebServicesFault` error is logged.

  Problems can occur with the application this property is enabled. The HTTP request that is resent can be received twice by the server and can cause an unexpected result.

Data type	String
Default	False
Valid values	True, false

- **http.proxyHost**

  This property specifies the host name of an HTTP proxy.

Data type	String

- **http.proxyPort**

  This property specifies the port of an HTTP proxy.

Data type	String

- **https.proxyHost**

  This property specifies the host name of an HTTPS proxy.

Data type	String

- **https.proxyPort**

  This property specifies the port of an HTTPS proxy.

Data type	String

Using the Java Message Service API to transport Web services requests

WebSphere Application Server supports use of the Java Message Service (JMS) API to transport Web services requests, as an alternative to HTTP transport. By using the JMS transport, your Web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections. One-way and synchronous two-way requests are supported.

A Web service must be implemented as an enterprise bean for accessibility through the JMS transport.

Review the API documentation for a complete list of API's. You can also review several articles about the development of Web services at Web services: Resources for learning.

The benefits of using JMS include:
- Reliable messaging for request and response messages.

- Flexible one-way requests for clients and servers. For example, the server does not have to be active when the client sends the one-way request.
- Simultaneous one-way requests can be sent to multiple servers through the use of a topic.

Perform this task after you have developed or implemented a Web service. This task explains how to configure the Web service to use JMS to transport the requests.

To configure a Web service to use JMS as a transport:

1. Add a JMS binding and a SOAP address to the Web Services Description Language (WSDL) file.

   The WSDL file of a Web service must include a JMS binding and a SOAP address, which specifies a JMS endpoint URL string, for accessibility on the JMS transport. A JMS binding is a wsdl:binding element that contains a wsdlsoap:binding element whose transport attribute ends in `soap/jms`, rather than the typical `soap/http` value.

   In addition to the JMS binding, a wsdl:port element referencing the JMS binding must be included in the wsdl:service element within the WSDL file. The wsdl:port element contains a wsdlsoap:address element with a location attribute that specifies a JMS endpoint URL string.

   The specification of the actual JMS endpoint URL string can be deferred until you configure endpoint URL information for JMS bindings. As you develop Web services, a placeholder such as `file:/unspecified_location` can be used for the endpoint URL string.

2. Decide the names and the types of the JMS objects that your application uses.

   Before your application can be installed, you need to:

   a. Decide whether your Web service receives requests from a queue or a topic.

   b. Decide whether to use a secure destination, like a queue or topic, or a nonsecure destination.

   c. Decide the names for your destination, connection factory and listener port.

      The following list provides examples of the names that can be used for the StockQuote Web service:
      - **Queue:** StockQuote_Q (Java Naming and Directory Interface (JNDI) name: `jms/StockQuote_Q`)
      - **Connection factory:** StockQuote_CF (JNDI name: `jms/StockQuote_CF`)
      - **Listener port:** StockQuoteEJB_ListenerPort

3. Define the JMS administered objects.

   After you decide on the names and types of the JMS objects, use the administrative console or the **wsadmin** scripting tool to define the JMS objects. There are various ways to administer JMS resources depending on what type of JMS provider is being used. See Using JMS resources of a generic provider for more information.

4. Add the JMS endpoints to your enterprise archive (EAR) file using the **endptEnabler** command. You must run the **endptEnabler** command to add a JMS endpoint or a router module for each enterprise bean Java archive (JAR) file that is enabled for Web services and is contained in the EAR file. By default, the **endptEnabler** command adds only HTTP endpoints, but the **-transport jms** command option can be used to request the addition of JMS endpoints.

5. Configure security for the JMS connection.

   For a secure JMS connection, add the basicAuth assembly property to the `ibm-webservicesclient-bnd.xmi` deployment descriptor file. Set the user ID and password attributes.

   If the basicAuth property is not provided in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file, the JMS connection can be rejected, depending on the security configuration of the JMS provider.

6. Deploy the Web services application.

   During the installation process you are prompted for two types of information for each enterprise bean JAR file that is enabled for Web services and is contained in your EAR file:
   - The JNDI name of the connection factory for the enterprise bean JAR file message-driven bean (MDB) listener to use for sending reply messages.

If your Web service contains two-way operations, the MDB listener that is defined inside the JMS endpoint added by **endptEnabler** command, needs to access a queue connection factory to add a reply message to the reply queue.

The MDB listener uses a resource environment reference of `java:comp/env/jms/WebServicesReplyQCF`. Therefore, during the application installation process, you must provide the actual JNDI name of the queue connection factory for the MDB listener to use for that Web service. You might want to use the same connection factory that you defined for use by clients in step 2.

- The name of the listener port for the MDB listener to use.

A listener port is an object that is used to associate a JMS connection factory with a JMS destination (queue or topic). When deployed, an MDB is configured with the correct listener port so that messages from the queue or topic are properly delivered to the MDB. During deployment, you can modify the name of the listener port that is associated with each MDB listener. The listener port name contained in the input EAR file is displayed as a default value. If you specify the correct listener port name to the **endptEnabler** command, you can accept the default value. Otherwise, enter the correct listener port name.

Hint: By default, the **endptEnabler** command produces listener port names of the form `<ejb-jar-name>_ListenerPort`. To simplify this step, define the listener ports that follow this naming convention during step 2.

7. Configure endpoint URL information for JMS bindings.

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the enterprise bean JAR file. The published WSDL file can be used by clients that need to invoke the Web service.

You have a Web service that is configured to use JMS to transport the requests.

Publish the WSDL file.

Java Message Service endpoint URL syntax: A Java Message Service (JMS) endpoint URL is used to access Web services with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

A JMS endpoint URL has the following general form:

```
jms:/[queue|topic]?<property>=<value>&<property>=<value>&...
```

The URL consists of the `jms:` transport type, followed by either `/queue` or `/topic` to indicate the JMS destination type, followed by the query string containing a list of property and value pairs that are used to specify the JMS endpoint information.

The properties supported in the URL string are described in the following tables:

Destination-related properties (required)

Property name	Description
destination	Specifies the Java Naming and Directory Interface (JNDI) name of the destination queue or topic.
connectionFactory	Specifies the JNDI name of the connection factory.
targetService	Specifies the name of the port component to which the request is dispatched.

JNDI-related properties (optional)

Property name	Description
initialContextFactory	Specifies the name of the initial context factory to use which is mapped to the java.naming.factory.initial property.
jndiProviderURL	Specifies the JNDI provider URL, which is mapped to the java.naming.provider.url property.

JMS-related properties (optional)

Property name	Description
deliveryMode	Indicates whether the request message is persistent or not. The valid values are 1 for nonpersistent and 2 for persistent. The default value is 1.
timeToLive	Specifies the lifetime, in milliseconds, of the request message. A value of 0 indicates an infinite lifetime.
priority	Specifies the JMS priority associated with the request message. Valid values are between 0 to 9. The default value is 4. A value of 0 is the lowest priority and a value of 9 is the highest priority.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

The required properties, destination, connectionFactory, and targetService must appear in the JMS endpoint URL string. The rest of the properties are optional.

You can set any of the properties on the client Stub object. The various properties can be specified by including them as part of the endpoint URL or they can be set programmatically by the client on the Stub object. Properties specified on the client Stub object take precedence over properties that are specified as part of a JMS endpoint URL string.

Using WSDL EJB bindings to invoke an EJB from a Web services client

WebSphere Application Server supports directly accessing an Enterprise JavaBeans (EJB) as a Web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client.

You need an EJB that you can directly access as a Web service.

You can achieve this task because of a multiprotocol technology that uses Java API for XML-based remote procedure call (JAX-RPC) and Remote Method Invocation over Internet Inter-ORB Protocol (RMI/-IIOP) together.

RMI-IIOP with JAX-RPC supports WebSphere Java clients to invoke enterprise beans with a WSDL file and the JAX-RPC programming model instead of the standard J2EE programming model. When a Web service is implemented by an enterprise bean, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients.

This method yields better performance and enables you to get support for client transactions, which are not standard for Web services.

To use EJB bindings of Web Services Description Language (WSDL) files to transport Web services requests:

1. (Optional) Create a WSDL file that contains non-SOAP protocol bindings.

   You can use the -bindingTypes option of the **Java2WSDL** command to create a WSDL file that contains non-SOAP protocol bindings. The -bindingTypes option specifies the binding types to write to the output of the WSDL document. Review the Java2WSDL article for more information on using the -bindingTypes option. The following command is an example that you can use to generate SOAP over HTTP, and EJB bindings for a service endpoint interface, my.pkg.MySEI and an EJB implementation, my.pkg.MyEJBClass:

   ```
   java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
   ```

2. (Optional) Obtain an existing WSDL file to add the EJB binding to.

3. Add an EJB binding to the WSDL file.

4. Add a port address that contains an endpoint using the wsejb prefix.

5. Deploy the Web services application.

6. Configure the endpoint URL information for EJB bindings.

   The WSDL publisher uses this partial Web address string to produce the actual enterprise bean Web address for each port component that is defined in the enterprise bean JAR file. The published WSDL file can be used by clients that need to invoke the Web service.

You have an EJB that can be accessed by a Web services client that uses the JAX-RPC programming model. The RMI-IIOP protocol is used instead of SOAP over HTTP

Publish the WSDL file.

EJB endpoint URL syntax: An Enterprise JavaBean (EJB) endpoint URL is used to access a Web service with the EJB Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) transport. The URL specifies the EJB endpoint, including the EJB home class, the EJB Java Naming and Directory Interface (JNDI) name, and optional properties.

An EJB endpoint URL has the following format:

```
wsejb:/[classname]?<property>=<value>&amp;<property>=<value>&amp;...
```

Where:

* wsejb is the transport type
* *classname* is the name of the home interface class associated with the EJB to be invoked
* *property* and *value* pairs represent the set of required and optional properties. These properties are used to set certain values in the EJB endpoint URL. The various properties and definitions are described in the table.

JNDI-related properties

Property name	Description
jndiName	Specifies the JNDI name of the EJB. This property is required.
initialContextFactory	Specifies the name of the JNDI initial context factory. This property is optional
jndiProviderURL	Specifies the JNDI provider URL. This property is optional.

Developing a Web service from a Java bean

This task explains how to develop a Web service from a Java bean.

Set up a Web services development and unmanaged client run-time environment.

This task is one of four ways that you can develop a Web service. You can also develop a Web service from an enterprise bean, develop a Web service with an existing Web Services Description Language (WSDL) file using a Java bean, or develop a Web service with an existing WSDL file using an enterprise bean. In this task, you need develop a new WSDL file.

You can use a Java bean that already exists and then enable the implementation for Web services. Enabling the Java bean for Web services includes developing the service endpoint interface, developing a WSDL file that is the engine of the Web service, generating and configuring the deployment descriptors, assembling all artifacts required for the Web service, and deploying the application into the WebSphere Application Server environment.

Develop a Web service from a Java bean by following the task steps provided in this section.

1. Access an existing Java bean Web archive (WAR) file.
2. Develop a Java bean service endpoint interface. The service endpoint interface defines the methods for a particular Web service. The Java bean must implement methods having the same signature as the methods on the service endpoint interface.
3. Develop a WSDL file. The WSDL file is the engine of a Java 2 Platform, Enterprise Edition (J2EE) Web service; without it there is no Web service.
4. Develop Web services deployment descriptor templates for a JavaBeans implementation. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.
5. Complete the JavaBeans implementation. When you complete the JavaBeans implementation, you are assembling a Java archive (JAR) file that contains a JavaBeans implementation and supported classes created from the WSDL file.
6. Configure the `webservices.xml` deployment descriptor. Configure the `webservices.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
7. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
8. Assemble a WAR file that is enabled for Web services from Java code. This article explains how to assemble the artifacts required to enable the Web module for Web services are added to the WAR file.
9. Assemble a WAR file that is enabled for Web services into an EAR file. This topic explains how to assemble the artifacts required to enable the Web module for Web services that are added to the EAR file.
10. Deploy the EAR file into WebSphere Application Server.

    This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

You have a Web service developed from a Java bean.

After you deploy the EAR file, test the Web service to make sure that it works with WebSphere Application Server.

Developing a service endpoint interface for a JavaBeans implementation:

This task explains how to develop a service endpoint interface if you are developing a Web service from a JavaBeans implementation.

You need to set up a Web services development and unmanaged client run-time environment and access an existing Java bean Web archive (WAR) file.

This task is a required step in developing a Web service from a Java bean.

The service endpoint interface defines the methods for particular Web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification, which is available through Web services: Resources for learning.

You can also create a service endpoint interface by using the assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:
1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

   > **Windows**   Use the **javac** commands.

You have developed a service endpoint interface that you can use to develop Web services.

The following example depicts the AddressBook interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the AddressBook interface to create the service endpoint interface:
1. Make a copy of the AddressBook.java interface and name it `AddressBook_SEI.java`. Use this copy as a template for the service endpoint interface.
2. Compile the interface.

Continue to gather the artifacts that are required to develop a Web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a Web service. Without a WSDL file, you do not have a Web service.

Developing a WSDL file:

This topic explains how to develop a Web Services Description Language (WSDL) file.

Depending on your development path, develop a Service Endpoint Interface for a Java bean implementation or develop a Service Endpoint Interface from an EJB remote interface.

You need a WSDL file to use Web services. You can develop your own WSDL file or get one from a Web services provider through e-mail, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:
1. Configure the service endpoint interface class and referenced classes into your CLASSPATH variable.
   - On Windows systems, set `CLASSPATH="%CLASSPATH%;`*<list your application Java archive (JAR) files and classes>"*.

- On UNIX and Linux systems, export `CLASSPATH="$CLASSPATH:`*<list your application JAR files and classes>*`"`.

2. Run the **Java2WSDL** *seiInterface* command. A WSDL file named *`seiInterface`*`.wsdl` is created.

   - Move the WSDL file to the `META-INF/wsdl` subdirectory if you are using Enterprise JavaBeans (EJB).

   - Move the WSDL file to the `WEB-INF/wsdl` subdirectory if you are using JavaBeans.

3. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.

4. (Optional) Use the **Java2WSDL** command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the **Java2WSDL** command tool. Generating and setting the part names is done by providing additional information to the **Java2WSDL** command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the **Java2WSDL -implClass** *seiImpl seiInterface* command to generate a WSDL file with the proper part names.

A WSDL file that defines the Web services described by the service endpoint interface.

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the **Java2WSDL -implClass addr.AddressBookBean addr.AddressBook** command to create the file, `AddressBook.wsdl`.

Depending on your development path, develop Web services deployment descriptor templates for a Java bean implementation or develop Web services deployment descriptor templates for an EJB implementation.

Developing Web services deployment descriptor templates for a JavaBeans implementation:

Deployment descriptors are standard text files, formatted using XML and packaged in a Web services application. Deployment descriptors are required to deploy Web services that are developed using the Web services for Java 2 Platform, Enterprise Edition (J2EE).

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use Web services. You can develop your own WSDL file or get one from a Web services provider through e-mail, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the Web address looks like this example: *file:drive:\path\file_name*.wsdl. If you are using the Linux or Unix platform, the Web address looks like this example: *file:/path/file_name*.wsdl. You can also specify local files using the absolute or relative file system path.

When the Web service is a JavaBeans implementation in a Web module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices.ext.xmi` deployment descriptors and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `WEB-INF` subdirectory.

Develop deployment descriptor templates by running the designated command:

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the `WEB-INF` subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

You have deployment descriptor templates that are required to implement or use Web services.

The following example uses a WSDL file named `AddressBookJ2WB.wsdl`:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the `WEB-INF` subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

Now, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that WebSphere Application Server can process the incoming Web services. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Completing the JavaBeans implementation:

This task explains how to complete the JavaBeans implementation after you have developed the deployment descriptor bindings and the bindings necessary to develop a Web service.

Develop JavaBeans implementation templates and bindings from a Web Services Description Language (WSDL) file. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation. This task is a required step in developing a Web service from a Java bean.

When you complete the JavaBeans implementation, you are assembling a Java archive (JAR) file that contains a JavaBeans implementation and supported classes created from the WSDL file.

Complete the JavaBeans implementation by following the steps provided in this task section.
1. Edit the JavaBeans implementation template, *binding*Impl.java. Where *binding* is the name of the <wsdl:binding> element in the WSDL file.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using Web module assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

You have a Java archive (JAR) file containing the JavaBeans implementation and supported classes created from the WSDL file.

You need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.

Developing a Web service from an enterprise bean

This task explains how to develop a Web service from an enterprise bean.

Set up a Web services development and unmanaged client run-time environment.

This task is one of four ways that you can develop a Web service. You can also develop a Web service from a Java bean, develop a Web service with an existing Web Services Description Language (WSDL) file using a Java bean, or develop a Web service with an existing WSDL file using an enterprise bean. In this task, you need develop a new WSDL file.

Enabling the enterprise bean for Web services includes developing the service endpoint interface, locating or developing a WSDL file that is the engine of the Web service, generating and configuring the deployment descriptors, completing the EJB implementation, assembling all the artifacts required for the Web service, enabling the modules and deploying the application into the WebSphere Application Server environment.

To use an enterprise bean as the basis for a Web service implementation, follow these requirements:
- The enterprise bean must be a stateless session bean.
- Web service method parameters must be one of the supported Java API for XML-based remote procedure call (JAX-RPC) types.

These requirements are documented in the JAX-RPC specification available through Web services: Resources for learning.

Create the artifacts that enable the enterprise bean to be a Web service and assemble the artifacts into the enterprise application:

1. Access an existing Java archive (JAR) file to use as a Web service. Make sure that the enterprise bean meets the requirements.
2. Develop an Enterprise JavaBeans (EJB) service endpoint interface. The service endpoint interface defines which enterprise bean methods should be made available as a Web service.
3. Develop a Web Services Description Language (WSDL) file. The WSDL file is the engine of a Java 2 Platform, Enterprise Edition (J2EE) Web service; without it there is no Web service.
4. Develop Web services deployment descriptor templates from an EJB implementation. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the EJB implementation.
5. Complete the EJB implementation.
6. Configure the `webservices.xml` deployment descriptor. Configure the `webservices.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
7. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
8. Assemble a JAR file that is enabled for Web services from an enterprise bean. This article explains how to assemble the artifacts required to enable the EJB module for Web services into the JAR file.
9. Assemble a Web services-enabled enterprise bean JAR file into an enterprise archive (EAR) file. This topic explains how to assemble the artifacts required for Web services into to the EAR file.
10. Enable the EAR file. When the EAR file contains EJB modules, it must have the Web services endpoint Web archive (WAR) file added with the endptEnabler tool before it is deployed.
11. Deploy the EAR file into WebSphere Application Server.

    This topic presents the steps necessary to deploy the EAR file that has been configured, assembled and enabled for Web services.

You have a Web service developed from a stateless session enterprise bean.

Publish the WSDL file.

Developing a service endpoint interface from an EJB:

This topic explains how to develop a service endpoint interface from an Enterprise JavaBeans (EJB).

Set up a Web services development and unmanaged client run-time environment.

This task is a required step in developing a Web service from an enterprise bean.

The service endpoint interface defines the Web services methods. The enterprise beans that implements the Web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification, which is available through Web services: Resources for learning.

The easiest method for creating the service endpoint interface for an EJB Web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using the assembly tools.

Develop a service endpoint interface by following the steps provided in this task section.

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

   ▶ Windows ◀ Use the **javac** commands.

You have a service endpoint interface that you can use to develop a Web service.

This example uses the EJB remote interface, AddressBook_RI, to create a service endpoint interface for an EJB implementation that is used as a Web service. The following code example illustrates the AddressBook_RI remote interface.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
     throws java.rmi.RemoteException;
}
```

Use the following steps to create the service endpoint interface with the AddressBook_RI remote interface:

1. Locate a remote interface that has already been created, like the `AddressBook_RI.java` remote interface.
2. Make a copy of the `AddressBook.java` remote interface and use it as a template for the service endpoint interface.
3. Compile the `AddressBook.java` service endpoint interface.

Continue gathering the artifacts that are required to develop a Web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a Web service; without a WSDL file, you have no Web service.

Developing Web services deployment descriptor templates for an EJB implementation:

This topic explains how to develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Web services.

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a Web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Web address of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like this: *file:drive:\path\ file_name.*wsdl. If you are using the UNIX or iSeries platform, the URL looks like this: *file:/path/file_name.*wsdl. You can also specify local files using the absolute or relative file system path.

When the Web service implementation contains an enterprise bean in an EJB module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `META-INF` subdirectory.

Develop deployment descriptor templates with the following step provided in this task section.

Run the **WSDL2Java -verbose -role develop-server -container ejb -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the `META-INF` subdirectory. If the -verbose option is specified, a list of all generated files displays when the command runs.

You have deployment descriptor templates that are required to implement a Web service.

The following example uses the `AddressBookJ2WE.wsdl` WSDL file:
1. Generate the template files with the following command syntax:

   ```
   WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
   ```

   The deployment descriptor templates are generated into the `META-INF` subdirectory as follows:

   ```
   Parsing XML file: AddressBookJ2WE.wsdl
   Generating: META-INF\webservices.xml
   Generating: META-INF\ibm-webservices-bnd.xmi
   Generating: META-INF\ibm-webservices-ext.xmi
   Generating: META-INF\AddressBookJ2WE_mapping.xml
   ```

Continue to complete the steps that are necessary to develop a Web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file.

Completing the EJB implementation:

This task explains how to complete the Enterprise JavaBeans (EJB) implementation.

Develop EJB implementation templates and bindings from a WSDL file. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the Web services development process.

When you complete the EJB implementation, you are assembling an enterprise bean Java archive (JAR) file that contains the EJB and supporting classes created from a WSDL file.

Complete the EJB implementation by following the steps provided in this task section.

1. Inspect the EJB remote interface template, *portType*_RI.java. If necessary, modify the template. The value *portType* is the name of the `<wsdl:portType>` element in the WSDL file.

2. Inspect the *portType*Home.java EJB home interface template. If necessary, modify the template.

3. Edit the *binding*Impl.java EJB implementation template. Where *binding* is the name of the `<wsdl:binding>` element in the WSDL file.

   a. Complete the implementation of the methods in the template.

   b. (Optional) Make changes if necessary.

   c. (Optional) Change the class name if the binding name is not acceptable.

4. Compile all the Java classes.

5. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using the typical EJB assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

You have an enterprise bean JAR file containing an EJB and supporting classes created from a WSDL file.

Now that you have gathered the required artifacts for developing a Web service with an enterprise bean, you need to configure the `webservices.xml` deployment descriptor .

Developing a new Web service with an existing WSDL file using JavaBeans technology

This task explains how to develop a new Web service with an existing Web Services Description Language (WSDL) file using the JavaBeans technology.

Locate the Web Services Description Language (WSDL) file that defines the Web service to be implemented. You can develop a WSDL or obtain one from an existing Web service through e-mail, downloading or a Uniform Resource Locator (URL).

This task is one of four ways that you can develop a Web service. You can also develop a Web service from an enterprise bean, develop a Web service from a Java bean, or develop a Web service with an existing WSDL file using an enterprise bean.

Develop a new Web service with an existing WSDL file using JavaBeans technology with the following steps:

1. Develop JavaBeans implementation templates and bindings from a WSDL file. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

2. Complete the JavaBeans implementation.

3. Configure the `webservices.xml` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.

4. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.

5. Assemble a Web archive (WAR) file when starting from a WSDL file. This article explains how to assemble the artifacts required to enable the Web module for Web services are added to the WAR file.

6. Assemble a Web services-enabled WAR into an enterprise archive (EAR) file. This topic explains how to assemble the artifacts required to enable the Web module for Web services that are added to the EAR file.

7. Deploy the enterprise archive (EAR) file into WebSphere Application Server.

   This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

You have a new Web service with an existing WSDL file using JavaBeans technology

After you deploy the EAR file, test the Web service to make sure that it works with WebSphere Application Server.

Developing Web services deployment descriptor templates for a JavaBeans implementation:

To develop the JavaBeans implementation templates and bindings from a Web Services Description (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the URL looks like this example: file:*drive:\path\file_name*.wsdl. If you are using the Linux, UNIX or i5/OS platform, the URL looks like this example: file:*/path/file_name*.wsdl. You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the -role develop-server option of the **WSDL2Java** command. The **WSDL2Java** command also generates bindings and deployment descriptors.

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command:

Run the **WSDL2Java -verbose -role develop-server -container web *wsdlURL*** command. Since the -verbose option is specified, a list of all the generated files is displayed when the command runs.

You have templates for the implementation and deployment descriptors required to implement a Web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

The following example uses the AddressBook JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the **WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

Complete the Java bean implementation.

Developing new Web services from an existing WSDL file using an EJB implementation

This task explains how to develop a new Web service from an existing Web Services Description Language (WSDL) file using a stateless session enterprise bean.

Set up a Web services development and unmanaged client run-time environment.

Locate the Web Services Description Language (WSDL) file that defines the Web service to implement. The SOAP address URI is not required because it is updated when your new implementation is deployed.

This task is one of four ways that you can develop a Web service. You can also develop a Web service from a JavaBeans implementation, develop a Web service from a stateless session enterprise bean, or develop a Web service with an existing WSDL file using a Java bean.

Create the enterprise bean and artifacts that enable the enterprise bean as Web services and assemble those artifacts into the enterprise application:

1. Develop implementation templates and bindings from a WSDL file. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the enterprise bean implementation.
2. Complete the enterprise bean implementation.
3. Configure the `webservices.xml` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
4. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that WebSphere Application Server can process the incoming Web services requests.
5. Assemble a JAR file that is enabled for Web services from an enterprise bean. This article explains how to assemble the artifacts required to enable the Enterprise JavaBeans (EJB) module for Web services into the JAR file.
6. Assemble a Web services-enabled enterprise bean JAR file into an enterprise archive (EAR) file. This topic explains how to assemble the artifacts required for Web services into to the EAR file
7. Enable the EAR file. When the EAR file contains EJB modules, the EAR file must have the Web services endpoint Web archive (WAR) file added with the **endptEnabler** command or with an assembly tool before deployment.
8. Deploy the EAR file into WebSphere Application Server. This topic presents the steps necessary to deploy the EAR file that has been configured and enabled for Web services.

You have an EJB implementation of a Web service that is defined in the WSDL file.

After you deploy the EAR file, test the Web service to make sure that it works with WebSphere Application Server.

Developing EJB implementation templates and bindings from a WSDL file:

This task explains how to develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and binding from a Web Services Description Language (WSDL) file.

To develop EJB implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If it is a local file and you are running the Windows platform, the URL looks like the following example: file:*drive:\path\file_name*.wsdl. If you are using the Linux, UNIX or i5/OS platform, the URL looks like the following example: file:*/path/file_name*.wsdl. You can also specify local files using the absolute or relative file system path.

This task is one a required step in developing a Web service from an enterprise bean.

Implementation templates are generated using the -role develop-server option of the **WSDL2Java** command.

Templates are generated for an EJB implementation for the following components:
- enterprise bean
- EJB remote interface
- EJB Home

The **WSDL2Java** command also generates bindings and deployment descriptors.

Develop implementation templates and bindings from a WSDL file:

Run the **WSDL2Java -verbose -role develop-server -container ejb *wsdlURL*** command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

You have templates for the implementation and deployment descriptors required to implement Web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

The following example uses the enterprise bean AddressBook enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the **WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

Configuring Web services deployment descriptors

This task is an entry-point to the tasks that explain how to configure the deployment descriptors for a Web services application.

Before you can configure the deployment descriptors you need to complete all tasks required to develop a Web service and create the deployment descriptor templates.

You have developed a Web service that contains all the necessary artifacts and have created the deployment descriptors; now it is time to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.

After you have finished configuring the deployment descriptors, you need to assemble the Web services application.

Viewing Web services deployment descriptors in the administrative console

This task is explains how to view the Web services client and server deployment descriptors for a deployed Web services application. You can view the bindings in the deployment descriptors.

Before you can view the deployment descriptors you need to complete all tasks required to develop a Web service, create the deployment descriptor templates that were generated by the **WSDL2Java** command-line tool, configure the deployment descriptors and bindings, and deploy the Web service application into WebSphere Application Server.

You have developed a Web service that contains all the necessary artifacts, created the deployment descriptors from the deployment descriptor templates, configured the deployment descriptors, and deployed the Web services application into WebSphere Application Server; now you can view the deployment descriptors and bindings in the administrative console.

To view the Web services client deployment descriptor extension, the Web services server deployment descriptor, and the Web services server deployment descriptor extension through the administrative console:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules**.
   - Click **View Web services client deployment descriptor extension**.
   - Click **View Web services server deployment descriptor**.
   - Click **View Web services server deployment descriptor extension**.
3. Click **Expand All** to view the deployment descriptor contents.
4. Verify deployment descriptor and bindings configurations.

You have viewed and verified the deployment descriptors and bindings for the Web services application.

View Web services client deployment descriptor extension:

The bindings for an EJB or Web module are displayed when you use this page to view the Web services client deployment descriptor extension.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Manage Modules** > *EJB or Web module*.

Deployment descriptors contain the information that is needed by a Web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a Web service is developed or an existing Web service is located. The data that you can view in the deployment descriptor includes the following:

- The Web service description including the name, WSDL file, WSDL file location and the mapping file.
- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the Enterprise Java Bean (EJB) that is used to implement the Web service.

View Web services server deployment descriptor:

The bindings for an EJB or Web module are displayed when you use this page to view the Web services server deployment descriptor extension.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Manage Modules** > *EJB or Web module*..

Deployment descriptors contain the information that is needed by a Web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a Web service is developed or an existing Web service is located. The data that you can view in the deployment descriptor includes the following:

- The Web service description including the name, WSDL file, WSDL file location and the mapping file.

- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the Enterprise Java Bean (EJB) that is used to implement the Web service.

View Web services server deployment descriptor extension:

The bindings for an EJB or Web module are displayed when you use this page to view the Web services server deployment descriptor extension.

To view this administrative console page, click **Applications** >**Enterprise Applications** > *application_instance* > **Manage Modules** > *EJB or Web module.*.

Deployment descriptors contain the information that is needed by a Web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a Web service is developed or an existing Web service is located. The data that you can view in the deployment descriptor includes the following:
- The Web service description including the name, WSDL file, WSDL file location and the mapping file.
- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the Enterprise Java Bean (EJB) that is used to implement the Web service.

Configuring the webservices.xml deployment descriptor

This topic explains how to configure the `webservices.xml` deployment descriptor with an assembly tool.

To configure the client deployment descriptor see ″Client Deployment Descriptor editor″ in the Application Server Toolkit documentation for more information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

This task is one of the steps in developing a Web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.

Depending on if you are developing a Web service from a Java bean or an enterprise bean:
- Develop Web services Java bean deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop Web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the Web module Web archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.
1. The Eclipse assembly tools, Application Server Toolkit (AST) and Rational Web Developer, provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2, 1.3 or 1.4 compliant deployment descriptors.
2. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.

4. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.

5. Configure the deployment descriptor. See ″Editing Web services″ in the Application Server Toolkit documentation for more information.

You have a `webservices.xml` deployment descriptor that is configured.

Now, you must configure the `ibm-webservices-bnd.xmi` deployment descriptor.

Configuring the ibm-webservices-bnd.xmi deployment descriptor

This topic explains how to configure the `ibm-webservices-bnd.xml` deployment descriptor.

To configure the client deployment descriptor see ″Client Deployment Descriptor editor″ in the Application Server Toolkit documentation for more information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

This task is one of the steps in developing a Web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.

Depending on if you are developing a Web service from a Java bean or an enterprise bean:
- Develop Web services Java bean deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop Web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the Web module Web archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.
1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.
4. Configure the client deployment descriptor. See ″Editing Web services″ in the Application Server Toolkit documentation for more information.

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the Web service implementation module.

If you are developing a Web service from a Java bean, assemble a WAR file that is enabled for Web services from Java code.

If you are developing a Web service from an enterprise bean, assemble a JAR file that is enabled for Web services from an enterprise bean. In this task you assemble the artifacts that are required to enable the EJB module for Web services into the JAR file.

ibm-webservices-bnd.xmi assembly properties:

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Web services-enabled Web module or an Enterprise JavaBeans (EJB) module. This file contains information for the Web services run time that is required by WebSphere Application Server.

You can edit these properties using an assembly tool. See Configuring the `ibm-webservices-bnd.xmi` deployment descriptor for instructions.

Note:

The following user-defined assembly properties are supported:
* **wsDescNameLink**

   Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> elemetn in the `webservices.xml` file.
* **pc-name-link**

   Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the `webservices.xml` file.
* **scope**

   Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed Web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

Configuring the webservices.xml deployment descriptor for handler classes

This topic explains how to use and assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a Web service or a Web service client.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require

configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see Chapter 6 of the Web Services for J2EE specification and Chapter 12 of the JAX-RPC specification available through Web services: Resources for learning. The application modules must contain the `webservices.xml` deployment descriptor.

Configure a handler in the `webservices.xml` deployment descriptor by following the listed steps:

1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.
4. Configure the client deployment descriptor. See ″Editing Web services″ in the Application Server Toolkit documentation for more information.

Configuring the Web services client deployment descriptor with an assembly tool

This topic explains how to configure the client deployment descriptor with an assembly tool.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, Web archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file.

Complete this task if you are developing a managed client that runs in the J2EE client container. This task is done after you assemble the EJB or Web module.

Configure the client deployment descriptor with an assembly tool by following the steps provided:

1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation.for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.
4. Configure the client deployment descriptor. See ″Client Deployment Descriptor editor″ in the Application Server Toolkit documentation for more information.

You have a client deployment descriptor that is configured. Now you can test the Web services client to make sure it works in the WebSphere Application Server run time environment.

Test the Web services client. This task explains how to test an unmanaged client JAR file and an unmanaged client application.

Configuring the client deployment descriptor for handler classes with an assembly tool

This topic explains how to use an assembly tool to configure the client deployment descriptor for user-provided handler classes.

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification available through Web services: Resources for learning. The application modules must contain the `webservices.xml`(for server) and the client deployment descriptors.

Configure a handler in the client deployment descriptor by following the steps provided:

1. Start an assembly tool. See ″Starting WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See ″Configuring WebSphere Application Server Toolkit″ in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See ″Importing Web archive (WAR) files″ in the Application Server Toolkit documentation for more information.
4. Configure the client deployment descriptor. See ″Creating Web services handlers″ in the Application Server Toolkit documentation for more information.

You have a client deployment descriptor that is configured.

Test the Web services client. This task explains how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Handler class properties: You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See Configuring the `webservices.xml` deployment descriptor for Handler classes or Configuring the client deployment descriptors for Handler classes for instructions on how to configure the properties.

Description

Standard Java 2 Platform, Enterprise Edition (J2EE) technology descriptor field.

Display name

Standard J2EE technology descriptor field.

Small icon

Standard J2EE technology descriptor field.

Large icon

Standard J2EE technology descriptor field.

Handler name

The name of the handler. This name must be unique within the module.

Handler class

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

Initial parameters

Property names and values available to the handler.

SOAP headers

Qualified names (Qnames) of the SOAP headers that are processed by this handler. See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through Web services: Resources for learning, for more information about setting this property.

SOAP roles

URIs containing the SOAP actor names for which the handler acts in the role. See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through Web services: Resources for learning, for more information about setting this property.

Example: Configuring handler classes for Web services deployment descriptors: This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
 package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
     public ClientHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleRequest");
   return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleResponse");
   return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleFault");
   return true;   }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() {
  }

public javax.xml.namespace.QName[] getHeaders() {
   return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
 package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
  public ServerHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext
 context) {
    System.out.println("ServerHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext
 context) {
    System.out.println("ServerHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
 context) {
    System.out.println("ServerHandler: In handleFault");
    return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() {   }

public javax.xml.namespace.QName[] getHeaders() {
    return null;   }
}
```

1. Compile these classes using

   %JAVA_HOME%\bin\java -extdirs %WAS_EXT_DIRS% ClientHandler.java ServerHandler.java (on Windows systems)

   $JAVA_HOME/bin/java -extdirs $WAS_EXT_DIRS ClientHandler.java ServerHandler.java (on Linux and Unix systems)

2. Open an assembly tool and import the two sample enterprise archive (EAR) files:

   - %WAS_HOME%\samples\lib\WebServicesSamples\WebServicesSamples.ear on Windows systems or $WAS_HOME/samples/lib/WebServicesSamples/WebServicesSamples.ear on Linux and Unix systems.
   - %WAS_HOME%\samples\lib\WebServicesSamples\ApplicationClients.ear on Windows systems or $WAS_HOME/samples/lib/WebServicesSamples/ApplicationClients.ear on Linux and Unix systems.

3. Import the compiled handler classes into the projects for the sample modules:

   - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
   - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.

4. Configure the client deployment descriptor for handler classes.

   This topic explains how to configure the client deployment descriptor for user-provided handler classes.

5. Configure the webservices.xml deployment descriptor for handler classes.

   This topic explains how to configure the webservices.xml deployment descriptor for user-provided handler classes.

6. Save your changes and export the EAR files.

7. Uninstall the WebServicesSamples.ear application from your server if it is already installed.

8. Install the new WebServicesSamples.ear application.

9. Start the server.

10. Run the client:

    launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar

    When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```
     IBM WebSphere Application Server
     J2EE Application Client Tool
     Copyright IBM Corp., 1997-2003
     WSCL0012I: Processing command line arguments.
     WSCL0013I: Initializing the J2EE Application Client
     Environment.
     WSCL0035I: Initialization of the J2EE Application Client
     Environment has completed.
     WSCL0014I: Invoking the Application Client class
     com.ibm.websphere.samples.webservices.addr.AddressBookClient
     >> Querying address for 'Purdue Boilermaker' using port
     AddressBookW2JE
     ClientHandler: In handleRequest
     ClientHandler: In handleResponse
     >> Response is:
          1 University Drive
          West Lafayette, IN 47907
          Phone: (765) 555-4900
     >> Querying address for 'Purdue Boilermaker' using port
     AddressBookJ2WE
     ClientHandler: In handleRequest
     ClientHandler: In handleResponse
     >> Response is:
          2 University Drive
          West Lafayette, IN 47907
          Phone: (765) 555-4900
     >> Querying address for 'Purdue Boilermaker' using port
     AddressBookJ2WB
     ClientHandler: In handleRequest
     ClientHandler: In handleResponse
     >> Response is:
          3 University Drive
          West Lafayette, IN 47907
          Phone: (765) 555-4900
     >> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
     ClientHandler: In handleRequest
     ClientHandler: In handleResponse
     >> Response is:
          4 University Drive
          West Lafayette, IN 47907
          Phone: (765) 555-4900
```

For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```
[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleResponse
```

Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming Web services requests.

What to do next

Deploy the EAR file that has been configured and enabled for Web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

Developing Web services clients

This topic explains how to develop a Web services client based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

You need a Web Services Description Language (WSDL) file to use Web services. Before you begin this task, locate the WSDL file that defines the Web service that you want to access. You can locate the WSDL from the services provider through e-mail, through a Uniform Resource Locator (URL) or by looking it up in a Universal Description, Discovery and Integration (UDDI) registry.

For a Java application to act as a Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification. You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request. This entire process is based on the Web Services for J2EE specification. The JAX-RPC specification defines the mapping between a WSDL file, Java code and XML Schema types.

Create the client code and artifacts that enable the application client to access a Web service by following the steps provided:

1. Develop client bindings from a WSDL file. The client-side bindings and deployment descriptors are generated.
2. Complete the client implementation.
3. (Optional) Assemble a Web services-enabled client Java archive (JAR) file. Complete this step if you are developing a managed client that runs in the J2EE client container.
4. (Optional) Assemble a Web services-enabled client Web archive (WAR) file. Complete this step if you are developing a managed client that runs in the J2EE client container.
5. (Optional) Configure the client deployment descriptor. Complete this step if you are developing a managed client that runs in the J2EE client container.
6. Test the Web services-enabled client application. This task explains how to test an unmanaged client JAR file and an unmanaged client application.

You have created and tested a Web services client application. For step-by-step information see Example: Developing Web services clients.

After you develop a Web services application client, and the client is statically bound, the service endpoint used by the implementation is the one that is identified in the WSDL file that you used during the development process. During or after installation of the Web services application, you might want to change the service endpoint. You can change the endpoint with the administrative console or the wsadmin scripting tool.

Developing client bindings from a WSDL file

This topic explains how to develop client bindings from a Web Services Description (WSDL) file.

To develop the client bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a Web service.

If it is a local file and you are running the Windows platform, the URL looks like the following example: file:*drive:\path\file_name*.wsdl. If you are using the Linux or UNIX platform, the URL looks like the following example: file:*/path/file_name*.wsdl. You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the -role develop-client option in combination with the -container option of the **WSDL2Java** command. The -container option takes the following parameters:

- **-container client**

  Generates bindings and deployment descriptors for a client residing in the application client container.
- **-container ejb**

  Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.
- **-container web**

  Generates bindings and deployment descriptors for a client residing in the Web container.

Develop client bindings from a WSDL file by running the appropriate command:

Run the **WSDL2Java -verbose -role develop-client -container** *type wsdlURL* command,

where *type* is `ejb` for an enterprise EJB client, `web` for a JavaBeans client, or `client` for an application client.

You can use the following combinations in the command-line:
- -container `web`
- -container `ejb`
- -container `client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

You have the bindings and deployment descriptors needed by a client to use a Web service.

The following example uses the AddressBook enterprise bean the `AddressBook.wsdl` WSDL file. After generating the bindings from the **WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

Complete the client implementation.

Assemble a Web services-enabled client JAR and EAR file.

Setting up a development and unmanaged client run-time environment for Web services

WebSphere Application Server provides command-line tools to develop Web services clients and implementations that are based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification. This topic explains how to set up your development and unmanaged client run environment in order to start the development process with these tools.

Before you can set up a Web services development and unmanaged client execution environment within WebSphere Application Server, you must Install WebSphere Application Server.

Set up a Web services development and thin client environment by following the listed actions:
1. Set up the environment.

   You can set **WAS_USER_SCRIPT** to *install_root*\profiles\<*application_server*>\bin\ `setupCmdLine.bat`, which has the same effect as running the **setupCmdLine** command.

Run the **setupCmdLine.bat** command if you are using a Windows platform.

Linux and UNIX-based platforms *source* the script to the parent shell to inherit the exported variables by running this command:

. ./setupCmdLine.sh   (Notice the space between the periods.)

from the/*install_root*/profiles/*<application_server>*/bin directory or *. /install_root*/profiles/ *<application_server>*/bin/setupCmdLine.sh, if the command is executed from anywhere else.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

   ▶ Windows   On Windows platforms:

   `set PATH=%WAS_PATH%;%PATH%`

3. Configure CLASSPATH. You can add `com.ibm.ws.webservices.thinclient__6.1.0.jar`, `com.ibm.ws.wccm__6.1.0.jar` and *<your_application_jars>* to CLASSPATH by typing:

   On Windows platforms:

   ```
   set CLASSPATH=.;%WAS_HOME%\runtimes\com.ibm.ws.webservices.thinclient_6.1.0.jar;
     %WAS_HOME%\plugins\com.ibm.ws.wccm__6.1.0.jar;%;<your_application_jars>;
     %WAS_CLASSPATH%;%CLASSPATH%
   ```

   On Unix platforms:

   ```
   export CLASSPATH=.:$WAS_HOME/runtimes/com.ibm.ws.webservices.thinclient_6.1.0.jar:
     $WAS_HOME/plugins/com.ibm.ws.wccm__6.1.0.jar:<your_application_jars>:
     $WAS_CLASSPATH:$CLASSPATH
   ```

4. Run the client application using the Java command to call the main class directory as follows: On Windows platforms:

   `%JAVA_HOME%\bin\java <your_client_application>`

   On Unix platforms:

   `$JAVA_HOME/bin/java <your_client_application>`

You have set up a development and unmanaged client run-time environment so that you can develop Web services. If you you get a `NullPointerException` error when the HTTP basic authentication fails, you can fix the problem by including `<JAVA_HOME>\jre\lib\ext` in the classpath at the command-line, or by manually editing it at WAS_EXT_DIRS.

Develop Web services. This topic is a good starting point in learning about how to develop a J2EE Web service.

Example: Developing Web services clients

This example takes you through the steps to develop a Web services client. The development process is based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) and the Java API for XML-based remote procedure call (JAX-RPC) specification.

You need a Web Services Description Language (WSDL) file to use Web services. Before you begin this task, locate the WSDL file that defines the Web service that you want to access. You can locate the WSDL from the services provider through e-mail, downloading, or through a Uniform Resource Locator (URL).

For a Java application to act as a Web service client, a mapping between the Web Services Description Language (WSDL) file and the Java application must exist. The mapping is defined by the Java API for XML-based RPC (JAX-RPC) specification. You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request. This entire process is based on the Web Services for J2EE specification. The JAX-RPC specification defines the mapping between a WSDL file, Java code and XML Schema types.

Create the client code and artifacts that enable the application client to access a Web service by following the steps provided.

Steps for this task

1. Obtain the Web Services Description Language (WSDL) document for the Web service that you want to access.

   You can locate the WSDL from the services provider through e-mail, through a Uniform Resource Locator (URL) or by looking it up in a Universal Description, Discovery and Integration (UDDI) registry.

2. Develop client bindings from your WSDL file.

   The **WSDL2Java** command-line tool is run against your WSDL file to develop client bindings.

   The information needed to invoke the Web service is generated, including the service endpoint interface and implementations, the generated service interface and the `ibm-webservicesclient-bnd.xmi` and `ibm-webservicesclient-ext.xmi` deployment descriptors.

3. Implement the client.

   See Chapter 4 of the JSR-109 specification. You can access the specification through Web services: Resources for learning.

   Note: If an application creates a number of threads in the JSR-109 client, the meta data (including the WebSphere Application Server configuration) is not copied to the thread, and the Global Security Handler is not called.

   You can also review the GetQuote client in the WebServicesSamples application available in the Samples Gallery.

4. Assemble the module.

   Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file.

5. Configure the deployment descriptors.

   Configure the client deployment descriptor.

6. Test the Web services client.

   You should test the client to make sure it correctly operates and binds to the Web service.

Configuring Web service client bindings

When a Web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the Web module or enterprise JavaBean (EJB) module, including client bindings.

Deploy the Web service into WebSphere Application Server.

To complete this task, you need to know the topology of the URL endpoint address of the Web services servers and which Web service the client depends upon. You can view the deployment descriptors in the administrative console to find topology information. See the article View Web services server deployment descriptors for more information.

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a Web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you must configure the client bindings to access the downstream Web service.

You can also configure client bindings with **wsadmin**.

To configure client bindings through the administrative console:

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.
3. Find the Web service you want to update.

   The Web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.

   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See RMI-IIOP Web services using JAX-RPC for more information about using non-SOAP protocols.

   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   Timeout values can be configured based on observed behavior of the overall system as integration proceeds. For example, a Web service client might time out because of changing network conditions or the performance of an external Web service. When you have applications containing Web services clients that timeout, you can change the request time out values for the clients.

   a. Click **Apply** and **OK**.

Your Web service client bindings are configured.

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the Web service.

Web services client bindings

The client bindings define the Web Service Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the Web services in a module.

A Web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

Web service:

Identifies the name of this Web service. A module can contain one or more Web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a Web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this Web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a Web service.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** >**Enterprise Application** > *application_instance* > **Manage Modules** > *module_instance* >**Web services client bindings** > **Edit** > *preferred_port_instance*.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a Web services client port.

A Web service can have multiple ports. You can view and configure the port attributes for each defined Web service port. The Web services are listed on the Web services client bindings panel.

To view this page, click **Applications** >**Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* >**Web services client bindings** > **Edit**.

For EJB modules, click **Applications** >**Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* >**Web services client bindings** > **Edit**.

Port:

Specifies the name of a port.

Request timeout:

Specifies the time, in seconds, that a Web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `360` seconds. If the value is set at `0` (zero), the client's request does not timeout.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a Web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a Web service implementation, it might be necessary to tune the timeout.

Overridden endpoint:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file.

If an assembled application contains a Web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified.

Developing Applications that use Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between Web services by defining a standard way to address Web services and to provide addressing information in messages. This task describes the steps required to create a Web service that is accessed using a WS-Addressing endpoint reference.

Perform these tasks if you are using endpoint references in your Web service application logic to address Web service endpoints, or if you are creating a Web service that complies with the WS-Addressing interoperability protocol.

1. To perform the basic WS-Addressing development activities required by Web services developers, such as creating a Web service that is referenced by an endpoint reference, refer to "Using the Web Services Addressing API: Creating an application that uses endpoint references" on page 478.

2. To perform more advanced WS-Addressing functions, such as setting or retrieving message addressing properties, refer to"Using the WS-Addressing SPI: Performing more advanced Web Service Addressing tasks" on page 485.

3. To configure a service or a client to use the WS-Addressing support, refer to "Enabling Web Services Addressing support" on page 493.

Web Services Addressing support

The Web Services Addressing (WS-Addressing) support in WebSphere Application Server provides the environment for Web services that use the W3C WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing.

You do not normally need to be aware of the underlying WS-Addressing support as WebSphere Application Server will ensure that your Web service applications are WS-Addressing compliant when required. Read this topic, and other WS-Adressing and Web Services Resource Framework (WSRF) topics, only if you need to use the WS-Addressing support directly. For example if you have one of the following roles:

- A Web service developer who needs to use the WS-Addressing APIs to create endpoint references within an application, and then use these references to target Web service resource instances. For example, a WSRF application developer.
- A system programmer who needs to use the WS-Addressing SPIs to perform more advanced WS-Addressing operations, such as specifying message addressing properties on Web services messages.

Features of the WS-Addressing support

The WS-Addressing support in WebSphere Application Server provides the following features:

For core WS-Addressing application development using the API

- Java representations of WS-Addressing endpoint references.
  - You can easily create Java endpoint reference instances at run time based on the application's deployment environment. You do not have to specify the URI of the endpoint reference. Additionally, endpoint references can represent highly available or workload managed objects.
  - Runtime and tooling to provide appropriate mapping between the Java and XML representations of an endpoint reference. This ensures that endpoint references appearing on application Web service interfaces are appropriately serialized and deserialized to or from SOAP automatically.
  - You can configure client JAX-RPC Stub or Call objects with a WS-Addressing endpoint reference. Future invocations on the client Stub or Call object are targeted at the endpoint represented by the endpoint reference. The invocations also automatically conform to the WS-Addressing specification (namespace) associated with that endpoint reference.
- Java support for endpoint references that represent Web Services Resource (WS-Resource) instances.
  - You can associate reference parameters with an endpoint reference at the time of its creation, to correlate it with a particular resource instance.
  - In targeted Web services, you can extract the reference parameters of an incoming message, so that the Web service can route the message to the appropriate WS-Resource instance.

For extended WS-Addressing system development using the SPI

- Reasoning and manipulation of endpoint references beyond what is available at the application programming level.
  - You can manipulate the contents of the endpoint reference as specified by the WS-Addressing specification.
  - You can associate a WS-Addressing namespace, and therefore specification behavior, with an endpoint reference.
- Java representations of the WS-Addressing message addressing properties.
  - You can specify WS-Addressing message addressing properties for outbound Web service messages. In the targeted Web service, you can extract message addressing properties from inbound Web service messages.
  - You can specify the WS-Addressing namespace of an outbound WS-Addressing message, although in most cases this is automatically derived based on the target endpoint reference. In a targeted Web service, you can acquire the WS-Addressing namespace of an incoming message.

Support for WS-Addressing specifications and interoperability

By default, WebSphere Application Server supports the W3C WS-Addressing 1.0 Core and SOAP Binding specifications identified by the http://www.w3.org/2005/08/addressing namespace. Unless otherwise stated, WS-Addressing semantics described in this documentation refer to these specifications.

For interoperability, other levels of the WS-Addressing specification are supported in this version of WebSphere Application Server; in particular, the WS-Addressing W3C submission with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing.

In addition, WebSphere Application Server supports the following features from the WS-Addressing WSDL binding specification:

- The wsaw:UsingAddressing extensibility element, on the WSDL Binding element only. The supported namespace for this element is the http://www.w3.org/2006/02/addressing/wsdl namespace.
- The wsaw:Action extensibility element. The supported namespaces for this element are the http://schemas.xmlsoap.org/ws/2004/08/addressing namespace and the http://www.w3.org/2006/02/addressing/wsdl namespace.

Web Services Addressing overview:

Web Services Addressing (WS-Addressing) is a W3C specification that aids interoperability between Web services by defining a standard way to address Web services and provide addressing information in messages. The WS-Addressing specification introduces two primary concepts: endpoint references, and message addressing properties. This topic contains an overview of each concept; for further details, refer to the WS-Addressing specifications.

Endpoint references

Endpoint references provide a standard mechanism to encapsulate information about specific endpoints. Endpoint references can be propagated to other parties and then used to target the Web service endpoint that they represent. The following table summarizes the information model for endpoint references.

Table 8. Information model for endpoint references

Abstract Property name	Property type	Multiplicity	Description
[address]	xs:anyURI	1..1	The absolute URI specifying the address of the endpoint.
[reference parameters]*	xs:any	0..unbounded	Namespace qualified element information items that are required to interact with the endpoint.
[metadata]	xs:any	0..unbounded	Description of the behavior, policies and capabilities of the endpoint.

The following prefix and corresponding namespace is used in the above table.

Table 9. Prefix and corresponding namespace

Prefix	Namespace
xs	http://www.w3.org/2001/XMLSchema

The following XML fragment illustrates an endpoint reference. This element references the endpoint at the URI http://example.com/fabrikam/acct, has metadata specifying the interface to which the endpoint reference refers, and has application-defined reference parameters of the http://example.com/fabrikam namespace.

```
<wsa:EndpointReference xmlns:wsa="http://www.w3.org/2005/08/addressing"
                       xmlns:wsaw="http://www.w3.org/2006/02/addressing/wsdl"
                       xmlns:fabrikam="http://example.com/fabrikam"
```

```
                   xmlns:wsdli="http://www.w3.org/2005/08/wsdl-instance"
                   wsdli:wsdlLocation="http://example.com/fabrikam
                   http://example.com/fabrikam/fabrikam.wsdl">
    <wsa:Address>http://example.com/fabrikam/acct</wsa:Address>
    <wsa:Metadata>
        <wsaw:InterfaceName>fabrikam:Inventory</wsaw:InterfaceName>
    </wsa:Metadata>
    <wsa:ReferenceParameters>
        <fabrikam:CustomerKey>123456789</fabrikam:CustomerKey>
        <fabrikam:ShoppingCart>ABCDEFG</fabrikam:ShoppingCart>
    </wsa:ReferenceParameters>
</wsa:EndpointReference>
```

Message addressing properties (MAPs)

MAPs are a set of well defined WS-Addressing properties that can be represented as elements in SOAP headers, and provide a standard way of conveying information such as the endpoint to which replies to the message should be directed, or information about the relationship that the message has with other messages. The MAPs defined by the WS-Addressing specification are summarized in the following table.

Table 10. Message addressing properties defined by the WS-Addressing specification

Abstract WS-Addressing MAP name	MAP content type	Multiplicity	Description
[action]	xs:anyURI	1..1	An absolute URI that uniquely identifies the semantics of the message. This corresponds to the [address] property of the endpoint reference to which the message is addressed. This value is required.
[destination]	xs:anyURI	1..1	The absolute URI that specifies the address of the intended receiver of this message. This value is OPTIONAL because, if not present, it will default to the anonymous URI defined in the specification, indicating that the address is defined by the underpinning protocol.
[reference parameters]*	xs:any	0..unbounded	Correspond to the [reference parameters] property of the endpoint reference to which the message is addressed. This value is optional.
[source endpoint]	EndpointReference	0..1	A reference to the endpoint from which the message originated. This value is optional.
[reply endpoint]	EndpointReference	0..1	An endpoint reference for the intended receiver of replies to this message. This value is optional.
[fault endpoint]	EndpointReference	0..1	An endpoint reference for the intended receiver of faults relating to this message. This value is optional.
[relationship]*	xs:anyURI plus optional attribute of type xs:anyURI	0..unbounded	A pair of values that indicate how this message relates to another message. The content of this element conveys the [message id] of the related message. An optional attribute conveys the relationship type. This value is optional.
[message id]	xs:anyURI		An absolute URI that uniquely identifies the message. This value is optional.

The abstract names in the above tables are used to refer to the MAPs throughout this documentation.

The following example SOAP message contains WS-Addressing MAPs:
```
<S:Envelope xmlns:S="http://www.w3.org/2003/05/soap-envelope"
            xmlns:wsa="http://www.w3.org/2005/08/addressing"
            xmlns:fabrikam="http://example.com/fabrikam">
    <S:Header>
        ...
        <wsa:To>http://example.com/fabrikam/acct</wsa:To>
```

```
            <wsa:ReplyTo>
          <wsa:Address> http://example.com/fabrikam/acct</wsa:address>
      </wsa:ReplyTo>
      <wsa:Action>...</wsa:Action>
      <fabrikam:CustomerKey wsa:IsReferenceParameter='true'>123456789</fabrikam:CustomerKey>
      <fabrikam:ShoppingCart wsa:IsReferenceParameter='true'>ABCDEFG</fabrikam:ShoppingCart>
      ...
    </S:Header>
    <S:Body>
    ...
    </S:Body>
</S:Envelope>
```

Web Services Addressing message exchange patterns:

The W3C Web Services Addressing (WS-Addressing) specification explicitly defines the WS-Addressing core properties for the message exchange patterns (MEPs) defined by WSDL 1.0. These MEPs are summarized in this topic, illustrating the mandatory WS-Addressing properties for each pattern.

One-way MEP

This is a straightforward one-way message defined in WSDL 1.0 as an input-only operation. The WSDL for this operation is of the form:

```
<operation name="myOperation">
    <input message="tns:myInputMessage"/>
</operation>
```

The following WS-Addressing message addressing properties (MAPs) are automatically added to the message header of a one-way WS-Addressing input message by the client WebSphere Application Server runtime, to ensure compliance with the WS-Addressing specification.

Tip: You can override these values using the WS-Addressing SPIs.

Table 11.

Abstract WS-Addressing MAP name	Default value for one-way input message
[action]	The WS-Addressing [action] generated in accordance with the version of the WS-Addressing specification that is in use.
[reply endpoint]	The WS-Addressing [reply endpoint] indicating that no replies are expected to this input message. The value of this MAP depends on the version of the WS-Addressing specification that is in use.
[message id]	A uniquely generated message identifier; although not mandated by the specification, the WebSphere Application Server runtime automatically sets this.

Although the WSDL operation for this message exchange does not specify any responses, related messages can be sent as part of other message exchanges. In particular, applications can use the WS-Addressing [reply endpoint] or [fault endpoint] MAPs to indicate to the target of a one-way message where related messages should be sent. In order to propagate a [reply endpoint] or [fault endpoint], associate the appropriate property with the JAX-RPC Stub or Call object as described in "Web Services Addressing SPI" on page 487, to override the defaults.

Two-way request-response

This is request-response as defined in WSDL 1.1. The response part of the operation might be defined as an output message, or a fault message or both. The WSDL definition for a request-response operation is, therefore, of one of the following forms:

```
<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <output message="tns:myOutputMessage"/>
   <fault="tns:myFaultMessage"/>
</operation>

<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <output message="tns:myOutputMessage"/>
</operation>

<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <fault="tns:myFaultMessage"/>
</operation>
```

The WebSphere Application Server client runtime ensures that the SOAP header of the outgoing request message contains the relevant WS-Addressing message information headers, in other words, the calling application does not have to set the WS-Addressing headers. In this case, a response is expected therefore a [reply endpoint] or [fault endpoint] must be specified in the request message.

Note: In the 2005/08 specification, an unspecified [reply endpoint] is valid as it defaults to an endpoint reference containing the anonymous URI.

The following table summarizes the MAPs that WebSphere Application Server sets by default on a Web service request that uses WS-Addressing. You can override or specify other MAPs using the WS-Addressing SPIs.

Table 12.

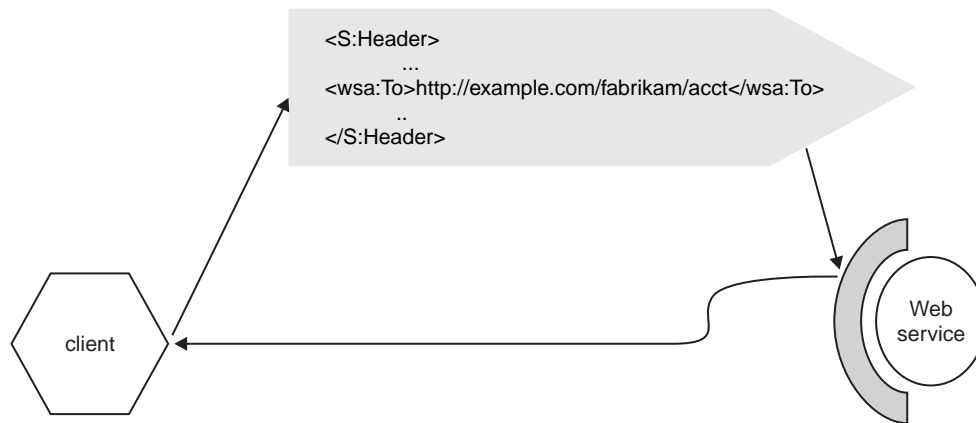
Abstract WS-Addressing MAP name	Default Value for input message of request-response operation
[action]	The WS-Addressing [action] generated in accordance with the version of the WS-Addressing specification that is in use.
[message id]	A uniquely generated message identifier.

The following table summarizes the MAPs that are set by default by WebSphere Application Server on a WS-Addressing response or fault message.

Table 13.

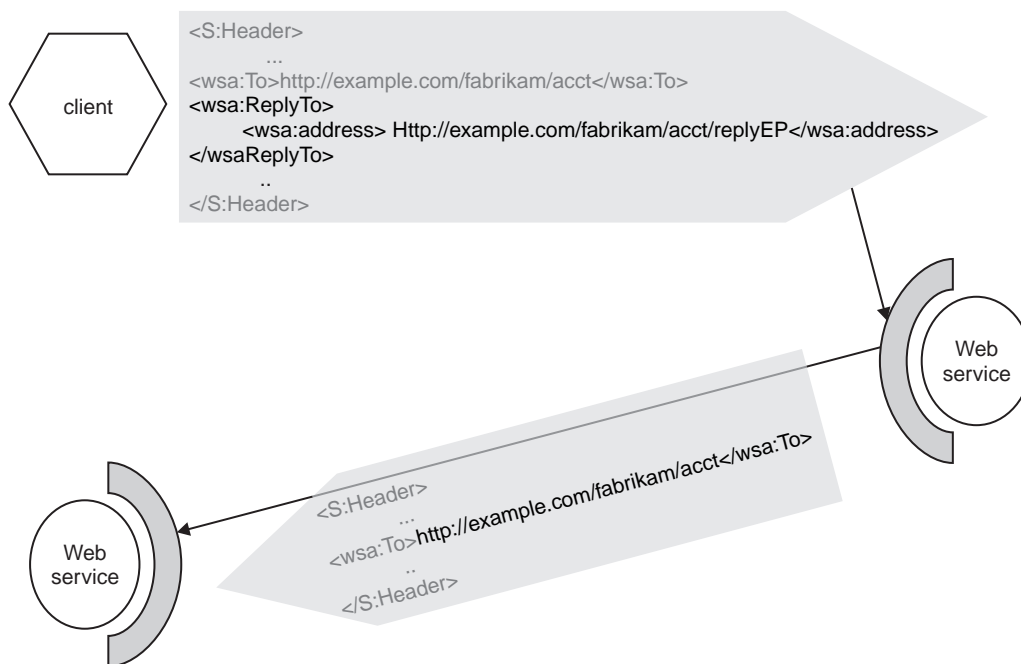
Abstract WS-Addressing MAP name	Default Value for input message of request-response operation
[action]	The WS-Addressing [action] generated in accordance with the version of the WS-Addressing specification that is in use.
[relationship]*	A relationship set containing a reply relationship to the [message id] passed in the request message.
[message id]	A uniquely generated message identifier; although not mandated by the spec, the WebSphere Application Server runtime automatically sets this property.

Synchronous request-response

By default, in other words if you do not use the WS-Addressing SPI to set the [reply endpoint] or [fault endpoint], the response part of a two-way message is returned according to the underlying protocol in use. In particular, in the case of an HTTP request, the response is returned synchronously in the HTTP response.


Asynchronous request-response

The JAX-RPC 1.0 programming model does not allow for asynchronous replies or faults to a two-way request-response operation.

Responses to, or faults generated from, requests directed at endpoints hosted on a WebSphere Application Server are targeted at the [reply endpoint] or [fault endpoint] in accordance with the WS-Addressing specification. The connection with the requesting client will be closed with an HTTP 202 response.


Web Services Addressing version interoperability:

The Web Services Addressing (WS-Addressing) support in WebSphere Application Server can interoperate with various versions of the WS-Addressing specification.

Table 14. Supported set of WS-Addressing versions

Associated namespace	Specification download location	Details
http://www.w3.org/2005/08/addressing	http://www.w3.org/2002/ws/addr/	W3C Candidate Recommendation (CR) versions of the WS-Addressing core and SOAP specifications. These specifications are sometimes referred to collectively as the 2005/08 version of WS-Addressing.
http://www.w3.org/2006/02/addressing/wsdl	http://www.w3.org/2002/ws/addr/	W3C Last Call (LC) version of the WS-Addressing WSDL specification. This is the default namespace used by WebSphere Application Server for the WSDL parts of the WS-Addressing specification.
http://schemas.xmlsoap.org/ws/2004/08/addressing	http://www.w3.org/Submission/ws-addressing/	W3C WS-A Submission This specification is sometimes referred to as the 2004/08 specification. It combines the core, SOAP and WSDL aspects of WS-Addressing in a single specification.

This version of WebSphere Application Server interoperates with each of the WS-Addressing specifications defined in the table above. This interoperability results in the following behavior:

- Incoming Web service messages containing WS-Addressing message addressing properties (MAPs) are appropriately bound to SOAP, and WS-Addressing SOAP elements appropriately de-serialized to their WS-Addressing programming model representations according to the namespace in use.
- WS-Addressing programming model artefacts are appropriately serialized into SOAP elements, and the MAPs bound to SOAP according to the namespace in use.
- Differing WS-Addressing semantics are adhered to according to the WS-Addressing version currently in use.

Determining the WS-Addressing namespace of inbound messages

The WS-Addressing namespace of incoming Web service messages is the namespace of the first WS-Addressing [action] MAP found. The WebSphere Application Server runtime looks for an [action] MAP of the default namespace prior to searching for other namespaces on the inbound message, in an undefined order. The namespace of the WS-Addressing core specification in use is available to the target endpoint through the message context.

Determining the WS-Addressing namespace of outbound messages

WS-Addressing messages issued from this version of WebSphere Application Server adopt the namespace associated with the destination endpoint reference. If this namespace is unknown, the message adopts the default WS-Addressing namespace.

WebSphere Application Server provides an SPI to change the namespace associated with an endpoint reference to any namespace in the supported set.

Which WS-Addressing specification should I use?

best-practices: In most cases, use the default WS-Addressing specification supported by WebSphere Application Server. You do not need to perform any additional actions to use this specification. The following list gives examples of occasions where you must override the default namespace:

- When interoperating with an endpoint that does not support the default namespace, for example, an earlier version of WebSphere Application Server.
- When a namespace other than the default is required. For example, when implementing a specification that uses a level of WS-Addressing other than the default.

Web Services Addressing application programming model:

The Web Services Addressing (WS-Addressing) specification defines an endpoint reference that is represented in XML by an EndpointReferenceType which encapsulates information about the endpoint address as well as additional contextual information associated with the endpoint. Some services might be addressable using a simple URI address and nothing more, as is most typical in Web services. Other services might require the use of an endpoint reference to address them, so that the additional contextual information associated with the endpoint is present in messages sent to the endpoint.

Examples of services that use WS-Addressing endpoint references include Web Services Resources and Web Services Notification message producers and message consumers, all of which have the notion of stateful resources associated with their endpoints. In these cases the endpoint reference not only contains the service address but also some data that is used to select the specific stateful resource instance for use in the processing of a Web services message.

A WS-Resource is defined as the combination of a resource and a Web service through which the resource is accessed. The figure below illustrates a Web service, at http://www.example.com/service, and three resources, A, B and C, that are accessed through the Web service. There are thus three WS-Resources illustrated in the figure:

A WS-Resource is referenced by a WS-Addressing endpoint reference which uniquely identifies the WS-Resource, typically by containing an identifier of the resource component of the WS-Resource inside the EndpointReference ReferenceParameter element. In the example above WS-Resource-C is the combination of the Web service and the resource identified by "C", and a reference to WS-Resource-C might appear as follows:

```
<wsa:EndpointReference>
    <wsa:Address>
        http://www.example.com/service
    </wsa:Address>
    <wsa:ReferenceParameters>
        <tns:SomeDisambiguatorElement>C</tns:SomeDisambiguatorElement>
    </wsa:ReferenceParameters>
    ...
</wsa:EndpointReference>
```

The WS-Addressing API provides the appropriate interfaces for implementing the above pattern.

Web Services Addressing security considerations:

It is essential that communications using Web Services Addressing (WS-Addressing) are adequately secured and that a sufficient level of trust is established between the communicating parties. You can achieve secure communications through the signing of WS-Addressing message addressing properties and the encryption of endpoint references.

Signing of WS-Addressing message addressing properties

You can use an assembly tool to specify the message addressing properties that require signing, or whose signature should be verified on inbound requests. The receiver of the message might rely on the presence of this verifiable signature to determine that the outbound message originated from a trusted source. Similarly, lack of a verifiable signature that is associated with the specified inbound message addressing properties causes the message to be rejected with a SOAP fault.

Encryption of endpoint references

You can encrypt endpoint references as part of the SOAP header or SOAP body. Alternatively, you can remove the need for encryption by not including sensitive information in the [address] or [reference parameters] properties of the endpoint reference.

Web Services Addressing, firewalls and intermediary nodes:

Using the Web Services Addressing (WS-Addressing) support in WebSphere Application Server, you can create endpoint references which can be distributed across firewalls and intermediary nodes. The topology of your system can have an affect the type of endpoint reference that is generated. For example, if the endpoint reference is created in a cluster environment, the generated endpoint reference might represent an endpoint that is workload managed.

There are situations where, as an application developer, you require specific behavior of an endpoint reference regardless of the topology into which the application is deployed. In particular, the WS-Addressing programming model allows you to indicate that an endpoint reference represents a stateful session bean that should not be workload managed because it maintains in-memory state. Additionally, if high availability for stateful session beans is enabled and the endpoint reference is created using the appropriate programming model, the endpoint reference remains valid even if the stateful session bean is failed over.

The topologies that are available to you are as follows:

Direct connection

> No intermediary node exists in this topology. The client communicates directly with the WebSphere Application Server on which the target endpoint resides.

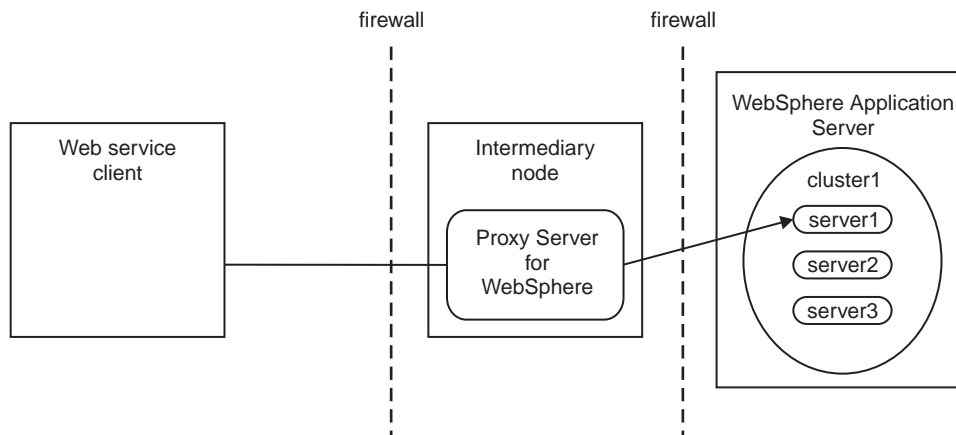
> Your application can create, on the WebSphere Application Server, endpoint references that represent endpoints located on that server. You can then export these endpoint references to the Web service client, for example as the return value of a Web service method. The WS-Addressing API automatically generates endpoint references that contain the appropriate address information.

> If the endpoint reference represents a highly available stateful session bean, the endpoint reference remains valid following stateful session bean failover only if the client targeting the WebSphere Application Server is a WebSphere Application Server client, at Version 6.1 or later.

Proxy Server for IBM WebSphere Application Server

In this topology, the client communicates with a Proxy Server for IBM WebSphere Application Server, which dynamically routes the client requests to the appropriate server within a WebSphere Application Server cluster.

Your application can create, on the WebSphere Application Server, endpoint references that represent endpoints located on that server. You can then export these endpoint references to the Web service client, for example as the return value of a Web service method. In this topology, the address of the endpoint reference is the address of the proxy server.

If the endpoint reference represents a highly available stateful session bean, the endpoint reference remains valid after stateful session bean failover. This high availability behavior occurs only if the proxy targeting the WebSphere Application Server is a Proxy Server for IBM WebSphere Application Server, at Version 6.1 or later.


HTTP server, such as IBM HTTP Server

In this topology, the client communicates with an HTTP server which always routes the client requests to a specific server. You can configure the HTTP server to specify the WebSphere Application Server to route requests to.

Your application can create and export endpoint references as described in the previous topology. In this topology, the address of the endpoint reference is the appropriate virtual host of the HTTP server's configuration. For the WS-Addressing API to automatically generate endpoint references containing this address, configure the address for the endpoint in your Web service deployment information.

If the endpoint reference represents a highly available stateful session bean, the endpoint reference ceases to be valid after stateful session bean failover.
If you want the endpoint reference to remain valid after stateful session bean failover, use a Proxy Server for IBM WebSphere Application Server in addition to your HTTP server, as described in the following section.

HTTP server in conjunction with a Proxy Server for IBM WebSphere Application Server

In this topology, the client communicates with an HTTP server which you configure to forward the client's requests to a Proxy Server for IBM WebSphere Application Server. The proxy then dynamically routes the requests to the appropriate server.

This topology is similar to the previous topology, but if the endpoint reference represents a highly available stateful session bean, the endpoint reference remains valid after stateful session bean failover. This high availability behavior occurs only if the proxy targeting the WebSphere Application Server is a Proxy Server for IBM WebSphere Application Server, at Version 6.1 or later.
Web Services Addressing and the service integration bus:

If you are using the Web Services Addressing (WS-Addresing) support, the presence of a service integration bus can affect the routing of messages. If you are also using a firewall you might have to perform some additional configuration.

In the following scenarios, the client must conform to the WS-Addressing specification.

One-way messaging scenario

The path taken by one-way messages is as follows:

1. The client sends a request, containing an endpoint reference specifying the end point to which replies will be sent, to the service integration bus. As this is a one way request, the client does not wait for a response.
2. The bus passes the message intact to the Web service.
3. The Web service sends a response directly to the endpoint specified in the request.
This scenario works if messages are able to flow directly from the Web service to the endpoint. If you have a configuration that does not allow direct message flow, for example if you have a firewall, you must create handlers that can redirect the message as required.

Request-response messaging scenario

For request-response scenarios, the messages take the following path:

1. The client sends a request, containing an endpoint reference specifying the end point to which replies will be sent, to the service integration bus.
2. The bus passes the message intact to the Web service, as a synchronous request. As the message leaves the bus, the endpoint reference is replaced with the anonymous URI listed in the WS-Addressing specification. This ensures that the Web service does not send a response directly to the endpoint.
3. The Web service sends a response back to the bus, as part of the synchronous interaction.
4. As the message leaves the bus, the anonymous URI is replaced with the original endpoint reference, enabling the bus to pass the message to the endpoint.
Using the Web Services Addressing API: Creating an application that uses endpoint references

WebSphere Application Server provides application programming interfaces for applications that need to create endpoint references and use those endpoint references to target Web service endpoints.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

Perform this task if you are a Web service developer who needs to create endpoint references within an application, and then use these references to target Web service resource instances. For example, a WSRF application developer.

1. Create a Web service that is referenced by an endpoint reference, and a client that accesses the Web service, using the instructions in "Creating a Web service application that is referenced through a Web Services Addressing endpoint reference."

2. **Optional:** You can extend the application that you created in the previous step so that it conforms to the Web Services Resource Framework (WSRF) specifications, by following the instructions in "Creating stateful Web services using the Web Services Resource Framework" on page 495.

Creating a Web service application that is referenced through a Web Services Addressing endpoint reference:

Web Services Addressing (WS-Addressing) aids interoperability between Web services by defining a standard way to address Web services and to provide addressing information in messages. This task describes the steps required to create a Web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the Web service.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

Perform this task if you are creating a Web service that complies with the WS-Addressing interoperability protocol, in other words one that is addressed through an endpoint reference.

1. Provide a Web service interface, by creating or generating a WSDL document for the Web service, that returns an endpoint reference to the target service. The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.

2. Implement the Web service created in the previous step. For the WS-Addressing portion of the implementation, perform the following steps:

    a. Create an endpoint reference that references the Web service, by following the instructions in "Creating endpoint references using the Web Services Addressing support" on page 480.

    b. **Optional:** If your interface involves a Web service that fronts a resource instance, create or lookup the resource instance.

    c. **Optional:** If you are using a resource instance, obtain the identifier of the resource and associate it with the endpoint reference as a reference parameter, using the EndpointReference.setReferenceParameter(QName resource_id_name, String value) method. The resource identifier is application dependent and might be generated during the creation of the resource instance itself.

    Note: Do not put sensitive information in the resource identifier, as the identifier is propagated in the SOAP message.
    The endpoint reference now targets the resource.

    d. Return the endpoint reference.

3. If your Web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference will contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not need to expose it on the Web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to perform the following actions:

a. Obtain the resource instance identifier from the message context, using the EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id_name) method.

b. Forward the message to the appropriate resource instance.

4. To configure a client to communicate with the service, use the endpoint reference produced by the service in the first step to send messages to the endpoint.

a. Obtain a Stub object in the normal J2EE fashion by looking up the Printer service in JNDI, or alternatively create an empty Call object.

b. Use the Stub or Call object's setProperty(String property_name, Object value) method to associate the endpoint reference with the Stub or Call object, using the WS-Addressing constant WSADDRESSING_DESTINATION_EPR as the property name, and the endpoint reference itself as the value.

This procedure automatically configures the Stub or Call object to represent the Web service, or resource instance if your interface uses a Web service that fronts a resource instance, of the endpoint reference. For Call objects, this process includes the configuration of interface and endpoint metadata (portType and port elements) associated with the endpoint reference.

Note: For Stub objects, if the endpoint defined by the endpoint reference conflicts with the Stub object's configuration, for example if it rendpoint referenceesents a different interface, a JAXRPCException is thrown on attempts to invoke the endpoint.

Invocations on the Stub or Call object are now targeted at the Web service, or resource instance, defined by the endpoint reference. When an invocation occurs, WebSphere Application Server adds appropriate message addressing properties, such as a reference parameter contained within the endpoint reference that identifies a target resource, to the message header.

The Web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see "Example: Creating a Web service that uses the Web Services Addressing API to access a generic Web service resource instance" on page 481.

1. Refer to "Web Services Addressing security considerations" on page 475 for information about security with WS-Addressing.

2. Deploy the application. For this scenario, you do not have to take any additional steps to enable the WS-Addressing support in WebSphere Application Server, because you specified a WS-Adressing property on the client. For more information, and for other scenarios which might require additional steps, see "Enabling Web Services Addressing support" on page 493.

Creating endpoint references using the Web Services Addressing support:

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. WebSphere Application Server provides interfaces for you to create endpoint references, and specify the behavior of those endpoint references within a cluster environment.

This task is part of "Creating a Web service application that is referenced through a Web Services Addressing endpoint reference" on page 479.

Perform this task if you are writing an application that uses the WS-Addressing support. Such applications require endpoint references to target Web service endpoints. When you are writing the application, you might not know the address of the endpoint, because this can change when the application is deployed. Using the WS-Addressing support, you can either specify the endpoint address, or allow WebSphere Application Server to generate it for you at run time.

- To create an endpoint reference with an address that you specify directly, use the WS-Addressing EndpointReferenceManager.createEndpointReference(URI address) SPI method. This method is useful in test scenarios, where the address of the service will not change.

- To create an endpoint reference with an address that is automatically generated by WebSphere Application Server, perform the following steps:

  1. If you created the Web service deployment descriptor file, webservices.xml, manually, ensure that the webservice-description-name in the file is the same as the local part of the Web Services Description Language (WSDL) service name. If you generated the webservices.xml file using the tools provided, the names match by default. This match is required for the generation of the correct URI for the endpoint reference.

  2. If you are creating an endpoint reference to represent a stateful session bean that maintains in-memory state, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName, Remote statefulSessionBean) API method. This method ensures that requests that are targeted at the endpoint are not workload managed. Additionally, if high availability for stateful session beans is specified, the endpoint reference remains valid even if the stateful session bean is failed over.

  3. If you are creating an endpoint reference to represent any other object, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) API method. Because the endpoint reference might be workload managed at a later date, ensure that the endpoint does not contain any in-memory state.

  When the application invokes either of the above two methods, WebSphere Application Server generates the address URI for the endpoint reference, and puts the service name and endpoint name into the metadata of the newly created endpoint reference.

  Note: If you have configured a virtual host for the server on which the endpoint is created, the URI of the endpoint reference refers to the virtual host of the HTTP server's configuration. You can override the HTTP endpoint URL information using the administrative console, see Provide HTTP endpoint URL information. The above methods will use the overridden value to generate the address URI for the endpoint reference.

Continue with "Creating a Web service application that is referenced through a Web Services Addressing endpoint reference" on page 479.

Example: Creating a Web service that uses the Web Services Addressing API to access a generic Web service resource instance:

Consider an IT organization that has a network of printers that it wants to manage using Web services. The organization might represent each Printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service using the Web Services Addressing (WS-Addressing) APIs provided by WebSphere Application Server.

Providing a Web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
```

```
                    element="pr:CreatePrinterRequest" />
  </wsdl:message>
 <wsdl:message name="CreatePrinterResponse">
   <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
 <wsdl:portType name="CreatePrinter">
   <wsdl:operation name="createPrinter">
     <wsdl:input name="CreatePrinterRequest"
                 message="pr:CreatePrinterRequest" />
     <wsdl:output name="CreatePrinterResponse"
                 message="pr:CreatePrinterResponse" />
   </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the example above returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

Implementing the Web service interface

The createPrinter method shown below creates an endpoint reference to the Printer service. The operation then obtains the identifier for the individual printer resource instance, and associates it with the endpoint reference. Finally, the createPrinter method returns the EndpointReference object, which now represents the new printer.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
import com.ibm.websphere.wsaddressing.EndpointReference;
...
public Constants
{

// Create the printer
...

// Define the printer resource ID as a static constant as it is required in later steps
public static final QName PRINTER_ID_PARAM_QNAME = new QName("example.printersample",
                                                 "IBM_WSRF_PRINTERID", "ws-rf-pr" );
}
public EndpointReference createPrinter(java.lang.Object createPrinterRequest)
{
   public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
   public static final String PRINTER_ENDPOINT_NAME = new String("PrinterService");

 // Create an EndpointReference that targets the appropriate WebService URI and port name.
 EndpointReference epr =  EndpointReferenceManager.createEndpointReference(PRINTER_SERVICE_QNAME,
                                                 PRINTER_ENDPOINT_NAME);

 // Create or lookup the stateful resource and derive a resource
 // identifier string.
 String resource_identifier = ...;
 // Associate this resource identifier with the EndpointReference as
 // a reference parameter.
 // The choice of name is arbitrary, but should be unique
 // to the service.
 epr.setReferenceParameter(PRINTER_ID_PARAM_QNAME,resource_identifier);
 // The endpoint reference now targets the resource rather than the service.
 ...

 return epr;
}
```

Extending the target service to match incoming messages to Web service resource instances

Because of the Web service implementation described earlier, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier appears as a reference parameter in the SOAP header of subsequent messages targeted at the Web service, and can be used by the Web service to match incoming messages to the appropriate printer.

When a Web service receives a message containing WS-Addressing message addressing properties, the WebSphere Application Server processes these before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer Web service application accesses the reference parameters associated with the target endpoint from the MessageContext object, as illustrated below:

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The Web service implementation can forward messages based on the printer identity acquired from the getReferenceParameterFromMessageContext method to the appropriate printer instances.

Using endpoint references to send messages to an endpoint

The client obtains a JAX-RPC Stub object in the normal J2EE fashion by looking up the Printer service in JNDI. The client then associates the EndpointReference object obtained previously with the Stub object, as illustrated below.

```
import javax.xml.rpc.Stub;
...
 // Associate the endpoint reference that represents the new printer with the Printer stub.
 Printer p = (Printer)((new PrinterServiceLocator()).getPort(Printer.class));
 Stub printerStub = (javax.xml.rpc.Stub)p;
 printerStub._setProperty(
        "com.ibm.websphere.wsaddressing.WSAConstants.
                        WSADDRESSING_DESTINATION_EPR ", epr);
```

The Stub object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the Stub object, WebSphere Application Server adds appropriate message addressing properties to the message header, in this case a reference parameter contained within the endpoint reference that identifies the target printer resource.

Alternatively, the client can use a Call object, which the client configures to represent the new printer as follows:

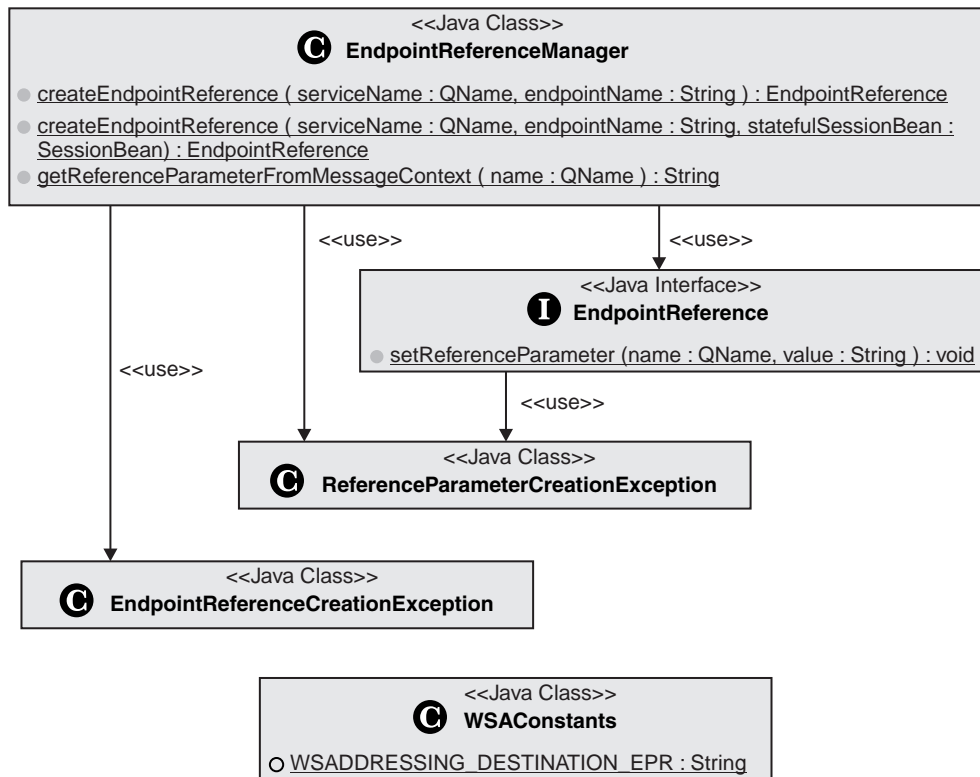
```
import javax.xml.rpc.Call;
...
 :
 // Associate the endpoint reference that represents the new printer with the call.
 call.setProperty(
        "com.ibm.websphere.wsaddressing.WSAConstants.
                        WSADDRESSING_DESTINATION_EPR ", epr);
```

From the client's perspective the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct Web service operations to the endpoint represented by the endpoint reference, as shown.

Web Services Addressing APIs:

WebSphere Application Server provides interfaces at the application programming level to enable application developers, including developers of Web Services Resource Framework applications, to create references to, and to target, Web service resource instances. If you are a system programmer you can use these interfaces in conjunction with the Web Services Addressing (WS-Addressing) system programming interfaces.

The programming interfaces in this topic are described in more detail in the WS-Addressing API documentation.

The application programming interfaces are contained in the com.ibm.websphere.wsaddressing package and are summarized in the following diagram.


These interfaces provide the following features:

- A mechanism to create a com.ibm.websphere.EndpointReference instance to represent a WS-Addressing endpoint reference using the com.ibm.websphere.EndpointReferenceManager.createEndpointReference interface.

- An interface com.ibm.websphere.EndpointReference.setReferenceParameter to enable the association of reference parameters with the EndpointReference created above.

- An interface to enable a client to configure its Stub or Call object based on the EndpointReference instance created above. All invocations on the Stub or Call object will subsequently be targeted at the endpoint represented by the EndpointReference. To achieve this behavior, set the com.ibm.websphere.wsaddressing.WSAConstants.WSADDRESSING_DESTINATION_EPR property on the Stub or Call object to the EndpointReference in question.

- A mechanism to acquire individual reference parameters associated with the incoming message context, to correlate the message to a specific resource instance through the com.ibm.websphere.EndpointReferenceManager.getReferenceParameterFromMessageContext interface.

Using the WS-Addressing SPI: Performing more advanced Web Service Addressing tasks

WebSphere Application Server provides system programming interfaces for more advanced Web Services Addressing (WS-Addressing) tasks, that involve the WS-Addressing message addressing properties that are passed in the SOAP header of a Web service message. The SPI also provides interfaces to enable you to choose a WS-Addressing specification level other than the WebSphere Application Server default.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

Perform this task in order to specify or acquire WS-Addressing message addressing properties, or if you have an application that needs to interoperate with a client or endpoint that is not using the default WS-Addressing specification supported by WebSphere Application Server.

- To manipulate message addressing properties, follow the instructions in "Specifying and acquiring message addressing properties using the Web Services Addressing SPI"
- To interoperate with the pre-W3C specification of WS-Addressing, with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing, refer to "Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server" on page 486.

Specifying and acquiring message addressing properties using the Web Services Addressing SPI:

The Web Services Addressing (WS-Addressing) SPI enables you to add WS-Addressing message addressing properties (MAPs) to the SOAP headers of an outbound message, through properties on the JAX-RPC Stub or Call interface. When the target endpoint receives the message, the SPI enables the endpoint to acquire the MAPs through properties on the message context.

Perform this task if you are a Web service developer using the WS-Addressing support, or a system programmer using the WS-Addressing SPIs to specify message addressing properties, such as fault or reply endpoint references, on Web services messages.

The properties that you can set or retrieve are detailed, along with the Java type of property instances, in "Web Services Addressing SPI" on page 487. Most properties are of type com.ibm.websphere.wsaddressing.EndpointReference, for example destination, reply or fault endpoint references. The relationship property is a java.util.Set object containing instances of the com.ibm.wsspi.wsaddressing.Relationship class. Use relationships when you want to specify an association between messages, for example in a response message you might want to specify the ID of the message that you are replying to. The action property is an AttributedURI object that identifies a specific method or operation within the target endpoint.

Note: The destination endpoint reference and action properties are required for the message to be WS-Addressing compliant.

1. On the client, obtain the endpoint reference from the service and associate it with your Stub or Call object as described in "Creating a Web service application that is referenced through a Web Services Addressing endpoint reference" on page 479.
2. Create instances of the required properties. For example, if you want to specify an endpoint reference for the target service to send replies to, create an instance of com.ibm.websphere.wsaddressing.EndpointReference, to use as the WSADDRESSING_REPLYTO_EPR property.

3. Set the required properties by associating them with the Stub or Call object, using the Stub or Call object's setProperty(String property_name, Object value) method. The following example sets a destination endpoint reference and a reply endpoint reference on a Call object:

```
import javax.xml.rpc.Call;
...
 // Associate the endpoint reference for the Web service. This property is required for the message
 // to be WS-Addressing compliant.
 call.setProperty(com.ibm.websphere.wsaddressing.WSAConstants.
                           WSADDRESSING_DESTINATION_EPR, destinationEpr);
 // Associate the endpoint reference that represents the reply to endpoint reference
 call.setProperty(com.ibm.wsspi.wsaddressing.WSAConstants.
                           WSADDRESSING_REPLYTO_EPR, replyToEpr);
```

When an invocation occurs on the Stub or Call object, WebSphere Application Server adds the appropriate MAPs to the message header.

4. On the server, retrieve the MAPs from the inbound message through the message context, using the MessageContext.getProperty(String propertyName) method. When WebSphere Application Server receives the message, it puts the MAP information into the message context on the thread, making it available to the service. You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 standard. The following example retrieves the reply endpoint reference:

```
import javax.xml.rpc.handler.MessageContext;
...

   // If the endpoint is implemented as an enterprise bean, you can use its session context
   // to obtain the message context
   private SessionContext sessionContext;
   MessageContext context = sessionContext.getMessageContext();

   // Retrieve the reply endpoint reference
   replyToEpr = context.getProperty(WSADDRESSING_INBOUND_REPLYTO_EPR);
```

Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server:

A target Web service endpoint might not support the same Web Services Addressing (WS-Addressing) namespace as WebSphere Application Server. In most cases, you do not need to perform any extra actions to interoperate with such endpoints, however some scenarios require additional steps in the implementation of your Web service.

WebSphere Application Server supports the default WS-Addressing 2005/08 namespace: http://www.w3.org/2005/08/addressing. Perform this task when you want to interoperate with endpoints that support other namespaces. This task specifically describes interoperation with endpoints that are hosted on a node that supports only the 2004/08 namespace: http://schemas.xmlsoap.org/ws/2004/08/addressing).

If you are sending or receiving messages to or from an endpoint that supports only the 2004/08 namespace, you do not have to perform any additional steps for interoperability. WebSphere Application Server recognizes and understands incoming WS-Addressing messages that conform to the 2004/08 specification, and outbound messages automatically adhere to the namespace of their destination endpoint reference. If you are sending a request, all WS-Addressing elements, such as [reply endpoint] or [fault endpoint] elements, must use the same namespace as that adhered to by the message. Any discrepancy will result in a JAX-RPC configuration error.

If you are interacting in a different way with an endpoint that supports only the 2004/08 namespace, such as exporting endpoint references in the message header or body, you must perform additional steps as detailed below.

- If you are generating a Web service for use by a client that supports only the 2004/08 specification, update the WS-Addressing namespace in the WSDL document for your Web service, as follows: change `http://www.w3.org/2006/02/addressing/wsdl` to `http://schemas.xmlsoap.org/ws/2004/08/addressing`.

  Note: Only the WS-Addressing WSDL Action extensibility element is recognized by pre-W3C WS-Addressing clients.

- If you are creating endpoint references at runtime, for export to an endpoint that supports the 2004/08 namespace only, perform the following extra steps.

  1. Create the endpoint reference to be exported.

  2. Associate the appropriate namespace with the endpoint reference, using the setNamespace method. The following example illustrates the association of the 2004/08 namespace with an endpoint reference.

     ```
     import com.ibm.wsspi.wsaddressing.EndpointReference;
     import com.ibm.wsspi.wsaddressing.NamespaceNotSupportedException;
     import com.ibm.wsspi.wsaddressing.WSAConstants;

     :

     EndpointReference epr = ...

     try
     {
         epr.setNamespace(WSAConstants.WSADDRESSING_NAMESPACE_2004_08);
     } catch (NamespaceNotSupportedException e)
     {
         // Error handling code here
     }
     ```

  When you pass the endpoint reference to the target endpoint, in either the SOAP body or the SOAP header of a message, the endpoint reference is appropriately serialized into SOAP elements according to its namespace.

- To establish the namespace of an inbound request, use the WS-Addressing SPI to retrieve the WSADDRESSING_INBOUND_NAMESPACE property from the inbound message context. This property specifies the Core WS-Addressing specification namespace of the of the incoming message.

  You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 standard. The following code example shows how you can establish the namespace of an incoming message, on the receiving endpoint:

  ```
  import com.ibm.wsspi.wsaddressing.WSAConstants;
  import javax.xml.rpc.handler.MessageContext;

  :
    // If the endpoint is implemented as an enterprise bean, you can use its session context
    // to obtain the message context
    private SessionContext sessionContext;
    MessageContext context = sessionContext.getMessageContext();

    try
    {
      String namespace = (String)msgContext.getProperty(WSAConstants.WSADDRESSING_INBOUND_NAMESPACE);
    } catch (IllegalArgumentException e)
    {
      // Error handling code here
    }
  ```

Web Services Addressing SPI:

The Web Services Addressing (WS-Addressing) system programming interface extends the application programming interface to enable you to create and reason about the contents of endpoint references and other WS-Addressing artifacts, and to set or retrieve WS-Addressing message addressing properties (MAPs) on or from Web service messages.

The programming interfaces in this topic are described in more detail in the WS-Addressing SPI documentation.

Creating, refining and reasoning about the contents of endpoint references

The SPIs for creating, refining and reasoning about the contents of endpoint references are contained in the com.ibm.wsspi.wsaddressing package and are summarized below (the first two interfaces are API interfaces that are extended by the SPIs):

<<Java Interface>>
EndpointReference (I)

setReferenceParameter (name : QName, value : String) : void

<<Java Class>>
EndpointReferenceManager (C)

- createEndpointReference (serviceName : QName, endpointName : String) : EndpointReference
- createEndpointReference (serviceName : QName, endpointName : String, statefulSessionBean : SessionBean) : EndpointReference
- getReferenceParameterFromMessageContext (name : QName) : String

---

<<Java Class>>
EndpointReferenceManager (C)

- createEndpointReference (soapElement : SOAPElement) : EndpointReference
- createEndpointReference (address : URI) : EndpointReference
- createEndpointReference (address : AttributedURI) : EndpointReference
- getSOAPElementReferenceParameterFromMessageContext (name : QName) : SOAPElement

---

<<Java Interface>>
EndpointReference (I)

- getAddress ( ) : AttributedURI
- setAddress (address : AttributedURI) : void
- getReferenceParameter (referenceParameterName : QName) : String
- getReferenceParameter (name : QName, value : SOAPElement) : void
- getSOAPElementReferenceParameter (referenceParameterName : QName) : SOAPElement
- getMetadata ( ) : Metadata
- setMetadata (metadata : Metadata) : void
- getSOAPElement (rootNode : SOAPElement) : SOAPElement
- setNamespace (namespace : String) void
- clone ( ) : Object
- getNamespace ( ) : String

<<Java Interface>>
AttributedURI (I)

- getURI ( )
- setURI ( )
- clone ( )

<<Java Class>>
WSAddressingFactory (C)

- createAttributedQName ( )
- createAttributedURI ( )
- createRelationship ( )
- createMetadata ( )
- createServiceName ( )
- generateMessageID ( )

<<Java Interface>>
Metadata (I)

- getInterfaceName ( )
- setInterfaceName ( )
- getServiceName ( )
- setServiceName ( )

<<Java Interface>>
ServiceName (I)

- getQName ( )
- setQName ( )
- getEndpointName ( )
- setEndpointName ( )
- clone ( )

<<Java Class>>
WSAConstants (C)

- WSAADDRESSING_NAMESPACE_2005_08 : String
- WSAADDRESSING_NAMESPACE_2004_08 : String
- WSAADDRESSING_NAMESPACE : String

The SPI extends the WS-Addressing com.ibm.websphere.wsaddressing.EndpointReference API to provide a number of additional methods through the com.ibm.wsspi.wsaddressing.EndpointReference interface. You can cast instances of com.ibm.websphere.wsaddressing.EndpointReference to com.ibm.wsspi.wsaddressing.EndpointReference in order to access this additional functionality.

Similarly, the SPI com.ibm.wsspi.wsaddressing.EndpointReferenceManager extends the functionality provided in the com.ibm.websphere.wsaddressing.EndpointReferenceManager API.

The additional methods provided by the EndpointReference and EndpointReferenceManager SPIs allow you to perform the following actions:

Create endpoint references

Create EndpointReference objects by specifying the URI of the endpoint that the EndpointReference object is to represent, using the createEndpointReference(URI) operation, or the EndpointReferenceManager.createEndpointReference(AttributedURI) operation. These methods differ from the createEndpointReference method provided at the API level, in that they do not automatically generate the URI for the EndpointReference. You might use these methods when you know that the URI of the endpoint is stable, for example in a test environment with no deployment considerations.

Map between XML and Java representations of an endpoint reference

You can serialize instances of the EndpointReference interface to their corresponding SOAP element instances using the EndpointReference.getSOAPElement operation. Conversely, you can de-serialize SOAP elements of type EndpointReferenceType into their corresponding EndpointReference Java representation, by using the EndpointReference.createEndpointReference(SOAPElement) operation. You might find these serialization and de-serialization interfaces useful if you are creating custom binders for types which contain EndpointReference instances.

Use more complex reference parameter types

The interfaces provided at the API level are restricted to reference parameters of type xsd:string to allow for a simpler programming model. The SPIs extend this support to allow reference parameters of type <xsd:any>. The EndpointReference interface provides mechanisms for getting and setting reference parameters as SOAP elements. Additionally, the EndpointReferenceManager class provides the getSOAPElementReferenceParameterFromMessageContext operation, which enables receiving endpoints to acquire reference parameters which are not of type String from the incoming message.

Set and reason about endpoint reference contents

The EndpointReference interface provides operations for you to set and reason about the contents of an EndpointReference instance, such as its WS-Addressing [address] and [metadata] properties. Additional interfaces are provided to represent the artefacts making up an endpoint reference: Metadata, AttributedURI, and ServiceName. You create instances of these interfaces using operations provided by the WSAddressingFactory class.

Acquire and change the supported namespace

The WS-Addressing support in WebSphere Application Server supports multiple namespaces. The setNamespace and getNamespace operations provided on the EndpointReference interface enable you to change and acquire the namespace associated with a particular EndpointReference object. Serialization to SOAP elements is in accordance with the namespace of the EndpointReference object. By default, the namespace of the destination endpoint reference (the endpoint reference set as the com.ibm.websphere.wsaddressing.WSAConstants.WSADDRESSING_DESTINATION_EPR property on the JAX-RPC Stub or Call object), defines the namespace of the message addressing properties of the message.

Setting and Retrieving WS-Addressing message addressing properties

The WS-Addressing SPI provides a number of constants that identify JAX-RPC properties to set WS-Addressing MAPs on outbound messages, and message context properties to retrieve MAPs on inbound messages. These constants are shown in the diagram below in the class com.wsspi.wsaddresssing.WSAConstants. The diagram also shows the interfaces required for generating instances of the appropriate property value types AttributedURI and Relationship. The first WSAConstants interface is an API interface.

<<Java Class>>
C WSAConstants

○ WSADDRESSING_DESTINATION_EPR : String

<<Java Class>>
C WSAConstants

○ WSADDRESSING_FROM_EPR : String
○ WSADDRESSING_REPLYTO_EPR : String
○ WSADDRESSING_FAULTTO_EPR : String
○ WSADDRESSING_RELATIONSHIP_SET : String
○ WSADDRESSING_MESSAGE_ID : String
○ WSADDRESSING_ACTION : String
○ WSADDRESSING_INBOUND_TO : String
○ WSADDRESSING_INBOUND_ACTION : String
○ WSADDRESSING_INBOUND_MESSAGEID : String
○ WSADDRESSING_INBOUND_RELATIONSHIP_SET : String
○ WSADDRESSING_INBOUND_FROM_EPR : String
○ WSADDRESSING_INBOUND_REPLYTO_EPR : String
○ WSADDRESSING_INBOUND_FAULTTO_EPR : String
○ WSADDRESSING_INBOUND_NAMESPACE : String
○ WSADDRESSING_OUTBOUND_NAMESPACE : String

<<Java Class>>

● setURI ( )
● clone ( )

Setting WS-Addressing message addressing properties on outbound messages

You can add WS-Addressing message information headers to outgoing messages by setting the appropriate properties on the JAX-RPC Stub or Call interface prior to invoking a message in the Stub or Call object. The table below summarizes the relevant properties and their types.

Table 15. Outbound properties that you can set on the Stub or Call object, their Java types and equivalent abstract WS-Addressing MAP name or names.

JAX-RPC Stub or Call property name (of type String)	Java type of property value	Abstract WS-Addressing MAP name or names	Default value when the Stub or Call object property is not set
WSADDRESSING_ DESTINATION_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[destination] URI [reference parameters]* (any)	Not set Note that this property comes from the API.
WSADDRESSING_ FROM_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[source endpoint]	Not set
WSADDRESSING_ REPLYTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[reply endpoint]	Not set, unless the message is a one-way message with no reply
WSADDRESSING_ FAULT_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[fault endpoint]	Not set
WSADDRESSING_ RELATIONSHIP_SET	java.util.Set containing instances of com.ibm.wsspi.wsaddressing. Relationship	[relationship]	Not set
WSADDRESSING_ MESSAGE_ID	com.ibm.wsspi.wsaddressing. AttributedURI	[message id]	Generated and set to a unique value
WSADDRESSING_ ACTION	com.ibm.wsspi.wsaddressing. AttributedURI	[action]	Generated and set, according to the WS-Addressing specification
WSADDRESSING_ OUTBOUND_ NAMESPACE	String	none	The WS-Addressing namespace of the WSADDRESSING_ DESTINATION_EPR property, if specified, otherwise the default namespace

Retrieving WS-Addressing message addressing properties from inbound messages

WS-Addressing message information headers that correspond to the last inbound message are available from the inbound properties defined in the WSAConstants class. The following table summarizes the available inbound properties. (You can acquire reference parameters from the message context using the EndpointReferenceManager.getReferenceParameter interface.)

Table 16. Inbound properties that you can acquire from the message context, their Java types and equivalent abstract WS-Addressing MAP name.

Message context property name (of type String)	Java type of property value	Abstract WS-Addressing MAP name
WSADDRESSING_INBOUND_TO	com.ibm.wsspi.wsaddressing. AttributedURI	[destination]
No specific property. Use the EndpointReferenceManager. getReferenceParameter(QName name) method to obtain the associated MAP.	Any	[reference parameters]*
WSADDRESSING_INBOUND_FROM_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[source endpoint]

Table 16. Inbound properties that you can acquire from the message context, their Java types and equivalent abstract WS-Addressing MAP name. (continued)

Message context property name (of type String)	Java type of property value	Abstract WS-Addressing MAP name
WSADDRESSING_INBOUND_REPLYTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[reply endpoint]
WSADDRESSING_INBOUND_FAULTTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[fault endpoint]
WSADDRESSING_INBOUND_RELATIONSHIP	java.util.Set containing instances of com.ibm.wsspi.wsaddressing. Relationship	[relationship]
WSADDRESSING_INBOUND_MESSAGE_ID	com.ibm.wsspi.wsaddressing. AttributedURI	[message id]
WSADDRESSING_INBOUND_ACTION	com.ibm.wsspi.wsaddressing. AttributedURI	[action]
WSADDRESSING_INBOUND_NAMESPACE	String	The WS-Addressing namespace of the incoming message

Enabling Web Services Addressing support

Web Services Addressing (WS-Addressing) is a W3C specification that aids interoperability between Web services, by defining a standard way to address Web services and provide addressing information in messages. To enable the WS-Addressing support, you must either configure the Web Services Description Language (WSDL) file for a service that runs on WebSphere Application Server, or use the WS-Addressing API or SPI to add WS-Addressing properties in a WebSphere Application Server client.

Perform this task to enable the WS-Addressing support, either as a service provider, or as a client of a service provided by another party.

If you are creating a Web service, you can enable the WS-Addressing support during development of the service, by including the UsingAddressing extensibility element in the WSDL binding element for the service. This element contains a 'required' attribute that has a value of either false, specifying that WS-Addressing information is accepted but not required in incoming messages, or true, specifying that WS-Addressing information is required in incoming messages. The default value is false. Messages from WebSphere Application Server Version 6.1 clients always include WS-Addressing information if your service WSDL file includes the UsingAddressing element, regardless of the value of the required attribute.

If you are creating a client application to use a service from another provider, you might not have access to the WSDL file for the service, or the service might use a version of WSDL that does not support the UsingAddressing element (if the service is not running on a current version of WebSphere Application Server). However, you can still enable WS-Addressing support, during run time, by setting WS-Addressing properties on the JAX-RPC Stub or Call object that you use to communicate with the service.

The following table summarizes the behavior of the WS-Addressing support in each of the scenarios mentioned previously.

Table 17. The behavior of the WS-Addressing support in WebSphere Application Server

	The WSDL for the service specifies UsingAdressing required = ″false″	The WSDL for the service specifies UsingAdressing required = ″true″	The WSDL for the service does not specify UsingAdressing
A client sends a message that contains WS-Addressing information	The WS-Addressing information is processed by WebSphere Application Server.	The WS-Addressing information is processed by WebSphere Application Server.	The WS-Addressing information is processed by WebSphere Application Server.
A non-WebSphere Application Server client sends a message that does not contain WS-Addressing information	The message is accepted.	The service returns a fault.	The message is accepted.
A WebSphere Application Server client sends a message, without specifying addressing properties	The message automatically contains the mandatory WS-Addressing information as defined in the WS-Addressing specification. The information is processed by WebSphere Application Server.	The message automatically contains the mandatory WS-Addressing information as defined in the WS-Addressing specification. The information is processed by WebSphere Application Server.	WS-Addressing information is not added by WebSphere Application Server. The message is accepted.

- To enable WS-Addressing support from the server, perform the following steps:

    1. Ensure that the WSDL file for the service contains the UsingAddressing extensibility element on the binding element. If you generated the WSDL file using the Java2WSDL tool, this element is automatically added for you. If you created the WSDL file yourself, for use with the WSDL2Java tool, you must add the extensibility element. The UsingAddressing element has a required attribute with a default value of false. For example:

    ```
    <wsdl:binding name="TestServiceSoapBinding" type="intf:TestService">
        <wsaw:UsingAddressing wsdl:required="false"
                                xmlns:wsaw="http://www.w3.org/2006/02/addressing/wsdl"/>

        <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

        <wsdl:operation name="invokeInstance">
          ...
        </wsdl:operation>

    </wsdl:binding>
    ```

    This code indicates that the endpoint understands WS-Addressing information, but this information is not required.

    2. **Optional:** To specify that WS-Addressing information is required, change the value of the required attribute to true. If the endpoint receives a message that does not contain the mandatory WS-Addressing elements within the message header, the endpoint returns a fault, as defined in the WS-Addressing specification. WebSphere Application Server clients, and Proxy Server for IBM WebSphere Application Server, always send WS-Addressing conformant messages to endpoints whose binding specifies the UsingAddressing element.

- To enable WS-Addressing support from a WebSphere Application Server client, use the WS-Addressing API or SPI provided, to associate one or more WS-Addressing properties with the JAX-RPC Stub or Call object that is used to send messages to the endpoint. These properties become message addressing properties (MAPs) in the SOAP message header. If the node receiving the message is a WebSphere Application Server node, it processes the incoming MAPs in accordance with the WS-Addressing specification, even if the service does not have a UsingAddressing element in its WSDL file. Use this method when communicating with endpoints that use earlier versions of the

WS-Addressing specification (for example: http://schemas.xmlsoap.org/ws/2004/08/addressing) which do not support the UsingAddressing element, or when the target endpoint's WSDL file is not available to the client.

Creating stateful Web services using the Web Services Resource Framework

You can implement a stateful Web service as a WS-Resource, and reference it using an a WS-Addressing endpoint reference. You develop WS-Resources in the same way as ordinary Web services using the same tools, however there are some additional tasks that you must perform, as described in this topic.

Perform this task when you want to create a WS-Resource, which is a combination of a stateful resource and a Web service through which the resource is accessed. To complete this task you must have knowledge of standard Web services development tasks, and the Web Services Resource Framework (WSRF) specifications. For an introduction to the WSRF specifications, read the OASIS WSRF Primer document.

1. Identify or create the resource component that the WS-Resource provides access for. This resource component can be an existing legacy system or entity, or it can be a new component. There are no constraints on how you implement the resource; it can be a simple Java class, a stateless session EJB, an entity bean backed by a relational database, a Service Data Object (SDO), a Java Connector, or any other component.

2. Identify or create a resource properties schema document for the WS-Resource. Use the WebSphere Application Server Toolkit, or any XML schema authoring tool, to create an XML schema. The schema defines the XML complexType element for the root element of the resource properties document.

3. Create or generate a WSDL document for the Web service component of the WS-Resource. See "Developing a WSDL file" on page 441 for information about creating WSDL files.

4. Edit the WSDL file to add a ResourceProperties attribute to the portType element. This attribute identifies the root element of the resource properties document that you created earlier. For example, if a ″Printer″ service has a resource properties document with a root element <printer_properties> in the namespace http://example.org/printer, then the wsdl:portType element might look as follows:

```
<wsdl:portType xmlns:pr="http://example.org/printer"
               xmlns:wsrf-rp="http://docs.oasis-open.org/wsrf/rp-2"
               name="Printer" wsrf-rp:ResourceProperties="pr:printer_properties">
```

5. Provide a means to obtain an EndpointReference that points to the WS-Resource. You might define a wsdl:operation element called Create, that returns a wsdl:output message of type EndpointReferenceType. See "Example: Creating a Web service that uses the Web Services Addressing API to access a Web Services Resource (WS-Resource) instance" on page 505 for an example of a CreatePrinter operation that returns an EndpointReference to a ″Printer″ WS-Resource.

6. Define each WSRF-defined operation that the WS-Resource supports as a child element of the wsdl:portType element. For each WSRF-defined operation supported by the port type, specify the WS-Addressing action attribute on each wsdl:message element. For example, the GetResourceProperty operation is defined in the WSDL as follows:

```
<wsdl:operation name="GetResourceProperty"
                xmlns:wsaw="http://www.w3.org/2006/02/addressing/wsdl"
                xmlns:wsrf-rpw="http://docs.oasis-open.org/wsrf/rpw-2">
  <wsdl:input name="GetResourcePropertyRequest" message="wsrf-rpw:GetResourcePropertyRequest"
    wsaw:Action="http://docs.oasis-open.org/wsrf/rpw-2/GetResourceProperty/GetResourcePropertyRequest"/>
  <wsdl:output name="GetResourcePropertyResponse" message="wsrf-rpw:GetResourcePropertyResponse"
    wsaw:Action="http://docs.oasis-open.org/wsrf/rpw-2/GetResourceProperty/GetResourcePropertyResponse"/>
  ...
</wsdl:operation>
```

The wsaw:Action attribute ensures that the WSRF-defined wsaw:Action URIs are used for the WSRF-defined messages, rather than default URI values.

Note: The WS-ResourceProperties specification requires the presence of the GetResourceProperty operation if the ResourceProperties attribute is present on the PortType element.

7. Follow the instructions from step 2 in "Creating a Web service application that is referenced through a Web Services Addressing endpoint reference" on page 479 to create the implementation of the WS-Resource, enable the client to access the WS-Resource using an endpoint reference, and deploy the application.

Review "Example: Creating a Web service that uses the Web Services Addressing API to access a Web Services Resource (WS-Resource) instance" on page 505 for sample WS-Resource code.

Web Services Resource Framework support

The Web Services Resource Framework (WSRF) support in WebSphere Application Server provides the environment for Web service applications that follow the OASIS WSRF specifications.

WSRF overview

Web service interfaces often need to provide stateful interactions with the clients of the service. For example, a Web service interface such as a shopping cart, where the result of one operation influences the execution of the succeeding ones. The OASIS Web Services Resource Framework (WSRF) defines a generic framework for modelling and accessing stateful resources using Web services, so that the definition and implementation of a service and the integration and management of multiple services is made easier.

WSRF introduces the concept of an XML document description, called the *resource properties document schema*, which is referenced by the WSDL description of a Web service and which explicitly describes a view of the state of the resource with which the client interacts. A service described in this way is called a *WS-Resource*.

A WS-Resource is defined as the combination of a resource and a Web service through which the resource is accessed. The figure below illustrates a Web service, at http://www.example.com/service, and three resources, A, B and C, that are accessed through the Web service. There are thus three WS-Resources illustrated in the figure:

A WS-Resource is referenced by a WS-Addressing endpoint reference which uniquely identifies the WS-Resource, typically by containing an identifier of the resource component of the WS-Resource inside the EndpointReference ReferenceParameter element. In the example above WS-Resource-C is the combination of the Web service and the resource identified by "C", and a reference to WS-Resource-C might appear as follows:

```
<wsa:EndpointReference>
    <wsa:Address>
        http://www.example.com/service
    </wsa:Address>
    <wsa:ReferenceParameters>
        <tns:SomeDisambiguatorElement>C</tns:SomeDisambiguatorElement>
    </wsa:ReferenceParameters>
    ...
</wsa:EndpointReference>
```

Each such WS-Resource has a resource property document (an XML instance document) that describes a view of the state of the resource. The WSDL for a WS-Resource identifies the XML schema that describes the type of the resource property document through a ResourceProperties attribute of the wsdl:PortType element. By specifying this standard WSDL extension for the resource properties document schema, WSRF enables the definition of simple, generic messages which interact with the WS-Resource.

For example, consider a Printer WS-Resource which has the following resource properties document schema:

```
<?xml version="1.0"?>
<xsd:schema ...
   xmlns:pr="http://example.org/printer.xsd"
   targetNamespace="http://example.org/printer.xsd" >
 <xsd:element name="printer_properties">
   <xsd:complexType>
     <xsd:sequence>
        <xsd:element ref="pr:printer_name" />
        <xsd:element ref="pr:queued_job_count" />
     </xsd:sequence>
   </xsd:complexType>
 </xsd:element>
 ...
</schema>
```

The WSDL PortType element for such a WS-Resource would declare the Resource Properties Document type as follows:

```
<wsdl:portType xmlns:pr="http://example.org/printer.xsd"
               xmlns:wsrf-rp="http://docs.oasis-open.org/wsrf/rp-2"
               name="Printer" wsrf-rp:ResourceProperties="pr:printer_properties">
```

Each WS-Resource has a unique, logical resource properties document instance that is a view of the state of the resource. The WS-ResourceProperties specification describes the interoperable protocol messages that a WS-Resource can implement to get, set, or query the state of the resource by operating on the resource properties document. Some of these operations affect the resource properties document as a whole, and some of them operate on one or more elements within the document (the individual resource properties, for example pr:printer_name). Each WS-Resource can have a finite lifecycle and can be created and destroyed; the WS-ResourceLifetime specification describes the interoperable protocol messages that a WS-Resource can implement to destroy it or to alter its termination time.

For more information about WSRF, refer to the WSRF Primer document published by the OASIS Technical Committee.

WSRF Programming Model

The WSRF specifications define only the protocol messages and the semantic behavior expected of a WS-Resource when it processes these messages; the specifications do not prescribe the means to implement WS-Resources. WSRF is primarily an application-level protocol and the tools for implementing WS-Resources are the same tools that are used for implementing any other type of Web service. WSRF makes use of WS-Addressing endpoint references and, for the most part, the programming model for WS-Resources is the same as for any Web service that uses WS-Addressing; this is described in "Web Services Addressing application programming model" on page 474.

WSRF extends the WebSphere Application Server WS-Addressing programming model in two ways, which therefore differentiate a WS-Resource from a generic resource that is accessed through a Web service using WS-Addressing:
- WSRF requires the ResourceProperties attribute on the wsdlPortType element. This attribute declares that the portType is implemented by a WS-Resource rather than a generic Web service. The WS-Resource must declare which WSRF operations it supports by copying those operations into the portType element of its WSDL definition. The WS-Resource is free to choose any implementation

strategy desired to represent the stateful resource and to process the WSRF messages; you can implement a resource using a simple Java class, a stateless session EJB, a entity bean backed by a relational database, a Service Data Object (SDO), or anything else.

• WSRF defines a hierarchy of Java BaseFault types.

Web Services Resource Framework base faults:

The Web Services Resource Framework (WSRF) provides a recommended basic fault message element type from which you can derive all service-specific faults. The advantage of a common basic type is that all faults can, by default, contain common information. This is useful in complex systems where faults night be systematically logged, or forwarded through several layers of software before being analyzed.

The common information includes the following items:

• A mandatory timestamp.

• An element which can be used to indicate the originator of the fault.

• Other elements which can describe and classify the fault.

The following two standard faults are defined for use with every WSRF operation:

ResourceUnkownFault
>This fault is used to indicate that the WS-Resource is not known by the service which receives the message.

ResourceUnavailableFault
>This fault is used to indicate that the Web service is active, but temporarily unable to provide access to the resource.

The following XML fragment shows an example of a base fault element:

```
<wsrf-bf:BaseFault>
   <wsrf-bf:Timestamp>2005-05-31T12:00:00.000Z</wsrf-bf:Timestamp>
   <wsrf-bf:Originator>
     <wsa:Address>
       http://www.example.org/Printer
     </wsa:Address>
     <wsa:ReferenceParameters>
       <pr:pr-id>P1</pr:pr-id>
     </wsa:ReferenceParameters>
   </wsrf-bf:Originator>
   <wsrf-bf:Description>Offline for service maintenance</wsrf-bf:Description>
   <wsrf-bf:FaultCause>OFFLINE</wsrf-bf:FaultCause>
</wsrf-bf:BaseFault>
```

WebSphere Application Server provides Java code mappings for all the base fault element types defined by the WSRF specifications, forming an exception hierarchy where each Java exception extends the com.ibm.websphere.wsrf.BaseFault class. Each fault class follows a similar pattern. For example, the BaseFault class itself defines the following two constructors:

```
package com.ibm.websphere.wsrf;
public class BaseFault extends Exception
{
    public BaseFault()
    {
       ...
    }
    public BaseFault(EndpointReference originator,
                    ErrorCode errorCode,
                    FaultDescription[] descriptions,
                    IOSerializableSOAPElement faultCause,
                    IOSerializableSOAPElement[] extensibilityElements,
                    Attribute[] attributes)
    {
```

```
        ...
    }
    ...
}
```

The IOSerializableSOAPElement class

Because the BaseFault class extends the java.lang.Exception class, it must implement the
java.io.Serializable interface. To meet this requirement, all properties of a BaseFault instance must
themselves be serializable. Because the javax.xml.soap.SOAPElement class is not serializable,
WebSphere Application Server provides a IOSerializableSOAPElement class, which you can use to wrap a
javax.xml.soap.SOAPElement instance to provide a serializable form of that instance.

Create an IOSerializableSOAPElement instance by using the IOSerializableSOAPElementFactory class, as
follows:

```
// Get an instance of the IOSerializableSOAPElementFactory class
IOSerializableSOAPElementFactory factory = IOSerializableSOAPElementFactory.newInstance();

// Create an IOSerializableSOAPElement from a javax.xml.soap.SOAPElement
IOSerializableSOAPElement serializableSOAPElement = factory.createElement(soapElement);

// You can retrieve the wrapped SOAPElement from the IOSerializableSOAPElement
SOAPElement soapElement = serializableSOAPElement.getSOAPElement();
```

Any application-specific BaseFault instances must also adhere to this serializable requirement.

Application-specific faults

Applications can define their own extensions to the BaseFault element. Use XML type extensions to define
a new XML type for the application fault that extends the BaseFaultType element. For example, the
following XML fragment creates a new PrinterFaultType element:

```
 <xsd:complexType name="PrinterFaultType">
   <xsd:complexContent>
     <xsd:extension base="wsrf-bf:BaseFaultType"/>
   </xsd:complexContent>
 </xsd:complexType>
```

The following example shows how a Web service application, whose WSDL definition might define a print
operation that declares two wsdl:fault messages, constructs a PrinterFault object:

```
import com.ibm.websphere.wsrf.BaseFault;
import com.ibm.websphere.wsrf.*;
import javax.xml.soap.SOAPFactory;
...
    public void print(PrintRequest req) throws PrinterFault, ResourceUnknownFault
    {
        // Determine the identity of the target printer instance.
        PrinterState state = PrinterState.getState ();
        if (state.OFFLINE)
        {
            try
            {
                // Get an instance of the SOAPFactory
                SOAPFactory soapFactory = SOAPFactory.newInstance();

                // Create the fault cause SOAPElement
                SOAPElement faultCause = soapFactory.createElement("FaultCause");
                faultCase.addTextNode("OFFLINE");

                // Get an instance of the IOSerializableSOAPElementFactory
                IOSerializableSOAPElementFactory factory = IOSerializableSOAPElementFactory.newInstance();

                // Create an IOSerializableSOAPElement from the faultCause SOAPElement
```

```
            IOSerializableSOAPElement serializableFaultCause = factory.createElement(faultCause);

            FaultDescription[] faultDescription = new FaultDescription[1];
            faultDescription[0] = new FaultDescription("Offline for service maintenance");
            throw new PrinterFault(
                    state.getPrinterEndpointReference(),
                    null,
                    faultDescription,
                    serializableFaultCause,
                    null,
                    null);
        }
        catch (SOAPException e)
        {
            ...
        }
    }
    ...
```

The following code shows how base fault hierarchies are handled as Java exception hierarchies:

```
import com.ibm.websphere.wsrf.BaseFault;
import com.ibm.websphere.wsrf.*;
...
try
{
    printer1.print(job1);
}
catch (ResourceUnknownFault exc)
{
    System.out.println("Operation threw the ResourceUnknownFault");
}
catch (PrinterFault exc)
{
    System.out.println("Operation threw PrinterFault");
}
catch (BaseFault exc)
{
    System.out.println("Exception is another BaseFault");
}
catch (Exception exc)
{
    System.out.println("Exception is not a BaseFault");
}
```

Custom binders

When you define a new application-level base fault, for example the PrinterFault of type PrinterFaultType
shown above, you must provide a custom binder to define how the Web services runtime serializes the
Java class into an appropriate XML message, and conversely how to deserialize an XML message into an
instance of the Java class.

The custom binder must implement the com.ibm.wsspi.webservices.binding.CustomBinder interface.
Package the binder in a Java Archive (JAR) file along with a declarative metadata file,
CustomBindingProvider.xml, located in the /META-INF/services directory of the JAR. This metadata file
defines the relationship between the custom binder, the Java BaseFault implementation and the BaseFault
type. For example you might define a custom binder called PrinterFaultTypeBinder, to map between the
XML PrinterFaultType element and its Java implementation, PrinterFault, as follows:

```
<customdatabinding:provider
   xmlns:customdatabinding="http://www.ibm.com/webservices/customdatabinding/2004/06"
   xmlns:pr="http://example.org/printer.xsd"
   xmlns="http://www.ibm.com/webservices/customdatabinding/2004/06">
 <mapping>
  <xmlQName>pr:PrinterFaultType</xmlQName>
```

```
  <javaName>PrinterFault</javaName>
  <qnameScope>complexType</qnameScope>
  <binder>PrinterFaultTypeBinder</binder>
 </mapping>
</customdatabinding:provider>
```

The BaseFaultBinderHelper class

WebSphere Application Server provides a BaseFaultBinderHelper class, which provides support for
serializing and deserializing the data that is specific to a root BaseFault class, which all specialized
BaseFault classes must extend. If a custom binder uses the BaseFaultBinderHelper class, the custom
binder then needs to provide only the additional logic for serializing and deserializing the extended
BaseFault data.

The following code shows how you can implement a custom binder for the PrinterFaultType element to
take advantage of the BaseFaultBinderHelper class support:

```
import com.ibm.wsspi.wsrf.BaseFaultBinderHelper;
import com.ibm.wsspi.wsrf.BaseFaultBinderHelperFactory;
import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;
...

public PrinterFaultTypeBinder implements CustomBinder
{
   // Get an instance of the BaseFaultBinderHelper
   private BaseFaultBinderHelper baseFaultBinderHelper = BaseFaultBinderHelperFactory.getBaseFaultBinderHelper();

   public SOAPElement serialize(Object data, SOAPElement rootNode, CustomBindingContext context) throws SOAPException
   {
     // Serialize the BaseFault specific data
     baseFaultBinderHelper.serialize(rootNode, (BaseFault)data);

     // Serialize any PrinterFault specific data
     ...

     // Return the serialized PrinterFault
     return rootNode;
   }

   public Object deserialize(SOAPElement rootNode, CustomBindingContext context) throws SOAPException
   {
     // Create an instance of a PrinterFault
     PrinterFault printerFault = new PrinterFault();

     // Deserialize the BaseFault specific data - any additional data which
     // forms the PrinterFault extension will be returned as a SOAPElement[].
     SOAPElement[] printerFaultElements = baseFaultBinderHelper.deserialize(printerFault, rootNode);

     // Deserialize the PrinterFault specific data contained within the printerFaultElements SOAPElement[]
     ...

     // Return the deserialized PrinterFault
     return printerFault;
   }

  ...

}
```

Web Services Resource Framework resource property and lifecycle operations

The Web Services Resource Framework (WSRF) contains specifications that describe the operations that
a Web Services Resource (WS-Resource) can implement to get, set, or query the state of the resource by
operating on the resource properties document.

For a complete description of all the standard property and lifetime operations defined by the Web
Services Resource Framework (WSRF) see the WS-ResourceProperties and WS-ResourceLifetime
specifications. The principle WSRF operations that a Web Services Resource (WS-Resource) can support
are described below.

Table 18. Principle WSRF operations supported by WS-Resources

Operation	Description

GetResourcePropertyDocument	Returns the entire resource properties document for the WS-Resource.
	
	Message format
	`<wsrf-rp:GetResourcePropertyDocument/>`
	
	Response format
	`<wsrf-rp:GetResourcePropertyDocumentResponse>`
	`  {any}`
	`</wsrf-rp:GetResourcePropertyDocumentResponse>`
	
	where *{any}* is the content of the resource properties document

PutResourcePropertyDocument	Replaces the entire resource properties document for the WS-Resource with the document specified.
	
	Message format
	`<wsrf-rp:PutResourcePropertyDocument>`
	`  {any}`
	`</wsrf-rp:PutResourcePropertyDocument>`
	
	where *{any}* is the content of the new resource properties document.
	
	Response format
	`<wsrf-rp:PutResourcePropertyDocumentResponse>`
	`  {any} ?`
	`</wsrf-rp:PutResourcePropertyDocumentResponse>`
	
	where *{any}* is the content of the new resource properties document. If the content is the same as the requested content then the *{any}* element must not be present.

GetResourceProperty	Returns the value or values of the specified resource property found within the resource properties document for the WS-Resource.
	
	Message format
	`<wsrf-rp:GetResourceProperty>`
	`  QName`
	`</wsrf-rp:GetResourceProperty>`
	
	Response format
	`<wsrf-rp:GetResourcePropertyResponse>`
	`  {any}*`
	`</wsrf-rp:GetResourcePropertyResponse>`
	
	where *{any}** is a sequence of elements that match the *QName* specified in the request.

GetMultipleResourceProperties	Returns the value or values of the specified resource properties found within the resource properties document for the WS-Resource.
	
	Message format
	`<wsrf-rp:GetMultipleResourceProperties>`
	`  <wsrf-rp:ResourceProperty>QName<wsrf-rp:ResourceProperty>+`
	`</wsrf-rp:GetMultipleResourceProperties>`
	
	Response format
	`<wsrf-rp:GetMultipleResourcePropertiesResponse>`
	`  {any}*`
	`</wsrf-rp:GetMultipleResourcePropertiesResponse>`
	
	where *{any}** is a sequence of elements that match the *QNames* specified in the request.

Table 18. Principle WSRF operations supported by WS-Resources (continued)

Operation	Description
InsertResourceProperties	Inserts the resource property elements specified into the resource properties document for the WS-Resource. **Message format** ``` <wsrf-rp:InsertResourceProperties> <wsrf-rp:Insert> {any}* </wsrf-rp:Insert> </wsrf-rp:InsertResourceProperties> ``` where {any}* is a sequence of elements with the same QName. **Response format** ``` <wsrf-rp:InsertResourcePropertiesResponse/> ```
UpdateResourceProperties	Updates the resource property elements specified into the resource properties document for the WS-Resource. **Message format** ``` <wsrf-rp:UpateResourceProperties> <wsrf-rp:Upate> {any}* </wsrf-rp:Upate> </wsrf-rp:UpateResourceProperties> ``` where *{any}** is a sequence of elements with the same QName. **Response format** ``` <wsrf-rp:UpateResourcePropertiesResponse/> ```
DeleteResourceProperties	Deletes the resource property elements specified from the resource properties document for the WS-Resource. **Message format** ``` <wsrf-rp:DeleteResourceProperties> <wsrf-rp:Delete ResourceProperty="QName"/> </wsrf-rp:DeleteResourceProperties> ``` where *QName* is the QName of the resource property to be deleted. **Response format** ``` <wsrf-rp:DeleteResourcePropertiesResponse/> ```

Table 18. Principle WSRF operations supported by WS-Resources (continued)

Operation	Description

QueryResourceProperties	Query the resource properties document using a query expression such as XPath.
	
	Message format
	``
	<wsrf-rp:QueryResourceProperties>
	  <wsrf-rp:QueryExpression
	          Dialect="http://www.w3.org/TR/1999/REC-xpath-19991116">
	    xsd:any
	  </wsrf-rp:QueryExpression>
	</wsrf-rp:QueryResourceProperties>
	``
	
	where *xsd:any* is the XPath query expression to apply to the resource properties document.
	
	Response format
	``
	<wsrf-rp:QueryResourcePropertiesResponse>
	  {any}
	</wsrf-rp:QueryResourcePropertiesResponse>
	``
	
	where *{any}* is the result of evaluating the query expression against the resource properties document.

Destroy	Destroys the WS-Resource. **Message format** ``` <wsrf-rl:Destroy/> ``` **Response format** ``` <wsrf-rl:DestroyResponse/> ``` This response indicates successful destruction of the WS-Resource.

Table 18. Principle WSRF operations supported by WS-Resources (continued)

Operation	Description

SetTerminationTime	WS-Resources that support scheduled termination can implement this operation to allow a requester to change the time at which the WS-Resource destroys itself.
	
	Message format
	<pre><wsrf-rl:SetTerminationTime>
	  [<wsrf-rl:RequestedTerminationTime>
	    xsd:dateTime
	  </wsrf-rl:RequestedTerminationTime>]
	       |
	  [<wsrf-rl:RequestedLifetimeDuration>
	    xsd:duration
	  </wsrf-rl:RequestedLifetimeDuration>]
	</wsrf-rl:SetTerminationTime></pre>
	where the termination time is either an absolute time or a relative duration.
	
	Response format
	<pre><wsrf-rl:SetTerminationTimeResponse>
	  <wsrf-rl:NewTerminationTime>
	    xsd:dateTime
	  </wsrf-rl:NewTerminationTime>
	  <wsrf-rl:CurrentTime>
	    xsd:dateTime
	  </wsrf-rl:CurrentTime>
	<wsrf-rl:SetTerminationTimeResponse></pre>
	This response contains the time, from the WS-Resource's perspective, when the WS-Resource will destroy itself. The response also contains the WS-Resource's value of the current time.
	
	There are a variety of ways in which a WS-Resource can implement scheduled destruction. For example, a WS-Resource that is implemented as an EJB might use the EJB container timer service by implementing the ejbTimeout callback method of the javax.ejb.TimedObject interface, and by creating a Timer object that expires at the scheduled destruction time and drives this callback method. EJB timer service Timer objects are persistent and survive server restarts, and are therefore a simple means to manage the lifecycle of WS-Resources that have a finite lifecycle and require a time-based destruction mechanism.

Example: Creating a Web service that uses the Web Services Addressing API to access a Web Services Resource (WS-Resource) instance

This example extends the example ″Creating a Web service that uses the Web Services Addressing API to access a generic Web service resource instance″, to use a WS-Resource instance. A WS-Resource, by definition, is a combination of a resource and a Web service through which the resource is accessed. As described in the WS-Resource specification, part of the Web Services Resource Framework (WSRF) specification, a WS-Resource is accessed through a WS-Addressing endpoint reference, and a view on the state of its resource is maintained in a *resources properties* XML document. Use of a WS-Resource, for representing stateful resources, provides an interoperable means to interact with the state representation of resources using standardized web service messages.

Creating a resource properties schema document for the WS-Resource

A WS-Resource must have a resource properties XML document, described by XML schema, which describes a particular view of the state of the WS-Resource. The printer WS-Resource schema document is illustrated below.

```
<?xml version="1.0"?>
<xsd:schema ...
   xmlns:pr="http://example.org/printer.xsd"
   targetNamespace="http://example.org/printer.xsd" >
 <xsd:element name="printer_properties">
   <xsd:complexType>
     <xsd:sequence>
       <xsd:element ref="pr:printer_reference" />
       <xsd:element ref="pr:printer_name" />
       <xsd:element ref="pr:printer_state" />
       <xsd:element ref="pr:printer_accepting_jobs" />
       <xsd:element ref="pr:queued_job_count" />
       <xsd:element ref="pr:operations_supported" />
       <xsd:element ref="pr:document_format_supported" />
       <xsd:element ref="pr:job_hold_until_default"
                   minOccurs="0" />
       <xsd:element ref="pr:job_hold_until_supported"
                   minOccurs="0"
                   maxOccurs="unbounded" />
       <xsd:element ref="wsrf-rp:QueryExpressionDialect"
                   maxOccurs="unbounded" />
       <xsd:element ref="pr:job_properties" minOccurs="0"
                   maxOccurs="unbounded" />
     </xsd:sequence>
   </xsd:complexType>
 </xsd:element>
 ...
</schema>
```

Creating and editing the WSDL definition for the Web service component of the WS-Resource

The WSDL definition for the Printer WS-Resource server is the same as in "Example: Creating a Web service that uses the Web Services Addressing API to access a generic Web service resource instance" on page 481, with the addition of a ResourceProperties attribute on the wsdlPortType element. This attribute declares that the portType is implemented by a WS-Resource rather than a generic Web service. Because the interface contains a resource properties document type declaration, the interface must also contain the WSRF-defined operation GetResourceProperty; this is required by the WS-ResourceProperties specification.

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
          xmlns:wsrf-rp="http://docs.oasis-open.org/wsrf/rp-2"

    </wsdl:portType>
</wsdl:definitions>
```

Implementing the Web service component of the WS-Resource

You implement the Web service in the same way as a normal Web service, as described in "Example: Creating a Web service that uses the Web Services Addressing API to access a generic Web service resource instance" on page 481. This example discusses the use of endpoint references that refer to generic Web service resource instances. A WS-Resource instance is a specific type of such a resource instance, that supports the standardized message exchanges defined in the WSRF specification.

Getting started with the UDDI registry

This section covers the basic knowledge you need to get started either as an administrator of a UDDI registry or as a user of a UDDI registry that has already been set up.
- Getting started for UDDI Administrators
- Getting started for UDDI users

Getting started for UDDI Administrators

Use this topic if you are involved in installing (setting up and deploying), customizing, or managing a UDDI registry.

This section contains a list of some of the topics that you will need to refer to as an administrator of a UDDI registry:
- UDDI registry Terminology introduces some terms with which you will need to be familiar in order to administer a UDDI registry
- Setting up and deploying a new UDDI registry explains how to install a UDDI registry node by setting up the resources that it will use, and deploying the UDDI registry application.

- Migrating the UDDI registry explains how to use the scripts provided to migrate UDDI registries from the previous version of WebSphere Application Server.
- Migrating to Version 3 of the UDDI registry explains how to migrate UDDI Version 2 registries to UDDI Version 3, introduced in WebSphere Application Server Version 6.0, by creating a migration datasource.
- Configuring UDDI registry security explains how to configure different levels of security for the UDDI registry, and how other UDDI node settings can influence security.
- Managing the UDDI registry explains how to use the UDDI pages in the administrative console, or the UDDI registry Administrative interface, to administer a UDDI registry node. It also covers how to back up and restore your UDDI registry data.
- UDDI node settings explains how to view and set UDDI properties and policies, and how to manage UDDI publishers, tiers and user entitlements.
- UDDI registry Management Interfaces covers details of programmatic interfaces that you can use to administer a UDDI registry node (UDDI registry Administrative (JMX) Interface), to add custom Value Set data to a UDDI registry (User Defined Value Set Support), and to export and import UDDI version 2 entities (UDDI Utility Tools).
- Removing and reinstalling the UDDI registry

UDDI registry troubleshooting might be useful if you encounter any problems or unexpected behavior while using the UDDI registry, and Troubleshooter reference: Messages links to messages that you might see.

Getting started for UDDI users

Use this topic if you use a UDDI registry to publish or find UDDI entities either through a user interface or by writing UDDI client applications.

This section contains a list of some of the topics that you might want to refer to as a user of a UDDI registry:
- UDDI registry Terminology introduces some terms with which you might need to be familiar in order to use a UDDI registry.
- Using the UDDI registry user interface explains how to access the UDDI User Console, which is a user interface that allows you to find UDDI entities and carry out simple UDDI publish operations.
- UDDI registry SOAP Service End Points contains details for accessing the UDDI version 3 Inquiry, Publish, Security, and custody transfer APIs, as well as the UDDI version 1 and version 2 APIs.
- UDDI registry Client Programming explains how to write UDDI client application programs. The recommended client programming interface is the UDDI version 3 Client for Java.
- IBM JAXR Provider for the UDDI registry is for users who want to use the Java API for XML Registries to access UDDI.
- User Defined Value Set Support in the UDDI registry explains how to add custom value set data to a UDDI registry.

UDDI registry troubleshooting might be useful if you encounter any problems or unexpected behavior while using the UDDI registry, and Troubleshooter reference: Messages links to messages that you might see.

Using the UDDI registry user interface

Configure the application server hosting the UDDI registry for UTF-8 encoding support, as described in refer to Configuring application servers for UTF-8 encoding.

This topic describes the UDDI registry user interface (also referred to as the UDDI registry user console), which you can use to explore the UDDI registry.

The user console provides a graphical user interface to the majority of the UDDI Version 3 API. It is not intended to support the full API set. There is some focus on inquiry operations, as the main purpose of the

UDDI user console is to allow you to issue inquiry requests and to familiarize yourself with general UDDI concepts. This section documents the areas for which support through the user console is not provided, and other known restrictions to the user console.

- General
  - Help is provided in the form of explanatory text on the screens.
  - Maximum rows cannot be specified on finds. The single maximum rows value for the registry can be set through the *Maximum inquiry result set size* general property on the administrative console.
- Find business
  - The identifier feature is not supported.
- Find technical model (tModel)
  - The identifier feature is not supported.
- Add business
  - There is no support for adding Discovery URLs, Identifiers or Digital Signatures.
- Add technical model (tModel)
  - There is no support for adding Identifiers or Digital Signatures.
- Business Relationships
  - There is no support for Business Relationships

Use the related links below to find the appropriate topic for the task you want to perform using the UDDI registry user interface.

Displaying the UDDI registry user interface

Use this task to perform actions on UDDI information through the UDDI user console. The exact behavior of the user console depends on several configurable factors, such as:

- Whether WebSphere Application Server security is enabled.
- How the UDDI registry GUI role mappings are set. The UDDI registry supports a number of security roles, including two for the user console: GUI_Publish_User and GUI_Inquiry_User.
- How the UDDI registry GUI SSL transport guarantee constraints are set. The UDDI registry allows SSL settings to be configured and this includes two settings for the user console.

The following table summarizes the behavior of the UDDI registry user console.

Table 19.

WebSphere Application Server security status	URL used to access the UDDI user console	Behavior of the UDDI user console
Enabled	http:// *host_name*:*http_port*/ uddigui	Inquiry requests do not require authentication; they use the HTTP URL and are not secure. Publish requests do require WebSphere Application Server authentication. When you access the publish pane you will be dynamically redirected to use HTTPS, and will be prompted for a user ID and password. For the request to be successful , the authenticated user must be registered as a UDDI publisher.

If the GUI_Inquiry_User role is mapped to all authenticated users, and the transport guarantee in the user data constraint section for that role is set to CONFIDENTIAL, *all* requests, including inquiry, require authentication and use of HTTPS. |
| | https:// *host_name*:*ssl_port*/ uddigui | Requests are secure; you are prompted to authenticate with a user ID and password. For the request to be successful , the authenticated user must be registered as a UDDI publisher. |

Table 19. (continued)

WebSphere Application Server security status	URL used to access the UDDI user console	Behavior of the UDDI user console
Disabled	http:// *host_name*:*http_port*/ uddigui	No requests, either publish or inquire, are authenticated and the data flow is *not* secure (non SSL). Even though SSL transport-guarantee settings are defined, they are not enforced if security is disabled. All publish operations are performed using a user ID of UNAUTHENTICATED or a value that can be configured using the administrative console or the JMX management interface (this applies to new requests only).
	https:// *host_name*:*ssl_port*/ uddigui	No requests, either publish or inquire, are authenticated, but the data flow is secure because the SSL URL and port are used explicitly. All publish operations are performed using a user ID of UNAUTHENTICATED or a value that can be configured using the administrative console or the JMX management interface (this applies to new requests only).

The variables in the table have the following values:
* *host_name* is the name of the machine that is running the relevant profile.
* *http_port* is the internal HTTP port for the profile, for example 9080.
* *ssl_port* is the internal SSL port for the profile, for example 9443.
1. Start the UDDI application, if it is not already running.
2. Open a browser window and ensure that cookies are enabled.
3. Access the UDDI registry user console using one of the following default URLs.
   * http://*host_name*:*http_port*/uddigui
   * https://*host_name*:*ssl_port*/uddigui

The user console displays the default frameset containing the following items:
* The header frame.
* The navigation frame showing find options.
* The details frame.

You can now use the UDDI user console to find, edit or publish UDDI information.

Finding an entity using the UDDI registry user interface

Make sure that the UDDI registry application is started, then display the UDDI registry user interface as described in Displaying the user interface.

This topic describes how to use the UDDI registry user interface (also referred to as the UDDI registry user console) to find services, businesses and technical models.
1. Activate the **Find** tab by clicking it, or by clicking the **Find** link at the top of the page or on the Welcome page.
2. To perform a quick find, complete the following steps:
   a. In the **Quick Find** section of the **Find** tab, select the kind of entity you want to find; service, business or technical model.
   b. In the **Starting with** field, enter name of the entity. Use the '%' wildcard character to search for a partial name.
   c. Click **Find**.

   The results are displayed in the detail frame on the right.

3. To perform an advanced find, complete the following steps:

   a. In the **Advanced Find** section of the **Find** tab, click the appropriate link for the kind of entity you want to find; service, business or technical model. The advanced search form is displayed in the frame to the right.

   b. Enter your search criteria in the advanced search form, and select any find qualifiers you require. You must enter at least one name to search for, using the **Add Name** link. You can use this link to enter multiple names. You can also add multiple categorizations. To add a categorization, use the **Show category tree** link in the **Categorizations** section to display, in the pane on the left, a tree of categories (or taxonomies) defining the types of item to find according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced search form, then use the **Add Categorization** link to include the category in the search.

   c. Click **Find** *entities*.

   The results are displayed in the detail frame on the right.

Publishing an entity using the UDDI registry user interface

Make sure that the UDDI registry application is started, then display the UDDI registry user interface as described in Displaying the user interface.

This topic describes how to use the UDDI registry user interface (also referred to as the UDDI registry user console) to publish businesses and technical models. To publish a service, first publish a business and then add a service to that business, as described in Editing or deleting an entity using the UDDI registry user interface.

1. Activate the **Publish** tab by clicking it, or by clicking the **Publish** link at the top of the page or on the Welcome page.

2. To publish an entity by name only, use the quick publish section as follows:

   a. In the **Quick Publish** section of the **Publish** tab, select the kind of entity you want to publish; business or technical model.

   b. In the **Name** field, enter name of the entity.

   c. Click **Publish**.

   The details of the published entity are displayed in the frame on the right.

3. To publish an entity with more information, complete the following steps:

   a. In the **Advanced Publish** section of the **Publish** tab, click the appropriate link for the kind of entity you want to publish; business or technical model. The advanced publish form is displayed in the frame to the right.

   b. Enter the details for the entity in the advanced publish form. You can enter multiple names, descriptions, contacts or categorizations by using the relevant **Add** link. To add a categorization, first use the **Show category tree** link in the **Categorizations** section to display, in the pane on the left, a tree of categories (or taxonomies) defining the types of item to publish according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced publish form, then click the **Add Categorization** link.

   c. Click **Publish** *entity* to publish the business or technical model to the UDDI registry.

Editing or deleting an entity using the UDDI registry user interface

Make sure that the UDDI registry application is started, then display the UDDI registry user interface as described in Displaying the user interface.

This topic describes how to use the UDDI registry user interface (also referred to as the UDDI registry user console) to edit or delete the businesses and technical models that you own, including adding services to businesses.

1. Activate the **Publish** tab by clicking it, or by clicking the **Publish** link at the top of the page or on the Welcome page.
2. At the bottom of the **Publish** tab is the **Registered Information** section. Click **Show owned entities** to show the businesses and technical models that you have registered in the UDDI registry.
3. **Optional:** To delete a business or technical model, click the **Delete** link in the **Actions** column for that entity.

   Note: When you delete a technical model, it is hidden rather than physically deleted, as specified by the UDDI Version 3.0 specification. If you click the **Shown owned entities** link the technical model will still appear, but you will not be able to find it using the **Find** function. All other entities are deleted from the UDDI registry in the normal way.

4. **Optional:** To edit a business or technical model, click the **Edit** link in the **Actions** column for that entity, fill in the required details and click **Update** *entity* to save the changes in the UDDI registry.
5. **Optional:** To add a service to a business, click the **Add service** link in the **Actions** column for the business. Fill in the details and click **Add Service** to publish the service to the UDDI registry. The service details are displayed.

Creating business relationships using the UDDI registry user interface

If your business has an association with another business in the UDDI registry, for example a preferred supplier, you can describe this association in the UDDI registry by creating a *business relationship*.

1. The UDDI registry contains the following default relationship types:

   Parent-child
   A hierarchical relationship exists between the two business entities, which might represent, for example, a large organization and a subsidiary.

   Peer-peer
   The two business entities represent peer organizations, for example a company and its supplier.

   Identity
   The two business entities represent the same organization.

   If you require a different relationship type, create a user-defined value set to represent the relationship type that you require, as described in User-defined value set support in the UDDI registry.

2. Each business that is involved in the relationship must already exist in the UDDI registry.
3. Make sure that the UDDI registry application is started, then display the UDDI registry user interface as described in Displaying the user interface.

Perform this task when you want to publicize an association between two businesses in the UDDI registry. For example, your organization, represented by a business entity in the UDDI registry, might have several departments, each one represented by a different business entity in the UDDI registry. You might want to declare these departments as being linked to the parent organization, by creating parent-child relationships between the appropriate business entities.

1. Activate the **Publish** tab by clicking it, or by clicking the **Publish** link at the top of the page or on the Welcome page.
2. Under **Registered Information**, click **Show owned entities**. The entities that you own are displayed in the detail frame on the right.
3. In the section for the businesses that you own, find the business that you want to link from, and click the **Add relationship** link for that business. The Add Business Relationship pane appears. The business key for the business that you selected is already listed in the From section.
4. Click **Add** to add the second business, the business that you want to link to. The advanced find pane appears.
5. Find the second business, as described in the advanced find step of "Finding an entity using the UDDI registry user interface" on page 510.

6. Click **Select** to add the second business to the relationship. If you want to change the positions of the businesses, click **Swap**.

7. Select the type of relationship from the **Type** list.

8. If required, type a description in the **Usage** field.

9. Click **Add relationship** to create the relationship. If you own both businesses, no further action is required. The relationship appears as a *publisher assertion* in the list of entities that you own. The status of the assertion is complete.

10. If you do not own the second business, the status of the assertion is pending. The owner of the second business must create a relationship from their business to yours, for the relationship to be complete and visible to other parties. The relationship type must match the type that you chose earlier.

The business relationship is published to the UDDI registry. The UDDI user interface only shows publisher assertions for entities that you own. To view other relationships, use the UDDI inquiry API provided.

For more information about publisher assertions, refer to the UDDI specification.

To remove an assertion that you own, display your owned entities and click the **Delete** link for the relevant publisher assertion. If the business in the To field is owned by someone else, the status of the assertion becomes pending, and the relationship is no longer visible to other parties.

Example: Publishing a business, service and technical model using the UDDI registry user interface

This example describes how to use the UDDI registry user interface to publish a used car business called Modern Cars to the UDDI registry, and how to publish a service and technical model for the business.

Before you begin, make sure that the UDDI registry application is started, then display the UDDI user interface as described in Displaying the user interface.

Adding the Business

1. Click the **Publish** tab to activate the **Publish** pane.

2. Under **Advanced Publish** click **Add a business**. The advanced publish form is displayed on the right.

3. Type 'Modern Cars' in the **Name** field for the business. Select the language of the business name from the drop down list, then click **Add Name** to add the name to the business.

4. Type a description for the business, such as 'Used cars for sale' in the **Description** field. Select the language of the description from the drop down list, then click **Add Description** to add the description to the business. You can add multiple descriptions in a variety of languages as required.

5. In the **Contact** section, type your name as a contact for customers of the business. Select the language as before, and click **Add Contact**. The business contact form is displayed. Fill in the details, using the **Add** *entity* links to add the information as you reach the end of each subsection. Note that all the text fields in the form are cleared when you click an **Add** *entity* link. Click **Add Contact** to save the contact information into the Modern Cars business.

6. Use the **Categorizations** section to describe the Modern Cars business according to the NAICS 2002 categorization system:

   a. Click **Show category tree** to display the various categorization systems.

   b. Expand the **NAICS 2002** tree, then in that tree expand **Retail Trade [44]** → **Motor Vehicle and Parts Dealers [441]** → **automobile Dealers [4411]** → **Used Car Dealers [44112]**. Click the **Used Car Dealers [441120]** category to add the category type, key name and key value to the advanced publish form.

   c. Click **Add Categorization** to add the information to the business.

   d. Close the category tree by clicking the **close** link near the top of the tree.

7. Click **Publish Business** to publish the Modern Cars business to the UDDI registry. The details of the business will be displayed.

Adding a service to the business

1. Click the **Publish** tab to activate the **Publish** pane.
2. Under **Registered Information** click **Show owned entities** to display the Modern Cars business, and any other entities that are owned by you.
3. Click **Add service** in the **Actions** column of the Modern Cars business. The publish service page is displayed.
4. Add a name and description for the service, in the same way as for the business itself.
5. Click **Add a Service Binding** to display the service binding form. Enter an access point (the URL for the service on the network) and a description for the service binding. Click **Add Technical Model Instance Information** to display a page where you can describe and publish a technical model instance for the service binding. In the technical model information page, click **Add Technical Model**. Search for the technical model which is used by the instance, select the technical model from the results and click **Add**. Fill in the other fields on the form and click **Add Technical Model Instance**. Click **Add Binding** to save the information into the service.
6. Add a categorization as you did for the business itself.
7. Click **Add Service** to publish the service to the UDDI registry.

Adding a technical model

1. In the **Advanced Publish** section on the left, click **Add a technical model** to display the publish technical model form on the right.
2. Add a name and description for the technical model, in the same way as for the business and the service.
3. Click **Add an Overview Document** to display the overview document form. The overview document describes the technical model. Type the location of the overview document in the **Overview URL** field, and click **Add Overview Document URL**. Add a description and click **Add Overview Document** to save the information in the technical model.
4. Add a categorization in the same way as for the business.
5. Click **Publish Technical Model** to publish the technical model to the UDDI registry.

Setting up and deploying a new UDDI registry

Start WebSphere Application Server, and create a server to host the UDDI registry. Use Starting and stopping quick reference for information about starting WebSphere Application Server using either commands or the administrative console.

A UDDI registry node consists of the UDDI registry application (a J2EE application that is supplied as part of WebSphere Application Server), a store of data (using a relational database management system) referred to as the UDDI database, and a means to connect the application to the data (a datasource and related elements). The 'Setting up' sub-topics describe how to create the database (which can be local or remote) and datasource, and how to deploy the UDDI registry application.

You can create either a *default* UDDI node or a *customized* UDDI node. The main difference between default and customized, in the context of these set up tasks, refers to a number of mandatory UDDI registry properties such as the UDDI node ID and description, and the prefix to be used for generated discovery URLs.

Default UDDI node
> The mandatory properties are automatically set to default values and cannot be changed. A default UDDI node is a suitable option for initial evaluation of the UDDI registry, and for development and test purposes.

Customized UDDI node

You must set the mandatory properties, but once set they cannot be changed for this configuration. With a customized UDDI node you have more control over the database management system used for the UDDI database, and the properties used to set up the UDDI database. With a customized UDDI node, you create the UDDI database and datasource to your own specifications before deploying the UDDI registry application. A customized node is a suitable option for production purposes. To move from a default UDDI node to a customized node, see "Changing the UDDI registry application environment after deployment" on page 534.

Proceed to one of the following topics:

- "Setting up a default UDDI node"
- "Setting up a customized UDDI node" on page 524

Database considerations for production use of the UDDI registry

The UDDI registry fully supports a number of databases (see An overview of the Version 3 UDDI registry for details) and can be used for development and test purposes, however you should be aware of the following factors when considering which database is appropriate for your anticipated UDDI registry production use.

It is important to consult the information supplied by your chosen database vendor for advice, but additionally you need to consider the likely size and volume of requests, and whether the general performance and scalability of the UDDI registry is important to you.

For example, while Cloudscape supports the full function of the UDDI registry, it is not an enterprise level database and consequently it does not have the same characteristics (for example, scaling or performance) as enterprise databases such as DB2.

If you need multiple connections to the UDDI registry database (for example if you are using the UDDI registry in a cluster configuration) and Cloudscape is your preferred database, you will need to use the network Cloudscape option as embedded Cloudscape has a limitation of allowing only one Java virtual machine to access or load a database instance at any one time (in other words two application servers cannot access the same Cloudscape database instance at the same time).

Note: The UDDI registry can support multiple users even if there is a single database connection.

More information on Cloudscape is available in this information center.

Setting up a default UDDI node

Use this task to create a UDDI node with predetermined property values. You will not be able to change the mandatory node properties, such as node ID, either during the creation of the node or afterwards. Such a node is suitable for initial evaluation of the UDDI registry and for development and test purposes. If you want to choose the mandatory node properties yourself, set up a customized node as detailed in "Setting up a customized UDDI node" on page 524.

Note: If you are deploying the UDDI registry application into a cluster, and you want to use Cloudscape for your database, you must use the network version of Cloudscape. Embedded Cloudscape is not supported for cluster configurations.

1. Create a database schema to hold the UDDI registry by completing one of the following tasks, ensuring that you use the default node options where specified:
   - "Creating a DB2 distributed database for the UDDI registry" on page 516
   - "Creating a DB2 for z/OS database for the UDDI registry" on page 518
   - "Creating a Cloudscape database for the UDDI registry" on page 519
   - "Creating an Oracle database for the UDDI registry" on page 520

Note: If you are creating the UDDI node in a cluster, it is assumed that a single database will be used for all members of the cluster.

2. Set up a datasource for the UDDI registry application to use to access the database, as described in "Creating a data source for the UDDI registry" on page 521.

3. Deploy the UDDI registry application, as described in "Deploying the UDDI registry application" on page 523.

4. `Linux` If you are using DB2, stop the server if it is running. Edit the user profile for the DB2 user that will start the node agent or server. Modify the user profile to run the db2profile script which is located in the root directory of the DB2 userid (for example /home/db2inst1/sqllib/db2profile). Alternatively you can run the db2profile script manually by entering the following command, however you will need to do this every time you restart the node agent or server :

   ```
   . /home/db2inst1/sqllib/db2profile
   ```

   Note: In the above example, notice that the '.' is followed by a single space character.

5. Click **Applications** → **Enterprise Applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to it and clicking **Start**. Alternatively start the application server if it is not already running; this will automatically start the UDDI registry application. The UDDI node is now active.

   Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

6. Click **UDDI** → **UDDI Nodes > ** *UDDI_node_id* to display the properties page for the UDDI registry node. Set **Prefix for generated discoveryURLs** to a valid URL for your configuration. This property specifies the URL prefix that is applied to generated discovery URLs that are used by the HTTP GET service for UDDI version 2.

As you have chosen to use a default UDDI node, the node will be initialized when the UDDI application is started for the first time. Follow the instructions in "Using the UDDI registry Installation Verification Program (IVP)" on page 533 to verify that you have successfully set up the UDDI node.

Creating a DB2 distributed database for the UDDI registry:

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used, and suggested values are:

<DataBaseName>
   is the name of the UDDI registry database. A recommended value is UDDI30, and this name is assumed throughout the UDDI documentation. If you use some other name, then you should substitute that name whenever you see 'UDDI30' in other sections of the documentation.

<DB2UserID>
   is a DB2 userid with administrative privileges.

<DB2Password>
   is the password for the DB2 userid.

<BufferPoolName>
   is the name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, as the buffer pool is created as part of this task.

<TableSpaceName>
   is the name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
is the name of a temporary table space. A suggested value is udditstemp, but any name can be used, as the temporary table space is created as part of this task.

You only need to perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt (for Windows platforms, enter `db2cmd` and then enter `db2` in the new DB2 window).
3. Run the following command to setup the DB2 environment variables:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```
   where <DataBaseName> is the name of the database being created.
5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`
   c. `connect reset`
   d. `terminate`
   e. `force application all`
   f. `terminate`
   g. `stop`
   h. `start`
7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`
   c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`
8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:
   a. `db2 -tvf uddi30crt_10_prereq_db2.sql`
   b. `db2 -tvf uddi30crt_20_tables_generic.sql`
   c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`
   d. `db2 -tvf uddi30crt_30_constraints_generic.sql`
   e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`

    f. db2 -tvf uddi30crt_40_views_generic.sql

    g. db2 -tvf uddi30crt_45_views_db2udb.sql

    h. db2 -vf uddi30crt_50_triggers_db2udb.sql

    i. db2 -tvf uddi30crt_60_insert_initial_static_data.sql

9. Run this step only if you want your database to be used as a default UDDI node. Enter the following command:

   ```
   db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
   ```

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for z/OS database for the UDDI registry:

Perform this task if you want to use DB2 for z/OS as the database store for your UDDI registry data.

In order to connect from a machine running a distributed operating system to a remote DB2 database on the z/OS operating system, you must have DB2 Version 8.2 or later. You must also have a DB2 Connect license (see the DB2 documentation for more information).

You only need to perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

1. Copy the createddl.sh script supplied in *app_server_root*/UDDIReg/rexx, to a temporary directory of your choice.

2. Using the UNIX System Services (USS) command prompt, edit the copy of the createddl.sh script, as follows:

   a. Search for the text 'Define some constants'.

   b. If you have installed WebSphere Application Server in a non default location, update the root_dir constant to reflect this (note that the UDDIReg directory must remain at the end of the path).

   c. Update the temp_dir constant to a temporary directory of your choice, if you do not want to accept the default.

3. Using the USS command prompt, run the copy of the createddl.sh script by entering the following command:

   ```
   createddl.sh database_name tablespace_name hlq
   ```

   where the parameters are as follows:

   database_name
   > This is the name which will be used when defining the required DB2 tables and other components. The default is UDDI30.

   tablespace_name
   > This is the tablespace in which the database's tables will be defined. The default is UDDI30TS.

   hlq   This is the high level qualifier under which the SQL and JCL partitioned datasets (PDS) will be created. The default is IBMUSER.

   The script generates the partitioned data sets *hlq*.UDDI.SQL and *hlq*.UDDI.JCL, containing members that are required for subsequent steps.Using the default parameters listed above, a successful execution of the script results in the following output:

   ```
   database.tablespace = UDDI30.UDDI30TS
    HLQ = IBMUSER
    (  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_10_prereq_db2.sql
    ( 436) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_20_tables_generic.sql
    ( 136) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_25_tables_db2udb.sql
   ```

```
( 452) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_30_constraints_generic.sql
(  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_35_constraints_db2udb.sql
( 559) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_40_views_generic.sql
(  94) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_45_views_db2udb.sql
( 329) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_50_triggers_db2udb.sql
(  16) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_60_insert_initial_static_
         data.sql
(  39) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_70_insert_default_database_
         indicator.sql
Conversion complete
/tmp/udditmp/makedb71.jcl     ===> IBMUSER.UDDI.JCL(MAKEDB71)
/tmp/udditmp/makedb81.jcl     ===> IBMUSER.UDDI.JCL(MAKEDB81)
/tmp/udditmp/table.sql        ===> IBMUSER.UDDI.SQL(TABLE)
/tmp/udditmp/table7.sql       ===> IBMUSER.UDDI.SQL(TABLE7)
/tmp/udditmp/index.sql        ===> IBMUSER.UDDI.SQL(INDEX)
/tmp/udditmp/view.sql         ===> IBMUSER.UDDI.SQL(VIEW)
/tmp/udditmp/trigger.sql      ===> IBMUSER.UDDI.SQL(TRIGGER)
/tmp/udditmp/alter.sql        ===> IBMUSER.UDDI.SQL(ALTER)
/tmp/udditmp/initial.sql      ===> IBMUSER.UDDI.SQL(INITIAL)
/tmp/udditmp/insert.sql       ===> IBMUSER.UDDI.SQL(INSERT)
```

4. There are two sample jobs in the JCL library for creating the DB2 database, one for DB2 version 7 and one for DB2 version 8. The JCL for these jobs can be found in members MAKEDB71 and MAKEDB81 respectively, in the *hlq*.UDDI.JCL PDS. These JCL scripts are templates; modify the template in the appropriate MAKEDB member according to your DB2 setup and whether you want a default or a customized UDDI node:

   - Add or modify the JOB accounting information, if required.

   - If you used a different high level qualifier from the default when running the script in step one, ensure that all occurrences of IBMUSER are changed to the qualifier that you specified.

   - If you do not want your database to be used as a default UDDI node, comment out the line of the job which specifies the INSERT member of the SQL PDS; this should be the last line in the job.

   - Ensure that all occurrences of the LIB parameter correctly reflect the directory into which you installed DB2.

5. Use TSO to submit the job that you modified in the previous step. The job will create the DB2 database.

Continue with setting up and deploying your UDDI registry node.

Creating a Cloudscape database for the UDDI registry:

Perform this task if you want to use Cloudscape (embedded or network) as the database store (either local or remote) for your UDDI registry. You need only perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

The commands below use a number of arguments for which you need to enter appropriate values. You should decide the values that you will use before you start. The arguments used, and suggested values, are:

arg1   is the path of the SQL files, which on a standard installation will be *app_server_root*/UDDIReg/databasescripts

arg2   is the path to the location where you want to install the Cloudscape database.

        For example, *app_server_root*/profiles/*profile_name*/databases/com.ibm.uddi

arg3   is the name of the Cloudscape database. A recommended value is UDDI30, and this name is

assumed throughout the UDDI documentation. If you use another name, you should substitute that name whenever you see 'UDDI30' in other sections of the UDDI documentation.

arg4   is an optional argument, and must either be omitted or be the string 'DEFAULT'. DEFAULT should only be specified if you want your database to be used as a default UDDI node. Note that this argument is case sensitive.

1. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Cloudscape database using UDDIDerbyCreate.jar. `Windows`

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib;app_server_root/java/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   `AIX`   `Linux`   `HP-UX`   `Solaris`

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Cloudscape database already exists, you will be asked if you want to recreate it. If you choose to recreate the database, your existing database will be deleted and a new one created in its place. If you choose not to recreate the database, the command will exit and a new database will not be created.

   Note: If the application server already accessed the existing Cloudscape database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in Removing a UDDI registry node, restart the server and run the uddiDeploy.jacl script again.

2. If you are using a remote database (which requires network Cloudscape), or you want to use network Cloudscape for other reasons, for example if you want to use Cloudscape with a cluster, configure the Cloudscape Network Server framework as described in the managing derby network server section of the Cloudscape information center.

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry:

Note: Only Version 9i[1] and Oracle 10g[2]

Perform this task if you want to use Oracle as the database store (either local or remote) for your UDDI registry data. You need only do this once for each UDDI registry, as part of Setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

1.

   Restrictions:
   discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

2.

   Restrictions:
   discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
   is the Oracle userid to be used to create the database.

<OraclePassword>
   is the password for the Oracle userid.

1. Run the following commands:
   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`
   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`
   c. Complete one of the following actions depending on your level of Oracle:
      - For Oracle 9i:
        `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql`
      - For Version 10g and later:
        `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql`
   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`
   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`
   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`
   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`
   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`
   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`
2. This last command should only be run if you want the database to be used as a default UDDI node.
   `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql`

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry:

You must have already created the database for the UDDI registry. These instructions assume that, if you are installing into a cluster, a single database will be used by all members of the cluster.

Note: If you are connecting to a remote DB2 database on the z/OS operating system, you must have installed a DB2 Connect license (See the DB2 documentation for more information).

Perform this task as part of setting up and deploying a new UDDI registry. The data source is used by the UDDI registry to access the UDDI database.

1. Create a J2C Authentication Data Entry (not required for embedded Cloudscape, but required for network Cloudscape):
   a. Click **Security** → **Secure administration, applications, and infrastructire** → **[Authentication] Java Authentication and Authorization Service** → **J2C authentication data**.
   b. Click **New** to create a new J2C authentication data entry
   c. Fill in the details as follows:

      Alias   a suitable (short) name, such as ″UDDIAlias″

      Userid

the database userid (such as db2admin for DB2 or IBMUDDI for Oracle), which is used to read and write to the UDDI registry database. For network Cloudscape the userid can be any value.

If you are using a remote DB2 database on the z/OS operating system, the userid must be one that is valid on the remote system.

Password
the password associated with the userid specified above. For network Cloudscape the password can be any value.

Description
a suitable description to describe the chosen userid.

Click **Apply** and then Save the changes to the master configuration.

2. Create a JDBC Provider (if a suitable one does not already exist), using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 Universal JDBC Driver Provider	Connection Pool data source
Oracle	Oracle JDBC Driver	Connection Pool data source
Embedded Cloudscape	Derby JDBC Driver	Connection Pool data source
Network Cloudscape	Derby Network Server JDBC Driver provider	Connection Pool data source

Note: If you are setting up a UDDI node in a cluster, select 'cluster' as the scope of the JDBC provider.

For details on how to create a JDBC provider, see Creating and configuring a JDBC provider using the administrative console.

3. Create the data source for the UDDI registry by following these steps:

   a. Click **Resources** → **JDBC** → **JDBC Providers**.

   b. Select the desired 'scope' of the JDBC provider you selected or created earlier. For example, select:

      `Server: yourservername`

      to show the JDBC providers at the server level.

   c. Select the JDBC provider created earlier.

   d. Under **Additional Properties**, select **Data sources** (not the **Data sources (WebSphere Application Server V4)** option).

   e. Click **New** to create a new data source.

   f. In the **Create a data source** wizard, enter the following data:

   g. Click **Next**.

   h. On the database specific properties page of the wizard, enter the following data:

   i. Click **Next**, then check the summary and click **Finish**.

   j. Click the data source to display its properties, and add the following information:

   k. Click **Apply** and save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application:
You must have already created the database and datasource for the UDDI registry.

Use this task as part of "Setting up a default UDDI node" on page 515 or "Setting up a customized UDDI node" on page 524.

Run the uddiDeploy.jacl script as shown below, from the *app_server_root*/bin directory. This script deploys the UDDI registry to a server (or cluster) specified by you.

▶ Linux

Note: If you are using either the UNIX or Linux operating systems, add the `.sh` suffix to the wsadmin command.
```
wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
            {node_name server_name | cluster_name}
```

where
- '-profileName *profile_name*' is the deployment manager profile. If you do not specify a profile, the default profile will be used.
- '-conntype none' is optional, and is only needed if the application server is not running.
- *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
- *server_name* is the name of the target server on which you wish to deploy the UDDI registry, such as server1. Note the server name entered is case sensitive.
- *cluster_name* is the name of the target cluster into which you wish to deploy the UDDI registry. Note that the cluster name entered is case sensitive.

For example, to deploy UDDI on node 'MyNode' and server 'server1' on a Windows system, (assuming that server1 is already started):
```
wsadmin -f uddiDeploy.jacl MyNode server1
```

To deploy UDDI into cluster 'MyCluster' on a Windows system:
```
wsadmin -f uddiDeploy.jacl MyCluster
```

You can also deploy the UDDI application (the uddi.ear file) using the administrative console, in the normal way. However, some steps that are performed automatically by the uddiDeploy.jacl script do not take place in this scenario. If you use the administrative console to install the UDDI application, you must perform some actions manually, according to the following steps:
1. Install the application.
2. Click **Applications** → **Enterprise Applications >** *uddi_application* **> [Detail Properties] Class loading and update detection**.
3. Ensure that **Class loader order** is set to **Classes loaded with application class loader first**.
4. Ensure that **WAR class loader policy** is set to **Single class loader for application**.

The UDDI application is deployed. If you see the following error message, check that you ran the uddiDeploy.jacl script using the deployment manager profile.
```
WASX7017E: Exception received while running file "uddiDeploy.jacl"; exception in
formation: com.ibm.ws.scripting.ScriptingException: WASX7070E: The configuration
 service is not available.
```

Continue with setting up the UDDI node.

Setting up a customized UDDI node

Use this task to set up a UDDI node with property values that are chosen by you. You will not be able to change the mandatory node properties, such as node ID, after the initialization of the node. Such a node is suitable for production purposes.

Note: If you are deploying the UDDI registry application into a cluster, and you want to use Cloudscape for your database, you must use the network version of Cloudscape. Embedded Cloudscape is not supported for cluster configurations.

1. Review the information in "Database considerations for production use of the UDDI registry" on page 515 to help you decide which database system to use, then create a database schema to hold the UDDI registry by completing one of the following tasks, ensuring that you do NOT use the default node options where specified:

   - "Creating a DB2 distributed database for the UDDI registry" on page 516
   - "Creating a DB2 for z/OS database for the UDDI registry" on page 518
   - "Creating a Cloudscape database for the UDDI registry" on page 519
   - "Creating an Oracle database for the UDDI registry" on page 520

   Note: If you are creating the UDDI node in a cluster, it is assumed that a single database will be used for all members of the cluster.

2. Set up a datasource for the UDDI registry application to use to access the database, as described in "Creating a data source for the UDDI registry" on page 521.

3. Deploy the UDDI registry application, as described in "Deploying the UDDI registry application" on page 523.

4. ▶ `Linux` If you are using DB2, stop the server if it is running. Edit the user profile for the DB2 user that will start the node agent or server. Modify the user profile to run the db2profile script which is located in the root directory of the DB2 userid (for example /home/db2inst1/sqllib/db2profile). Alternatively you can run the db2profile script manually by entering the following command, however you will need to do this every time you restart the node agent or server :

   ```
   . /home/db2inst1/sqllib/db2profile
   ```

   Note: In the above example, notice that the '.' is followed by a single space character.

5. Click **Applications** → **Enterprise Applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to it and clicking **Start**. Alternatively start the application server if it is not already running; this will automatically start the UDDI registry application. The UDDI node is now active.

   Note: Restarting the UDDI application, or the application server, will always result in the reactivation of the UDDI node, even if the node was previously deactivated.

As you have chosen a user customized UDDI node, you will need to set the properties for the UDDI node using UDDI administration, and initialize the node before it is ready to accept UDDI requests. See "Initializing the UDDI registry node" on page 532 for details.

Creating a DB2 distributed database for the UDDI registry:

Perform this task if you want to use DB2 on the Windows, Linux or UNIX operating systems, as the database store for your UDDI registry data.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used, and suggested values are:

<DataBaseName>
  is the name of the UDDI registry database. A recommended value is UDDI30, and this name is

assumed throughout the UDDI documentation. If you use some other name, then you should substitute that name whenever you see 'UDDI30' in other sections of the documentation.

<DB2UserID>
> is a DB2 userid with administrative privileges.

<DB2Password>
> is the password for the DB2 userid.

<BufferPoolName>
> is the name of a buffer pool to be used by the UDDI registry database. A suggested name is uddibp, but any name can be used, as the buffer pool is created as part of this task.

<TableSpaceName>
> is the name of a table space. A suggested value is uddits, but any name can be used.

<TempTableSpaceName>
> is the name of a temporary table space. A suggested value is udditstemp, but any name can be used, as the temporary table space is created as part of this task.

You only need to perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

1. Change directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor by entering `db2` at the command prompt (for Windows platforms, enter `db2cmd` and then enter `db2` in the new DB2 window).
3. Run the following command to setup the DB2 environment variables:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database by entering the following command:
   ```
   create database <DataBaseName> using codeset UTF-8 territory en
   ```

   where <DataBaseName> is the name of the database being created.
5. Configure the DB2 database by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `update db cfg for <DataBaseName> using applheapsz 2048`
   c. `update db cfg for <DataBaseName> using logfilsiz 8192`
   d. `connect reset`
   e. `terminate`
6. Create additional database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create bufferpool <BufferPoolName> size 250 pagesize 32K`
   c. `connect reset`
   d. `terminate`
   e. `force application all`
   f. `terminate`
   g. `stop`
   h. `start`
7. Create further database structures by entering the following commands:
   a. `connect to <DataBaseName> user <DB2UserID> using <DB2Password>`
   b. `create regular tablespace uddits pagesize 32K managed by system using ('<TableSpaceName>') extentsize 64 prefetchsize 32 bufferpool <BufferPoolName>`

    c. `create system temporary tablespace <TempTableSpacename> pagesize 32K managed by system using ('<TempTableSpacename>') extentsize 32 overhead 14.06 prefetchsize 32 transferrate 0.33 bufferpool <BufferPoolName>`

8. Exit the DB2 Command Line Processor and enter the following commands exactly as shown, noting that one step uses -vf rather than -tvf (on Windows platforms, run the commands from the db2cmd window). These commands define the database structures needed to store the UDDI data:

    a. `db2 -tvf uddi30crt_10_prereq_db2.sql`

    b. `db2 -tvf uddi30crt_20_tables_generic.sql`

    c. `db2 -tvf uddi30crt_25_tables_db2udb.sql`

    d. `db2 -tvf uddi30crt_30_constraints_generic.sql`

    e. `db2 -tvf uddi30crt_35_constraints_db2udb.sql`

    f. `db2 -tvf uddi30crt_40_views_generic.sql`

    g. `db2 -tvf uddi30crt_45_views_db2udb.sql`

    h. `db2 -vf uddi30crt_50_triggers_db2udb.sql`

    i. `db2 -tvf uddi30crt_60_insert_initial_static_data.sql`

9. Run this step only if you want your database to be used as a default UDDI node. Enter the following command:

    `db2 -tvf uddi30crt_70_insert_default_database_indicator.sql`

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for z/OS database for the UDDI registry:

Perform this task if you want to use DB2 for z/OS as the database store for your UDDI registry data.

In order to connect from a machine running a distributed operating system to a remote DB2 database on the z/OS operating system, you must have DB2 Version 8.2 or later. You must also have a DB2 Connect license (see the DB2 documentation for more information).

You only need to perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

1. Copy the createddl.sh script supplied in *app_server_root*/UDDIReg/rexx, to a temporary directory of your choice.

2. Using the UNIX System Services (USS) command prompt, edit the copy of the createddl.sh script, as follows:

    a. Search for the text 'Define some constants'.

    b. If you have installed WebSphere Application Server in a non default location, update the root_dir constant to reflect this (note that the UDDIReg directory must remain at the end of the path).

    c. Update the temp_dir constant to a temporary directory of your choice, if you do not want to accept the default.

3. Using the USS command prompt, run the copy of the createddl.sh script by entering the following command:

    `createddl.sh database_name tablespace_name hlq`

where the parameters are as follows:

database_name
        This is the name which will be used when defining the required DB2 tables and other components. The default is UDDI30.

tablespace_name
> This is the tablespace in which the database's tables will be defined. The default is UDDI30TS.

hlq This is the high level qualifier under which the SQL and JCL partitioned datasets (PDS) will be created. The default is IBMUSER.

The script generates the partitioned data sets *hlq*.UDDI.SQL and *hlq*.UDDI.JCL, containing members that are required for subsequent steps.Using the default parameters listed above, a successful execution of the script results in the following output:

```
database.tablespace = UDDI30.UDDI30TS
 HLQ = IBMUSER
 (  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_10_prereq_db2.sql
 ( 436) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_20_tables_generic.sql
 ( 136) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_25_tables_db2udb.sql
 ( 452) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_30_constraints_generic.sql
 (  14) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_35_constraints_db2udb.sql
 ( 559) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_40_views_generic.sql
 (  94) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_45_views_db2udb.sql
 ( 329) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_50_triggers_db2udb.sql
 (  16) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_60_insert_initial_static_
        data.sql
 (  39) /WebSphere/V6R0M0/AppServer/UDDIReg/databaseScripts/uddi30crt_70_insert_default_database_

```

4. There are two sample jobs in the JCL library for creating the DB2 database, one for DB2 version 7 and one for DB2 version 8. The JCL for these jobs can be found in members MAKEDB71 and MAKEDB81 respectively, in the *hlq*.UDDI.JCL PDS. These JCL scripts are templates; modify the template in the appropriate MAKEDB member according to your DB2 setup and whether you want a default or a customized UDDI node:

   - Add or modify the JOB accounting information, if required.
   - If you used a different high level qualifier from the default when running the script in step one, ensure that all occurrences of IBMUSER are changed to the qualifier that you specified.
   - If you do not want your database to be used as a default UDDI node, comment out the line of the job which specifies the INSERT member of the SQL PDS; this should be the last line in the job.
   - Ensure that all occurrences of the LIB parameter correctly reflect the directory into which you installed DB2.

5. Use TSO to submit the job that you modified in the previous step. The job will create the DB2 database.

Continue with setting up and deploying your UDDI registry node.

Creating a Cloudscape database for the UDDI registry:

Perform this task if you want to use Cloudscape (embedded or network) as the database store (either local or remote) for your UDDI registry. You need only perform this task once for each UDDI registry, as part of setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

The commands below use a number of arguments for which you need to enter appropriate values. You should decide the values that you will use before you start. The arguments used, and suggested values, are:

arg1   is the path of the SQL files, which on a standard installation will be *app_server_root*/UDDIReg/ databasescripts

arg2   is the path to the location where you want to install the Cloudscape database.

   For example, *app_server_root*/profiles/*profile_name*/databases/com.ibm.uddi

arg3   is the name of the Cloudscape database. A recommended value is UDDI30, and this name is assumed throughout the UDDI documentation. If you use another name, you should substitute that name whenever you see 'UDDI30' in other sections of the UDDI documentation.

arg4   is an optional argument, and must either be omitted or be the string 'DEFAULT'. DEFAULT should only be specified if you want your database to be used as a default UDDI node. Note that this argument is case sensitive.

1. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory, to create a UDDI Cloudscape database using UDDIDerbyCreate.jar. ▶ Windows

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib;app_server_root/java/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   ▶ AIX   ▶ Linux   ▶ HP-UX   ▶ Solaris

   ```
   java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/lib/ext -jar UDDIDerbyCreate.jar
   arg1 arg2 arg3 arg4
   ```

   If the Cloudscape database already exists, you will be asked if you want to recreate it. If you choose to recreate the database, your existing database will be deleted and a new one created in its place. If you choose not to recreate the database, the command will exit and a new database will not be created.

   Note: If the application server already accessed the existing Cloudscape database, the uddiDeploy.jacl script cannot recreate the database. Use the uddiRemove.jacl script to remove the database, as described in Removing a UDDI registry node, restart the server and run the uddiDeploy.jacl script again.

2. If you are using a remote database (which requires network Cloudscape), or you want to use network Cloudscape for other reasons, for example if you want to use Cloudscape with a cluster, configure the Cloudscape Network Server framework as described in the managing derby network server section of the Cloudscape information center.

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry:

Note: Only Version 9i[3] and Oracle 10g[4]

3.

> **Restrictions:**
>
> discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters; instanceParms (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 8192 characters; overviewURL (tModelInstanceInfo) maximum 4000 bytes, UDDI specification 4096 characters; Digital Signature maximum 4000 bytes.

4.

Perform this task if you want to use Oracle as the database store (either local or remote) for your UDDI registry data. You need only do this once for each UDDI registry, as part of Setting up and deploying a UDDI registry.

If you are creating a remote database, use the database product documentation to familiarize yourself with the relevant capabilities of the product before proceeding with this task.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You will be unable to complete this task if you already have existing schemas with these names.

The steps below use a number of variables for which you need to enter appropriate values. You should decide the values that you will use before you start. The variables used are:

<OracleUserID>
        is the Oracle userid to be used to create the database.

<OraclePassword>
        is the password for the Oracle userid.

1. Run the following commands:

   a. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_10_prereq_oracle.sql`

   b. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_20_tables_generic.sql`

   c. Complete one of the following actions depending on your level of Oracle:

      - For Oracle 9i:

        `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle_pre10g.sql`

      - For Version 10g and later:

        `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_25_tables_oracle.sql`

   d. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_30_constraints_generic.sql`

   e. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_35_constraints_oracle.sql`

   f. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_40_views_generic.sql`

   g. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_45_views_oracle.sql`

   h. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_50_triggers_oracle.sql`

   i. `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_60_insert_initial_static_data.sql`

2. This last command should only be run if you want the database to be used as a default UDDI node.

   `sqlplus <OracleUserID>/<OraclePassword> @ uddi30crt_70_insert_default_database_indicator.sql`

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry:

You must have already created the database for the UDDI registry. These instructions assume that, if you are installing into a cluster, a single database will be used by all members of the cluster.

Note: If you are connecting to a remote DB2 database on the z/OS operating system, you must have installed a DB2 Connect license (See the DB2 documentation for more information).

Restrictions:
        discoveryURL (Business) maximum 4000 bytes, UDDI specification 4096 characters; accessPoint (bindingTemplate) maximum 4000 bytes, UDDI Specification 4096 characters.

Perform this task as part of setting up and deploying a new UDDI registry. The data source is used by the UDDI registry to access the UDDI database.

1. Create a J2C Authentication Data Entry (not required for embedded Cloudscape, but required for network Cloudscape):

   a. Click **Security** → **Secure administration, applications, and infrastructire** → **[Authentication] Java Authentication and Authorization Service** → **J2C authentication data**.

   b. Click **New** to create a new J2C authentication data entry

   c. Fill in the details as follows:

   Alias a suitable (short) name, such as ″UDDIAlias″

   Userid

   > the database userid (such as db2admin for DB2 or IBMUDDI for Oracle), which is used to read and write to the UDDI registry database. For network Cloudscape the userid can be any value.

   > If you are using a remote DB2 database on the z/OS operating system, the userid must be one that is valid on the remote system.

   Password

   > the password associated with the userid specified above. For network Cloudscape the password can be any value.

   Description

   > a suitable description to describe the chosen userid.

   Click **Apply** and then Save the changes to the master configuration.

2. Create a JDBC Provider (if a suitable one does not already exist), using the following table to determine the provider type and implementation type for your chosen database:

Database	Provider type	Implementation type
DB2	DB2 Universal JDBC Driver Provider	Connection Pool data source
Oracle	Oracle JDBC Driver	Connection Pool data source
Embedded Cloudscape	Derby JDBC Driver	Connection Pool data source
Network Cloudscape	Derby Network Server JDBC Driver provider	Connection Pool data source

   Note: If you are setting up a UDDI node in a cluster, select ′cluster′ as the scope of the JDBC provider.
   For details on how to create a JDBC provider, see Creating and configuring a JDBC provider using the administrative console.

3. Create the data source for the UDDI registry by following these steps:

   a. Click **Resources** → **JDBC** → **JDBC Providers**.

   b. Select the desired ′scope′ of the JDBC provider you selected or created earlier. For example, select:

   `Server: yourservername`

   to show the JDBC providers at the server level.

   c. Select the JDBC provider created earlier.

   d. Under **Additional Properties**, select **Data sources** (not the **Data sources (WebSphere Application Server V4)** option).

   e. Click **New** to create a new data source.

   f. In the **Create a data source** wizard, enter the following data:

   g. Click **Next**.

    h.   On the database specific properties page of the wizard, enter the following data:

    i. Click **Next**, then check the summary and click **Finish**.

    j. Click the data source to display its properties, and add the following information:

    k.   Click **Apply** and save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. You will see a message similar to ″Test Connection for datasource UDDI Datasource on server server1 at node MyNode was successful″. If you do not see this message investigate the problem with the help of the error message.

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application:

You must have already created the database and datasource for the UDDI registry.

Use this task as part of "Setting up a default UDDI node" on page 515 or "Setting up a customized UDDI node" on page 524.

Run the uddiDeploy.jacl script as shown below, from the *app_server_root*/bin directory. This script deploys the UDDI registry to a server (or cluster) specified by you.

> Linux

Note: If you are using either the UNIX or Linux operating systems, add the .sh suffix to the wsadmin command.

```
wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
            {node_name server_name | cluster_name}
```

where

- '-profileName *profile_name*' is the deployment manager profile. If you do not specify a profile, the default profile will be used.
- '-conntype none' is optional, and is only needed if the application server is not running.
- *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
- *server_name* is the name of the target server on which you wish to deploy the UDDI registry, such as server1. Note the server name entered is case sensitive.
- *cluster_name* is the name of the target cluster into which you wish to deploy the UDDI registry. Note that the cluster name entered is case sensitive.

For example, to deploy UDDI on node 'MyNode' and server 'server1' on a Windows system, (assuming that server1 is already started):

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

To deploy UDDI into cluster 'MyCluster' on a Windows system:

```
wsadmin -f uddiDeploy.jacl MyCluster
```

You can also deploy the UDDI application (the uddi.ear file) using the administrative console, in the normal way. However, some steps that are performed automatically by the uddiDeploy.jacl script do not take place in this scenario. If you use the administrative console to install the UDDI application, you must perform some actions manually, according to the following steps:

1. Install the application.

2. Click **Applications** → **Enterprise Applications >** *uddi_application* **> [Detail Properties] Class loading and update detection**.

3. Ensure that **Class loader order** is set to **Classes loaded with application class loader first**.

4. Ensure that **WAR class loader policy** is set to **Single class loader for application**.

The UDDI application is deployed. If you see the following error message, check that you ran the uddiDeploy.jacl script using the deployment manager profile.

```
WASX7017E: Exception received while running file "uddiDeploy.jacl"; exception in
formation: com.ibm.ws.scripting.ScriptingException: WASX7070E: The configuration
 service is not available.
```

Continue with setting up the UDDI node.

Initializing the UDDI registry node:

Use this topic to initialize a UDDI registry node after set up or migration.

You must have already set up a UDDI registry node, either as a new node or to use for migrating a UDDI registry Version 2 node.

The UDDI registry node has various properties, some of which must be set before initializing the node. There are two categories of UDDI registry node properties:

- Mandatory node properties. These properties must be set before the UDDI node can be initialized. You may set these properties as many times as you wish before initialization. However, once the UDDI node has been initialized, these properties will become read only for the lifetime of that UDDI node. It is very important to set these properties correctly.

- All other properties. These properties may be set before, and after, initialization.

Configure these properties and initialize the node using the UDDI administrative console or JMX management interface.

1. Click **UDDI** → **UDDI Nodes** > *UDDI_node_id* to display the properties page for the UDDI registry node.
2. Set the mandatory node properties to suitable, and valid, values. These properties are indicated by the presence of a '*' next to the input field. The properties are listed below; more information on each property is given in the context help of the administrative console.

   UDDI node ID
   > This must be a text string beginning with 'uddi:' that is unique to this UDDI node. The default value may be sufficient, but if you accept it you should ensure that it is unique.

   UDDI node description
   > This is a text string describing the node.

   Root key generator
   > This must be a text string beginning with 'uddi:' that is unique to this UDDI node. The default value may be sufficient but may contain text, such as 'keyspace_id', that you should modify to match your system. If you accept the default value, ensure that it is unique for this UDDI node.

   Prefix for generated discoveryURLs
   > This should be a valid URL.

3. If you are migrating from Version 2 of the UDDI registry, use the table below to perform the following steps:
   - Set any properties from uddi.properties that **must** remain the same as Version 2.
   - Set any properties from uddi.properties that you would like to keep the same (such as dbMaxResultCount).

Version 2 UDDI property (set in uddi.property file)	Version 3 UDDI Property (set via Administrative Console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
dbMaxResultCount	maximum inquiry response set size	You might want to retain the value from Version 2, but can safely change this (or use the default)
persister	no equivalent	Not applicable
defaultLanguage	default language code	You are recommended to retain the value from Version 2
operatorName	UDDI node ID	You must use a valid value for the UDDI node ID. This will be applied to your Version 2 data as it is migrated.
maxSearchKeys	maximum search keys	You might want to retain the value from Version 2, but can safely change this (or use the default)
getServletURLprefix	Prefix for generated discoveryURLs	You should enter a valid value for your configuration, which should therefore be the same as the value used for Version 2.
getServletName	no equivalent	Not applicable

4. Set any other properties, such as policy values, that you wish to change from the default settings (or these can be changed at a later time). For an explanation of policies and properties see UDDI node settings.

5. Click **Apply** to save your changes.

   Important: You cannot change mandatory node properties after initialization. If you do not save your changes before proceeding to the initialize step, you will have to delete and recreate the database.

6. After saving your changes, initialize the UDDI node by clicking **Initialize**, at the top of the pane.

   If you are migrating from Version 2 of the UDDI registry, the Version 2 data is migrated now. The initialization may take some time to complete; to track its progress, return to the node collection page and click the refresh icon at the top of the **Status** column. Alternatively, open a second administrative console window, and use the refresh icon in the same manner. The UDDI node passes through the following states

   a. Initialization pending.
   b. Initialization in progress.
   c. Migration in progress. (This state will only occur if you are migrating.)
   d. Value set creation in progress.
   e. Activated.

If you have migrated the node from a previous version, return to Migrating to Version 3 of the UDDI registry to verify that the migration was successful. If you have created a new node, follow the instructions in "Using the UDDI registry Installation Verification Program (IVP)" to verify that you have successfully set up the UDDI node.

Using the UDDI registry Installation Verification Program (IVP)

This topic describes a simple test that you can carry out as an Installation Verification Program (IVP) to verify that you have deployed a UDDI registry successfully. You should perform this task *after* you have followed the instructions in Setting up and Deploying a new UDDI registry.

1. Open a browser window and enter the URL that accesses the UDDI registry User Interface (see "Displaying the UDDI registry user interface" on page 509).
2. Under the **Quick Find** heading on the **Find** tab, click the **Business** radio button and enter % in the **Starting with** field.
3. Click **Find**. If you have deployed your UDDI registry successfully, the detail frame displays the business entity which represents this UDDI node. You can click on the business entity to see its detail.

As a further installation verification test, you can publish and find more UDDI entities by using the UDDI registry User Interface, or you can compile and run one or more of the UDDI registry samples available through the UDDI registry link on the Samples for WebSphere Application Server page of the IBM developerWorks WebSphere Web site.

Changing the UDDI registry application environment after deployment

After you have deployed the UDDI registry application, you might want to change its environment. For example, you might perform initial evaluation of the UDDI registry using a Cloudscape database, and then want to put the UDDI registry into production using a DB2 database, or you might want to move from a standalone application server to a network deployment cell.

1. **Optional:** To incorporate a standalone application server into a network deployment cell, run the addNode command included with WebSphere Application Server. Use the includeapps parameter to ensure that the UDDI registry application, and any other applications on the server, are included in the move. See the addNode command for details.
2. **Optional:** To move from a default UDDI node to a customized UDDI node, delete the UDDI registry database and recreate it by completing one of the following tasks, ensuring that you do NOT use the default node options where specified:
   - "Creating a DB2 distributed database for the UDDI registry" on page 516
   - "Creating a DB2 for z/OS database for the UDDI registry" on page 518
   - "Creating a Cloudscape database for the UDDI registry" on page 519
   - "Creating an Oracle database for the UDDI registry" on page 520

   Note: Any data saved in the default node (policies, properties and user data) will be lost when you delete the database. If you do not want to delete the database, you can instead create an entirely new customized UDDI node in a separate application server. The default UDDI node will still exist for you to use for test purposes.
3. **Optional:** To change the database type for the UDDI registry, perform the following steps:
   a. Stop the UDDI registry application (click **Applications** → **Enterprise Applications**, select the relevant check box and click **Stop**).
   b. Either change the JNDI name of the existing datasource from datasources/uddids to another value, or delete the datasource. To display the datasource properties click **Resources** → **JDBC** → **JDBC providers >** *database_type* **JDBC Provider > [Additional Properties] Data sources >** *uddi_datasource*.
   c. Create the new database by referring to one of the following topics:
      - "Creating a DB2 distributed database for the UDDI registry" on page 516
      - "Creating a DB2 for z/OS database for the UDDI registry" on page 518
      - "Creating a Cloudscape database for the UDDI registry" on page 519
      - "Creating an Oracle database for the UDDI registry" on page 520
   d. To transfer your UDDI data, use the standard capabilities of the database products to export the data from the old database, and import it into the new one.
   e. Create the new datasource. See "Creating a data source for the UDDI registry" on page 521.
   f. Restart the UDDI registry application.
   g. Check that you can access your UDDI data, then delete the old database.

Web Services Invocation Framework (WSIF): Enabling Web services

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)).

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework includes an EJB provider for EJB invocation using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based Web service invocation you should instead invoke RMI-IIOP Web services using JAX-RPC.

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

To use WSIF, see the following topics:
- Learning about WSIF.
- Using WSIF to invoke Web services.
- WSIF system management and administration.
- WSIF API.

Learning about the Web Services Invocation Framework (WSIF)

The Web Services Invocation Framework (WSIF) is a WSDL-oriented Java API. You use this API to invoke Web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)).

Using WSIF, you can move away from the usual Web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

To learn about WSIF, see the following topics:
- "Goals of WSIF" on page 536.

For more information about working with WSIF, visit the Web sites listed in Web services: Resources for Learning.

Goals of WSIF

WSIF aims to extend the flexibility provided by SOAP services into a general model for invoking Web services, irrespective of the underlying binding or access protocols.

SOAP bindings for Web services are part of the WSDL specification, therefore when most developers think of using a Web service, they immediately think of assembling a SOAP message and sending it across the network to the service endpoint, using a SOAP client API. For example: using Apache SOAP the client creates and populates a Call object that encapsulates the service endpoint, the identification of the SOAP operation to invoke, the parameters to send, and so on.

While this process works for SOAP, it is limited in its use as a general model for invoking Web services for the following reasons:
- Web services are more than just SOAP services.
- Tying client code to a particular protocol implementation is restricting.
- Incorporating new bindings into client code is hard.
- Multiple bindings can be used in flexible ways.
- A freer Web services environment enables intermediaries.

The goals of the Web Services Invocation Framework (WSIF) are therefore:
- To give a binding-independent mechanism for Web service invocation.
- To free client code from the complexities of any particular protocol used to access a Web service.
- To enable dynamic selection between multiple bindings to a Web service.
- To help the development of Web service intermediaries.

WSIF - Web services are more than just SOAP services:

You can deploy as a Web service any application that has a WSDL-based description of its functional aspects and access protocols. If you are using the Java 2 platform, Enterprise Edition (J2EE) environment, then the application is available over multiple transports and protocols.

For example, you can take a database-stored procedure, expose it as a stateless session bean, then deploy it into a SOAP router as a SOAP service. At each stage, the fundamental service is the same. All that changes is the access mechanism: from Java DataBase Connectivity (JDBC) to Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and then to SOAP.

The WSDL specification defines a SOAP binding for Web services, but you can add binding extensions to the WSDL so that, for example, you can offer an enterprise bean as a Web service using RMI-IIOP as the access protocol. You can even treat a single Java class as a Web service, with in-thread Java method invocations as the access protocol. With this broader definition of a Web service, you need a binding-independent mechanism for service invocation.

WSIF - Tying client code to a particular protocol implementation is restricting:

If your client code is tightly bound to a client library for a particular protocol implementation, it can become hard to maintain.

For example, if you move from Apache SOAP to Java Message Service (JMS) or enterprise bean, the process can take a lot of time and effort. To avoid these problems, you need a protocol implementation-independent mechanism for service invocation.

WSIF - Incorporating new bindings into client code is hard:

If you want to make an application that uses a custom protocol work as a Web service, you can add extensibility elements to WSDL to define the new bindings. But in practice, achieving this capability is hard.

For example you have to design the client APIs to use this protocol. If your application uses just the abstract interface of the Web service, you have to write tools to generate the stubs that enable an abstraction layer. These tasks can take a lot of time and effort. What you need is a service invocation mechanism that allows you to update existing bindings, and to add new bindings.

WSIF - Multiple bindings can be used in flexible ways:

To take advantage of Web services that offer multiple bindings, you need a service invocation mechanism that can switch between the available service bindings at run time, without having to generate or recompile a stub.

Imagine that you have successfully deployed an application that uses a Web service which offers multiple bindings. For example, imagine that you have a SOAP binding for the service and a local Java binding that lets you treat the local service implementation (a Java class) as a Web service.

The local Java binding for the service can only be used if the client is deployed in the same environment as the service. In this case, it is more efficient to communicate with the service by making direct Java calls than by using the SOAP binding.

If your clients could switch the actual binding used based on run-time information, they could choose the most efficient available binding for each situation.

WSIF - Enabling a freer Web services environment promotes intermediaries:

Web services offer application integrators a loosely-coupled paradigm. In such environments, intermediaries can be very powerful.

Intermediaries are applications that intercept the messages that flow between a service requester and a target Web service, and perform some mediating task (for example logging, high-availability or transformation) before passing on the message. The Web Services Invocation Framework (WSIF) is designed to make building intermediaries both possible and simple. Using WSIF, intermediaries can add value to the service invocation without needing transport-specific programming.

WSIF: Overview

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked. This framework addresses all of the issues identified in "The goals of WSIF".

WSIF provides the following features:
*   An API that provides binding-independent access to any Web service.
*   A close relationship with WSDL, so it can invoke any service that you can describe in WSDL.
*   A stubless and completely dynamic invocation of a Web service.
*   The capability to plug a new or updated implementation of a binding into WSIF at run time.
*   The option to defer the choice of a binding until run time.

WSIF is designed to work both in an unmanaged environment (stand-alone) and inside a managed container. You can use the Java Naming and Directory Interface (JNDI) to find the WSIF service, or you can use the location described in the WSDL.

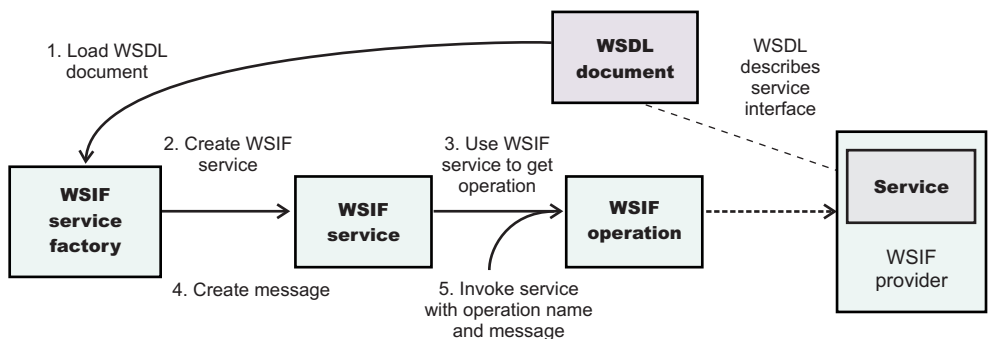
For more conceptual information about WSIF and WSDL, see the following topics:
*   WSIF and WSDL
*   WSIF architecture

- WSIF and Web services that offer multiple bindings
- WSIF usage scenarios
- Dynamic invocation

WSIF supports Internet Protocol Version 6, and Java API for XML-based Remote Procedure Calls (JAX-RPC) Version 1.1 for SOAP.

WSIF architecture:

A diagram depicting the Web Services Invocation Framework (WSIF) architecture, and a description of each of the major components of the architecture.

The Web Services Invocation Framework (WSIF) architecture is shown in the figure.


The components of this architecture include:

WSDL document

The Web service WSDL document contains the location of the Web service. The binding document defines the protocol and format for operations and messages defined by a particular portType.

WSIF service

The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation. For more information, see Finding a port factory or service

WSIF operation

The run-time representation of an operation, called *WSIFOperation* is responsible for invoking a service based on a particular binding. For more information, see WSIF API reference: Using ports.

WSIF provider

A WSIF provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol. WSIF includes SOAP providers, JMS providers, Java providers and EJB providers. For more information, see Linking a WSIF service to the underlying implementation of the service.

WSIF and Web services that offer multiple bindings:

Using WSIF, a client application can choose dynamically the optimal binding to use for invoking Web service operations.

For example, a Web service might offer a SOAP binding, and also a local Java binding so that you can treat the local service implementation (a Java class) as a Web service. If a client application is deployed in the same environment as the service, then this client can use the local Java binding for the service. This provides more efficient communication between the client and the service by making direct Java calls rather than indirect calls using the SOAP binding.

For more information about how to configure a client to dynamically select between multiple bindings, see Developing a WSIF service.

WSIF and WSDL:

There is a close relationship between the metadata-based Web Services Invocation Framework (WSIF) and the evolving semantics of Web Services Description Language (WSDL).

In WSDL, a service is defined in three distinct sections:
* The **portType**. This section defines the abstract interface offered by the service. A portType defines a set of *operations*. Each operation can be In-Out (request-response), In-Only, Out-Only and Out-In (Solicit-Response). Each operation defines the input and/or output *messages*. A message is defined as a set of *parts*, and each part has a schema-defined type.
* The **binding**. This section defines how to map between the abstract portType and a real service format and protocol. For example the SOAP binding defines the encoding style, the SOAPAction header, the namespace of the body (the targetURI), and so on.
* The **port**. This section defines the actual location (endpoint) of the available service. For example, the HTTP Web address at which a SOAP service is available.

Currently in WSDL, each port has one and only one binding, and each binding has a single portType. But (more importantly) each service (portType) can have multiple ports, each of which represents an alternative location and binding for accessing that service.

The Web Services Invocation Framework (WSIF) follows the semantics of WSDL as much as possible:
* The WSIF dynamic invocation API directly exposes run-time equivalents of the model from WSDL. For example, invocation of an operation involves executing an operation with an input message.
* WSDL has extension points that support the addition of new ports and bindings. This enables WSDL to describe new systems. The equivalent concept in WSIF is a provider, that enables WSIF to understand a class of extensions and thereby to support a new service implementation type.

As a metadata-based invocation framework, WSIF follows the design of the metadata. As WSDL is extended, WSIF is updated to follow.

The implicit and primary type system of WSIF is XML schema. WSIF supports invocation using dynamic proxies, which in turn support Java type systems, but when you use the WSIFMessage interface it is your responsibility to populate WSIFMessage objects with data based on the XML schema types as defined in the WSDL document. You should define your object types by a canonical and fixed mapping from schema types into the run-time environment.

For more information about WSDL, see Web services: Resources for learning.

WSIF usage scenarios:

This topic describes two brief scenarios that illustrate the role WSIF plays in the emerging Web services environment.

Scenario: Redevelopment and redeployment

When you first implement a Web service, you create a simple prototype. When you want to move a prototype Web service into production, you often need to redevelop and redeploy it.

The Web Services Invocation Framework (WSIF) uses the same API calls irrespective of the underlying technologies, therefore if you use WSIF:
* You can reimplement and redeploy your services without changing the client code.

- You can use existing reliable and high-performance infrastructures like Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) and Java Message Service (JMS) without sacrificing the location-independence that the Web service model offers.

Scenario: Service Flow composition

A service flow typically invokes a Web service, then passes the response from one Web service to the next Web service, perhaps performing some transformation in the middle.

There are two key aspects to this flow that WSIF provides:
- A representation of the service invocation based on the metadata in WSDL.
- The ability to build invocations based solely on the portType, which can therefore be used in any implementation.

For example, imagine that you build a meta-service that uses a number of services to build a process. Initially, several of those services are simple Java bean prototypes that are written and exposed through SOAP, but you plan to reimplement some of them as EJB components, and to out-source others.

If you use SOAP, it ties up multiple threads for every onward invocation, because they pass through the Web server and servlet engine and on to the SOAP router. If you use WSIF to call the beans directly, you get much better performance compared to SOAP and you do not lose access or location transparency. Using WSIF, you can replace the Java bean implementations with EJB implementations without changing the client code. To move some of the Web services from local implementations to external SOAP services, you just update the WSDL.

Dynamic invocation:

The Web Services Invocation Framework (WSIF) can provide runtime support for Web services, and for WSDL extensions and bindings, that were not known at build time.

WSIF supports WSDL extensions and bindings that were not known at build time through the use of providers. The providers support Web services that were not known at build time by using the WSDL description to access the target service.

Using WSIF to invoke Web services

You invoke a Web service dynamically by using the WSIF API directly.

You only specify the location of the WSDL file for the service, the name of the operation to invoke, and any operation arguments. All the information needed to access the Web service (the abstract interface, the binding, and the service endpoint) is available through the WSDL.

This kind of invocation does not require stub classes and does not need a separate compilation cycle.

More information on using the Web Services Invocation Framework (WSIF) to invoke Web services is provided in the following topics:
- Linking a WSIF service to the underlying implementation of the service.
- Developing a WSIF service.
- Using complex types.
- Using WSIF to bind a JNDI reference to a Web service .
- Passing SOAP messages with attachments using WSIF.
- Interacting with the J2EE container in WebSphere Application Server.
- Running WSIF as a client.

Linking a WSIF service to the underlying implementation of the service

A Web Services Invocation Framework (WSIF) service is linked to the underlying service through a WSIF provider. A provider is an implementation of a WSDL binding that can run a WSDL operation through a binding-specific protocol. Providers implement the interface between the WSIF API and the actual implementation of a service.

Providers are pluggable within the WSIF framework, and are registered according to the namespace of the WSDL extension that they implement. Some providers use the Java 2 platform, Enterprise Edition (J2EE) programming model to utilize J2EE services. If a provider is available, but its required class libraries are not, then the provider is disabled.

To use the providers that are supplied with WebSphere Application Server, see the following topics:
- Linking a WSIF service to a SOAP over HTTP service.
- Linking a WSIF service to a JMS-provided service (SOAP over JMS, and native JMS).
- Linking a WSIF service to a local Java application.
- Linking a WSIF service to a service implemented as an enterprise bean.

Linking a WSIF service to a SOAP over HTTP service:

The SOAP provider allows WSIF stubs and dynamic clients to invoke SOAP services.

The Web Services Invocation Framework (WSIF) SOAP provider supports SOAP 1.1 over HTTP.

The SOAP provider is JSR 101/109 compliant and uses Web Services for J2EE for parsing and creating SOAP messages.

Note: The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This restriction is due to the fact that the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service. For more information see WSIF SOAP provider: working with legacy applications.

The SOAP provider supports:
- SOAP-ENC encoding.
- RPC style and Document style SOAP messages.
- SOAP messages with attachments.

The SOAP provider is not transactional.

The SOAP provider does not support the WSIF synchronous timeout. The SOAP provider uses the default client timeout value that is set for Web Services for J2EE.

If you have a Web service that you expect multiple clients to use connecting over SOAP, then before you deploy the service you must set up your application deployment descriptor file `dds.xml` to handle multiple connections correctly. For more information, see WSIF troubleshooting tips.

For an example of the sort of code changes that need to be made in the WSDL file for a SOAP provider, see the following topics:
- The SOAP over JMS provider - writing the WSDL extension.
- SOAP messages with attachments - Writing the WSDL extensions.

WSIF SOAP provider: working with legacy applications:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are designed to run on the former (Apache SOAP) provider. This is due to the fact that

the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant Web service, and Apache SOAP cannot provide such a service.

As a result of this change in SOAP providers, previous WSIF clients might not work in either of the following cases:

1. The Web service uses any of the following parameter types: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName` (for more information, see the **Type Mappings** section of WSIF - Known restrictions).
2. The Web service was built upon the former (Apache SOAP) provider.

To get your legacy services working again, you have two options:

- Change the default WSIF SOAP provider back to the former Apache SOAP provider (in which case any future invocations to a JAX-RPC compliant Web service will not work if that Web service uses parameter types `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`).
- Modify your services to use the current IBM Web Service SOAP provider.

Changing the default WSIF SOAP provider:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant Web service, and therefore the current default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your legacy services working again, you can either modify your Web services to use the current IBM Web Service SOAP provider, or you can change the WSIF default provider back to Apache SOAP as described in this topic.

WSIF uses a properties file named wsif.properties to choose what SOAP provider to use. The SOAP provider is a node-wide setting, so all servers on the node must be restarted for any changes to take effect. The wsif.properties file is shipped in the `com.ibm.ws.runtime_6.1.0.jar` file that is located in the *app_server_root*/plugins directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server), and the "as shipped" properties file is accessed in this location by being put on the class path. However when you make changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime_6.1.0.jar` file. Instead, you save the modified version in the *app_server_root*/lib/properties directory.

To change the WSIF default SOAP provider back to Apache SOAP, complete the following steps:

1. Extract the `wsif.properties` file from the `com.ibm.ws.runtime_6.1.0.jar` file that is located in the *app_server_root*/plugins directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server).
2. Open the `wsif.properties` file in a text editor.
3. Remove the leading "#" character from the following lines:

```
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#
```

   After the update, the preceding lines should look like this:

```
wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
http://schemas.xmlsoap.org/wsdl/soap/
#
```

4. Save the updated `wsif.properties` file in the *app_server_root*/lib/properties directory.
5. Stop then restart all application servers on the node.

Modifying Web services to use the IBM Web Service SOAP provider:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant Web service, and therefore the current default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your legacy services working again, you can either modify your Web services to use the current IBM Web Service SOAP provider as described in this topic, or you can change the WSIF default provider back to Apache SOAP.

To modify a legacy Web service, use the assembly tool to complete the following steps and thereby generate new deployment artifacts for access to the service from the IBM Web Service provider:

1. Import into the Workspace the project that contains your legacy Web services.
2. For every legacy SOAP service in the project, repeat the following steps :
   a. From the pop-up menu for *your_service*.wsdl, select **Generate Deploy Code**.
   b. In the Generate Deploy Code window, change the **Inbound Binding Type** from SOAP to IBM Web Service.
   c. Click **Finish**.
3. Export the EAR file that contains all of the deployment artifacts for the IBM Web Service Web service.

Linking a WSIF service to a JMS-provided service:

The JMS providers enable a WSIF service to be invoked through JMS.

The Java Message Service (JMS) is an API for transport technology. The mapping to a JMS destination is defined during deployment and maintained by the container.

The JMS destination endpoint for a Web service can be realized in any of the following ways:
• The JMS destination for the queue can be the Web service implementation.
• The JMS destination can be (but is not required to be) associated with a message-driven bean by the EJB container, thereby allowing the message-driven bean to be the Web service implementation.
• (For SOAP over JMS) The JMS destination can unwrap the JMS message and route the SOAP message to a Web service that is implemented as a stateless session bean.

The JMS destination endpoint must respect the interaction model expected by the client and defined by the WSDL. It must return a response if one is required.

When the JMS destination endpoint creates the JMS response message the following rules must be followed:
• The response message must be sent to JMSReplyTo from the incoming request.
• The JMSCorrelationID value of the response message must be set to the JMSMessageID value from the request message.
• The response must be sent with a deliveryMode value equal to the JMSDeliveryMode value of the request message.
• The response must be sent with a priority value equal to the JMSPriority value of the request message.
• The TimeToLive/JMSExpiration value must be set to a value that equals the JMSExpiration value of the request message.

The client does not see any of these headers. The container receives the JMS message and (for SOAP over JMS) removes the SOAP message to send to the client.

See also the following topics:
• Linking a WSIF service to a SOAP over JMS service
• Linking a WSIF service to a service provided at a JMS destination
• The JMS providers - Configuring the client and server

Linking a WSIF service to a SOAP over JMS service:

If a SOAP message contains only XML, it can be carried on the Java Message Service (JMS) transport mechanism. Here are links to a set of topics that explain how a WSIF service can access a SOAP service that uses the JMS transport.

For information about working with the Java Message Service (JMS) API, see Linking a WSIF service to a JMS-provided service.

The SOAP message, including the SOAP envelope, is wrapped with a JMS message and put on the appropriate queue. The container receives the JMS message and removes the SOAP message to send to the client.

For detailed implementation information, see the following topics:
* The SOAP over JMS provider - writing the WSDL extension.
* The JMS providers - Configuring the client and server.

The SOAP over JMS provider - Writing the WSDL extension:

Here is detailed information, and associated code fragments, to help you to write the WSDL extension that enables your WSIF service to access a SOAP service that use the Java Message Service (JMS) as its transport mechanism.

If a SOAP message contains only XML, then it can be carried on the JMS transport with the JMS message body type **TextMessage**.

The WSDL binding extension for SOAP over JMS varies only slightly from the SOAP over HTTP binding.
* **Selecting the SOAP over JMS binding.**

  You set the `transport` attribute of the `<soap:binding>` tag to indicate that JMS is used. If you also set the `style` attribute to `rpc` (Remote Procedure Call), then the Web Services Invocation Framework (WSIF) assumes that an operation is invoked on the Web service endpoint:

```
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/jms"/>
```
* **Setting the JMS address.**

  Note: See also the alternative method for specifying the JMS address that is given in the final section of this topic.

  For SOAP over JMS, the `<wsdl:port>` tag must contain a `<jms:address>` element. This element provides the information required for a client to connect correctly to the Web service using the JMS programming model. Typically, it is the stubs generated to support the SOAP over JMS binding that act as the JMS client. Alternatively, the Web service client can use the JMS programming model directly.

  The `<jms:address>` element takes this form:

```
<jms:address

   destinationStyle="queue"
   jmsVendorURI="http://ibm.com/ns/mqseries"?
   initialContextFactory="com.ibm.NamingFactory"?
   jndiProviderURL="iiop://something:900/wherever"?
   jndiConnectionFactoryName="orange"
   jndiDestinationName="fred">

   <jms:propertyValue name="targetService" type="xsd:string"
                      value="StockQuoteServicePort"/>

</jms:address>
```

  where attributes marked with a question mark (?) are optional.

The optional `jmsVendorURI` attribute is a string that uniquely identifies the JMS implementation. WSIF ignores this URI, which is used by the client developer and perhaps the client implementation to determine if it has access to the correct JMS provider in the client run-time environment.

The optional attributes `initialContextFactory` and `jndiProviderURL` can only be omitted if the run-time environment has a default Java Naming and Directory Interface (JNDI) provider configured.

The `jndiConnectionFactoryName` attribute gives the name of a JMS `ConnectionFactory` object, which can be looked up within the JNDI context given by the `jndiContext` attribute. This `ConnectionFactory` object is used to create a JMS connection to the JMS provider instance that owns the queue. In a simple configuration, the same `ConnectionFactory` object is used by the server message listener and by the clients. However the server and the clients can use different `ConnectionFactory` objects, provided that they all create connections to the same JMS provider instance.

The `value` attribute of the `targetService` `<jms:propertyValue>` element is the name of the port component for the target service as defined in the `<port-component-name>` element of the `webservices.xml` file for the target service.

- **Setting the JMS headers and properties.**

  You use the `<jms:property>` tag to set the JMS headers and properties. This tag maps either a message part, or a literal value, into a JMS property:

```
<jms:property name="Priority" {part="requestPriority" | value="fixedValue"}/>
```

  If the `<jms:property>` has a literal value, then it can also be nested within the `<jms:address>` tag:

```
<jms:property name="Priority" value="fixedValue" />
```

  This form of the `<jms:property>` tag is also used in the native JMS binding.

Here is an example of a WSDL that defines a SOAP over JMS binding:

```
<!-- Example: SOAP over JMS Text Message -->

<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
        name="StockQuoteInterfaceDefinitions"
        targetNamespace="urn:StockQuoteInterface"
        xmlns:tns="urn:StockQuoteInterface"
        xmlns:xsd="http://www.w3.org/2000/10/XMLSchema"
        xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
        xmlns:jms="http://schemas.xmlsoap.org/wsdl/jms/"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
    <wsdl:message name="GetQuoteInput">
        <part name="symbol" type="xsd:string"/>
    </wsdl:message>
    <wsdl:message name="GetQuoteOutput">
        <part name="value" type="xsd:float"/>
    </wsdl:message>

    <wsdl:portType name="StockQuoteInterface">
        <wsdl:operation name="GetQuote">
            <wsdl:input message="tns:GetQuoteInput"/>
            <wsdl:output message="tns:GetQuoteOutput"/>
        </wsdl:operation>
    </wsdl:portType>

    <wsdl:binding name="StockQuoteSoapJMSBinding" type="tns:StockQuoteInterface">
        <soap:binding style="rpc"
                transport="http://schemas.xmlsoap.org/soap/jms"/>
        <wsdl:operation name="GetQuote">
            <soap:operation soapAction="urn:StockQuoteInterface#GetQuote"/>
            <wsdl:input>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                        encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
            </wsdl:input>
            <wsdl:output>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                        encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
```

```
            </wsdl:output>
        </wsdl:operation>
    </wsdl:binding>
    <wsdl:service name="StockQuoteService">
        <wsdl:port name="StockQuoteServicePort"
                    binding="sqi:StockQuoteSoapJMSBinding">
            <jms:address destinationStyle="queue"
                    jndiConnectionFactoryName="myQCF"
                    jndiDestinationName="myQ"
                    initialContextFactory="com.ibm.NamingFactory"
                    jndiProviderURL="iiop://something:900/">

                    <jms:propertyValue name="targetService"
                                        type="xsd:string"
                                        value="StockQuoteServicePort"/>

            </jms:address>

        </wsdl:port>
    </wsdl:service>
</wsdl:definitions>
```

Setting the JMS address (alternative method).

For the SOAP over JMS provider you can instead specify the JMS address using the <soap:address> tag in the following format:

`jms:/[queue|topic]?<property>=<value>&<property>=<value>&...`

Where the specification of *queue* or *topic* corresponds to the JMS address `destinationStyle` attribute.

The following table lists the valid properties for use with the <soap:address> tag:

Property name	Property description	Corresponding JMS address value
destination	The JNDI name of the destination queue or topic	jndiDestinationName
connectionFactory	The JNDI name of the connection factory.	jndiConnectionFactory
targetService	The name of the port component of the target service	targetService jms:propertyValue within jms:address
JNDI-related properties (optional):		
initialContextFactory	The name of the initial context factory.	initialContextFactory
jndiProviderURL	The JNDI provider URL	jndiProviderURL
JMS-related properties (optional):		
deliveryMode	An indication as to whether the request message should be persistent or not. The valid values are DeliveryMode.NON_PERSISTENT (default) and DeliveryMode.PERSISTENT	JMSDeliveryMode
password	The password to be used to gain access to the connection factory.	JMSPassword
priority	The JMS priority associated with the request message. Valid values are 0 to 9. The default value is 4.	JMSDeliveryMode
replyTo	The JNDI destination queue to which reply messages should be sent.	JMSReplyTo

Property name	Property description	Corresponding JMS address value
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.	JMSTimeToLive
userid	The userid to be used to gain access to the connection factory.	JMSUserid

Here is an example of this format:

<jms:address> format:

```
<wsdl:port name="StockQuoteServicePort"

        binding="sqi:StockQuoteSoapJMSBinding">

    <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myQ"
        initialContextFactory="com.ibm.NamingFactory"
        jndiProviderURL="iiop://something:900/">

        <jms:propertyValue name="targetService"
                           type="xsd:string"
                           value="StockQuoteServicePort"/>

    </jms:address>

</wsdl:port>
```

<soap:address> format:

```
<wsdl:port name="StockQuoteServicePort"
        binding="sqi:StockQuoteSoapJMSBinding">
    <soap:address location="jms:/queue?connectionFactory=myQCF&destination
=myQ&initialContextFactory=com.ibm.NamingFactory&jndiProviderURL
=iiop://something:900/&targetService=StockQuoteServicePort" />

</wsdl:port>
```

Linking a WSIF service to a service provided at a JMS destination:

Using the native JMS provider, WSIF clients can treat a service that is available at a JMS destination as a Web service.

For information about working with the Java Message Service (JMS) API, see Linking a WSIF service to a JMS-provided service.

For detailed implementation information, see the following topics:
- The native JMS provider - Writing the WSDL extension
- The JMS providers - Configuring the client and server

The native JMS provider - Writing the WSDL extensions:

Here is detailed information, and associated code fragments, to help you to write the WSDL extensions that enable your WSIF service to access an underlying service at a Java Message Service (JMS) destination.

The WSDL extensions for JMS are identified with the namespace prefix `jms`. For example, `<jms:binding>`.

Operations

The supported operations are either one-way operations (`send` for JMS point-to-point messaging, or `publish` for JMS publish and subscribe messaging) or request-response operations (`send` and `receive` for JMS point-to-point messaging). The WSDL operations therefore specify either an input message only, or an input and an output message.

Fault messages

Operations that describe message interfaces with a native JMS binding do not have fault messages. No assumptions are made about the message schema or the semantics of message properties, therefore no distinction can be made between output and fault messages.

Setting the JMS message body type

You use the `<jms:binding>` extension to specify the JMS message body type:

```
<wsdl:binding ... >
   <jms:binding type="messageBodyType" />
   ...
</wsdl:binding>
```

where *messageBodyType* is either `ObjectMessage` or `TextMessage`.

Specifying the parts to use for the input and output messages

For JMS text messages and JMS object messages created from one or more WSDL message parts, you use the `<jms:input>` and `<jms:output>` extensions to specify the message parts to use for the JMS messages:

```
<wsdl:input ... >
   <jms:input parts="part1 part2 ..." />
</wsdl:input>

<wsdl:output ... >
   <jms:output parts="part1 part2 ..." />
</wsdl:output>
```

In the next example, the WSDL message has just one part that contains the complete message body. This message body might result from a mapping of some other representation (see **Mapping data types**).

```
<wsdl:input ... >
   <jms:input parts="part1" />
</wsdl:input>
```

If no parts are defined, then all the message parts are used.

Mapping data types

You use the `<format>` extensions to map data types:

```
<wsdl:binding ... >
   <jms:binding type="..." />

   <format:typeMapping encoding="Java" style="Java">
     <format:typeMap typeName="..." formatType="targetType"/>
   </format:typemapping>
   ...
</wsdl:binding>
```

The value of *targetType* is dependent on the JMS message body type (see **Setting the JMS message body type**). For JMS object messages, the target data type implements the java.io.Serializable class. For JMS text messages, the target data type is always java.lang.String.

The `<format>` extensions are also used in other bindings that deal with Java interfaces.

Setting the JMS headers and properties

JMS does not make assumptions about message headers. For example, if the JMS provider is MQSeries then each JMS message carries an RFH2 header. However you can access data in this message header indirectly, by getting and setting JMS message properties.

When you want your application to pass a property into the Web Services Invocation Framework (WSIF) as a part on the WSIF message, you use a `<jms:property>` tag. When you want to hard code an actual property value into the WSDL, you use a `<jms:propertyValue>` tag. The `<jms:propertyValue>` tag contains a specification of a literal value and its associated XML schema type.

You can specify `<jms:property>` and `<jms:propertyValue>` extensions within the `<wsdl:input>` tag in the binding operation, and also within the `<jms:address>` tag. For the `<wsdl:output>` tag in the binding operation, you can only specify the `<jms:property>` extension. Property values that are set in the `<jms:property>` tag take precedence over values set in the `<<jms:propertyValue>` tag, and property values that are set in the binding operation (in the `<input>` and `<output>` tags) take precedence over values set in the `<jms:address>` tag.

Here is an example of the `<jms:property>` and `<jms:propertyValue>` tags nested within the `<input>` and `<output>` tags:

```
<wsdl:input ... >

    <jms:property name="propertyName" part="partName" />

    <jms:propertyValue name="propertyName"
                type="xsdType" value="actualValue" />

</wsdl:input>

<wsdl:output ... >

    <jms:property name="propertyName" part="partName" />

</wsdl:output>
```

where *propertyName* identifies the JMS property that is associated with the header field, and *partName* identifies the message part that is associated with the property.

The JMS property identified by *propertyName* can be user-defined, or it can be one of the following predefined JMS message header fields:

Value	Java type
JMSMessageId	java.lang.String
JMSTimeStamp	long
JMSCorrelationId	byte [ ] or java.lang.String
JMSReplyTo	javax.jms.Destination
JMSDestination	javax.jms.Destination
JMSDeliveryMode	int
JMSRedelivered	boolean
JMSType	java.lang.String
JMSExpiration	long
JMSTimeToLive	long

See the JMS specification for restrictions that apply when setting JMS header field values. Attempts to set restricted values are ignored.

For application-defined JMS message properties, the Java types used in the native JMS binding implementation (used for calls to the corresponding JMS methods) are derived from the XML schema type in the abstract interface (`<wsdl:part>` tag), and from the type mapping information in the format binding (`<format:typemap>` tag).

Handling transactions

Independent of other JMS properties, the asynchronous processing of request-response operations has implications for callers running in a transaction scope. The send request part and the receive response part are separated into two transactions, because the send needs to be committed in order for the request message to become visible. Implementations that process WSDL for asynchronous request-response operations (such as WSIF) must therefore take the following additional actions:

- They must ensure that the send request transaction returns a correlation ID to the user, and provides a **callback** with which users can pass in the response message to process the receive response transaction.
- They might implement their own response message "listener" in order to recognize the arrival of response messages, and to manage the correlation to the request message.

Example 1: JMS Text Message

The JMS text message contains a **java.lang.String**. In this example, the WSDL message contains only one part that represents the whole message body:

```
<wsdl:definitions ... >

  <!-- simple or complex types for input and output message -->
  <wsdl:types> ... </wsdl:types>

  <wsdl:message name="JmsOperationRequest"> ... </wsdl:message>
  <wsdl:message name="JmsOperationResponse"> ... </wsdl:message>

  <wsdl:portType name="JmsPortType">
     <wsdl:operation name="JmsOperation">
        <wsdl:input name="Request"
                   message="tns:JmsOperationRequest"/>
        <wsdl:output name="Response"
                    message="tns:JmsOperationResponse"/>
     </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="JmsBinding" type="JmsPortType">
     <jms:binding type="TextMessage" />

     <format:typemapping style="Java" encoding="Java">
        <format:typemap name="xsd:String" formatType="String" />
     </format:typemapping>

     <wsdl:operation name="JmsOperation">
        <wsdl:input message="JmsOperationRequest">
           <jms:input parts="requestMessageBody" />
        </wsdl:input>
        <wsdl:output message="JmsOperationResponse">
           <jms:output parts="responseMessageBody" />
        </wsdl:output>
     </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="JmsService">
     <wsdl:port name="JmsPort" binding="JmsBinding">
        <jms:address destinationStyle="queue"
                    jndiConnectionFactoryName="myQCF"
                    jndiDestinationName="myDestination"/>
```

```
        </wsdl:port>
    </wsdl:service>

</wsdl:definitions>
```

As an extension to the previous JMS message example, the following example WSDL describes a request-response operation in which specific JMS property values of the request and response message are set for the request message and retrieved from the response message.

The JMS properties in the request message are set according to the values in the input message. Likewise, selected JMS properties of the response message are copied to the corresponding values of the output message. The direction of the mapping is determined by the appearance of the `<jms:property>` tag in the input or output section, respectively.

Example 2: JMS Message with JMS Properties

```
<wsdl:definitions ... >

   <!-- simple or complex types for input and output message -->
   <wsdl:types> ... </wsdl:types>

   <wsdl:message name="JmsOperationRequest">
      <wsdl:part name="myInt" type="xsd:int"/>
      ...
   </wsdl:message>

   <wsdl:message name="JmsOperationResponse">
      <wsdl:part name="myString" type="xsd:String"/>
      ...
   </wsdl:message>

   <wsdl:portType name="JmsPortType">
      <wsdl:operation name="JmsOperation">
         <wsdl:input name="Request"
                     message="tns:JmsOperationRequest"/>
         <wsdl:output name="Response"
                      message="tns:JmsOperationResponse"/>
      </wsdl:operation>
   </wsdl:portType>

   <wsdl:binding name="JmsBinding" type="JmsPortType">
      <!-- the JMS message type may be any of the above -->
      <jms:binding type="..." />

      <format:typemapping style="Java" encoding="Java">
         <format:typemap name="xsd:int" formatType="int" />
         ...
      </format:typemapping>

      <wsdl:operation name="JmsOperation">
         <wsdl:input message="JmsOperationRequest">
            <jms:property message="tns:JmsOperationRequest" parts="myInt" />
            <jms:propertyValue name="myLiteralString"
                        type="xsd:string" value="Hello World" />
            ...
         </wsdl:input>
         <wsdl:output message="JmsOperationResponse">
            <jms:property message="tns:JmsOperationResponse" parts="myString" />
            ...
         </wsdl:output>
      </wsdl:operation>
   </wsdl:binding>

   <wsdl:service name="JmsService">
      <wsdl:port name="JmsPort" binding="JmsBinding">
         <jms:address destinationStyle="queue"
```

```
                        jndiConnectionFactoryName="myQCF"
                        jndiDestinationName="myDestination"/>
    </wsdl:port>
   </wsdl:service>

</wsdl:definitions>
```

The JMS providers - Configuring the client and server:

Here is a description of the ways in which the Web Services Invocation Framework (WSIF) interacts with the Java Message Service (JMS), and of the steps you need to take to enable a service to be invoked through JMS by a WSIF client application.

This topic assumes that you installed a JMS provider when you installed WebSphere Application Server (either the JMS provider that is embedded in WebSphere Application Server, or another provider such as WebSphere MQ). If not, install one now as described in Installing and configuring a JMS provider.

Here are the ways in which the Web Services Invocation Framework (WSIF) interacts with JMS:
*   Only input JMS properties are supported.
*   WSIF needs two queues when invoking an operation: one for the request message and one for the reply. The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the JMSReplyTo property to the JNDI name of a queue.
*   WSIF uses the default values for properties set by the JMS implementation. However in MQSeries and in some other JMS implementations, messages are persistent by default, and the default temporary queue is of type *temporary dynamic* and cannot have persistent messages written to it. Therefore your JMS listener can fail to write a persistent response message to the temporary replyTo queue.

   Note:
       – If you are using MQSeries, you need to create a temporary model queue that is of type *permanent dynamic*, then pass this model as the *tempmodel* of your queue connection factory. This will ensure that persistent messages are written to a temporary replyTo queue that is of type *permanent dynamic*.
       – If your client is running on an application server that is migrated from WebSphere Application Server Version 5 to Version 6, you might get basic authentication errors and therefore need to modify your security settings. For more information see Tips for troubleshooting the Web Services Invocation Framework.

To enable a service to be invoked through JMS by a WSIF client application, complete the following steps:
1. Use the administrative console to create and configure a queue connection factory and a queue destination.

    This task is described in Configuring resources for the default messaging provider or Configuring JMS resources for a generic messaging provider.
2. Use the administrative console to add the new queue destination to the list of JMS Server destination names for your application server. Ensure that the Initial State is started.
3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the WSDL file.

JMS message header: The TimeToLive property reference:

The range of permitted values for the TimeToLive property of a JMS message that WSIF puts onto a queue.

The JMS message header property `JMSTimeToLive` is of type `long`. It sets the time to live of a message put onto a queue, in milliseconds. A value of `0` means live indefinitely.

The factors that determine the time to live of a JMS message are as follows:

- For a one-way (input only) operation, the default time to live is `0`, so the message remains on the queue indefinitely or until the server end-processes the message. If the `JMSTimeToLive` property is specified in the service endpoint URL or the JMS Address, then this value is used for one-way messages. The client never waits for a response to a one-way operation and so it never times out. The only time a client for a one-way operation will fail is if the queue itself is unavailable.

- For a two-way (request and response) operation, the default time to live is determined by the client response timeout setting. The time to live for the message is never greater than the client response timeout, even if a larger value is specified in the `JMSTimeToLive` property of the service endpoint URL or the JMS Address, so the message will never be read from the queue after the client has timed out waiting for a response. The client response timeout setting that is used as the default time to live is the WSIF synchronous timeout. This is the case even for an asynchronous JMS message.

Linking a WSIF service to a local Java application:

Using the WSIF Java provider, WSIF can invoke Java code.

This means that, in a thin-client environment such as a Java virtual machine (JVM) or Tomcat test run-time environment, you can define shortcuts to local Java programs.

The Web Services Invocation Framework (WSIF) Java provider is not intended for use in a Java 2 platform, Enterprise Edition (J2EE) environment. There is a difference between a client using the WSIF Java provider to invoke a Java component, and implementing a Web service as a Java component on the server side.

The Java binding exploits the format binding for type mapping. Using the format binding, your WSDL can define the mapping between XML schema types and Java types.

The Java provider requires that the targeted Java classes reside in the class path of the client. The Java method is invoked synchronously, in-process, in-thread, with the current thread and Object Request Broker (ORB) contexts.

The Java provider is not transactional.

The Java provider does not support the WSIF synchronous timeout. The Java provider will not time out waiting for a Java method to complete.

For examples of the code changes that need to be made in the WSDL file, see The Java provider - Writing the WSDL extension.

The Java provider - Writing the WSDL extension:

The Java provider supports the invocation of a method on a local Java object.

To use the Java provider, you need the following binding specified in the WSDL:

```
<!-- Java binding -->
<binding .... >
    <java:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
    <operation>*
        <java:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            methodType="instance|constructor" />
```

```
            <input name="nmtoken"? />?
            <output name="nmtoken"? />?
            <fault name="nmtoken"? />?
        </operation>
    </binding>
```

In this example:
- A question mark (?) means optional, and an asterisk (*) means 0 or more.
- The `name` attribute of the `<format:typeMap>` element is a qualified name of a simple or complex type used by one of the Java operations.
- The `formatType` attribute of the `<format:typeMap>` element is the fully qualified class name for the Java class to which the element specified by `name` maps.
- The `methodName` attribute of the `<java:operation>` element is the name of the method on the Java object that is called by the operation.
- The `parameterOrder` attribute of the `<java:operation>` element contains a white space-separated list of part names that define the order in which they are passed to the Java object method.
- The `methodType` attribute of the `<java:operation>` element must be set to either `instance` or `constructor`. The value specifies whether the method that is invoked on the object is an instance method or a constructor for the object.

In the next example, the `className` attribute of the `<java:address>` element specifies the fully qualified class name of the object containing the method to invoke:
```
    <service ... >
        <port>*
            <java:address
                className="nmtoken"/>
        </port>
    </service>
```

Linking a WSIF service to a service implemented as an enterprise bean:

Using the EJB provider, WSIF clients can invoke enterprise beans.

Although you can use the EJB provider for EJB(IIOP)-based Web service invocation, it is recommended that you instead invoke RMI-IIOP Web services using JAX-RPC.

The EJB client JAR file must be available in the client run-time environment with the current provider. The enterprise bean is invoked using normal EJB invocation methods, using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP), with the current security and transaction contexts. If the EJB provider is invoked within a transaction, the transaction is passed to the onward service and the standard EJB transaction attribute applies.

If there are multiple implementations of the service, it is up to the service providers to make sure that every implementation offers the same semantics. For example, in the case of transactions, the bean deployer must specify TX_REQUIRES_NEW to force a new transaction.

The EJB provider does not support the WSIF synchronous timeout. The EJB provider will not time out waiting for a Java method to complete.

For examples of the code changes that need to be made in the WSDL file, see The EJB provider - Writing the WSDL.

The EJB provider - Writing the WSDL extension:

The EJB provider supports the invocation of an enterprise bean through Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP).

Although you can use the EJB provider for EJB(IIOP)-based Web service invocation, it is recommended that you instead invoke RMI-IIOP Web services using JAX-RPC.

To use the EJB provider, you need the following binding specified in the WSDL:

```
<!-- EJB binding -->
<binding .... >
    <ejb:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
    <operation>*
        <ejb:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            interface="remote|home" />
        <input name="nmtoken"? />?
        <output name="nmtoken"? />?
        <fault name="nmtoken"? />?
    </operation>
</binding>
```

In this example:
- A question mark (?) means optional, and an asterisk (*) means 0 or more.
- The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the EJB operations.
- The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
- The methodName attribute of the <ejb:operation> element is the name of the method on the enterprise bean that is called by the operation.
- The parameterOrder attribute of the <ejb:operation> element contains a white space-separated list of part names that define the order in which they are passed to the EJB method.
- The interface attribute of the <ejb:operation> element must be set to either remote or home. The value specifies the interface of the enterprise bean on which the method named by the methodName attribute is accessible.

In the next example:
- The className attribute of the <ejb:address> element specifies the fully qualified class name of the home interface class of the enterprise bean.
- The jndiName attribute of the <ejb:address> element specifies the full Java Naming and Directory Interface (JNDI) name that is used to look up the enterprise bean.
- The initialContextFactory attribute of the <ejb:address> element is optional and specifies the initial context factory class.
- The jndiProviderURL attribute of the <ejb:address> element is optional and specifies the JNDI provider Web address.

```
<service ... >
    <port>*
        <ejb:address
            className="nmtoken"
            jndiName="nmtoken"
            initialContextFactory="nmtoken" ?
            jndiProviderURL="nmtoken" ? />
    </port>
</service>
```

Developing a WSIF service
A Web Services Invocation Framework (WSIF) service is a Web service that uses WSIF.

To develop a WSIF service, develop the Web service (or use an existing Web service), then develop the WSIF client based on the WSDL document for that Web service.

There are also two pre-built WSIF Samples available for download from the Samples Central page of the DeveloperWorks WebSphere Web site:
* The Address Book Sample.
* The Stock Quote Sample.

For more information about using the pre-built Samples, see the documentation that is included in the download package.

To develop a WSIF service, complete the following steps:

1. Develop the Web service.

   Use Web services tools to discover, create, and publish the Web service. You can develop Java bean, enterprise bean, and URL Web services. You can use Web service tools to create skeleton Java code and a sample application from a WSDL document. For example, an enterprise bean can be offered as a Web service, using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) as the access protocol. Or you can use a Java class as a Web service, with native Java invocations as the access protocol.

   You can use the WebSphere Studio Application Developer to create a Web service from a Java application, as described in its StockQuote service tutorial. The Java application that you use in this scenario returns the last trading price from the Internet Web site www.xmltoday.com, given a stock symbol. Using the Web service wizard, you generate a binding WSDL document named `StockQuoteService-binding.wsdl` and a service WSDL document named `StockQuoteService-service.wsdl` from the `StockQuoteService.java` bean. You then deploy the Web service to a Web server, generate a client proxy to the Web service, and generate a sample application that accesses the StockQuoteService through the client proxy. You test the StockQuote Web service, publish it using the IBM UDDI Explorer, and then discover the StockQuote Web service in the IBM UDDI Test Registry.

2. Develop the WSIF client. The information you need to develop a WSIF client is provided in the following topics:
   * Developing the WSIF client - the Address Book Sample gives example code to show how you define a Web service in WSDL.
   * Linking a WSIF service to the underlying implementation of the service describes the available providers, and gives example code of how their WSDL extensions are coded.
   * WSIF API defines the main interfaces that your client uses to support the invocation of Web services defined in WSDL.

   The Address Book Sample is written for synchronous interaction. If you are using a JMS provider, your WSIF client might need to act asynchronously. WSIF provides two main features that meet this requirement:
   * A **correlation service** that assigns identifiers to messages so that the request can match up with the (eventual) response.
   * A **response handler** that picks up the response from the Web service at a later time.

   For more information, see the WSIF API topic WSIFOperation - Asynchronous interactions reference.

Developing the WSIF client - the Address Book Sample:

The code fragments in this topic show you how to use the Web Services Invocation Framework (WSIF) API to invoke the AddressBook Sample Web service dynamically.

This is example code for dynamic invocation of the AddressBook sample Web service using WSIF:

```
try {
    String wsdlLocation="clients/addressbook/AddressBookSample.wsdl";

    // The starting point for any dynamic invocation using wsif is a
    // WSIFServiceFactory. We create ourselves one via the newInstance
```

```
        // method.
        WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

        // Once we have a factory, we can use it to create a WSIFService object
        // corresponding to the AddressBookService service in the wsdl file.
        // Note: since we only have one service defined in the wsdl file, we
        // do not need to use the namespace and name of the service and can pass
        // null instead. This also applies to the port type, although values have
        // been used below for illustrative purposes.
        WSIFService service = factory.getService(
            wsdlLocation,     // location of the wsdl file
            null,             // service namespace
            null,             // service name
           "http://www.ibm.com/namespace/wsif/samples/ab", // port type namespace
            "AddressBookPT" // port type name
        );

        // The AddressBook.wsdl file contains the definitions for two complexType
        // elements within the schema element. We will now map these complexTypes
        // to Java classes. These mappings are used by the Apache SOAP provider
        service.mapType(
            new javax.xml.namespace.QName(
                "http://www.ibm.com/namespace/wsif/samples/ab/types",
                "address"),
            Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFAddress"));
        service.mapType(
            new javax.xml.namespace.QName(
                "http://www.ibm.com/namespace/wsif/samples/ab/types",
                "phone"),
            Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFPhone"));
            // We now have a WSIFService object. The next step is to create a WSIFPort
            // object for the port we wish to use. The getPort(String portName) method
            // allows us to generate a WSIFPort from the port name.
        WSIFPort port = null;

        if (portName != null) {
            port = service.getPort(portName);
        }
        if (port == null) {
            // If no port name was specified, attempt to create a WSIFPort from
            // the available ports for the port type specified on the service
            port = getPortFromAvailablePortNames(service);
        }

        // Once we have a WSIFPort, we can create an operation. We are going to execute
        // the addEntry operation and therefore we attempt to create a WSIFOperation
        // corresponding to it. The addEntry operation is overloaded in the wsdl ie.
// there are two versions of it, each taking different parameters (parts).
// This overloading requires that we specify the input and output message
// names for the operation in the createOperation method so that the correct
// operation can be resolved.
        // Since the addEntry operation has no output message, we use null for its name.
        WSIFOperation operation =
            port.createOperation("addEntry", "AddEntryWholeNameRequest", null);

        // Create messages to use in the execution of the operation. This should
        // be done by invoking the createXXXXXMessage methods on the WSIFOperation.
        WSIFMessage inputMessage = operation.createInputMessage();
        WSIFMessage outputMessage = operation.createOutputMessage();
        WSIFMessage faultMessage = operation.createFaultMessage();

        // Create a name and address to add to the addressbook
        String nameToAdd="Chris P. Bacon";
        WSIFAddress addressToAdd =
            new WSIFAddress (1,
                "The Waterfront",
                "Some City",
```

```
            "NY",
            47907,
            new WSIFPhone (765, "494", "4900"));

    // Add the name and address to the input message
    inputMessage.setObjectPart("name", nameToAdd);
    inputMessage.setObjectPart("address", addressToAdd);

    // Execute the operation, obtaining a flag to indicate its success
    boolean operationSucceeded =
        operation.executeRequestResponseOperation(
            inputMessage,
            outputMessage,
            faultMessage);

    if (operationSucceeded) {
        System.out.println("Successfully added name and address to addressbook\n");
    } else {
        System.out.println("Failed to add name and address to addressbook");
    }

    // Start from fresh
    operation = null;
    inputMessage = null;
    outputMessage = null;
    faultMessage = null;

    // This time we will lookup an address from the addressbook.
    // The getAddressFromName operation is not overloaded in the
    // wsdl and therefore we can simply specify the operation name
    // without any input or output message names.
    operation = port.createOperation("getAddressFromName");

    // Create the messages
    inputMessage = operation.createInputMessage();
    outputMessage = operation.createOutputMessage();
    faultMessage = operation.createFaultMessage();

    // Set the name to find in the addressbook
    String nameToLookup="Chris P. Bacon";
    inputMessage.setObjectPart("name", nameToLookup);

    // Execute the operation
    operationSucceeded =
        operation.executeRequestResponseOperation(
            inputMessage,
            outputMessage,
            faultMessage);

    if (operationSucceeded) {
        System.out.println("Successful lookup of name '"+nameToLookup+"' in addressbook");

        // We can obtain the address that was found by querying the output message
        WSIFAddress addressFound = (WSIFAddress) outputMessage.getObjectPart("address");
        System.out.println("The address found was:");
        System.out.println(addressFound);
    } else {
        System.out.println("Failed to lookup name in addressbook");
    }

} catch (Exception e) {
    System.out.println("An exception occurred when running the sample:");
    e.printStackTrace();
}
}
```

The preceding code refers to the following Sample method:

```
WSIFPort getPortFromAvailablePortNames(WSIFService service)
        throws WSIFException {
    String portChosen = null;

    // Obtain a list of the available port names for the service
    Iterator it = service.getAvailablePortNames();
    {
        System.out.println("Available ports for the service are: ");
        while (it.hasNext()) {
            String nextPort = (String) it.next();
            if (portChosen == null)
                portChosen = nextPort;
            System.out.println(" - " + nextPort);
        }
    }
    if (portChosen == null) {
        throw new WSIFException("No ports found for the service!");
    }
    System.out.println("Using port " + portChosen + "\n");

    // An alternative way of specifying the port to use on the service
    // is to use the setPreferredPort method. Once a preferred port has
    // been set on the service, a WSIFPort can be obtained via getPort
    // (no arguments). If a preferred port has not been set and more than
    // one port is available for the port type specified in the WSIFService,
    // an exception is thrown.
    service.setPreferredPort(portChosen);
    WSIFPort port = service.getPort();
    return port;
}
```

The Web service uses the following classes:

WSIFAddress:

```
public class WSIFAddress implements Serializable {

    //instance variables
    private int streetNum;
    private java.lang.String streetName;
    private java.lang.String city;
    private java.lang.String state;
    private int zip;
    private WSIFPhone phoneNumber;

    //constructors
    public WSIFAddress () { }

    public WSIFAddress (int streetNum,
                        java.lang.String streetName,
                        java.lang.String city,
                        java.lang.String state,
                        int zip,
                        WSIFPhone phoneNumber) {
        this.streetNum = streetNum;
        this.streetName = streetName;
        this.city = city;
        this.state = state;
        this.zip = zip;
        this.phoneNumber = phoneNumber;
    }

    public int getStreetNum() {
        return streetNum;
    }

    public  void setStreetNum(int streetNum) {
```

```
            this.streetNum = streetNum;
    }

    public java.lang.String getStreetName() {
            return streetName;
    }

    public  void setStreetName(java.lang.String streetName) {
            this.streetName = streetName;
    }

    public java.lang.String getCity() {
            return city;
    }

    public  void setCity(java.lang.String city) {
            this.city = city;
    }

    public java.lang.String getState() {
            return state;
    }

    public  void setState(java.lang.String state) {
            this.state = state;
    }

    public int getZip() {
            return zip;
    }

    public  void setZip(int zip) {
            this.zip = zip;
    }

    public WSIFPhone getPhoneNumber() {
            return phoneNumber;
    }

    public  void setPhoneNumber(WSIFPhone phoneNumber) {
            this.phoneNumber = phoneNumber;
    }
}
```

WSIFPhone:

```
public class WSIFPhone implements Serializable {

    //instance variables
    private int areaCode;
    private java.lang.String exchange;
    private java.lang.String number;

    //constructors
    public WSIFPhone () { }

    public WSIFPhone (int areaCode,
                      java.lang.String exchange,
                      java.lang.String number) {
        this.areaCode = areaCode;
        this.exchange = exchange;
        this.number = number;
    }

    public int getAreaCode() {
            return areaCode;
    }
```

```java
    public  void setAreaCode(int areaCode) {
        this.areaCode = areaCode;
    }
}

    public java.lang.String getExchange() {
        return exchange;
    }

    public  void setExchange(java.lang.String exchange) {
        this.exchange = exchange;
    }

    public java.lang.String getNumber() {
        return number;
    }

    public  void setNumber(java.lang.String number) {
        this.number = number;
    }
}
```

WSIFAddressBook:

```java
public class WSIFAddressBook {
    private Hashtable name2AddressTable = new Hashtable();

    public WSIFAddressBook() {
    }

    public void addEntry(String name, WSIFAddress address)
    {
        name2AddressTable.put(name, address);
    }

    public void addEntry(String firstName, String lastName, WSIFAddress address)
    {
        name2AddressTable.put(firstName+" "+lastName, address);
    }

    public WSIFAddress getAddressFromName(String name)
        throws IllegalArgumentException
    {

        if (name == null)
        {
            throw new IllegalArgumentException("The name argument must not be " +
                                               "null.");
        }
        return (WSIFAddress)name2AddressTable.get(name);
    }

}
```

The following code is the corresponding WSDL file for the Web service:

```xml
<?xml version="1.0" ?>

```

Using complex types

WSIF supports user-defined complex types through the mapping of complex types to Java classes.

You specify this mapping manually or automatically as described in the following sections:
*   Manual mapping of complex types.
*   Automatic mapping of complex types.

Any calls to the WSIFService mapType and mapPackage methods used for manual mapping override any equivalent mapping information that is produced automatically. This override helps to maintain backwards compatibility, and also accommodates less standard mappings.

Manual mapping of complex types

The method to use when you create these mappings manually depends on the provider that is used. For the Java and EJB providers, the mappings are specified in the WSDL file in the binding element. The following example provides the syntax for specifying the mapping:

```
    <binding .... >
        <ejb:binding|java:binding/>
          <format:typeMapping style="Java" encoding="Java"/>?
              <format:typeMap typeName="qname" formatType="nmtoken"/>*
          </format:typeMapping>
      ...
    </binding>
```

In this example:

- A question mark ("?") means "optional" and an asterisk ("*") means "0 or more".
- The format:typeMap **typeName** attribute is a qualified name of a complex type or simple type used by one of the operations.
- The format:typeMap **formatType** attribute is the fully qualified class name for the Java class to which the element specified by **typeName** maps.

If you use the Apache SOAP provider then you specify the mapping of a complex type to a Java class in the client code through two methods on the org.apache.wsif.WSIFService interface:

```
public void mapType(QName elementType, Class javaType)
```

and

```
public void mapPackage(String namespaceURI, String packageName)
```

Use the **mapType** method to specify a mapping between an XML schema element and a Java class. The method takes a QName representing the complex type or simple type, and the corresponding Java class to which it maps.

Use the **mapPackage** method to specify a more general mapping between a namespace and a Java package. Any custom, complex or simple type whose namespace matches that of the mapping is mapped to a Java class in the corresponding package. The name of the actual class is derived from the name of the complex type using standard XML to Java naming conventions.

Automatic mapping of complex types

For complex types defined in the WSDL, where a generated bean is used to represent this type in Java, the Web Services Invocation Framework (WSIF) programming model requires that a call is made to the WSIFService.mapType() method. This call tells WSIF the package and class name of the bean representing the XML schema type that is identified with a QName. To make things easier, the WSIFService.mapPackage() method provides a mechanism to specify a wildcard version of this, where any class within a specified package is mapped to the namespace of a QName. This is a mechanism for manually mapping an XML schema type to a Java class and back again (one mapping entry provides a bidirectional mapping).

There are many ways to convert a QName representing an XML schema type name to a Java package name and class. To enable automatic type mapping, set the WSIF_FEATURE_AUTO_MAP_TYPES feature on the WSIFServiceFactory instance:

```
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
factory.setFeature(WSIFConstants.WSIF_FEATURE_AUTO_MAP_TYPES, new Boolean(true));
```

WSIF maps types by converting the URI part of the XML schema type <tt>QName</tt> to a package name, and converting the local part to a class name. WSIF does this mapping using the WSIFUtils methods <tt>getPackageNameFromNamespaceURI</tt> and <tt>getJavaClassNameFromXMLName</tt>.

Using WSIF to bind a JNDI reference to a Web service

This example task shows you how to use WSIF to bind a reference to a Web service, then look up the reference using JNDI.

You access a Web service through information provided in the WSDL document for the service. If you do not know where to find the WSDL document for the service, but you know that it has been registered in a UDDI registry, then you look it up in the registry. Java programs access Java objects and resources in a similar manner, but using a JNDI interface.

The following example shows how, using the Web Services Invocation Framework (WSIF), you can bind a reference to a Web service then look up the reference using JNDI.

Specifying the argument values for the Web service

The Web service is represented in WSIF by an instance of the org.apache.wsif.naming.WSIFServiceRef class. This simple Referenceable object has the following constructor:

```
public WSIFServiceRef(
        String WSDL,
        String sNS,
        String sName,
        String ptNS,
        String ptName)
{
    [...]
}
```

In this example
- *WSDL* is the location of the WSDL file containing the definition of the service.
- *sNS* is the full namespace for the service definition (you can specify `null` if only one service is defined in the WSDL file).
- *sName* is the local name for the service definition (you can specify `null` if only one service is defined in the WSDL file).
- *ptNS* is the full namespace for the port type within the service that you want to use (you can specify `null` if only one port type is available for the service).
- *ptName* is the local name for the port type (you can specify `null` if only one port type is available for the service).

For example, if the WSDL file for the Web service is available from the Web address `http://myServer/WSDL/Example.WSDL` and contains the following service and port type definitions:

```
  <definitions targetNamespace="http://hostname/namespace/example"
               xmlns:abc="http://hostname/namespace/abc"
[...]
    <portType name="ExamplePT">
      <operation name="exampleOp">
        <input name="exampleInput" message="tns:ExampleInputMsg"/>
      </operation>
    </portType>
[...]
    <service name="abc:ExampleService">
[...]
    </service>
[...]
  </definitions>
```

You can specify the following argument values for the WSIFServiceRef class:
- *WSDL* is http://myServer/WSDL/Example.WSDL
- *sNS* is http://hostname/namespace/abc
- *sName* is ExampleService
- *ptNS* is http://hostname/namespace/example
- *ptName* is ExamplePT

Binding the service using JNDI

To bind the service reference in the naming directory using JNDI, you can use the com.ibm.websphere.naming.JndiHelper class in WebSphere Application Server:

```
[...]
    import com.ibm.websphere.naming.JndiHelper;
    import org.apache.wsif.naming.*;
[...]
    try {
        Context startingContext = new InitialContext();
        WSIFServiceRef ref = new WSIFServiceRef("http://myServer/WSDL/Example.WSDL",
```

```
                                        "http://hostname/namespace/abc"
                                        "ExampleService",
                                        "http://hostname/namespace/example",
                                        "ExamplePT");
        JndiHelper.recursiveRebind(startingContext,
             "myContext/mySubContext/myServiceRef", ref);

    }
    catch (NamingException e) {
        // Handle  error.
    }
[...]
```

Looking up the service using JNDI

The following code fragment shows the lookup of a service using JNDI:

```
[...]
    try {
[...]
        InitialContext ic = new InitialContext();
        WSIFService myService =
         (WSIFService) ic.lookup("myContext/mySubContext/myServiceRef");
[...]
    }
    catch (NamingException e) {
        // Handle error.
    }
[...]
```

Passing SOAP messages with attachments using WSIF

Use the WSIF SOAP provider to pass attachments within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

The W3C SOAP Messages with Attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. It defines specific use of the "Multipart/Related" MIME media type, and rules for the use of URI references to entities bundled within the MIME package. It thereby outlines a technique for carrying a SOAP 1.1 message within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

The Web Services Invocation Framework (WSIF) supports passing attachments in a MIME message using the SOAP provider. The attachment is a javax.activation.DataHandler object. The mime:multipartRelated, mime:part and mime:content tags are used to describe the attachment in the WSDL.

For more information, see the following topics:
* SOAP messages with attachments - Writing the WSDL extensions.
* SOAP messages with attachments - Passing attachments to WSIF.
* SOAP messages with attachments - Working with types and type mappings.

The following scenarios are not supported:
* Using DIME.
* Passing in `javax.xml.transform.Source` and `javax.mail.internet.MimeMultipart`.
* Using the mime:mimeXml WSDL tag.
* Nesting a mime:multipartRelated tag inside a mime:part tag.
* Using types that extend `DataHandler`, `Image`, and so on.
* Using types that contain `DataHandler`, `Image`, and soon.
* Using Arrays or Vectors of `DataHandlers`, `Images`, and so on.
* Using multiple in/out or output attachments.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for Content-Type, Content-Id and Content-Transfer-Encoding that are created by WSIF.

SOAP messages with attachments - Writing the WSDL extensions:

These example code fragments show you how to write the WSDL extensions for SOAP messages with attachments

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
    <soap:operation soapAction=""/>
    <input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="encoded" namespace="http://mynamespace"
            encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
        </mime:part>
        <mime:part>
          <mime:content part="attch" type="text/html"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </operation>
</binding>
```

In this type of WSDL extension:
- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.
- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The `type` attribute inside the `<mime:content>` tag is not checked or used by the Web Services Invocation Framework (WSIF). It is there to suggest to the application using WSIF what the attachment contains. Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the backend service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute (optional) inside the `<soap:body>` tag is assumed to contain the names of all the MIME parts as well as the names of all the SOAP parts in the message.

SOAP messages with attachments - Passing attachments to WSIF:

These example code fragments show you how to use WSIF to pass SOAP messages with attachments.

The following code fragment can invoke the service described by the example WSDL in the topic writing the WSDL extensions:

```
import javax.activation.DataHandler;
. . .
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
```

```
WSIFOperation op = service.getPort().createOperation("MyOperation");
WSIFMessage in = op.createInputMessage();
in.setObjectPart("attch",dh);
op.executeInputOnlyOperation(in);
```

The associated type mapping in the `DeploymentDescriptor.xml` file depends upon your SOAP server. For example if you use Tomcat with SOAP 2.3, then the `DeploymentDescriptor.xml` file contains the following type mapping:

```
<isd:mappings>
<isd:map encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:x="http://mynamespace"
 qname="x:datahandler"
 javaType="javax.activation.DataHandler"
 java2XMLClassName="org.apache.soap.encoding.soapenc.MimePartSerializer"
 xml2JavaClassName="org.apache.soap.encoding.soapenc.MimePartSerializer" />
</isd:mappings>
```

In this case, the backend service is invoked with the following signature:

```
public void MyOperation(DataHandler dh);
```

You can also use stubs to pass attachments into the Web Services Invocation Framework (WSIF):

```
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
MyInterface stub = (MyInterface)service.getStub(MyInterface.class);
stub.MyOperation(dh);
```

Attachments can also be returned from an operation, but only one attachment can be returned as the return parameter.

SOAP messages with attachments - Working with types and type mappings:

By default, attachments are passed into the Web Services Invocation Framework (WSIF) as DataHandler objects. If the part on the message that is the DataHandler object maps to a `<mime:part>` tag in the WSDL, then WSIF automatically maps the fully qualified name of the WSDL type to the DataHandler class and sets up that type mapping with the SOAP provider.

In your WSDL, you might have defined a schema for the attachment (for instance as a `binary[]` type). WSIF silently ignores this mapping and treats the attachment as a DataHandler object, unless you explicitly issue a `mapType()` method. WSIF lets the SOAP provider set the MIME content type based on the type of the DataHandler object, instead of the `type` attribute specified for the `<mime:content>` tag in the WSDL.

Interacting with the J2EE container in WebSphere Application Server

A description of how, and to what extent, WSIF interacts with the J2EE container that is provided in WebSphere Application Server.

Interaction with a container is limited to the following aspects:

*   Using the application server administrative console to define Web services to WebSphere Application Server. This task is described in Using the Java Naming and Directory Interface (JNDI) and WSIF system management and administration. As part of the definition of a service, the administrator might define a "preferred port".
*   Using the Web Services Invocation Framework (WSIF) to make log and trace calls to the JRAS services in WebSphere Application Server, as described in Trace and logging for WSIF.
*   Using WSIF providers to access Java 2 platform, Enterprise Edition (J2EE) services. For example using the EJB provider to access the Java Naming and Directory Interface (JNDI) and make calls to remote enterprise beans.

- Using WSIF to wrap the use of container services so that, when WSIF is run in an unmanaged (thin) environment, the operation can succeed.

Running WSIF as a client

The Web Services Invocation Framework (WSIF) runs in the Application Client for WebSphere Application Server, and in similar clients from other suppliers.

To simplify the process of launching client applications in the Application Client for WebSphere Application Server, use the `launchClient` tool as described in Running application clients.

WSIF API

The Web Services Invocation Framework (WSIF) provides a Java API for invoking Web services, independent of the format of the service or the transport protocol through which it is invoked.

This framework includes an EJB provider for EJB invocation using Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based Web service invocation you should instead invoke RMI-IIOP Web services using JAX-RPC.

The WSIF API supports the invocation of services defined in WSDL. WSIF is intended for use in both WSIF clients and Web service intermediaries.

The WSIF API is driven by the abstract service description in WSDL; it is completely independent of the actual binding used. This independence makes the API more natural to work with because it uses WSDL terms to refer to message parts, operations, and so on.

The WSIF API was designed for the WSDL usage model: Pick a port that supports the port type needed, then invoke the operation by providing the necessary abstract input message consisting of the required parts, without worrying about how the message is mapped to a specific binding protocol.

Other Web service APIs, for example SOAP APIs, are not designed on WSDL, but for a specific binding protocol with its associated syntax; for example, target URIs and encoding styles.

The WSIF API main interfaces are described in the following topics:
- Creating a message for sending to a port (the WSIFMessage interface).
- WSIF API reference: Finding a port factory or service (the WSIFService interface and the WSIFServiceFactory class).
- WSIF API reference: Using ports (the WSIFPort interface and the WSIFOperation interface).

Note: You must ensure that your application uses only one thread to call WSIF.

For additional technical details of the WSIF API, see the generated API information.

WSIF API reference: Creating a message for sending to a port

For message management (that is, message construction and parsing) the underlying API is modeled on WSDL semantics. There is a simple and direct mapping from the WSDL model to the Web Services Invocation Framework (WSIF) classes.

In WSDL, a message describes the abstract type of the input or output to an operation. The corresponding WSIF class is WSIFMessage, which represents in memory the actual input or output of an operation. A WSIFMessage class is a container for a set of named parts. The WSIFMessage interface separates the actual representation of the data from the abstract type defined by WSDL. WSDL defines messages as XML schema types. There are two natural ways to represent a WSDL message in a run-time environment:
- The generated Java class, based on a WSDL to Java mapping such as that provided by a Java API for XML-based remote procedure call (JAX-RPC).
- The XML representation of the data, for example using SOAP Encoding.

Each option offers benefits in different scenarios. The Java class is the natural approach when WSIF is used in a standard Java client. However, in other scenarios where WSIF is used in an intermediary, it might be more efficient to keep a WSDL message in the SOAP encoded format.

The style used to define messages must be consistent within the message, so all the parts in one message must be consistent. A string - `getRepresentationStyle()` - always returns `null`. This indicates that parts on this WSIFMessage class are represented as Java objects.

You add parts to a WSIFMessage class with the setObjectPart or set*Type*Part methods. Each part is named. Part names within a message are unique. If you set a part more than once, the last setting is the one that is used.

You retrieve parts by name from a WSIFMessage class with the getObjectPart or get*Type*Part methods. If the named part does not exist, the method returns a WSIFException exception.

You can use Iterators to retrieve parts from the message through the getParts() and getPartNames() methods.

The order in which you set the parts is not important, but the message implementation might be more efficient if the parts are set in the parameter order specified by WSDL.

WSIFMessage classes are cloneable and serializable. If the parts set are not cloneable, the implementation can try to clone them using serialization. If the parts are not serializable either, then a CloneNotSupportedException exception is thrown if cloning is attempted.

WSIFMessage classes can be sent between Java Virtual Machines (JVMs).

In addition to the containing parts, a WSIFMessage class also has a message name. This is required for operation overloading, which is supported by WSDL and WSIF.

For more information about the WSIFMessage interface (/wsi/org/apache/wsif/WSIFMessage.html) see the generated API information.

WSIF API reference: Finding a port factory or service

To find a port you use the WSIFService interface, which is a factory for ports.

The port factory models and supports the WSDL approach in which a service is available on one or more ports. The factory hides the implementation of the port from the user. The Web Services Invocation Framework (WSIF) supports dynamic ports that are based on a particular protocol and transport, and configured using the WSDL at run time. For example, the dynamic SOAP port can invoke any SOAP service based on the WSDL description of that service. Using this service you can hide and modify the set of available ports at run time.

Here is the WSIFService interface.

To find a service from a WSDL document at a Web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

WSIFService interface:

The WSIFService interface is responsible for generating an instance of the WSIFOperation interface to use for a particular invocation of a service operation.

The Web Services Invocation Framework (WSIF) service stores a list of providers that can each generate a WSIF operation for a particular WSDL binding. This service looks up providers by the provider type. For

example the service knows about one provider that handles SOAP ports and other providers that handle Java ports that you define. In a managed environment, the container can configure the WSIFService interface.

For more information about the WSIFService interface (/wsi/org/apache/wsif/WSIFService.html) see the generated API information.

A WSIFService implementation can choose a preferred port based on a number of criteria. The WSIFService implementation can set the preferred port, or it can be set by calling the setPreferredPort method.

The getPort method returns an instance of the WSIFPort class that is used to invoke a service on the port. Variants of the getPort method are used to define the characteristics of the port to be created:

- the getPort method with no arguments returns the preferred port.
- the getPort method with a string argument returns the port named by the string containing the WSDL identifier for the selected port.

The return value is `null` if the port name is not valid.

If a port is chosen (either by the WSIFService implementation, or by the setPreferredPort method), then the WSIFService implementation validates that the relevant provider exists and is configured. If the provider fails this validation check, the WSIFService interface chooses any other port for which a provider is defined. For example, if the preferred port is SOAP over JMS but the JMS libraries are not available, then WSIF chooses another port. If no preferred port is set, or the preferred port is not available, the WSIF implementation chooses the first available port listed in the WSDL.

The getAvailablePortNames() method returns, as an iteration of strings, the list of WSDL port names filtered by the set of available providers.

The getDefinition() method returns the WSDL definition for the service. If the WSDL definition is not available, this method returns `null`.

WSIFServiceFactory class:

To find a service from a WSDL document at a Web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

Note: When you create a WSIFService interface from a WSIFServiceFactory class, you can specify a ClassLoader object to use in locating the WSDL file. You need to specify this object when the WSDL file is in a JAR file. In such a case, specify the location of the WSDL file relative to the root of the JAR file, using forward slashes (/) with the preceding slash removed.

For example:

```
com/myCompany/wsdl/MyWSDLFile.wsdl
```

rather than

```
/com/myCompany/wsdl/MyWSDLFile.wsdl
```

For more information about the WSIFServiceFactory class (/wsi/org/apache/wsif/WSIFServiceFactory.html) see the generated API information.

The WSIFServiceFactory class returns `null` if no service is found with that identifier.

WSIF API reference: Using ports

A WSIFPort interface handles the details of invoking an operation. The port provides access to the actual implementation of the service.

A WSDL document can provide many different WSDL bindings, and these bindings can drive multiple ports. The client can choose a port, the service stub can choose a port, or the Web Services Invocation Framework (WSIF) can choose a default port.

The port offers an interface to retrieve an Operation object. A WSIFOperation interface offers the ability to execute the given operation.

If the port is serialized and deserialized at a later time, then WSIF ensures that the client provides the correct information to the server to identify the instance. If the server instance is no longer available, then it is up to the server to decide whether to throw a fault or provide a new instance. That behavior can depend on the type of service.

For example, for an enterprise bean the WSIFPort interface stores the EJB Home, and uses it to select the bean before each invocation. It is the responsibility of the client to serialize or maintain the port instance if it wants instance support. The client must create a new operation and messages for each invocation.

Here is the WSIFPort interface.

Here is the WSIFOperation interface.

WSIFPort interface:

The port implements a factory method for the WSIFOperation interface.

For detailed information about the WSIFPort interface (/wsi/org/apache/wsif/WSIFPort.html) see the generated API information.

The createOperation(String) method returns a new instance of a WSIFOperation object. If the operationName value is not valid or the operation is overloaded, then the method throws an exception.

The createOperation(String, String, String) method supports overloaded WSDL operations. You can overload based on the input parameters, but not on the output parameters.

It is the duty of the client to call the close method when a port is no longer in use. In many cases, where the transport is sessionless, like HTTP, this has no effect. However, if the port is using a session-based protocol such as MQSeries, Java Message Service (JMS), or External Call Interface (ECI), this supports the port in caching an open connection to the server and then closing it as required. Responsibly-written applications will call the close method if appropriate.

WSIFOperation interface:

You use the WSIFOperation interface to invoke a service based on a particular binding.

The WSIFOperation interface is the run-time representation of an operation. This interface provides methods to create input, output, and fault messages, and to invoke the operation.

For more information about the WSIFOperation interface (/wsi/org/apache/wsif/WSIFOperation.html) see the generated API information.

createInputMessage, createOutputMessage and createFaultMessage
    These are factory methods to create the messages required by the invocation methods. All invocation methods require an input message.

executeRequestResponseOperation
    This method invokes "In Out" operations.

executeInputOnlyOperation

This method invokes "In only" operations.

executeRequestResponseOperation

If this method is used for invocation, then an output and a fault message are instantiated and passed on the call to the method. If the method returns `true`, then the output message contains the response message. If the message returns `false`, then a fault occurred and is returned in the fault message.

executeRequestResponseAsync

This method allows "In Out" operations to be invoked with the reply handled using an alternate thread. Use of this method is discussed further in WSIFOperation - Asynchronous interactions.

setContext and getContext

Use of these methods is discussed in WSIFOperation - Context.

All of the **execute*Nnnn*** methods fail with an exception if there is an error in processing the request in the WSIF provider.

Setting the timeouts for synchronous and asynchronous operations is discussed in WSIFOperation - Synchronous and asynchronous timeouts.

WSIFOperation - Context:

Although WSDL does not define context, a number of uses of the Web Services Invocation Framework (WSIF) require the ability to pass context to the port that is invoking the service.

For example, a SOAP over HTTP port might require an HTTP user name and password. This information is specific to the invocation, but is not a parameter of the service. In general, context is defined as a set of name-value pairs. However, because Web services tend to define the types of data using XML schema types, WSIF represents the name-value pairs of the context using the same representation that WSIFMessage classes use; that is a set of named parts, each of which equates to an instance of an XML schema type.

You use the WSIFOperation interface setContext and getContext methods to pass context information to the binding. The port implementation can use this context, for example to update a SOAP header. There is no definition of how a port can utilize the context.

The parameter of the setContext and getContext methods is a WSIFMessage interface, and this interface has named parts defining the context information. The WSIFConstants class defines constants for the part names that can be set in a context WSIFMessage interface.

The following code fragment shows how to set the user name and password for HTTP basic authentication:

```
 // set a basic authentication header
    WSIFMessage headers = new WSIFDefaultMessage();
    headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_USER, "user name" );
    headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_PSWD, "password" );
    operation.setContext( headers );
```

The WSIFOperation interface ignores context parts that it does not support. For example, the previous code is ignored by the WSIF Java provider.

The WSIFConstants class includes the following constants that can be used for context part names:
* CONTEXT_HTTP_USER
* CONTEXT_HTTP_PSWD
* CONTEXT_SOAP_HEADERS

The HTTP header values are expected to be of type String, and the SOAP header value is expected to be of type java.util.List, which should contain entries of type org.w3c.dom.Element.

WSIFOperation - Asynchronous interactions reference:

The Web Services Invocation Framework (WSIF) supports asynchronous operation. In this mode of operation, the client puts the request message as part of one transaction, and carries on with the thread of execution. The response message is then handled by a different thread, with a separate transaction.

Asynchronous operation is supported by the WSIF providers for SOAP over JMS and native JMS.

The WSIFPort class uses the supportsAsync method to test if asynchronous operation is supported.

An asynchronous operation is initiated with the WSIFOperation interface executeRequestResponseAsync method. This method lets a Remote Procedure Call (RPC) method be invoked asynchronously. The method returns before the operation is completed, and the thread of execution continues.

The response to the asynchronous request is processed by the WSIFOperation interface fireAsyncResponse or processAsyncResponse methods.

To initiate the request, there are two forms of the executeRequestResponseAsync method:

```
public WSIFCorrelationId executeRequestResponseAsync
                         (WSIFMessage input, WSIFResponseHandler handler)
```

and

```
public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input)
```

executeRequestResponseAsync(WSIFMessage input, WSIFResponseHandler handler)

> This method takes an input message and a WSIFResponseHandler handler. The handler is invoked on another thread when the operation completes. When using this method the client listener calls the fireAsyncResponse method, which then calls the WSIFResponseHandler interface executeAsyncResponse method.

> For more information about the WSIFResponseHandler interface (/wsi/org/apache/wsif/ WSIFResponseHandler.html), see the generated API information.

executeRequestResponseAsync(WSIFMessage input)
> This method only takes an input message, and does not use a response handler. The client listener processes the response by calling the WSIFOperation interface processAsyncResponse method. This process updates the WSIFMessage output and fault messages with the result of the request.

WSIF supports correlation between the asynchronous request and response. When the request is sent, the WSIFOperation object is serialized into the WSIFCorrelationService object. The executeRequestResponseAsync methods return a WSIFCorrelationId object which identifies the serialized WSIFOperation object. The client listener can use this to match a response to a particular request.

The correlation service is located with the WSIFCorrelationServiceLocator class getCorrelationService() method in the org.apache.wsif.utils package.

In a managed container a default correlation service is defined in the default Java Naming and Directory Interface (JNDI) namespace using the name: java:comp/wsif/WSIFCorrelationService. If this correlation service is not available, then WSIF uses the WSIFDefaultCorrelationService.

For more information about the WSIFCorrelationService interface (/wsi/org/apache/wsif/ WSIFCorrelationService.html) see the generated API information.

and this is the correlator ID:

```
public interface WSIFCorrelator extends Serializable {
    public String getCorrelationId();
}
```

The client must implement its own response message listener or message data base so that it can
recognize the arrival of response messages. This client implementation manages the correlation of the
response message to the request and call of one of the asynchronous response processing methods. As
an example of the requirement for a client listener, the following code fragment shows what can be in the
onMessage method of a Java Message Service (JMS) listener:

```
public void onMessage(Message msg) {
    WSIFCorrelationService cs = WSIFCorrelationServiceLocator.getCorrelationService();
        WSIFCorrelationId cid = new JmsCorrelationId( msg.getJMSCorrelationID() );
        WSIFOperation op = cs.get( cid );
        op.fireAsyncResponse( msg );
}
```

WSIFOperation - Synchronous and asynchronous timeouts reference:

When you use the Web Services Invocation Framework (WSIF) with the Java Message Service (JMS) you
can set timeouts for synchronous and asynchronous operations.

Default values for these timeouts are defined in the WSIF properties file:

```
# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined or invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

If you use these default values, a synchronous request (such as a WSIFOperation interface
executeRequestResponseOperation method call) times out after ten seconds, and an asynchronous
request (such as a WSIFOperation interface executeRequestResponseAsync method call) times out after
sixty seconds.

Note:

> The code that processes both of these timeout values uses milliseconds as its unit of time. The
> WSIFProperties class getAsyncTimeout method multiplies the wsif.asyncrequest.timeout value by
> 1000, to convert the value from seconds to milliseconds.

You can override these default values for a given request by setting a JMS property on the operation
request with the `<jms:property>` and `<jms:propertyValue>` WSDL elements. Set the name of the property
to be the name of the timeout from the WSIF properties file.

The following example sets synchronous requests to time out after two minutes (120 seconds):

```
<jms:propertyValue name="wsif.syncrequest.timeout" type="xsd:string" value="120000"/>
```

and the following example disables asynchronous timeouts (a value of zero means wait forever):

```
<jms:propertyValue name="wsif.asyncrequest.timeout" type="xsd:string" value="0"/>
```

When an asynchronous timeout expires, no listener or message data base waiting for the response is
notified. The asynchronous timeout is only used to tell the correlation service that the stored
WSIFOperation can be deleted.

UDDI registry client programming

This topic covers programmatic use of the UDDI APIs. The first subtopics describe some standard aspects of the UDDI APIs:

- UDDI registry Version 3 Entity Keys explains UDDI entity keys, and the capability with UDDI Version 3 to save UDDI entities with publisher-assigned keys.
- Use of digital signatures with the UDDI registry explains about the support for digital signing of UDDI entities, and for validation of signatures.
- UDDI registry Application Programming Interface contains a summary of the UDDI Version 3 APIs as defined in the UDDI Version 3 specification.

There are several ways in which you can programmatically access the UDDI APIs. The recommended client API is the UDDI Version 3 Client for Java, which allows access to the UDDI Version 3 APIs from Java client code. Other client APIs are provided for compatibility with previous versions of the UDDI registry:

- UDDI4J provides Java class libraries for accessing UDDI Version 1 and Version 2 APIs. These class libraries are both deprecated in this release, and replaced by the UDDI Version 3 Client for Java. See UDDI4J programming interface (Deprecated) for further details.
- EJB Interface for the UDDI registry (Deprecated) provides an EJB interface to the UDDI Version 2 APIs. The UDDI EJB interface is deprecated in this release.

Although the recommended programmatic access to the UDDI APIs is through the UDDI Version 3 Client for Java, it is also valid to use the UDDI APIs directly using SOAP. This can be done by constructing a properly-formed UDDI message within the body of a SOAP request, and sending it using HTTP POST to the appropriate SOAP endpoint for the UDDI service (see UDDI registry SOAP Service End Points. The response will be returned within the body of the HTTP reply.

Support is also provided for the use of HTTP GET to return XML representations of UDDI entities: see HTTP GET Services for UDDI registry data structures for details.

UDDI registry Version 3 Entity Keys
Entity Keys, UDDI v1/2 uuid and UDDI v3 uddi keys

Entity keys are identifiers used to address entities within a UDDI registry. Each entity, for example businessEntity, businessService, bindingTemplate or tModel, has a unique identifier generated or assigned when first published in the UDDI registry. Within a particular registry, a key MUST be unique. The UDDI version 3 specification expands the space available for keys; it is not limited to a UUID as in versions 1 and 2. Entity keys can now be any URI (Universal Resource Identifier) that follows the recommended UDDI scheme.

Another difference introduced by the UDDI Version 3 specification is that depending on registry policy, keys can be assigned, not only by the UDDI registry, but also by the publisher of the entity. These differences raise issues in maintaining key uniqueness and managing key space.

UDDI Scheme

The UDDI Version 3 registry implements the recommended UDDI scheme, as detailed in Section 4.4 of the UDDI Version 3 Specification. (http://uddi.org/pubs/uddi_v3.htm). This scheme defines the format of the keys, the valid characters, and the concept of key space.

In the UDDI Version 3 registry, a key is any URI (Universal Resource Identifier) and is limited to 255 characters. The following diagram shows the different types of keys within the UDDI key scheme:
All keys are composed of a set of tokens that are separated by ':'. The first token for all keys that follow the UDDI scheme is "uddi". There are three types of keys:

1. The uuidKeys contain two tokens, the mandatory "uddi" and a <UUID>. These keys assure uniqueness through the UUID algorithm.

2. The domainKeys also contain 2 tokens but its second token is a Domain Name. These keys are intended for creating additional mutually-exclusive key spaces.

3. The derivedkeys are composite keys based on a subkey, which is any uddiKey, and an additional token, kss, which is a key specific string. The kss is what differentiates keys and it can be assigned by a publisher or calculated algorithmically (UUID).

Another concept included in the UDDI key scheme is a key generator. A key generator is used to represent a key space. A publisher is only allowed to save entities using keys from a certain key space if it owns the key generator that represents the key space. This aids in securing unique keys. The key generator is a tModel entity, which key is in the form <subkey>:keyGenerator. By owning this tModel, a publisher can assign keys in the form <subkey>:<kss>. The publisher can also publish new tModel key generators of the form <subkey>:<kss>:keygenerator.

Key uniqueness and registry root key space

Instances of UDDI registry can be configured to be a 'Root' registry, or an 'Affiliate' registry.

Root registries define their own 'root' key space by defining their own root key generator. This defines the total key space the registry manages. All keys the registry generates are within this key space, and, if allowed by Policy, publishers may request sub-divisions of this key space by publishing new tModel key generators of the form <rootkeygenerator>:<subdivisionIdentifier>:keygenerator and then may include publisher-supplied-keys in subsequent publish requests which are within their allocated key space subdivision. (<rootkeygenerator>:<subdivisionIdentifier>:<kss>).

To avoid key collisions, affiliate registries must establish their root key generator by first submitting a tModel:keygenerator request to the root registry they wish to be an affiliate of, and then using this (subdivision of the root registry's key space) as their own root key generator. This ensures there are no collisions between keys generated or accepted by an affiliate registry and other keys in the root registry key space.

To maintain key uniqueness simple rules are applied, the registry only generates new keys within the key space defined by its own root key generator, and only accepts publisher-supplied-keys which are within a subdivisions of key space owned by the publisher (as the result of a prior successful tModel 'tModel:keygenerator' publish request).

Simple example for a private Root Registry:

```
with a Root keygenerator:

uddi:aPrivateRegistryKeySpaceIdentifier:keygenerator

generates Entity Keys of format:

uddi:aPrivateRegistryKeySpaceIdentifier:<uuid>

depending on Policy, accepts tModel:keygenerator requests from Publishers for 'top-level' subdivisions
of format:
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:keygenerator
```

Publishing 'tModel:keyGenerator' requests for subdivisions of key space

As identified above, depending on Policy, (whether the registry supports publisher supplied keys and whether a particular publisher's User entitlements allow the publisher to submit requests for key space) a publisher can submit a request for a (top-level) subdivision of the root registry's key space for its own use.

In addition to 'top-level' subdivisions of the root registry's key space, a publisher can also create further subdivisions of key space for its own use.

A simple example of this is (continuing the example above):

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:keygenerator
```

This request for a further subdivision 'a' is successful when requested by the publisher who previously requested (and hence owns) the tModel for the 'level above' (in this case uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:keygenerator).

Publishing with a 'publisher supplied' key

Having successfully requested a subdivision of a root registry's key space, a publisher must establish and maintain their own scheme for ensuring that the keys generated to be used as publisher-supplied-keys in subsequent publish requests are unique within the subdivision.

Valid schemes need to generate keys which are unique derived keys within the allocated key space subdivision, for example including a unique (incremented) numeric index.

A simple example of this is (continuing the example above):

For key space subdivision resulting from tModel:keyGenerator request:

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:keygenerator

valid keys are:

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:1

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:2
```

Use of digital signatures with the UDDI registry

In UDDI Version 3, Publishers can digitally sign UDDI elements while they are publishing. The UDDI Version 3 schema supports the signing of businessEntity, businessServices, bindingTemplate, tModel, and publisherAssertion elements.

You can validate UDDI elements that have been digitally signed to prove that they have not been modified or tampered with and that their integrity is intact.

For full details about signing UDDI entities and verifying signatures, see *Appendix I: Support for XML Digital Signatures* in the UDDI Version 3.0.2. specification.

The UDDI registry does not validate signatures at the time that signed elements are published. When the signed elements are retrieved, the retrieving client is responsible for validating the signature and to provide his own mechanism for ensuring the signer's certificate is signed by a Certificate Authority (CA) that the clients approves and trusts. If a signature is decrypted successfully by using the signer's public key, it is an indication that only the owner of the corresponding private key could have signed and published this element.

Generating a signature

Because an element's attributes are included in the generation of an element's signature, all entity keys must be available at the time that the signature is generated. Publishers are recommended to generate publisher-assigned-keys for all of an element's keys before signing. Alternatively, publishers can publish the element without keys; this causes the registry node to generate the required entity keys and then retrieve, sign, and republish the signed element.

Validating a signature

The signature element to validate is the one in the top level element that is returned by a call to getXXDetails(). It is the client's responsibility to perform the validation. The client must have previously imported the publishers X509.3 certificate and validated it based on the CA it trusts. This way the client will have access to the publisher's public validation key that corresponds to the private signing key that the publisher used to sign the entity before publishing it.

The UDDI Version 3 Client can be used to construct JAX-RPC objects and to invoke the UDDI Version 3 WebService. As part of this client a helper class, *com.ibm.uddi.v3.client.apilayer.xmldig.SignatureUtilities*, can be used to create and validate digital signatures on the UDDI Version 3 Entities that support them. See the API documentation page for details of API of this class and its Exception *SignatureUtilitiesException*.

An example of how to use this class can be found at Samples for WebSphere Application Server called UDDIv3ClientSignedBusinessSample.java.

Note: For UDDI, digital signatures are being used to sign the data and **not** to authenticate the SOAP message.

UDDI registry Application Programming Interface

The UDDI Version 3 registry supports multiple versions of UDDI. In addition to UDDI Version 3, it supports UDDI Version 1 and Version 2.

For details of the Version 1 and Version 2 API, visit `http://www.oasis-open.org/committees/uddi-spec/doc/tcspecs.htm#uddiv2`.

For details of the UDDI Version 3.0.2 API, visit `http://uddi.org/pubs/uddi_v3.htm`.

The UDDI registry information in this information center defines the support provided by the UDDI registry for the UDDI Version 3.0.2 specification and associated addenda.

The following UDDI Version 3 API sets are supported:
- The UDDI V3 Inquiry API
- The UDDI V3 Publish API
- The UDDI V3 Custody and Ownership Transfer API
- The UDDI V3 Security API

Note: There is a known restriction within DB2 for zSeries Version 7 that limits the length of publish and inquiry strings to 255 characters. Exceeding this limit will result in an Error 10500 (E_Fatal) error being returned. If you use a character set that uses multiple byte characters, this limit can very easily be exceeded. Care must be taken when using these character sets.

Inquiry API for the UDDI Version 3 registry:

The Inquiry API provides four forms of query that follow broadly used conventions that match the needs of software traditionally used within registries.
* The browse pattern
* The drill-down pattern
* The invocation pattern
* Inquiry API functions

For more information refer to the UDDI Version 3 Specification.

Browse pattern for the UDDI registry:

Software that allows people to explore and examine data - especially hierarchical data - requires browse capabilities. The browse pattern characteristically involves starting with some broad information, performing a search, finding general result sets and then selecting more specific information for drill-down.

The UDDI API specifications accommodate the browse pattern by way of the *find_xx* API calls. These calls form the search capabilities provided by the API and are matched with summary return messages that return overview information about the registered information that is associated with the inquiry message type and the search criteria specified in the inquiry.

A typical browse sequence might involve finding whether a particular business you know about has any information registered. This sequence would start with a call to *find_business*, perhaps passing the first few characters of a business name that you already know. This returns a *businessList* result. This result is overview information (keys, names and descriptions) derived from the registered businessEntity information, matching on the name fragment that you provided. If you spot the business you are looking for within this list, you can drill down into the corresponding businessService information, looking for particular technical models (for example purchasing, shipping, and so on) using the *find_service* API call. Similarly, if you know the technical *fingerprint* (tModel signature) of a particular software interface and want to see if the business you have chosen provides a Web service that supports that interface, you can use the find_binding inquiry message.

Drilldown pattern for the UDDI registry:

When you have a key for one of the four main data types managed by a UDDI registry, you can use that key to access the full registered details for a specific data instance. The UDDI data types are businessEntity, businessService, bindingTemplate and tModel. You can access the full registered information for any of these structures by passing a relevant key type to one of the *get_xx* API calls.

Continuing the example from the Browse pattern for the UDDI registry, one of the data items returned by all of the *find_x* return sets is key information. In the case of the business we were interested in, the businessKey value returned within the contents of a businessList structure can be passed as an argument to *get_businessDetail*. The successful return to this message is a *businessDetail* message containing the full registered information for the entity whose key value was passed. This will be a full *businessEntity* structure.

Invocation pattern for the UDDI registry:

To prepare an application to take advantage of a remote Web service that is registered within the UDDI registry by other businesses or entities, you must prepare that application to use the information found in the registry for the specific service being invoked.

The *bindingTemplate* data obtained from the UDDI registry represents the specific details about an instance of a given interface type, including the location at which a program starts interacting with the service. The calling application or program should cache this information and use it to contact the service at the registered address whenever the calling application needs to communicate with the service instance. In previously popular remote procedure technologies tools have automated the tasks associated with caching (or hard coding) location information. Problems arise however when a remote service is moved without any knowledge on the part of the callers. Moves occur for a variety of reasons, including server upgrades, disaster recovery, and service acquisition and business name changes.

When a call fails using cached information previously obtained from a UDDI registry, the proper behavior is to query the UDDI registry for fresh bindingTemplate information. If the data returned is different from the cached information, the service invocation should automatically retry the invocation using the fresh information. If the result of this retry is successful, the new information should replace the cached information.

By using this pattern with Web services, a business using a UDDI registry can automate the recovery of a large number of partners without undue communication and coordination costs. For example, if a business has activated a disaster recovery site, most of the calls from partners fail when they try to invoke services at the failed site. By updating the UDDI information with the new address for the service, partners who use the invocation pattern automatically locate the new service information and recover without further administrative action.

Inquiry API functions in the UDDI registry:

The inquiry API set allows you to locate and obtain details about entries in a UDDI registry. The API is split into a number of functions (see below), each requiring a variety of optional and mandatory arguments.

Use the UDDI Version 3 Client for Java (see UDDI Version 3 Client) to access programmatically all API calls and arguments supported by the UDDI Version 3 registry. You can also access the API functions graphically by using the UDDI user interface, however not all of the functions are available with this method.

The UDDI Version 3 registry supports the following Inquiry API calls:
find_binding
> Locates specific bindings within a registered businessService. Returns a bindingDetail message that contains zero or more bindingTemplate structures matching the criteria specified in the argument list.

find_business
> Locates information about one or more businesses. Returns a businessList message that matches the conditions specified in the arguments.

find_relatedBusinesses
> Locates information about businessEntity registrations that are related to a specific business entity whose key is passed in the inquiry. The Related Businesses feature is used to manage registration of business units and subsequently relate them based on organizational hierarchies or business partner relationships. Returns a relatedBusinessList message containing results that match the conditions specified in the arguments.

find_service
> Locates specific services within a registered businessEntity. Returns a serviceList message that matches the conditions specified in the arguments.

find_tModel

Locates a list of tModels that match a set of specified criteria. The response will be a list of abbreviated information about registered tModel data that matches the criteria specified. The result will be returned in a tModelList message.

get_bindingDetail

Requests the runtime bindingTemplate information for the purpose of invoking a registered business API. Returns a bindingDetail message.

get_businessDetail

Returns complete businessEntity information for one or more specified businessEntity registrations matching the businessKey values specified. Returns a businessDetail message.

get_opertionalInfo

Gets full operational information pertaining to one or more entities in the registry. Returns an operationalInfos structure.

get_serviceDetail

Requests full information about a known businessService structure. Returns a serviceDetail message.

get_tModelDetail

Gets full details for a given set of registered tModel data. Returns a tModelDetail message.

For full details of the syntax of the above queries, refer to the UDDI Version 3 API specification at `http://www.uddi.org/pubs/uddi_v3.htm`.

Find_qualifiers for API functions in the UDDI registry:

Each of the APIs (find_business, find_service, find_binding, find_tModel and find_relatedBusinesses) accepts an optional findQualifiers argument, which may contain multiple findQualifier values. Below is a list of the findQualifier short names with a brief description and which find function is applicable.

The arguments available are:

andAllKeys

This changes the behavior for identifyerBag to AND keys rather than OR them. This is the **default** for categoryBag and tModelbag. Applicable to find_business, find_service, find_binding and find_tModel (but not for find_relatedBusinesses).

approximateMatch

Signifies that wildcard search behavior is desired. This is no longer the default behavior (see 'exactMatch'). This applies to find_business, find_service, find_binding, find_tModel and find_relatedBusiness.

binarySort

Allows for greater speed in sorting. It causes a binary sort by name, as represented in Unicode codepoints. It is applicable to find_business, find_service and find_tModel only.

bindingSubset

This is used only in conjunction with a categoryBag argument in the find_business or find_services APIs.

caseInsensitiveMatch

Signifies that the matching behavior for name, keyValue and keyName (where applicable) should be performed without regard to case. It is applicable to find_business, find_service and find_tModel.

caseInsensitiveSort

Signifies that the matching behavior for name, keyValue and keyName (where applicable) should be performed without regard to case. This overrides the default case sensitive sorting behavior.

caseSensitiveMatch

Signifies that the matching behavior for name, keyValue and keyName (where applicable) should be performed with regard to case. This is the **default** behavior. It is applicable to find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

caseSensitiveSort

Signifies that the result set should be sorted with regard to case. this is the **default** behavior. It is applicable to find_business, find_service and find_tModel.

combineCategoryBags

This may only be used in the find_business and find_service calls.

- In the case of find_business, this makes the categoryBag entries for the full businessEntity element behave as though all categoryBag elements found at the businessEntity level and in all contained or referenced businessService elements and bindingTemplate elements were combined.
- In the case of find_service, this makes the categoryBag entries for the full businessService element behave as though all categoryBag elements found at the businessService level and in all contained or referenced elements in the bindingTemplate elements were combined.

diacriticInsensitiveMatch

Signifies that matching behavior for name, keyValue and keyName (where applicable) should be performed without regard to diacritics. Support for this findQualifier is optional. It applies to find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

diacriticSensitiveMatch

Signifies that the matching behavior for name, keyValue and keyName (where applicable) should be performed with regard to diacritics. This is the **default** behavior. It applies to find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

exactMatch

Signifies that only entries with names, keyValues and keyNames (where applicable) that exactly match the name argument passed in, after normalization, will be returned. It is sensitive to case and diacritics where applicable and is the **default** behavior. It applies to find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

signaturePresent

This is used with any find API to restrict the result set to entities which either contain an XML Digital Signature element, or are contained in an entity which contains one. It applies to find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

orAllKeys

This changes the behavior for tModelBag and categoryBag to OR the keys within a bag, rather than to AND them. It is not possible to OR the categories and retain the default AND behavior of the tModels. For the find_business qualifier this is the **default** behavior for identifierBag, and it is applicable to find_service, find_binding (for categoryBag and tModelbag) and find_tModel where it is the **default** behavior for identifierBag and applicable to categoryBag.

orLikeKeys

Used when a bag container (that is a categoryBag or identifierBag) contains multiple keyedReference elements. In this situation any keyedReference filters that come from the same namespace (have the same tModelKey value) are OR'd together rather than AND'd. It is applicable to find_business, find_service, find_binding and find_tModel.

serviceSubset

This is only used with the find_business API and used only in conjunction with the categoryBag argument. It causes the component of the search that involves categorization to use only the categoryBag elements from contained or referenced businessService elements within the registered data and ignores any entries found in the categoryBag which are not direct descendent elements of registered businessEntity elements.

sortByNameAsc

This causes the result set returned by a find or get inquiry API to be sorted on the name field in ascending order. It is applicable to find_business, find_service, find_tModel and find_relatedBusinesses. This findQualifier takes precedence over sortByDateAsc and sortByDateDesc qualifiers, but if a sortByDateXxx findQualifier is used without a sortByNameXxx qualifier, sorting is performed based on date with or without regard to name.

sortByNameDesc

This causes the result set returned by a find or get inquiry API to be sorted on the name field in descending order. It is applicable to find_business, find_service, find_tModel and find_relatedBusinesses. This findQualifier takes precedence over sortByDateAsc and

sortByDateDesc qualifiers, but if a sortByDateXxx findQualifier is used without a sortByNameXxx qualifier, sorting is performed based on date with or without regard to name.

sortByDateAsc

This causes the result set returned by a find or get inquiry to be sorted based on the most recent date when each entity, or any entities they contain, were last updated, in ascending chronological order (the oldest is returned first). When used in conjunction with names in the result set returned, the date-based sort is secondary to the name-based sort (that is, the results are sorted within name by date, oldest to newest). This is the **default** behavior for find_binding and is applicable for find_business, find_service, find_tModel and find_relatedBusinesses.

sortByDateDesc

This causes the result set returned by a find or get inquiry to be sorted based on the most recent date when each entity, or any entities they contain, were last updated, in descending chronological order (the most recently changed are returned first). When used in conjunction with names in the result set returned, the date-based sort is secondary to the name-based sort (that is, the results are sorted within name by date, newest to oldest). This is applicable for find_business, find_service, find_binding, find_tModel and find_relatedBusinesses.

suppressProjectedServices

Signifies that service projections **MUST NOT** be returned by the find_service or find_business APIs with which this findQualifier is associated. This findQualifier is automatically enabled by default whenever find_service is used without a businessKey.

For further details on the findQualifiers refer to the UDDI Version 3 Specification documentation.

Publish API for the UDDI Version 3 registry:

The UDDI Publish API allows you to publish, delete and update information contained in a UDDI registry. The messages defined in this section all behave synchronously.

Use the UDDI Version 3 Client for Java (see UDDI Version 3 Client) to access programmatically all API calls and arguments supported by the UDDI Version 3 registry. You can also access the API functions graphically by using the UDDI user interface, however not all of the functions are available with this method.

The UDDI Version 3 registry supports the following Publication API calls:

add_publisherAssertions

Causes one or more publisherAssertions to be added to an individual publisher's assertion collection.

delete_binding

Causes one or more instances of bindingTemplate data to be deleted from the UDDI registry.

delete_business

Removes one or more business registrations and all direct contents from a UDDI registry.

delete_publisherAssertions

Causes one or more publisherAssertion elements to be removed from a publisher's assertion collection.

delete_service

Removes one or more businessService elements from the UDDI registry and from its containing businessEntity parent.

delete_tModel

Logically deletes one or more tModel structures. Logical deletion hides the deleted tModels from find_tModel result sets but does not physically delete them, so they are returned on a get_registeredInfo request.

get_assertionStatusReport

Provides administrative support for determining the status of current and outstanding publisher assertions that involve any of the business registrations managed by the individual publisher

account. Using this message, a publisher can see the status of assertions that they have made, as well as see assertions that others have made that involve businessEntity structures controlled by the calling publisher account.

get_publisherAssertions
Obtains the full set of publisher assertions that are associated with an individual publisher account. Publisher assertions are used to control publicly visible business relationships.

get_registeredInfo
Gets an abbreviated list of all businessEntity and tModel data that are controlled by the individual associated with the credentials passed.

save_binding
Saves or updates a complete bindingTemplate element. this message can be used to add or update one or more bindingTemplate elements as well as the container/contained relationship that each bindingTemplate has with one or more existing businessService elements.

save_business
Saves or updates information about a complete businessEntity element. This API has the broadest scope of all the save_xx API calls in the publisher API, and can be used to make sweeping changes to the published information for one or more businessEntity elements controlled by an individual.

save_service
Adds or updates one or more businessService elements exposed by a specified businessEntity.

save_tModel
Adds or updates one or more registered tModel elements.

set_publisherAssertions
Manages all of the tracked relationship assertions associated with an individual publisher account.

For full details of the syntax of the above queries, refer to the UDDI Version 3 API specification at `http://www.uddi.org/pubs/uddi_v3.htm`.

Custody and Ownership Transfer API for the UDDI Version 3 registry:

The UDDI Custody and Ownership Transfer API allows you to transfer custody or ownership of one or more entities contained in a UDDI Version 3 registry.

Use the UDDI Version 3 Client for Java (see UDDI Version 3 Client) to access programmatically all API calls and arguments supported by the UDDI Version 3 registry. You can also access the API functions graphically by using the UDDI user interface, however not all of the functions are available with this method.

Note: The UDDI Version 3 registry supports only intra-node ownership transfer; it does **not** support inter-node custody transfer.

The UDDI Version 3 registry supports the following Custody and Ownership Transfer API calls:

discard_transferToken
Discards a transferToken obtained through the get_transferToken API.

get_transferToken
Initiates the transfer of ownership of one or more businessEntity or tModel entities from one publisher to another. No actual transfer takes place with the invocation of the API. Instead, the relinquishing publisher uses this API to obtain permission from the custodial node, in the form of a transferToken, to perform the transfer. The relinquishing publisher gives the transferToken to the recipient publisher, who must invoke the transfer_entities API to actually transfer the entities.

transfer_entities
Performs the actual transfer of entities when called by the recipient publisher. The recipient publisher must specify an unexpired transferToken on the call.

For full details of the syntax of the above queries, refer to the UDDI Version 3 API specification at `http://www.uddi.org/pubs/uddi_v3.htm`.

Security API for the UDDI Version 3 registry:

In UDDI Version 1 and Version 2 the security API was part of the Publish API. In UDDI Version 3 the security API is independent.

Use the UDDI Version 3 Client for Java (see UDDI Version 3 Client) to access programmatically all API calls and arguments supported by the UDDI Version 3 registry. You can also access the API functions graphically by using the UDDI user interface, however not all of the functions are available with this method.

The UDDI Version 3 registry supports the following Security API calls:

discard_authToken
> Used to inform a node that a previously obtained authentication token is no longer required and should be considered invalid if used after this message is received. The token is to be discarded and the session is effectively ended.

get_authToken
> Used to request an authentication token in the form of an authInfo element from a UDDI node.

For full details of the syntax of the above queries, refer to the UDDI Version 3 API specification at `http://www.uddi.org/pubs/uddi_v3.htm`.

UDDI Version 3 Client

The UDDI Version 3 Client for Java is a JAX-RPC Java class library that provides an API that can be used by client programs to interact with a Version 3 UDDI registry. This class library can be used to construct UDDI JAX-RPC objects and to invoke the UDDI Version 3 WebService.

This client also contains an XML Digital Signature utility class called SignatureUtilities, provided to construct and validate Digital Signatures on UDDI elements. See Use of digital signatures with the UDDI registry for full details.

Client Jar

WebSphere Application Server provides a class library:

uddiv3client.jar
> This jar contains the JAX-RPC UDDI Version 3 types and UDDI WebService invocation classes.

This jar is located in *app_server_root*/UDDIReg/clients

The UDDI Version 3 client provides port types which map onto the UDDI Version 3 SOAP inquiry, publish, custody transfer and security APIs. These APIs are protected as described in Access control for UDDI registry interfaces. A client program using the UDDI Version 3 client should get the appropriate port type for the request that is to be issued (such as the UDDI_Publication_PortType for a save_business request). If the role mappings are such that the request will require a WebSphere Application Server authenticated user ID, the client program should pass the user ID and password by setting the relevant properties on the JAX-RPC stub for that port.

UDDI Version 3 Client samples

Samples illustrating the use of the Version 3 Client are available through the UDDI registry link on the Samples for WebSphere Application Server page of the IBM developerWorks WebSphere Web site.:

UDDIv3ClientBindingSample.java
> An example of how to save and find Binding Templates.

UDDIv3ClientBusinessSample.java
> An example of how to save and find Business Entities.

UDDIv3ClientServiceSample.java
> An example of how to save and find Business Services.

UDDIv3ClientSignedBusinessSample.java
> An example of how to sign and verify a Business Entity.

UDDIv3ClientTModelSample.java
> An example of how to save and find TModels.

UDDIv3ClientSignedTModelSample.java
> An example of how to sign and verify TModels.

These classes contain details on how to compile and execute them.

HTTP GET Services for UDDI registry data structures

The UDDI registry offers an HTTP GET service for access to the XML representations of the UDDI data structures businessEntity, businessService, bindingTemplate and tModel. The URL at which these are accessible uses the entity key as a URL parameter. The XML element returned will be a businessDetail, serviceDetail, bindingDetail or tModelDetail, according to the type of entity key supplied. XML for both UDDI version 2 and 3 can be retrieved, at different URLs.

The formats of the URLs to send the HTTP GET requests to are as follows:

For UDDI version 2:
> http://<server>:<port>/uddisoap/get?<entityKey type>=<v2 entityKey>

For UDDI version 3:
> http://<server>:<port>/uddiv3soap/get?<entityKey type>=<v3 entityKey>

For example, if <server> = ″myserver.com″ and <port>=″9080″, then the uddi-org:types tModel can be accessed at the following URLs:

UDDI v2:
> http://myserver.com:9080/uddisoap/get?tModelKey=uuid:c1acf26d-9672-4404-9d70-39b756e62ab4

UDDI v3:
> http://myserver.com:9080/uddiv3soap/get?tModelKey=uddi:uddi.org:categorization:types

There are a number of UDDI property and policy settings that relate to the HTTP GET services:
- Version 3 HTTP GET for UDDI entities
  - Node supports HTTP GET
  - URL Prefix for V3 GET servlet
  - Node generates discovery URLs
- Version 2 HTTP GET for discovery URLs
  - Prefix for generated discovery URLs
  - Node generates discovery URLs

For details, refer to UDDI node miscellaneous policy settings and UDDI node settings.

UDDI registry SOAP Service End Points

UDDI Version 3 supports multiple versions and, depending on WebSphere Application Server security settings and UDDI SOAP service user data constraint transport guarantee settings, supports different end points for different services.

The default context root and URL values listed in this topic apply when you have enabled WebSphere Application Server security and have not changed the default supplied security settings. If you use a non

default security set up, the context root and URL values may differ (see Configuring UDDI registry security for more information about the various security settings).

In the URLs listed below, the variables have the following values:
- *host_name* is the name of the machine that is running the relevant profile.
- *http_port* is the internal HTTP port for the profile, for example 9080.
- *ssl_port* is the internal SSL port for the profile, for example 9443.

Version 1 and Version 2 SOAP API services

Inquiry service
> Default (soap.war) context-root='/uddisoap' and url-pattern = 'inquiryAPI' or 'inquiryapi'.
>
> Default URL: http://*host_name*:*http_port*/uddisoap/inquiryapi

Publish service
> Default (soap.war) context-root='/uddisoap' and url-pattern = 'publishAPI' or 'publishapi'.
>
> Default URL: https://*host_name*:*ssl_port*/uddisoap/publishapi or http://*host_name*:*http_port*/uddisoap/publishapi

Version 3 SOAP API services

Inquiry service
> Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Inquiry_Port'
>
> Default URL: http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Inquiry_Port

Publish service
> Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Publish_Port'
>
> Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Publish_Port or
> http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Publish_Port

Custody transfer service
> Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Custody_Port'
>
> Default URL: https://hostname:9443/uddiv3soap/services/UDDI_Custody_Port or
> http://hostname:9080/uddiv3soap/services/UDDI_Custody_Port

Security service
> Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Security_Port'
>
> Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Security_Port or
> http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Security_Port

There is also an endpoint for using HTTP GET to return XML representations of UDDI entities, described in HTTP GET Services for UDDI registry data structures.

Additional information

If you configure the UDDI registry to use WebSphere Application Server security, and you do not change the default data confidentiality settings for the UDDI SOAP service, then services with default end point URLs with HTTPS and SSL port require their data to be transported confidentially. Requests that are not using HTTPS will be rejected.

If you configure the UDDI registry to use WebSphere Application Server security and you change the data confidentiality setting for the UDDI SOAP service to NONE, or you disable WebSphere Application Server security, then services with default end point URLs with HTTPS and SSL port can also use HTTP and HTTP port.

To understand how access to the SOAP APIs is protected, see Access Control for UDDI registry Interfaces.

The UDDI registry SOAP API:

To use the SOAP API, construct a properly formed UDDI message within the body of a SOAP request, and send it using HTTP POST to the URL of the API that the request relates to. The response is returned within the body of the HTTP reply. The UDDI registry samples include samples that demonstrate how to program directly to the SOAP API. Although the samples are written in Java code, you can use other programming languages to create your SOAP client, providing you still send requests compliant to the SOAP specification. Valid UDDI requests should conform to the UDDI schema, and be as detailed within the UDDI specification:

http://www.uddi.org/pubs/uddi_v3.htm

For more information on using the SOAP API, refer to UDDI registry application programming interface.

UDDI4J programming interface (Deprecated)

Note: Note that the UDDI4J Version 2 APIs are deprecated in this version of WebSphere Application Server. The UDDI Version 3 Client for Java is the preferred API for accessing UDDI using Java code.

WebSphere Application Server provides UDDI4J classes within the com.ibm.uddi_1.0.0.jar file. This file contains classes which support Version 1 and Version 2 of the UDDI specification, providing compatability with earlier versions of WebSphere Application Server. The UDDI4J classes in this file are deprecated.

The UDDI4J methods map onto the UDDI Version 1 and Version 2 SOAP inquiry and publish APIs. These APIs are protected as described in Access control for UDDI registry interfaces. If the role mappings for these APIs are such that requests to these interfaces will require a WebSphere Application Server authenticated user ID, a client program using UDDI4J should pass the user name and password by setting the system properties http.basicAuthUserName and http.basicAuthPassword. A UDDI4J client program can also specify details for a proxy server, including a user name and password, using the following system properties:

- http.proxyHost
- http.proxyPort
- http.proxyUserName
- http.proxyPassword

UDDI EJB Interface (Deprecated)

The UDDI EJB interface is deprecated in WebSphere Application Server Version 6.0 and later versions, and supports UDDI version 2 API requests only.

This section describes how to use the EJB application programming interface (API) of the UDDI registry component to publish, find and delete UDDI entries.

The client classes that are required for the EJB interface are contained in *app_server_root*/UDDIReg/ clients/uddiejbclient.jar. You can read the Javadoc for these classes at the Javadoc welcome page.

The EJB API is contained in two stateless session beans, one for the Inquiry API (com.ibm.uddi.ejb.InquiryBean) and one for the Publish API (com.ibm.uddi.ejb.PublishBean), whose public methods form an EJB interface for the UDDI registry. All the public methods on the InquiryBean correspond to UDDI Version 2 Inquiry API functions, and all the public methods on the PublishBean correspond to UDDI Version 2 Publish API functions. Not all UDDI Version 2 API functions are implemented, for example get_authToken, discard_authToken, get_businessDetailExt.

Within each interface there are groups of overloaded methods that correspond to the operations in the UDDI 2.0 specification. There is a separate method for each major variation in function. For example, the single UDDI operation find_business is represented by 10 variations of findBusiness methods, with different variations for finding by name, finding by categoryBag and so on.

The arguments for the EJB interface methods are Java objects in the package com.ibm.uddi.datatypes. Roughly speaking, there is a one to one correspondence between classes in this package and elements of the UDDI Version 2 XML schema. Exceptions to this are, for example, where UDDI XML elements can be represented by a single String. See the Javadoc for package com.ibm.uddi.datatypes for more information at Javadoc welcome page

The methods on the EJB InquiryBean map to the EJB Inquiry Role, and those of the EJB PublishBean map to the EJB Publish Role. The EJB Inquiry and Publish roles protect the EJB interface as described in Access control for UDDI registry interfaces. If the role mapping is such that a method will require a WebSphere Application Server authenticated user ID, a client program can supply the user ID and password either when prompted by WebSphere Application Server, or by providing application code which logs in to the default realm using the user ID and password. Use the `sas.client.props` configuration file to determine how the user ID and password should be specified (see Configuring security with scripting for information on how to do this).

Using the EJB Client

In this section it is assumed that you have installed both WebSphere Application Server and the UDDI registry (and they are both running). You cannot use the EJB Client from a machine that does not have WebSphere Application Server installed.

1. Set up your environment for communicating with WebSphere Application Server:

   ▶ Linux ◀   `. app_server_root/bin/setupCmdLine.sh` (note that there is a space between the '.' and *app_server_root*)

   ▶ Windows ◀   `app_server_root/bin/setupCmdLine.bat`

2. Ensure that your CLASSPATH includes the uddiejbclient.jar (from *app_server_root*/UDDIReg/clients) and the code for your client.

3. Compile your EJB client programs:

   ▶ Linux ◀   `$JAVA_HOME/bin/javac -extdirs $WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext -classpath $WAS_CLASSPATH:$CLASSPATH yourcode.java`

   ▶ Windows ◀   `$JAVA_HOME/bin/javac -extdirs $WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext -classpath $WAS_CLASSPATH:$CLASSPATH yourcode.java`

4. Execute the compiled programs:

   ▶ Linux ◀   `$JAVA_HOME/bin/java -Djava.ext.dirs=$WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext -Dwas.install.root=$WAS_HOME -Dserver.root=$WAS_HOME $CLIENTSAS $CLIENTSOAP -cp $WAS_CLASSPATH:$WAS_HOME/UDDIReg/clients/uddiejbclient.jar:$CLASSPATH <class name> <args>`

   ▶ Windows ◀   `%JAVA_HOME%\bin\java -Djava.ext.dirs=%WAS_EXT_DIRS%;%JAVA_HOME%\jre\lib\ext -Dwas.install.root=%WAS_HOME% -Dserver.root=%WAS_HOME% %CLIENTSAS% %CLIENTSOAP% -cp %WAS_CLASSPATH%;%WAS_HOME%\UDDIReg\clients\uddiejbclient.jar:%CLASSPATH% <class name> <args>`

Ensure that your PATH statement starts with *app_server_root*/java/bin

---

Service integration

Learning about file stores

Use the subtopics to learn about various aspects of file stores, such as different types of files within it and high availability.

- "File stores"
- "File store high availability considerations" on page 593
- Files in a file store
- "File store configuration attributes"
- File store performance

File stores

File stores enable messaging engines to preserve operating information and to persist those objects that messaging engines need for recovery in the event of a failure, using a file system.

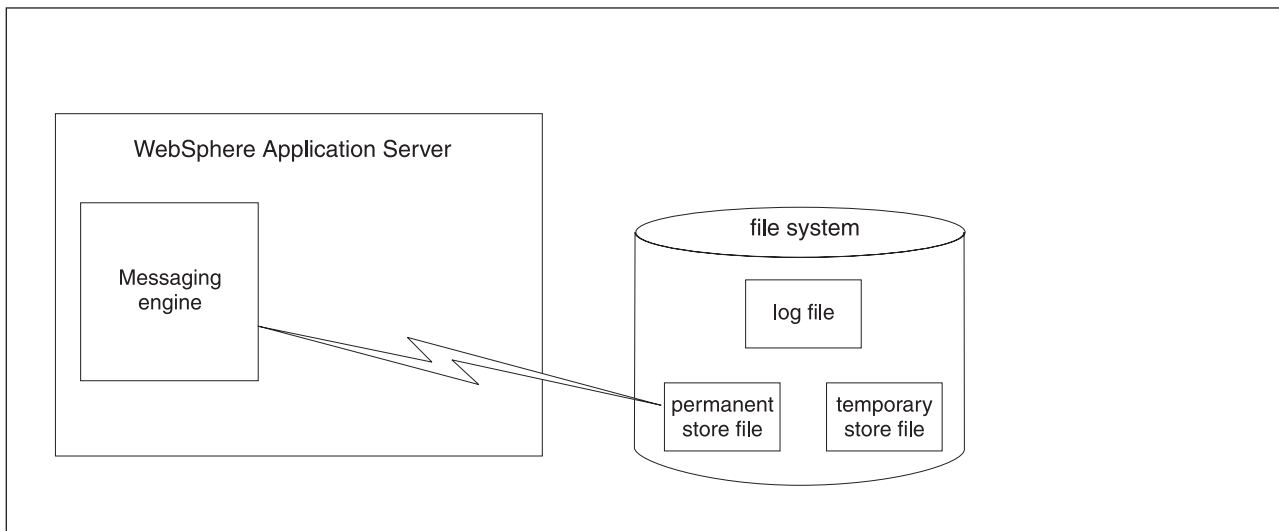
A file store is a type of message store which directly uses files in a file system via the operating system. File store mechanisms splits data storage into three levels: the log file, permanent store files and temporary store files. For more information on these files see "File store configuration attributes."


Figure 6. The relationship between a messaging engine and its file store.

File store configuration attributes:

The log file, permanent store file and temporary store file make up a file store. You preserve appropriate amount of space within these three files so that operations and transactions behave predictably.

Data is first written to the log file sequentially, that is, new records are added to the end of the file. When the end of the log file is reached, old records at the beginning of the log file are overwritten by new records and this process repeats. Subsequently data is written to the permanent store file and temporary store file, although extremely short-lived data is only written to the log file.

The permanent store file and temporary store files have a minimum reserved sizes and a maximum size each. When created, the permanent and temporary store files consume their minimum reserved sizes, plus the size of the log. If the maximum size is larger, they grow up to the maximum size as required. The maximum size can be unlimited. It is recommended for production use that the minimum and maximum sizes are the same, as it prevents the store files from growing and shrinking at runtime so that the messaging engine does not gradually fill a file system. Another advantage is that if the file system does fill up while the messaging engine is operating, it is not affected.

The default configuration is intended to be sufficient to be used in typical messaging workloads without any administration. To improve the performance or availability of the log or the two store files, the administrator can modify the file store attributes to control where these files are placed. Similarly, the

administrator can modify the attributes which control the sizes of the log and two store files to handle workloads with a large number of active transactions, large messages or a large volume of message data resident in the messaging engine

Note: This behavior cannot be guaranteed on a compressing file system, for example, NT file system with the **Compress this directory** option selected. You should avoid configuring file store to use a compressing file system for production use.

Table 20. File stores have the following attributes and values

Name	Description	Minimum and Default Values in mega bytes
Log size	Size of the log file, in mega bytes	• *Minimum*: 10 MB • *Default*: 100 MB
Minimum permanent store size	The minimum number of mega bytes reserved by the permanent store file. **Note:** The store files must always be at least as big as the log file.	• *Minimum*: 0 • *Default*: 200 MB
Maximum permanent store size	The maximum size in mega bytes of the permanent store file. **Note:** The store files must always be at least as big as the log file.	• *Minimum*: 50 MB • *Default*: 500 MB
Minimum temporary store size	The minimum number of mega bytes reserved by the temporary store file. **Note:** The store files must always be at least as big as the log file.	• *Minimum*: 0 • *Default*: 200 MB
Maximum temporary store size	The maximum size in mega bytes of the temporary store file. **Note:** The store files must always be at least as big as the log file.	• *Minimum*: 50 MB • *Default*: 500 MB
Unlimited permanent store size	Indicates whether the permanent store file is unlimited in size	• *Default*: false
Unlimited temporary store size	Indicates whether the temporary store file is unlimited in size	• *Default*: false
Log directory	Name of the directory that the log file is in	• *Default*: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/<me_name>.<me_build>/log`
Permanent store directory	Name of the permanent store file's directory	• *Default*: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/<me_name>.<me_build>/permanentStore`
Temporary store directory	Name of the temporary store file's directory	• *Default*: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/<me_name>.<me_build>/temporaryStore`

File store high availability considerations

High availability refers to the capability of failing over messaging engines between servers. File stores can be used in highly available environments.

You can achieve high availability by choosing a file store as the message store of a messaging engine. In order to make a file store highly available, you should use hardware or software facilities to maximize the availability of the file store data, for example, SAN.

Note: It is important to ensure that the directories containing the log file and store files are universally accessible with the same directory name from all members of the cluster.

WebSphere Application Server v6.1 supports two styles of file system access to enable this:

- Cluster-managed file system

  This style of file system access uses high availability clustering and failover of shared disks to ensure that the file store's directories are accessible from the server that is currently running the messaging engine. The file store's directories are located on file systems in the shared disks, and high availability cluster scripts are used to mount the file systems on the node with the server that is running the messaging engine.

- Networked file system

  This style of file system access uses a network file system. The most popular protocols for accessing remote files are Common Internet File System (CIFS) and Network File System (NFS). It is recommended that you adopt Version 4 of NFS, which supports automated failover to ensure access locking. Access locking ensures the integrity of the log files, that is, only a single client process can access the log at a time.

Note: It is important to check that the file system configuration is correct, because it cannot be checked by the WebSphere configuration system or messaging engine. Errors only surface at runtime, so thorough failover testing is recommended.

Further information:
These considerations for enabling access to the file store's directories are similar to those for enabling access to the recovery log in a cluster. For more information see the following article: Transactional high availability and deployment considerations in WebSphere Application Server V6

Exclusive access to file store
A messaging engine has exclusive access to file store by design of file stores.

Each file store contains information which uniquely identifies the messaging engine which created it. A file store can only be used by the messaging engine which created it.

The messaging engine opens the file store's files in exclusive mode to prevent multiple instances of the same messaging engine from simultaneously using the file store, for example, by accidental activation on the messaging engine of multiple servers in a cluster. When a messaging engine stops, either in a controlled fashion or as a result of server failure, the file store's files are closed. Then another instance of the same messaging engine is able to open the file store.

Using durable subscriptions

This topic describes things to consider when using *durable subscriptions* for publish/subscribe messaging. A durable subscription can be used to preserve messages published on a topic while the subscriber is not active.

If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscriber, or until they expire, or until the durable subscription is deleted. This enables subscriber applications to operate disconnected from the JMS provider for periods of time, and then reconnect to the provider and process messages that were published during their absence.

Each JMS durable subscription is identified by a subscription name (*subName*), which is defined when the durable subscription is created. A JMS connection also has an associated client identifier (*clientID*), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client. The subName assigned to a durable subscription must be unique within a given client ID.

If an application needs to receive messages published on a topic while the subscriber is inactive, it uses a *durable subscriber*.

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, when running inside an application server it is possible to clone the application server for failover and load-balancing purposes. In this case, a cloned durable subscription can have multiple simultaneous consumers.

For information about durable subscriptions, see the JMS 1.1 Specification (for example, section 9.3.3 "Using Durable Subscriptions").

The following operations for durable subscriptions are in addition to the usual JMS operations, such as to first look up a connection factory and a JMS destination, and to create a connection and session.

The following are the main operations for using durable subscriptions:
- Creating a new durable subscription
- Reconnecting to an existing durable subscription
- Unsubscribing (deleting) a durable subscription
- Define the Durable Subscription Home This property must be set on the JMS connection factory if durable subscriptions are to be created using connections created from this connection factory. The value is the name of the messaging engine where all durable subscriptions accessed through this connection are managed.

  You can also set the Durable Subscription Home on the JMS topic destination, which enables a single connection to access durable subscriptions on more than one messaging engine.

  To be able to create durable subscriptions, the property on the connection factory must not be null (the default). Setting a value of null or empty string on the property of a destination indicates that the value specified on the connection factory should be inherited.
- Creating a new durable subscription A durable TopicSubscriber can be created by a Session or by a TopicSession.

  Having performed the normal setup, an application can create a durable subscriber to a destination. To do this, the client program creates a durable TopicSubscriber, using session.createDurableSubscriber. The name *subName* is used as an identifier of the durable subscription.

```
session.createDurableSubscriber( Topic topic,
        java.lang.String subName,
        java.lang.String messageSelector,
        boolean noLocal);
```

  Alternatively, you can use the two-argument form of this operation, which takes only a topic and name (*subName*) as parameters. This alternative form invokes the four-argument operation with null as the messageSelector and false as the noLocal parameters.

```
session.createDurableSubscriber( Topic topic, java.lang.String subName);
```

  A JMS durable subscription is created with a unique identifier of the form $clientID+"##"+subName$. The characters ## should not be used in the clientID or subName if the JMS connection is to use a durable subscription.

  Handling exceptions. The following JMS exceptions can be thrown for the reasons listed in the exception messages:
  - InvalidDestination - The name of this durable subscription ($clientID+"##"+subName$) clashes with an existing destination.
  - IllegalState - The method was invoked on a closed connection.
  - IllegalState - This destination is not accepting consumers. This probably means that there is already an active subscriber for this durable subscription.
  - InvalidDestination - The mediation named in the parameters cannot be found.
  - InvalidDestination - The destination cannot be found.

- – JMSSecurity - The user does not have authorization to perform this operation.
- – JMSException - Errors occurred in the MsgStore, Comms or Core layers.
- Reconnecting to an existing durable subscription To reconnect to a topic that has an existing durable subscription, the subscriber application calls `session.CreateDurableSubscriber` again, using the same parameters that it used to originally create the durable subscription. However, consider the following important restrictions:
  - – The subscriber must be attached to the same connection.
  - – The destination and subscription name must be the same as in the original method call.
  - – If a message selector was specified, it must be the same as in the original method call.

  By calling createDurableSubscriber again, the subscriber application reconnects to the topic, and receives any messages that arrived while the subscriber was disconnected.
- Unsubscribing (deleting) a durable subscription To unsubscribe (delete) a durable subscription to a topic, the subscriber application calls `session.unsubscribe(java.lang.String `*`name`*`)`.

  Do not call the unsubscribe method to delete a durable subscription if there is a TopicConsumer currently consuming messages from the topic.

Learning about programming mediations

This topic describes additional mediation concepts that you will need for the mediation programming task.

Using the capabilities of the mediation infrastructure, you can program your own mediations to customize the way the service integration bus handles messages. (For further information about mediations, see Mediations and Mediation handlers.

For example, your mediations can
- reformat messages from the format produced by one application to the format required by another
- route messages based on message content
- distribute messages to more than one destination
- augment messages by adding information to a message from another data source
- transcode messages from one concrete representation to another

There are some topics that you should understand before you start to program your own mediations.
1. Read "Overview of programming process" for an overview of how you can program mediations.
2. Read "SI programming resources" on page 597 for an overview of the programming resources available to you.
3. Read "SDO data graphs" on page 597 for information about SDO data graphs, the abstract representation of data that gives you a consistent interface to different message formats.
4. Read "Coding considerations for mediations" on page 598 for things to consider when writing mediation code. These are hints for successful mediation programming, rather than instructions on the task of programming a mediation, which you can read about in "Programming mediations" on page 599

Overview of programming process

This topic describes developing mediations, from coding through to deployment

Programming mediations involves two types of task that draw on different technical skills: programming and integration. Typically, Java programmers will design and code mediations as components called handlers. Integration involves aggregating the mediation handlers using handler lists, then assembling them into a deployable unit to deploy and install them.

Programming. The basic programming task is to create a mediation handler. This is a wrapper for the mediation code that operates on the message. You can create the handler code using information in "Writing a mediation handler" on page 600. Then you will need to add the function mediation code, see

"Adding mediation function to handler code" on page 601. There are three different APIs you will use to work with messages: the SIMessage and SIMessageContext APIs allow you to manipulate the contents of the message, and the SIMediationSession API gives access to the service integration bus so you can send and retrieve messages. See "SI programming resources" for an overview of the APIs, and see "SIMessageContext" on page 610 for reference information and access to the generated API information.

Integration. Mediations can be "pipelined" to create a more powerful set of operations to be performed on a message. At runtime, each handler in the list is invoked in sequence. Each time a handler returns a value of *True*, the same message context is passed to the next handler. If a handler returns *false*, then the context is not passed to any more handlers, which will result in the message being discarded and it will not be delivered to the destination. You use the Application Server Toolkit (AST) deployment wizard to create handler lists (which may be simply a list of one handler) before deploying the handler list as an Enterprise Archive (EAR file).

SI programming resources

This topic describes the programming APIs that are available for working with messages when you program a mediation.

A mediation handler must implement the MediationHandler interface. This interface defines the method which will be invoked by the mediation runtime. For further information on the MediationHandler API, see "MediationHandler" on page 610

The SIMessage and SIMessageContext APIs allow your mediation to operate on the contents of the message. The SIMediationSession API gives your mediation access to the SI Bus so that the mediation can send and receive messages.

- For further information on the SIMessageContext API, see "SIMessageContext" on page 610
- For further information on the SIMessage API, see "SIMessage" on page 611
- For further information on the SIMediationSession API, see "SIMediationSession" on page 612

SDO data graphs

This topic describes how SDO data graphs are used to represent different types of message information in a standard way giving a simple and powerful model for programming mediations.

SDO data graphs are an important concept for mediation programmers. Service Data Objects (SDO) is a technology designed to simplify and unify the way in which applications handle data. Using SDO, you can uniformly access and manipulate data from diverse data sources, including relational databases, XML data sources, Web services, and enterprise information systems.

For a good introduction to SDO, refer to Introduction to Service Data Objects.

SDO is based on data graphs, which are structured collections of data objects. In general, graphs generated from messages will have a tree structure. A mediation retrieves a data graph from a message, transforms the data graph, and the updates to the graph are reflected in the message.

In WebSphere Application Server, data access services connect mediations to data sources, allowing mediations to manipulate an abstract representation of the message, the SIMessage. The SIMessage API provides a method, getDataGraph(), that returns the SDO data graph containing the SIMessage content in a tree representation, or graph of data objects, each of which represents one or more fields in the message, or points to other objects.

When a data graph is requested from a message, the appropriate data access service is identified by a format property in the SIMessage. The format string controls which data access service is used to process the message, and may also contain additional control information for that data access service. In turn, the

structure of the message is controlled by the data access service. For more information about the data access services available in WebSphere Application Server, see "SDO data graph information" on page 612

You use the SIMessageContext API for access to the SIMessage and its rich set of message manipulation methods, and to the SIMediationSession, for Service Integration technologies functionality. For further information, see "SIMessageContext" on page 610

A data object holds a set of named properties, each of which contains either a primitive-type value or a reference to another data object. The Data Object API provides a dynamic data API for manipulating these properties, with the following interfaces that relate to instance data:

- The **DataObject** interface provides a set of methods to retrieve and update the contents of a data object. It also provides methods to access the container of the data object and the data graph to which the data object belongs, to create a new instance of a contained data object, and to delete a data object from its container. In addition, the DataObject interface provides the ability to get the type of the data object.

- A **DataGraph** is a graph of data objects. The graph consists of a single root data object along with all the data objects that can be reached by recursively traversing the containment references of the root data object.

SDO also contains a metadata API for examining the model of a DataGraph:

- A **Type** has a set of Property objects. SDO Types can be compared with type definitions in other type systems. For example, the SDO view of a Java Class would be a Type, and each field in the Class would be represented by a Property. For XML Schema, a ComplexType would be represented by a Type, with a Property for each element or attribute.

- **Property:** a data object is composed of properties. Each property can be accessed by specifying the Property object, the name of the property, or the index of the property.

Coding considerations for mediations

This topic contains programming hints for successful mediations programming.

- Take care to avoid looping in the Forward Routing Path. For example, if you set a destination in the path that is the same as the current destination, the message will endlessly circle, with the routing path being reset to the current destination each time. The mediation framework does not check for loops in routing paths.

- Avoid the use of static fields where possible. A single mediation may be deployed to process multiple messages concurrently.

- Do not cache values computed from the message context or message contents. Such values may change from message to message. The exception is caching values derived solely from the mediation handler properties for performance purposes.

- Mediation programming is subject to the same restrictions as programming an EJB. For more information about restrictions, see Section 18.1.2 of the EJB 1.1 specification.

- Choose the appropriate level of transactional control for your mediation: for example, a mediation that operates on fields within a message is unlikely to have implications for transactional control. At the other extreme, if your mediation updates database fields, it requires transactional control, and you should alert your administrator to set the UseGlobalTransaction flag in the mediation definition. This flag defaults to a value of *False*.

- Considerations that apply specifically to message format:

  – It is good practice to check that your message conforms to the expected format after your mediation function has operated on it. You should use the isWellFormed method in the SIMessage interface to check that all the values of the message properties can be serialized, and that the data graph of the message conforms to the format of the message.

  – Depending on how you want to process the message, you can specify a format that meets your needs rather than accept the natural format. For example, if you want to handle a SOAP message

simply as a byte string, use the getNewDataGraph method in the SIMessage interface and specify a format of `JMS/bytes`. getNewDataGraph returns a new SDO data graph containing a copy of the SIMessage payload content in the tree representation specified by the format field, in this example as a byte string.

    – It is good practice to check the message format in the mediation code because a mediation is unlikely to successfully process a message with an unexpected format. Use getFormat method on the SIMessage interface.

- Due to a restriction in the SDO user interface to the message, message access methods do not have a 'throws' clause. As a result, an exception thrown by an access method because of a parsing error is an unchecked exception. Your mediation can catch a parsing exception by checking for the exception class SIMessageParseException in the `com.ibm.websphere.sib.exception` package. Use code similar to the following example:

```
try {
  // Function involving SDO message access
} catch (SIMessageParseException e) {
  // Look at the real cause of the runtime exception, and act on it.
  // It is likely to indicate a parse failure...
  Throwable cause = e.getCause();
}
```

    Note: If a mediation does not catch the SIMessageParseException, the original version of the message is sent to the exception destination.

- When deploying your mediation, give the handler and the handler list memorable and descriptive names.
- Where you deploy a single mediation against a single destination, use exactly the same name for your mediation handler, the mediation handler list and the mediation object in the administrative console.
- For performance reasons, specify selector rules so that the mediation mediates required subsets only of the messages passing through a destination.

Programming mediations

This topic is an overview of the tasks involved in programming a mediation. Typically, the mediation code is written by a programmer, and is then deployed and administered by an integrator.

Code examples for writing a mediation are provided at "Adding mediation function to handler code" on page 601.

The following application programming interfaces are provided for you to work with messages:
- SIMessage API allows you to manipulate the contents of the message.
- SIMediationSession API provides access to the service integration bus so that your mediation can send and retrieve messages.

Mediations are deployed using the Application Server Toolkit (AST).

The tasks for programming a mediation are:

Developing
    Writing a mediation by adding functional code to a mediation handler.

Deploying
    Adding a mediation to a mediation handler list, and deploying it.

Administering
    Associating a mediation handler with a destination (optional), and configuring the parameters to be used by the mediation handler at runtime.

Take the following steps to program a mediation:

1. Create a mediation handler. For more information, see "Writing a mediation handler."
2. Add mediation function code to your mediation handler. For more information, see "Adding mediation function to handler code" on page 601.
3. Working with the message payload, for example for logging messages within a mediation. For more information, see "Working with the message payload" on page 607.
4. Use the Application Server Toolkit (AST) deployment wizard to create a handler list, add your mediation handler to the list, and deploy the handler list as an Enterprise Archive (EAR file). See the AST information center for information about how to do this.

Serializing the content of SIMessage

Use this task to convert an SIMessage object to a byte array.

If you want to save an SIMessage object in your local file system or in a database, you must first convert the object to a byte array and format string. You can reconstruct the message from the byte array and format string. To do this, take the following steps:

1. In your application program, record the format string associated with the SIMessage instance. For example:

   ```
   String savedFormat=message.getFormat();
   ```

2. Call the `getDataGraphAsBytes`. For example:

   ```
   Bytes newDataGraph = message.getNewDataGraph(newFormat);
   ```

   This method returns a copy of the payload as a byte stream. You can store the bytes and the associated format string, as you require.

3. To reconstruct the message, call the method `createDataGraph` provided by the SIDataGraphFactory API. This method requires a byte array and a format string. For example:

   ```
   DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
   ```

   This method creates a new data graph by parsing the bytes according to the format passed to the method.

You can use the newly created datagraph as the payload of an SIMessage instance by using the SIMessage setDataGraph() method. For example:

```
newMessage.setDataGraph(newDataGraph, savedFormat);
```

Writing a mediation handler

This topic outlines how to write a mediation handler, add mediation function to it, and prepare it for installation on an application server.

Before you start this task, you should have access to a Java programming environment, and the Eclipse development environment (part of the Application Server Toolkit, or AST, supplied with WebSphere Application Server.)

A mediation handler can be deployed. Each mediation handler executes some specific message processing at runtime, for example transforming a message format, or routing a message to a particular destination. A mediation handler is a Java program framework, to which you add the code that performs the mediation function. For more information about handlers, see Mediation handlers.

Your mediation handler class can be defined either in a Java project or an EJB project (which is needed for the deployment artefact.) Your programming and deployment artefacts can be separated in different projects. The steps below are for an EJB project, but the steps are very similar if you want to create a Java project, since you simply define a target server for either a Java project or an EJB project and the server runtime plug-in sets the classpath correctly.

1. Create a new EJB project:

a. Switch to the J2EE perspective to work with J2EE projects. Click **Window > Open Perspective > Other >J2EE**.

b. From the File menu, select **New > Project**.

c. Expand the J2EE folder, and select Enterprise Application Project. Click **Next**.

d. **Optional:** If you have created a Java project instead of an EJB project, right click on the Java project folder icon for the context menu and select Properties. When the Properties panel appears, select the Server properties and target the project to WebSphere Application Server Version 6.0, as in the next step.

e. Enter a name for the project and target the project to WebSphere Application Server Version 6.0. (If this is the first time you target this server you will need to click the **New...** button.) Click **Next** to take you to the EAR Module Projects window.

f. Click **New Module...**.

g. Create a new module project by selecting the check box against EJB project, and entering the name of your mediation handler.

h. Click **Finish**. You are returned to the EAR Module Projects window.

i. Click **Finish** to create the new project.

2. Create a mediation handler class by implementing the `com.ibm.websphere.sib.mediation.handler.MediationHandler` interface.

a. From the File menu, select **New > Java Class**.

b. Specify the source folder for your mediation EAR project.

c. Specify a name for your mediation handler.

d. Select Superclass `java.lang.Object`.

e. Select Interface `com.ibm.websphere.sib.mediation.handler.MediationHandler`.

f. Click in the check box to select Inherited abstract methods

g. Click **Finish** to create the new mediation handler class.

3. Add functional code that transforms or routes messages to your mediation handler using the Application Server Toolkit (AST). For more information, see "Adding mediation function to handler code." Beware that the default return value for the handle method created by the toolkit is `false`, which causes the message to be discarded. You need to change the return value to `true` to preserve the message.

4. Prepare your mediation handler for installation into the application server. Follow the instructions in the topic entitled ″Deploying a mediation handler″ in the AST information center. Note that AST is also available in the Rational Software Development Platform.

Next, you are ready to install your mediation handler into the application server.

Adding mediation function to handler code

This topic describes how to add mediation function to a preexisting mediation handler.

You should have created the basic mediation handler in an EJB project (see "Writing a mediation handler" on page 600

There are four ways in which you can work with a mediation to add to, or change, its function. You can work with the mediation context properties, with the message properties, with the contents of the message (the message payload), or with the message header, for instance to change the routing of the message.

1. To work with the message context, see "Working with the message context"

2. To work with the message properties, see "Working with the message properties" on page 602

3. To work with the message header, see "Working with the message header" on page 603

4. To work with the message payload, see "Working with the message payload" on page 607

Working with the message context:

This topic describes how to work with the message properties to affect the way a message is mediated.

Before you start this task, you should read about how information is carried in the mediation context in Mediation context information

Interface SIMessageContext has a superinterface MessageContext. Methods in MessageContext allow you to manage a set of message properties, which enable handlers in a handler chain to share processing-related state. Most importantly, you can get the value of a specific property from the MessageContext using the method getProperty, and you can set the name and value of a property associated with the MessageContext using the method setProperty. You can also view the names of the properties in this MessageContext and remove a property (that is, a name-value pair) from the MessageContext.

At mediation runtime, all of the user-defined properties that have been set during configuration for the current mediation (see Configuring mediation context properties) are applied to the MediationContext property set.

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. As you are working with the MessageContext methods that give you access to message properties, you do not need to cast the interface to SIMessageContext **unless** you are also interested in the methods provided by SIMessageContext.

2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`

3. Retrieve or set properties, using the MessageContext methods. For instance, if a property has been defined during configuration with the name streetName, the type String, and the value ″Main Street″ your code to retrieve and print the street name may look like this:

```
public boolean handle(MessageContext context) throws MessageContextException {

  ........
  {
    /* Retrieve the street name property */
    String myStreetName;
    myStreetName = (String) getProperty(streetName);

    /* Display property value */
    System.out.println(myStreetName);

  }
}
```

Working with the message properties:

This topic describes how to work with the message properties to affect subsequent processing.

Before you start this task, you should read about the properties that are supported by the SIMessage interface in Message properties support for mediations.

There are two different types of message properties:

- System properties (including JMS headers, JMSX properties, and JMS_IBM_properties)
- User properties.

You can work with message properties to affect which messages a later mediation should process, or to affect processing by a downstream application or mediation. The rule set in the selector field during mediation configuration tests values in the message properties.

You can access, modify and clear properties using the SIMessage interface (see "SIMessage" on page 611.) There are three different sets of methods:

- These properties operate on system properties, plus user properties if the name is qualified with a prefix `user.`:
  - getMessageProperty
  - setMessageProperty
  - deleteMessageProperty
  - clearMessageProperties
- These properties operate on user properties only, without the need for the prefix `user.`:
  - getUserProperty
  - setUserProperty
  - deletUserProperty
  - clearUserProperties
- getUserPropertyNames returns a list of the names of the user properties in the message.

Typically, you can work with message properties in the following way, when programming a mediation:

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.

2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`

3. Build your mediation header function in a similar way to these examples, using the reference information in Message properties support for mediations to help:

   a. Get a user property of the message. For instance, `String task = (String)msg1.getUserProperty("task");`. In this case, the task string may refer to an operation that the mediation should perform.

   b. Set a user property, where message Properties are stored as name-value pairs. The setUserProperty method may only be used to set user properties, so the name passed into the method should not include the "user." prefix. For example, `msg1.setUserProperty("background","green");`

   c. Delete a user property from the message. For instance, `msg1.deleteUserProperty("task");`

Mediation function code to work with message properties may look similar to the code snippet in this example:

```
String task = (String)msg1.getUserProperty("task");
if (task != null) {
  if (task.equals("addColor")) {
    msg1.setMessageProperty(SIProperties.JMS_IBM_Format, "colorful");
    msg1.setUserProperty("background","green");
    msg1.setUserProperty("foreground","purple");
    msg1.setUserProperty("depth",new Integer(3));
    msg1.deleteUserProperty("task");
  }
  else {
    msg1.clearUserProperties();
  }
}
```

Working with the message header:

This topic describes how to add function to a preexisting mediation handler to operate on the message header.

Before you start this task, you should have created the basic mediation handler in an EJB project (see "Writing a mediation handler" on page 600. It will be useful to have understood the elements of the task "Working with the message payload" on page 607, because some of those elements are used in this task

There are different types of field that you can set in message headers. Importantly, you can set the forward and return routing addresses for messages after they have been mediated at the current destination. In addition there are other fields that you can set, such as priority and reliability for the message and its reply, and the remaining time before the message (or the reply) expires.

1. To set routing addresses in the message header, see "Setting routing addresses in a message header."
2. To set all other fields in the message header, see "Working with non-routing path fields in a message header" on page 606.

Setting routing addresses in a message header:

This topic describes how to add function to a preexisting mediation handler to set routing addresses in the message header.

Before you start this task, you should have created the basic mediation handler in an EJB project (see "Writing a mediation handler" on page 600.

To work with routing addresses, you will use the SIDestinationAddress and SIDestinationAddressFactory APIs. The SIDestinationAddress is the public interface which represents an service integration bus, and gives your mediation access to the name of the destination and the bus name. SIDestinationAddressFactory enables you to create a new SIDestinationAddress to represent an service integration bus destination. For reference information about these APIs, see "SIDestinationAddress" on page 605 and "SIDestinationAddressFactory" on page 605.

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.

2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`

3. Build your mediation header function using these basic steps:

   a. Get a handle to the core runtime. For example, `....` `SIMediationSession mediationSession = mediationContext.getSession();`

   b. Create a forward routing path to set on the cloned object. Use, for example the Vector class to create a extendable array of objects.

   c. Get the SIDestinationAddressFactory which is to be used for creating SIDestinationAddress instances. For instance, `SIDestinationAddressFactory destFactory = SIDestinationAddressFactory.getInstance();`

   d. Create a new SIDestinationAddress, representing an SIBus Destination. For instance, `SIDestinationAddress dest = destFactory.createSIDestinationAddress(remoteDestinationName(),false);`. In this case, the second parameter, the boolean false, indicates that the destination should not be localized to the local messaging engine, but can be anywhere on the service integration bus.

   e. Use the add method of the Vector class to add another destination name to the array.

   f. Clone the message, and modify the forward routing path in the cloned message. For example, `clonedMessage.setForwardRoutingPath(forwardRoutingPath);`

   g. Send the cloned message using the send method in the SIMediationSession interface to send the message to the service integration bus. For instance, if named "clonedMessage", `mediationSession.send(clonedMessage, false);`

4. Return *true* to ensure the message passed into the handle method of the MediationHandler interface continues along the handler chain.

The complete mediation function code to changer the forward routing path may look similar to this example:

```
/* A sample mediation that simply clones a message
 * and sends the clone off to another destination  */

public class RoutingMediationHandler implements MediationHandler {

 public String remoteDestinationName="newdest";

 public boolean handle(MessageContext context) throws MessageContextException {
  SIMessage clonedMessage = null;
  SIMessageContext mediationContext = (SIMessageContext) context;
  SIMessage message = mediationContext.getSIMessage();
  SIMediationSession mediationSession = mediationContext.getSession();

  // Create a forward routing path which will be set on the cloned message
  Vector forwardRoutingPath = new Vector();
  SIDestinationAddressFactory destFactory = SIDestinationAddressFactory.getInstance();
  SIDestinationAddress dest = destFactory.createSIDestinationAddress(remoteDestinationName,false);
  forwardRoutingPath.add(dest);

  try {
   // Clone the message
   clonedMessage = (SIMessage) message.clone();
   // Modify the clone's frp
   clonedMessage.setForwardRoutingPath(forwardRoutingPath);
   // Send the message to the next destination in the frp
   mediationSession.send(clonedMessage, false);
  } catch (SIMediationRoutingException e1) {
   e1.printStackTrace();
  } catch (SIDestinationNotFoundException e1) {
   e1.printStackTrace();
  } catch (SINotAuthorizedException e1) {
   e1.printStackTrace();
  } catch (CloneNotSupportedException e) {
   // SIMessage should clone OK so we shouldn't really enter this block
   e.printStackTrace();
  }
  // allow original message to continue on its path
  return true;
 }
```

SIDestinationAddress:

This topic describes the SIDestinationAddress, the public interface which represents a service integration
bus destination.

The API has three methods:
- isTemporary: This method determines whether the SIDestinationAddress represents a temporary or
  permanent Destination, returning a boolean value.
- getDestinationName: Method to retrieve the name of the Destination represented by this
  SIDestinationAddress.
- getBusName: Method to retrieve the bus name of the Destination represented by this
  SIDestinationAddress.

For more information about the SIDestinationAddress interface, see the SIDestinationAddress generated
API information.

SIDestinationAddressFactory:

This topic describes the SIDestinationAddressFactory, the public interface which is used for the creation of
each instance of an SIDestinationAddress.

public abstract class SIDestinationAddressFactory extends java.lang.Object

This class creates an SIDestinationAddressFactory at static initialization that is subsequently used for the creation of all instances of SIDestinationAddress

The API has three methods:

* getInstance: This method gets the singleton SIDestinationAddressFactory which is to be used for creating SIDestinationAddress instances.
* createSIDestinationAddress: These two methods are used to create a SIDestinationAddress to represent a service integration bus destination. The first will create a SIDestination that exists only on the local service integration bus (and maybe localized to the "local" messaging engine depending on the localOnly flag). The second method is used to create a SIDestination that exists on a remote service integration bus.

`

For more information about the SIDestinationAddressFactory interface, see the SIDestinationAddressFactory generated API information.

Working with non-routing path fields in a message header:

This topic describes how to work with fields in a message header that identify and affect the behavior of messages.

In addition to the routing fields (see "Setting routing addresses in a message header" on page 604), there are a number of fields in the message header that you can work with. These fields affect important qualities and characteristics of the message, like priority and reliability, identity, and so on. See "Message header reference information" for information about the equivalence of the header fields to JMS message header fields, and the methods available to work with them.

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.
2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, using the reference information in "Message header reference information" to help:

   a. Set the reliability of the message. For instance, `siMessage.setReliability(Reliability.ASSURED_PERSISTENT);`. In this case, the quality of service is set to the highest level.

   b. Set the time to live for a message - that is, the time, in milliseconds, that the message is allowed to remain on a queue before it is removed if it is not processed. For example, `siMessage.setRemainingTimeToLive(1000000);` will set the remaining time before the message should expire to 1000 seconds.

Message header reference information:

This topic describes the mapping of the non-routing message property fields to JMS header fields, and the methods available to work with them.

Header fields

SIMessage header field	Field description	Corresponding JMS message header field	SIMessage methods
Priority (ReplyPriority)	Integer value 0-9, higher value is higher message priority	JMSPriority	• getPriority • setPriority • getReplyPriority • setReplyPriority
Reliability (ReplyReliability)	Specifies the reliability of message delivery. See Message reliability levels for a description of the possible values.	JMSDeliveryMode supports two levels of reliability: PERSISTENT and NON_PERSISTENT	• getReliability • setReliability • getReplyReliebility • setReplyReliability
TimeToLive (ReplyTimeToLive, RemainingTimeToLive)	Specifies the time in milliseconds a message can remain on the queue before it expires	JMSExpiration is the time of expiry calculated as current time plus time-to-live.	• getTimeToLive • getReplyTimeToLive • getRemainingTimeToLive • setTimeToLive • setReplyTimeToLive • setRemainingTimeToLive
Discriminator (ReplyDiscriminator)	String containing a topic that is tested by a selector rule to determine if message should be mediated.	No corresponding JMS field	• getDiscriminator • setDiscriminator • getReplyDiscriminator • setReplyDiscriminator
RedeliveredCount	Read-only field containing the count of each time a message has been redelivered	JMSRedelivered is an indicator it is likely, but not guaranteed, that this message was delivered but unacknowledged in the past.	getRedeliveredCount
ApiMessageId	A value that uniquely identifies each message sent.	JMSMessageId	• getApiMessageId • setApiMessageId
CorrelationId	Used to link one message with another - typically a response message with its request.	JMSCorrelationId	• getCorrelationId • setCorrelationId
UserId	The identity of the user sending the message.	JMSX Userid is a message property not used by WebSphere Application server.	• getUserId • setUserId

Working with the message payload:

This topic describes how to work with the message payload in a pre-existing mediation handler, and transcode the message payload from one message format to another.

This task requires a mediation handler in an EJB project. For more information, see "Writing a mediation handler" on page 600. You should also read the tips for successfully programming mediations in the topic "Coding considerations for mediations" on page 598.

You can use this task to perform some or all of the following actions on the message payload:
• Locate the data objects within the message payload

- Convert the payload into another format
- Convert the payload into a byte array, for example if you want your mediation to log messages.

To work with the contents of a message, use the SIMessage and SIMessageContext APIs. Additionally, use SIMediationSession to provide your mediation with access to the service integration bus, to send and receive messages. For more information, see:
- "SI programming resources" on page 597
- "MediationHandler" on page 610
- "SIMessageContext" on page 610

To work with specific fields within a message, use SDO data graphs. For more information, see "SDO data graphs" on page 597. For more information about the format of supported message types, and examples of how to work with them, see "SDO data graph information" on page 612.

To work with the message payload, take the following steps:

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext unless you only want to work with the methods provided by MessageContext.

2. Retrieve the data graph of the message payload as follows:

   a. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`

   b. Get the message format string to determine its type. For example, `String messageFormat = message.getFormat();`

   c. Retrieve the DataGraph object (see "SDO data graphs" on page 597) from the message. For example, `DataGraph dataGraph = message.getDataGraph();`

3. **Optional:** Locate data objects within the payload as follows:

   a. Navigate within the graph to a named DataObject. For example, where DataObject has the name `"data"`, `DataObject dataObject = dataGraph.getRootObject().getDataObject("data");`

   b. Retrieve information contained in the data object. For instance, if the message is a text message, `String textInfo = dataObject.getString("value");`

4. Work with the fields within the message, for an example of how to do this, see "Example code for message fields" on page 609.

5. **Optional:** Transcode the payload into another format as follows:

   a. Review the topic "Transcoding between different message formats" on page 629 to understand the implications of transcoding the payload.

   b. Call the method getNewDataGraph, passing the new format as a parameter, which returns a copy of the payload in the new format. For instance, `DataGraph newDataGraph = message.getNewDataGraph(newFormat);`

   c. Write the data graph in the new format back to the message using the setDataGraph method. For example, `message.setDataGraph(newDataGraph, newFormat);`

6. **Optional:** Convert the payload into a stream of bytes as follows:

   a. Review the topics "Data graph to bytes conversion" on page 628 and "Bytes to data graph conversion" on page 629 to understand the implications of converting between message format and byte stream, and back again.

   b. Call the method getDataGraphAsBytes, which returns a copy of the payload as a byte stream. For example, `byte[] newByteArray = message.getDataGraphAsBytes();`

   c. Call the method createDataGraph provided by the SIDataGraphFactory API which creates a new data graph by parsing the bytes according to the format passed to the method. For example, `DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph( byteArray, format);`

d. For an example of how to work with a message as a stream of bytes, see "Example code for message fields."

7. Return *True* in your mediation code so that the MessageContext is passed to the next mediation handler in the handler list. If the return value is *False* the MessageContext will be discarded and will not be delivered to the destination.

> **Note:** If your mediation handler is the last handler in the handler list, and the forward routing path is empty, the message is made available to consuming applications on that destination. If the forward routing path not empty, the message is not made available to any consumers on that destination. Instead, the message is forwarded to the next destination in the routing path.

Example code for message fields

Below is an example of the code for a mediation for working with a field in a message:

```
public boolean handle(MessageContext context) throws MessageContextException {

 /* Get the SIMessage from the MessageContext object */
 SIMessage message = ((SIMessageContext)context).getSIMessage();

 /* Get the message format string */
 String messageFormat = message.getFormat();

 /* If we have a JMS TextMessage then extract the text contained in the message. */
 if(messageFormat.equals("JMS:text"))
 {
  /* Retrieve the DataGraph object from the message */
  DataGraph dataGraph = message.getDataGraph();

  /* Navigate down the DataGraph to the DataObject named 'data'. */
  DataObject dataObject = dataGraph.getRootObject().getDataObject("data");

  /* Retrieve the text information contained in the DataObject. */
  String textInfo = dataObject.get("value");

  /* Use the text information retrieved */
  System.out.println(textInfo);
 }

 /* Return true so that the MessageContext is passed to any other mediation handlers
 * in the handler list */
 return true;

 }
```

The complete mediation function code for working with the message payload as a stream of bytes may look similar to this example:

```
 public boolean handle(MessageContext context)throws MessageContextException {

 /* Get the SIMessage from the MessageContext object */
 SIMessage message = ((SIMessageContext)context).getSIMessage();

   if (!SIApiConstants.JMS_FORMAT_MAP.equals(msg.getFormat()))
   {
     try
     {
       dumpBytes(msg.getDataGraphAsBytes());
     }
     catch(Exception e)
     {
       System.out.println("The message contents could not be retrieved due to a "+e);
     }
   }
```

```
    else
    {
      System.out.println("The bytes for a JMS:map format message cannot be shown.");
    }

    return true;
  }

  private static void dumpBytes(byte[] bytes)
  {
    // Subroutine to dump the bytes in a readable form to System.out
  }
}
```

MediationHandler:

This topic describes the interface which defines the method invoked by the mediation runtime.

public interface MediationHandler. This interface defines the method which will be invoked by the mediation runtime.

The method handle invokes a mediation. It is called by the runtime when a message is to be mediated. The method returns boolean *True* if the message passed into this method should continue along the handler list, otherwise *False*.

At the end of the handler list, the message is sent to the next destination on the routing path, unless the forward routing path is empty, when the message is made available to consuming applications on the current destination.

The API has just one method:
• handle: Method used by the runtime to invoke a mediation.

For more information about the MediationHandler interface, see the MediationHandler generated API information.

SIMessageContext:

This topic describes the interface which abstracts the message context processed by a message handler.

public interface SIMessageContext extends javax.xml.rpc.handler.MessageContext.

This is the object that is required on the interface of a mediation handler. In addition to the context information that may be passed from one handler to another, it can return a reference to an SIMessage and an SIMediationSession. The SIMessage is the service integration technologies representation of the message being processed by the MediationHandler The SIMediationSession is a handle to the run time resources.

The interface MessageContext abstracts the message context that is processed by a handler in the handle method. The MessageContext interface provides methods to manage a property set. MessageContext properties enable handlers in a handler chain to share processing related state.

As well as defining the method which will be invoked by the mediation runtime, the interface may also specify properties following the Enterprise JavaBeans naming pattern, or by providing a BeanInfo class. Each property of the bean will be initialized from a single environment entry with the same name as the property. Bean properties of simple type are specified using Java 2 Platform, Enterprise Edition (J2EE) **env-entry**. If the handler has properties that are of non-simple type, then other environment definitions may be used.

The API has two methods:

- getSIMessage: Method to get the service integration bus representation of the message being mediated. Read more about the SIMessage API in "SIMessage."
- getSession: Method to get an SIMediationSession object which is a handle to the core runtime. Read more about the SIMediationSession API in "SIMediationSession" on page 612.

For more information about SIMessageContext, see the SIMessageContext generated API information.

SIMessage:

This topic describes the SIMessage interface; the public interface to a service integration bus message for use by mediations and other service integration bus components.

The public interface SIMessage extends java.lang.Cloneable and java.lang.Serializable.

The SIMessage interface has many methods allowing you to work with message properties, header contents, routing path, metadata, and others:

- The method getDataGraph returns the SDO data graph. This contains the SIMessage payload content in a tree representation. Using the data graph, you can work directly with individual fields in the message payload. For more information about SDO data graphs, see "SDO data graphs" on page 597.
- You can transcode a message payload by calling the method getNewDataGraph(format). It returns a copy of the payload in the new format. You can write the new datagraph back to the message using setDataGraph(DataGraph, format). For more information, see "Transcoding between different message formats" on page 629.
- If you want to log a message as a simple byte stream, you can retrieve the message payload as a byte array using the method getDataGraphAsBytes. For more information about converting from data graph to bytes, and back again, see "Data graph to bytes conversion" on page 628 and "Bytes to data graph conversion" on page 629.
- There are methods to get, set, delete and clear user properties and message properties. You can also retrieve a list of user property names. For more information about working with properties, see "Working with the message properties" on page 602.
- Forward and reverse routing paths define a sequential list of intermediate bus destinations through which messages pass to reach a target bus destination. You use a routing path to apply the mediations configured on several destinations to the messages sent along the path. The following methods allow you to get and set the contents of the ForwardRoutingPath and ReverseRoutingPath for an SIMessage:
  - getForwardRoutingPath()
  - setForwardRoutingPath()
  - getReverseRoutingPath()
  - setReverseRoutingPath()

  For more information about routing paths, see Destination routing paths. For information about how to work with routing addresses, see "Setting routing addresses in a message header" on page 604.
- If your mediation changes the content of the message, there is a risk that the message is no longer valid. If the data graph is not valid, the message cannot be sent through the service integration bus or stored in the message store. In this case, the message is not **well formed**. A message is well formed when all the values of the message properties may be serialized, and the data graph of the message conforms to the format of the message. You can test your message using the method isWellFormed. It returns *true* when the message contains a well formed data graph. This test has implications for performance. For more information, see Setting tuning properties for a mediation.
- You can work with the time for the message to live, measured in milliseconds from the time when the message was originally sent:
  - The methods getTimeToLive and setTimeToLive allow you to get and set the value of the TimeToLive field in the message header. A value of 0 indicates that the message will never expire.

– The methods getRemainingTimeToLive and setRemainingTimeToLive allow you to get the remaining time in milliseconds before the message expires, and set the remaining time in milliseconds before the message should expire.

For more information about SIMessage, seeSIMessage.

SIMediationSession:

This topic describes the SIMediationSession interface which defines the methods for querying and interacting with the service integration bus. It also includes methods that provide information on where the mediation is being invoked from.

public interface SIMediationSession

As well as defining the methods for working with the service integration bus, this API also includes methods that provide information on where the mediation is invoked from, and the criteria that are applied before the message is mediated.

Both selector and discriminator control which messages are sent to the mediation, through a rule specified in a text string. The rule specified by the selector examines the header and properties of the message, while the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

The API has these methods:
- getBusName returns the name of the bus upon which the mediation is associated.
- getDestinationName returns the name of the destination with which the mediation is associated.
- getDiscriminator returns the discriminator that is defined in the mediation definition.
- getMediationName returns the name of the mediation that is being executed.
- getMessageSelector returns the message selector that is defined in the mediation definition.
- getMessagingEngineName returns the name of the messaging engine from which the mediation was invoked
- getSIDestinationConfiguration returns the SIDestinationConfiguration object associated with the destination, specified by destinationName or destinationAddress.
- receive receives an SIMessage from the service integration bus. There are four variants.
- resetIdentity changes the identity of the given message to the current run-as identity.
- send sends a copy of an SIMessage to the service integration bus, in addition to the message returned by the message interface.

See also the generated API information for SIMessageContext .

SDO data graph information:

This topic describes working with SDO data graphs to access message data.

A message published in one format (for instance, a Web services SOAP message) may be routed to a consumer that requires another format, such as enterprise beans, using the Java API for XML-based RPC (JAX-RPC). Equally, the routing could be in the other direction. If the message is operated on by a mediation as it passes through the bus, in either direction, the mediation must be able to operate on the message regardless of the underlying format.

This is achieved by using a common message model for the data mediators. The model is called SDO DataGraph (see "SDO data graphs" on page 597) and it gives an abstract view of the message, allowing

you to concentrate on the information being conveyed (such as the parameters of the request, the data of the response) without having to worry about the packaging of that information.

you can read the WebSphere Application Server information on data access with SDO in SDO view. The topic also contains a link to an introductory white paper, http://www-106.ibm.com/developerworks/java/library/j-sdo/.

For further information about the data graph format of:
- Web services messages, see "Web services overview"
- JMS messages, see "JMS formats" on page 625

Web services overview:

This topic describes how to work with the abstract data graph form of Web services messages.

The format of Web services messages

WebSphere Application Server supports two formats for Web services messages: SOAP and enterprise beans (similar to Java APIs for XML based RPC, or JAX-RPC).

The information you need to work with Web services messages is in three parts:
- The structure of the SDO data graphs for Web services messages. See "Mapping of SDO data graphs for Web services messages" on page 614 for more information about the data elements and the shape of the data graph.
- Reference information to help you develop code to navigate the data graphs of the messages that your program mediates. See "Mapping XML schema definitions to the SDO type system" on page 617.
- For XML representations of the shape of each part of Web services messages, sample code snippets and further information about the data graph format, see:"Web Services code example" on page 621.

Format types

The Web services message type is defined by a message format string within the message. The format string is prefixed with a domain identifier, either SOAP or Bean, followed by four comma separated fields as shown below:

```
SOAP:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>
Bean:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>
```

The fields are described in the following table:

Field name	Message format string	Field description
WSDL location	<wsdlLocation>	The URI where the WSDL for this message is located. The WSDL is deployed to the SDO Repository using this location as the key.
Service namespace	<serviceNamespace>	Service namespace and Service name uniquely identify the Service definition within the WSDL.
Service name	<serviceName>	Service name and Service namespace uniquely identify the correct Service definition within the WSDL.

Port name	`<portName>`	Locates the Port definition within the Service, giving the PortType and Binding information required for message processing.

Mapping of SDO data graphs for Web services messages:

This topic describes the layouts for the different parts of Web services messages

Overall Web service message layout

The Info node is the top of the graph for all Web services messages. It has these properties and associated types:

Property name	Property type	Property description
operationName	`java.lang.String`	Identifies the WSDL operation the message is associated with. If the data access service cannot identify the message this field may be null. See "Identifying Web services messages" on page 615
messageName	`java.lang.String`	Identifies the WSDL message this message is associated with. If the data access service cannot identify the message this field may be null. See "Identifying Web services messages" on page 615
messageType	`java.lang.String`	Identifies WebService type of message instance. The field can have the values *input*, *output*, *fault*, *ambiguous*. If the data access service cannot identify the message this field may be null. See "Identifying Web services messages" on page 615
headers	`java.util.List` of data objects.	Contains a list of header entry data objects. Each SOAP header in the message results in a header entry in this list. See "Message header layout " on page 615
attachments	`java.util.List` of data objects.	Contains a list of attachment entry data objects. In SOAP messages with attachments, each MIME part in the message (except the MIME part containing the SOAP envelope) is mapped to an entry in this list. See "Message attachment layout" on page 616
body	`commonj.sdo.DataObject`	A nested data object, which represents the body of the SOAP Envelope. See "Message body layout" on page 617

In addition to the format string, the message is described by the three metadata fields, operationName, messageName, and messageType. The payload of the message is split across the three other sections: headers, attachments and the body. These follow a section on the identification of messages.

Identifying Web services messages

Processing of messages depend on whether or not they have WSDL definitions. The minimum amount of information required for processing without WSDL is ″SOAP:″ The minimum amount of information required for processing with WSDL is: ″SOAP:location,namespace,service,port″. If the format string does not include all five of these fields, the SOAP data access service will attempt to process the message without WSDL.

- **Processing messages without WSDL definitions:** If the format string does not include full WSDL information, the SOAP data access service processes the message without attempting to match the message against definitions in WSDL. As a result, operationName and messageName are set to null, and the messageType field is only set when processing a fault message.

- **Processing messages with WSDL definitions:** If the format string includes <WSDL location>,<Service namespace>,<Service name>, and <Port name> then the SOAP and Beans data access services process the message using the WSDL definitions of the service.

    Note: SOAP message processing will fail after supplying all the required WSDL information,
    – if the SOAP data access service fails to locate the WSDL
    – if the WSDL fails to corroborate the message.

When the SOAP data access service processes a SOAP request or reply message, it tries to match it against the message definitions in the WSDL. Normally there is unique match, and the operationName, messageName, and messageType are filled in appropriately. If there is more than one possible match the data access service picks a message definition, and fills in the operationName and messageName. In this case the messageType is set to *ambiguous*.

When processing fault messages, identification is slightly different. In all cases the messageType will be set to *fault*. If the message matches a unique fault definition in the WSDL then the operationName and messageName properties will also be set.

Message header layout

The list of headers can have two types of entry, depending on whether the header is based on part of the message or not.

The first type is used to handle headers that are not parts of the message:
- either not modeled in WSDL,
- or modeled in WSDL but not based on a part of the message.

For a model of this header, see "Header entry"

The second type of entry is used when the SOAP binding for the message has bound a part of the body into a MIME attachment. (This occurs when you use a <MIME:content> element to bind a part of the message to an attachment.) For consistent mediation programming, all of the body data is stored in the body node in the graph. In place of the normal attachment entry a bound attachment entry is placed into the attachments list. The bound attachment entry contains the MIME meta-data for the attachment, and for completeness also contains the name of the message part that contains the data taken from this attachment. This allows mediations designed to process attachments to locate the data in the body part of the graph. For a model of this attachment see "Bound header entry" on page 616.

Header entry

Property name	Property type	Property description
mustUnderstand	`java.lang.Boolean`	Carries the value from the mustUnderstand attribute on the SOAP header, if present.

actor	`java.lang.String`	Carries the value from the actor attribute on the SOAP header, if present.
any	`commonj.sdo.Sequence`	Container for the contents of the SOAP Header.

Bound header entry

Property name	Property type	Property description
mustUnderstand	`java.lang.Boolean`	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	`java.lang.String`	Carries the value from the actor attribute on the SOAP header, if present.
messagePart	`java.lang.String`	Contains the name of the message part which carries the data from this message header.

Message attachment layout

Message attachments are handled in a similar way to headers, and instances of them populate the attachments list in the Info node.

There are two types of attachment entry to handle MIME attachments. The first is for general attachments: see "Attachment entry"

The second type of attachment entry includes <MIME:content> elements that bind a part of the body into a MIME attachment. If you are programming a mediation, you need to know how to locate the data within the graph. For consistent mediation programming, the attachment data is placed in the message body, referred to by the part name in the header entry, which includes the other MIME metadata. For a model of this attachment, see "Bound attachment entry."

Attachment entry

Property name	Property type	Property description
contentType	`java.lang.String`	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	`java.lang.String`	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	`java.lang.String`	Carries the contentId from the MIME part that is represented by the attachment entry.
data	`byte[]`	Carries the content of the MIME element, as a byte array.

Bound attachment entry

Property name	Property type	Property description

contentType	`java.lang.String`	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	`java.lang.String`	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	`java.lang.String`	Carries the contentId from the MIME part that is represented by the attachment entry.
messagePart	`java.lang.String`	Contains the name of the message part which carries the data from this attachment.

Message body layout

The layout of the data object in the body is defined by the service's WSDL. The type of the data object is derived from the message definition in the WSDL. The data object will have one property for each part in the message definition. The layout of each message part follows the convention for mapping XML Schema into SDO, see "Web Services code example" on page 621 for more information.

Web services fault message

If the message is a fault message, the messageType field (in the Info node of the graph) will be set to ″fault″, and the message body will have the following properties:

Property name	Property type	Property description
faultcode	`javax.xml.namespace.QName`	Carries the faultcode value from the SOAP Fault element
faultstring	`java.lang.String`	Carries the faultstring value from the SOAP Fault element
faultactor	`java.lang.String`	Carries the faultactor value from the SOAP Fault element
detail	`commonj.sdo.DataObject`	Carries the content within the detail child of the SOAP Fault Element

Note: As the detail element definition uses element and attribute wildcards, the content of the detail data object will contain a Sequence. See "Web Services code example" on page 621 for more information.

Mapping XML schema definitions to the SDO type system:

This topic contains reference information to help you develop code to navigate the data graphs of the messages that your program mediates.

XML schemas might be embedded in the WSDL sections that describe the message parts and SOAP headers. However the SOAP header description is more likely to be available as a separate schema, in which case you should load it into the SDO repository where it can be used to process any message with a matching header at runtime.

Schema to Java class mapping

Each XML schema complex type is mapped to an SDO type. This means that an element with a complex type will be represented by an instance of an SDO data object. The type has a property for each element, attribute, or wildcard that is contained in the schema type definition.

In turn, the instance will contain a value for each property that has been set. If the property is mapped from a schema complex type then the value will be another SDO data object. If the property is mapped from a schema simple type then the value will be an instance of a Java class, as shown in the following table.

Schema type	Java class	Notes
anyURI	java.lang.String	
base64Binary	byte[]	See note 2
boolean	java.lang.Boolean/ boolean	See note 1
byte	java.lang.Byte / byte	See note 1
date	java.lang.String	
dateTime	java.lang.String	
decimal	java.math.BigDecimal	
double	java.lang.Double / double	See note 1
duration	java.lang.String	
ENTITIES	java.util.List	
ENTITY	java.lang.String	
float	ava.lang.Float / float	See note 1
gDay	java.lang.String	
gMonth	java.lang.String	
gMonthDay	java.lang.String	
gYear	java.lang.String	
gYearMonth	java.lang.String	
hexBinary	byte[]	See note 2
ID	java.lang.String	
IDREF	java.lang.String	
IDREFS	java.util.List	
int	java.lang.Integer / int	See note 1
integer	java.math.BigInteger	
language	java.lang.String	
long	java.lang.Long / long	See note 1
Name	java.lang.String	
NCName	java.lang.String	
negativeInteger	java.math.BigInteger	
NKTOKENS	java.util.List	
NMTOKEN	java.lang.String	
nonNegativeInteger	java.math.BigInteger	
nonPositiveInteger	java.math.BigInteger	
normalisedString	java.lang.String	

NOTATION	javax.xml.namespace.QName	
positiveInteger	java.math.BigInteger	
QName	javax.xml.namespace.QName	
short	java.lang.Short / short	See note 1
string	java.lang.String	
time	java.lang.String	
token	java.lang.String	
unsignedByte	java.lang.Short / short	See note 1
unsignedInt	java.lang.Long / long	See note 1
unsignedLong	java.math.BigInteger	
unsignedShort	java.lang.Integer / int	See note 1

Notes:

1. SDO automatically converts primitives (int, long and so on) into objects as needed. This means that you can use a mixture of the specialized methods (getInt, setInt, getLong, setLong) as well as the generic get and set methods.

2. As byte arrays are mutable, it is possible to update the value without setting it back onto the data object. However when this occurs the data object may not be aware of implicit update. When working with byte array values you should always use the setBytes() method to explicitly update the data object.

Working with global elements and attributes

When a schema is mapped to SDO we also define a special SDO type, typically called 'DocumentRoot'. This type is a container for all the global elements and attributes in the schema. Whenever you need to locate an SDO property for a global element or attribute you should locate the 'DocumentRoot' type and then locate the appropriate property within it.

The following schema defines the layout of Web services messages. By comparing this schema with the information in "Mapping of SDO data graphs for Web services messages" on page 614 you can see the schema to SDO mapping in action.

```
<?xml version="1.0"?>
<xsd:schema
    targetNamespace="http://www.ibm.com/ns/2004/05/webservices/messagemodel"
    xmlns:tns="http://www.ibm.com/ns/2004/05/webservices/messagemodel"

```

Web Services code example:

This topic contains example WSDL and code snippets to show how to access fields within a Web services
message for programming a mediation.

Web services message definition

This topic contains an example of a Web services message. It is characterized in Web Services
Description Language (WSDL), an XML-based language used to describe the services a business offers
and how those services may be accessed.

Based upon this Web service, the rest of the topic shows how to program mediations to work with different
parts of the message (described with the SDO representation in "Mapping of SDO data graphs for Web
services messages" on page 614.) For each part of the message, you will see an XML description of the
message, representing its SDO data graph. To accompany each XML description, you will see some
snippets of code that illustrate how to work with that part of the message.

Note that in the following example the SOAP header schema is included in the WSDL. It could
alternatively have been included as a separate schema in the SDO repository.

Here is the WSDL description of the message that is used as an illustration for the subsequent code
snippets:

companyInfo Web service message description
```
<wsdl:definitions targetNamespace="http://example.companyInfo"
 xmlns:tns="http://example.companyInfo"
 xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:wsdlmime="http://schemas.xmlsoap.org/wsdl/mime/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema">

 <wsdl:types>
  <xsd:schema elementFormDefault="qualified"
   targetNamespace="http://example.header">

   <xsd:element name="sampleHeader">
    <xsd:complexType>
     <xsd:all>
      <xsd:element name="priority" type="xsd:int"/>
     </xsd:all>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>

  <xsd:schema elementFormDefault="qualified"
   targetNamespace="http://example.companyInfo">

   <xsd:element name="getCompanyInfo">
```

```
     <xsd:complexType>
      <xsd:all>
       <xsd:element name="tickerSymbol" type="xsd:string"/>
      </xsd:all>
     </xsd:complexType>
    </xsd:element>

    <xsd:element name="getCompanyInfoResult">
     <xsd:complexType>
      <xsd:all>
       <xsd:element name="result" type="xsd:float"/>
      </xsd:all>
     </xsd:complexType>
    </xsd:element>
   </xsd:schema>

 </wsdl:types>

 <wsdl:message name="getCompanyInfoRequest">
   <wsdl:part name="part1" element="tns:getCompanyInfo"/>
 </wsdl:message>

 <wsdl:message name="getCompanyInfoResponse">
  <wsdl:part name="part1" element="tns:getCompanyInfoResult"/>
  <wsdl:part name="part2" type="xsd:string"/>
  <wsdl:part name="part3" type="xsd:base64Binary"/>
 </wsdl:message>

 <wsdl:portType name="CompanyInfo">
  <wsdl:operation name="GetCompanyInfo">
   <wsdl:input message="tns:getCompanyInfoRequest"
               name="getCompanyInfoRequest"/>
   <wsdl:output message="tns:getCompanyInfoResponse"
                name="getCompanyInfoResponse"/>
  </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="CompanyInfoBinding" type="tns:CompanyInfo">
  <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

  <wsdl:operation name="GetCompanyInfo">
   <wsdlsoap:operation soapAction=""/>
   <wsdl:input name="getCompanyInfoRequest">
    <wsdlsoap:body use="literal"/>
   </wsdl:input>
   <wsdl:output name="getCompanyInfoResponse">
    <wsdlsoap:body use="literal"/>
   </wsdl:output>
  </wsdl:operation>
 </wsdl:binding>

 <wsdl:service name="CompanyInfoService">
  <wsdl:port binding="tns:CompanyInfoBinding" name="SOAPPort">
   <wsdlsoap:address location="http://somewhere/services/CompanyInfoService"/>
  </wsdl:port>
 </wsdl:service>

</wsdl:definitions>
```

Working with the info node

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
```

```
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

You can access the properties of the info node (see "Overall Web service message layout" on page 614) using code snippets like this:

```
// Get the info node (a child of the graph's root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Query the operationName, and messageType.
String opName = infoNode.getString("operationName");
String type   = infoNode.getString("messageType");
```

Working with a header

This is an example of a SOAP request including a header:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Header>
        <example:sampleHeader
          env:mustUnderstand='1'
          xmlns:example='http://example.header'>
            <example:priority>4</example:priority>
        </example:sampleHeader>
    </env:Header>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

You can see the properties of the header entry with a list of headers in "Header entry" on page 615. You can work with a header entry and its properties using code like this:

```
// Get the info node (a child of the graph's root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Access the list of headers
List headerEntries = infoNode.getList("headers");

// Get the first entry from the list
DataObject headerEntry = (DataObject) headerEntries.get(0);

// Query the mustUnderstand property of the header entry
boolean mustUnderstand = headerEntry.getBoolean("mustUnderstand");

// Get the Sequence which holds the content of the header entry
Sequence headerContent = headerEntry.getSequence("any");

// Get the first piece of content from the Sequence
DataObject header = (DataObject) headerContent.getValue(0);

// Read the priority from the header
int priority = header.getInt("priority");

// Shorthand for the above, using SDO path expressions that start from the
```

```
        // info node.
        mustUnderstand = infoNode.getBoolean("headers[1]/mustUnderstand");
        priority       = infoNode.getInt("headers[1]/any[1]/priority");
```

Working with an attachment

This is an example of a SOAP request including an XML attachment:

```
Content-Type: multipart/related; start="<start>"; boundary="boundary"

--boundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-ID: <start>

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
--boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: binary
Content-ID: <myAttachment>

<info>Some attached information</info>
--boundary--
```

You can see the properties of the attachment entry with byte array in "Attachment entry" on page 616. You can work with a header entry and its properties using code like this:

```
  // Get the info node (a child of the graph's root object)
    DataObject rootNode = graph.getRootObject();
    DataObject infoNode = rootNode.getDataObject("Info");

    // Access the list of attachments
    List attachmentEntries = infoNode.getList("attachments");

    // Get the first entry from the list
    DataObject attachmentEntry = (DataObject) attachmentEntries.get(0);

    // Query the contentId property of the header entry
    String contentId = attachmentEntry.getString("contentId");

    // Get the data contained in the attachment
    byte[] data = attachmentEntry.getBytes("data");
```

Working with the message body

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

You can see the properties of the body in "Message body layout" on page 617. You can work with the contents of the body using code like this:

```
// Get the info node (a child of the graph's root object)
DataObject rootNode = graph.getRootObject();
DataObject infoNode = rootNode.getDataObject("Info");

// Get hold of the body node
DataObject bodyNode = infoNode.getDataObject("body");

// Get hold of the data object for the first part of the body
DataObject part1Node = bodyNode.getDataObject("part1");

// Query the tickerSymbol
String ticker = part1Node.getString("tickerSymbol");

// Shorthand for the above, using a SDO path expression that starts from the
// info node.
ticker = infoNode.getString("body/part1/tickerSymbol");
```

JMS formats:

This topic directs you to the information you need to access the different types of JMS message.

Format types

Service integration technologies supports four different types of JMS message. Each message type is defined by a message format string within the message. You can retrieve the format string using the code snippet in the example below. The format string will be one of the following:

JMS Message type	Message format string	Mapping to SDO
JMS Bytes message	JMS:bytes	See "JMS Formats -- bytes"
JMS Text message	JMS:text	See "JMS Formats -- text" on page 626
JMS Stream message	JMS:stream	See "JMS formats -- Stream" on page 626
JMS Object message	JMS:object	See "JMS Formats -- object" on page 626

This code snippet is an example of how to retrieve the message format string from the message:

```
String format = siMsg.getFormat();
if (format.equals ....
```

JMS Formats -- bytes:

This topic contains reference information you can use to map from the body of a JMS bytes message to SDO:

Bytes body

You can retrieve the payload of a JMS bytes message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named ″data″, and that data object in turn contains a property named ″value″. In JMS bytes messages, the value property may be accessed as a Java byte array.

You can access the data within the data graph with code like this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:bytes")) {
  DataGraph graph = siMsg.getDataGraph();
  byte[] payload = graph.getRootObject().getBytes("data/value");
}
```

JMS Formats -- text:

This topic contains reference information you can use to map from the body of a JMS text message to SDO:

Text body

You can retrieve the payload of a JMS text message as a Java string value (java.lang.String). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS text messages the value property may be accessed as a Java string value.

You can access the data within the data graph with code like this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:text")) {
  DataGraph graph = siMsg.getDataGraph();
  String payload = graph.getRootObject().getString("data/value");
}
```

JMS formats -- Stream:

This topic contains reference information you can use to map from the body of a JMS Stream message to SDO.

Stream body

You can retrieve the payload of a JMS Stream message as a Java list value (java.util.List). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In the case of a JMS Stream message the value property may be accessed as a List value. The member functions of the List interface can be used to access the individual objects within the JMS Stream message instance. (Note that the JMS standard places constraints on the kinds of objects which may be placed in a Stream message.)

You can access the data within the data graph with code like this:

```
}SIMessage siMsg;
String format = siMessage.getFormat();
if (format.equals("JMS:stream")) {
  DataGraph graph = siMsg.getDataGraph();
  List payload = graph.getRootObject().getList("data/value");
  int streamLength = payload.size();
  if (streamLength > 0) {
    Object item1 = payload.get(0);
    // You can also access items directly, for example: (for the_same_ value)
    item1 = graph.getRootObject().get("data/value[1]");
  }
}
```

JMS Formats -- object:

This topic contains reference information you can use to map from the body of a JMS object message to SDO:

Object body

You can retrieve the payload of a JMS object message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named ″data″, and that data object in turn contains a property named ″value″. In the case of a JMS object message the value property may be accessed as a Java byte array. The original Object instance which the payload represents may be reconstructed from the byte array.

You can access the data within the data graph with code like this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:object")) {
  DataGraph graph = siMsg.getDataGraph();
  byte[] payload = graph.getRootObject().getBytes("data/value");
  if(payload != null) {
    // Need to deserialize to recover original object
    ObjectInputStream in =
      new ObjectInputStream(new ByteArrayInputStream(payload));
    Object obj = in.readObject();
  }
}
```

Message conversions:

This topic describes the information for converting or transcribing messages.

You can convert a message payload into a byte array, for example for the purpose of logging a message, and you can reconstruct the message from the byte array. Additionally, you can re-express the message payload in a different format using the transcoding operation. For more information, refer to the following topics:

- "XML Schema definition for stream messages." This describes the XML schema for stream messages, and describes some of the conversions between byte streams and message types.
- "Data graph to bytes conversion" on page 628. This describes converting messages into byte arrays, and the rules associated with each message format.
- "Bytes to data graph conversion" on page 629. This describes converting byte arrays into messages, and the rules associated with each message format.
- "Transcoding between different message formats" on page 629. This describes transcoding different message formats and the rules associated with each format pairing.

Note that JMS:map is not supported.

XML Schema definition for stream messages

The conversions defined in the following two tables use an XML Schema definition with target namespace http://www.ibm.com/xmlns/prod/websphere/messaging/jms/ for expressing JMS stream messages in XML.

```
<xsd:schema elementFormDefault="qualified" xml:lang="EN"
  targetNamespace="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <xsd:element name="data" type="StreamBody"/>

  <xsd:complexType name="StreamBody">
    <xsd:sequence>
```

```
      <xsd:element name="value"
        type="streamTypes"
        minOccurs="0"
        maxOccurs="unbounded"
        nillable="true"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:simpleType name="character">
    <xsd:restriction base="xsd:string">
      <xsd:minLength value="1"/>
      <xsd:maxLength value="1"/>
    </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="streamTypes">
   <xsd:union memberTypes="xsd:long xsd:int xsd:short xsd:byte xsd:boolean xsd:float xsd:double
                           xsd:string xsd:hexBinary character"/>
  </xsd:simpleType>
</xsd:schema>
```

Data graph to bytes conversion

You can convert a message payload into a byte array, for example for the purpose of logging a message. The following table summarizes the rules associated with each message format when converting a message payload into a byte array:

Table 21. Conversion of SIMessage data graph to bytes.

Datagraph format	Pre-conditions	Outcome	Character set encoding
JMS:	None	Returns null.	Not applicable.
JMS:text	None	Returns the result of java.lang.String:getBytes(String charSetName) when applied to the `data/value` element of the graph, where charSetName = "UTF-8"	UTF-8
JMS:bytes	None	Returns a copy of the value of the `data/value` element of the data graph for the message.	Not applicable.
JMS:stream	None	Returns a byte buffer containing an XML serialization of the stream message according to the XML schema for stream messages.	UTF-8
JMS:object	None	Returns a copy of the value of the `data/value` element of the data graph for the message.	Not applicable.
SOAP:	If the byte array must be generated by this operation (instead of using an existing byte array available through lazy parsing) then the data graph must be valid with respect to the WSDL model.	Returns a byte buffer containing a SOAP serialization of the data graph. If the SOAP message contains an attachment, the buffer has the multipart MIME format.	Either UTF-8, or that of the source message for the graph, where logically equivalent to the graph state.

Table 21. Conversion of SIMessage data graph to bytes. (continued)

Datagraph format	Pre-conditions	Outcome	Character set encoding
Bean:	The data graph must be valid with respect to the WSDL model. In the absence of a SOAP binding the serialization will be performed using RPC/literal encoding.	Returns a byte buffer containing a SOAP serialization of the data graph. If the Bean contains attachments then the buffer will be in multipart MIME format.	UTF-8

Bytes to data graph conversion

You can reconstruct the message payload from a byte array, for example after a mediation has logged a message. The following table summarizes the rules associated with converting the byte array into the message payload:

Table 22. Conversion of bytes to SIMessage data graph

Format argument	Pre-conditions	Outcome
JMS:	None	Returns null
JMS:text	`java.lang.String(inputBytes, "UTF-8")` does not result in an exception.	Returns new data graph instance of format JMS:text. Value of graph at path `data/value` has value equal to `java.lang.String(inputBytes, "UTF-8")`.
JMS:bytes	`inputBytes` is not null.	Returns new data graph instance of format JMS:bytes. Value of graph at path `data/value` is a copy of the `inputBytes` byte array.
JMS:stream	Byte array is XML, and is valid with respect to the `JmsStreamBody` type of the XML schema definition.	Returns new data graph instance of format JMS:stream. Value of graph at path `data/value` has type List, containing a sequence of simple typed values according to the types and values of each of the elements in the XML document.
JMS:object	Not null **Note:** You must ensure that the byte array is a valid serialized object.	Returns new data graph instance of format JMS:object. Value of graph at path `data/value` is a copy of the `inputBytes` byte array.
SOAP:	The byte buffer contains valid SOAP with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the SOAP payload.
Bean:	The byte buffer contains valid Bean with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the Bean payload.

Transcoding between different message formats

You can re-express the message payload in a different format using the transcoding operation. The following table summarizes the message formats that you can transcode, and the rules associated with each format pairing. Each cell in the table shows the result of attempting to transcode from the format given in the row title to the format given by the column title.

Note: The abbreviation DG is used for data graph.

Table 23. Allowed and disallowed transcodings between message formats

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)
From JMS:text	DG=null (2)	Yes (3)	Yes, bytes contain UTF-8	Yes, if text contains XML that conforms to the correct schema.	No	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:bytes	DG=null (2)	Yes, but only when the bytes can correctly be interpreted as a UTF-8 string.	Yes (3)	Yes, if bytes contain XML that conforms to the correct schema.	Yes - assume that bytes are a serialized object.	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:stream	DG=null (2)	Yes, text is XML transcoding.	Yes, bytes contain XML transcoding.	Yes (3)	No	No	No
From JMS:object	DG=null (2)	No	Yes, bytes contain the object serialization.	No	Yes (3)	No	No
From SOAP:	DG=null (2)	Yes	Yes	No	No	Yes, (3) - if message content matches the new WSDL.	Yes
From Bean:	DG=null (2)	Yes	Yes	No	No	Yes	Yes (3) - if message content matches the new WSDL.

Notes:
1. A message with format JMS: does not have a payload so the DataGraph returned is always null. It is not valid to have a JMS:text data graph with the data set to null. A mediation that has a JMS: message and requires a JMS:text data graph should call createDataGraph() rather than attempt to turn a null value into another value.
2. Since a JMS: message does not have a payload, all operations which specify a to format of JMS: will return a null value for the new data graph.
3. You can call getNewDataGraph() with the same format as the original data graph. It returns a copy of the data graph that you can edit, leaving the original message unchanged. For SOAP and Beans, you can change the message model by editing the format string to change the value that follows the ":".

Programming for interoperation with WebSphere MQ

This topic covers programming considerations for messaging applications that interoperate with WebSphere MQ applications.

There are some differences between the WebSphere Application Server environment and the WebSphere MQ environment. If you are writing messaging programs that interoperate between these two environments, you should be aware of these differences and take them into account when designing, coding and deploying your programs.

1. Learn more about the environment differences and other relevant concepts in "Learning about programming for interoperability with WebSphere MQ."

2. Read about design considerations for programs that interoperate with WebSphere MQ in "Designing for interoperation with WebSphere MQ" on page 634.

Learning about programming for interoperability with WebSphere MQ

This topic describes what you need to know to write programs that will interoperate with a WebSphere MQ network.

The WebSphere Application Server can be connected to other messaging systems based upon WebSphere MQ, including

- WebSphere Application Server Version 5.0 systems that include the MQ-based JMS provider.
- WebSphere MQ queue managers.
- WebSphere Application Server 5.0 J2EE application clients.

Interoperation with other JMS systems and clients is straightforward if your messaging application connections are built using a connection factory and stored in a JNDI namespace. The JNDI namespace insulates your application from provider-specific information, and there are no differences that are significant for programming messaging applications. Read more about how JNDI simplifies the programming task in "Using a JNDI namespace to connect to different JMS provider environments."

If your application has to interoperate with queue managers on WebSphere MQ systems, there are a few significant differences that programmers must account for in their messaging applications.

Application messages received from another WebSphere MQ-based messaging system are converted into JMS messages. When messages are sent to WebSphere MQ, the conversion is performed in the opposite direction. A configuration setting on the destination definitions determines whether JMS messages are forwarded to WebSphere MQ as MQ JMS messages (which include an MQRFH2 header) or as non-JMS MQ messages.

You can read more about how the two sets of formats are mapped to each other in "Mapping of messages flowing through the WebSphere MQ link" on page 636. You can read more about how the different delivery options for the two message formats map to each other in "Mapping of message delivery options flowing through the WebSphere MQ link" on page 635.

There are three main differences between the WebSphere Application Server service integration and WebSphere MQ messages. You will have to take these differences into account when you design your WebSphere messaging application (for more information about designing, see "Designing for interoperation with WebSphere MQ" on page 634). The differences are:

- "Addressing destinations across the WebSphere MQ link" on page 632.
- "Reply-to queues for use with WebSphere MQ" on page 633.
- "Reply-to topics for use with WebSphere MQ" on page 633.

For information about ways of interoperating with WebSphere MQ, including using a WebSphere MQ server, or using WebSphere MQ as an external JMS provider, see Learning about WebSphere MQ server.

Using a JNDI namespace to connect to different JMS provider environments:

This topic discusses how applications can use a JNDI namespace to connect to different JMS-provider environments to access the resources hosted by those environments.

The Java Naming and Directory Interface (JNDI) API enables JMS clients to look up configured JMS objects. By delegating all the provider-specific work to administration tasks for creating and configuring these objects, the clients can be completely portable between environments. In addition, the applications are easier to administer because they have no need for embedded administrative values in their code.

There are two types of JMS administered objects:
• ConnectionFactory - the object a client uses to create a connection with a provider.
• Destination - the object a client uses to specify the destination of messages it is sending and the source of messages it receives.

The messaging environment to which the application connects will depend upon the implementation type of the ConnectionFactory object that is obtained from JNDI. For example, if it's a WebSphere Application Server 6.0 default messaging ConnectionFactory, then a connection will be made to the same service integration bus.

Addressing destinations across the WebSphere MQ link:

This topic describes how to handle the issues relating to addressing a service integration bus destination from WebSphere MQ, and a WebSphere queue from a service integration bus.

The name characteristics and naming structure of the service integration bus and WebSphere MQ are not the same. WebSphere MQ essentially has a two-level addressing structure:
• Queue Manager name.
• Queue Name.

Each of these names is limited to 48 characters. The equivalents for the service integration bus are the messaging engine name and destination name, but the scope of a destination is not limited to a particular messaging engine. Both destination and messaging engine have a scope that spans the bus, so the service integration bus uses bus name and destination to uniquely address a particular target destination.

The service integration bus does not enforce the 48 character limit for names that is imposed by WebSphere MQ. Messages from a WebSphere MQ application sent to a bus destination with a name greater than 48 characters must have some means of using the shorter name (used in WebSphere MQ) to address the long name (used in the service integration bus). The service integration bus uses an alias destination to map between the shorter name and the long name. For more information about alias destinations, see Alias destinations.

An alias can also be used to send a message from a WebSphere Application Server application using a long name (greater than 48 characters) and route it to a WebSphere MQ queue. however, there is still an issue addressing a queue on an arbitrary queue manager in an MQ network. In the service integration bus environment, you specify the bus name (the WebSphere MQ link bus name) and the destination name, so there has to be a special format for a destination which allows you to specify the queue manager name: <queue>@<queue manager>. These destination names will only be parsed by the WebSphere MQ link, which uses the value to determine what values to place in the target queue and queue manager fields of the message header.

For example, you could define an alias on the local bus called ″MyLongQueueNameWithMoreThanFortyEightCharactersInTheName″, and set the target bus to the name of the foreign bus representing the MQ network and the target identifier to ″QUEUE1@QM2″ to address the WebSphere MQ queue called QUEUE1 on the queue manager QM2 in the WebSphere MQ network.

There are two fields in the JMS API that are used for sharing information about the destination to which a message is sent (JMSDestination) and the destination to which replies should be sent (JMSReplyTo). The JMSReplyTo field of a JMS message passing from a service integration bus to WebSphere MQ (or from

WebSphere MQ to a service integration bus) is automatically mapped so that a consuming application in WebSphere MQ can reply to the original WebSphere Application Server application.

Reply-to queues for use with WebSphere MQ:

This topic describes how reply-to queues, a feature of WebSphere MQ, are handled by the WebSphere MQ link.

WebSphere MQ allows the definition and usage of reply-to queues, which indicate to a receiving application where a reply should be sent. WebSphere MQ link emulates the reply-to queue functions in order to allow request/reply exchanges between applications on opposite sides of the WebSphere MQ link.

You can use reply-to queues for point-to-point request messages (queues) and for publish/subscribe request messages when exchanging information with a WebSphere MQ network.

WebSphere MQ reply-to queue names are limited to 48 characters or less. It is important when sending a message from WebSphere Application Server to WebSphere MQ that the reply queue name is less than 48 characters. This may require you to define an alias queue, as described in "Addressing destinations across the WebSphere MQ link" on page 632.

Deciding to use reply-to queues is part of application design (see "Designing for interoperation with WebSphere MQ" on page 634). Your sending application must contain a definition of where replies are to be sent and attach this information to its messages. The replying application looks at this data in the received message to discover the name of the queue to which to reply.

There are two fields in the JMS API that are used for sharing information about the destination to which a message is sent (JMSDestination) and the destination to which replies should be sent (JMSReplyTo).

The JMSReplyTo field allows a response message to be returned if required. It contains enough detail for the receiving application to send a response message to the intended queue or topic so that it can be read by an application associated with the sender of the request.

Reply-to topics for use with WebSphere MQ:

This text describes how reply-to topics, a feature of WebSphere MQ, are handled by WebSphere MQ link.

A WebSphere Application Server JMS application can publish a message to a topic space with a reply-to topic which is received by the publish/subscribe bridge on the WebSphere MQ link and passed to a message broker in a WebSphere MQ network. The WebSphere MQ JMS application receives the message from the message broker, obtains the reply destination and publishes a message to the message broker on the reply topic. In order for the reply message to be routed back to WebSphere Application Server subscribers, the administrator must have configured a topic mapping from WebSphere MQ to WebSphere Application Server on the reply topic (unless it is a temporary reply topic, as described below.)

A WebSphere MQ JMS application can publish a message to a broker with a reply-to topic which is received by the WebSphere Application Server application. An example is a WebSphere MQ JMS application publishing to a message broker in the WebSphere MQ network, on ″myTopic″ with a reply topic of ″myReplyTopic″. A mapping must have already been specified on the publish/subscribe bridge so that the publish/subscribe bridge is subscribing to ″myTopic″ on the message broker. When the message is sent over the WebSphere MQ link it is translated into the correct format, and delivered to the publish/subscribe bridge subscriber queue where it is processed and then sent on to the topic space as specified in the publish/subscribe topic mapping. It is then received by the WebSphere Application Server JMS application, which sends a reply message back to the message broker on the WebSphere MQ network by way of the publish/subscribe bridge. You must already have created a mapping to forward messages published on ″myReplyTopic″ from WebSphere Application Server to the WebSphere MQ broker.

The exceptions to this rule are temporary topic reply destinations which are automatically routed back across the WebSphere MQ link by the publish/subscribe bridge, without any intervention from the administrator. See Request-reply across the WebSphere MQ link for more information.

Note: for temporary topic reply messages to be routed from the service integration bus back to WebSphere MQ through the publish/subscribe bridge, you must configure the broker stream queue of the mapping on which the request message is sent. This field will already be specified for bi-directional topic mappings. While it is not a mandatory field for "From MQ" topic mappings, it must be completed if you want temporary topic reply messages to be routed.

Designing for interoperation with WebSphere MQ

This topic outlines the steps you should consider when designing an application that will interoperate with queue managers in a WebSphere MQ network.

You should identify the WebSphere MQ queues that your applications will interoperate with. The exact names and locations can be left to the installation.

1. Familiarize yourself with important reference information for the two interoperating environments, WebSphere MQ environment and the service integration bus. There are three types of reference material:
   a. Read about mapping unique to service integration bus messaging in "Mapping of additional MQRFH2 header fields in service integration."
   b. Read about mapping between WebSphere Application Server service integration bus messaging and WebSphere MQ in "Mapping between a WebSphere service integration bus and WebSphere MQ" on page 635.
   c. Read about the differences between the WebSphere MQ functions and the service integration bus in "WebSphere MQ functions not supported by service integration" on page 640

2. Design your JMS client based on the typical J2EE pattern:
   a. Use JNDI to find a ConnectionFactory object.
   b. Use JNDI to find one or more Destination objects.
   c. Use the ConnectionFactory to create a JMS Connection.
   d. Use the Connection to create one or more JMS Sessions.
   e. Use a Session and the Destinations to create the MessageProducers and MessageConsumers needed.
   f. Start delivery of messages by starting the Connection.

   At this point a client has the basic JMS setup needed to produce and consume messages.

3. Identify any name-handling incompatibilities between the service integration bus and WebSphere MQ environments. If necessary, identify alias requirements, so that the WebSphere MQ application can handle service integration bus destination names of greater than 48 characters. See "Addressing destinations across the WebSphere MQ link" on page 632 for more information.

4. Identify any reply destinations that are used by your application and check them for name-handling incompatibilities.

5. If your application publishes messages that you wish to be forwarded to WebSphere MQ brokers, work with your administrator to define appropriate topic mappings on a publish/subscribe broker profile. You will also need to define topic mappings for any permanent reply topics. See "Reply-to topics for use with WebSphere MQ" on page 633 and Request-reply across the WebSphere MQ link for more information.

Mapping of additional MQRFH2 header fields in service integration:

This topic describes additional fields added to the MQRFH2 header to allow for functions that can be used by service integration but that are unavailable in WebSphere MQ.

A set of message fields specific to the service integration bus convey extra information not used in WebSphere MQ.

- These properties are inserted in the MQRFH2 header of application messages in the *sib* and *jms* folders.

They can be used to influence the routing of messages within the service integration bus, but do not appear as JMS message fields or properties.

MQRFH2 header and field (jms folder)	SIBusMessage field or property
Frp (appended to Dst field)	Forward routing path header field
Rrp (appended to Rto field)	Reverse routing path header field

MQRFH2 header and field (sib folder)	SIBusMessage field or property
RTopic	Reply topic
RPri	Reply priority
RPer	Reply persistence
RTTL	Reply time to live

When a message is sent to WebSphere MQ across a WebSphere MQ link, a sib folder is included in the MQRFH2 header of the message if both of the following are true:

- The setting on the destination definition is configured to propagate the MQRFH2 header.
- Fields corresponding to the sib folder content are set in the message.

Mapping between a WebSphere service integration bus and WebSphere MQ:

This topic directs you to different sets of mapping information to help you program applications that interoperate with WebSphere MQ.

The specifics of delivery options, message types, and fields can differ between the two environments as messages flow to a WebSphere MQ environment, and back. The WebSphere MQ link maps values between the two, selecting appropriate values according to the reference information in these tables:

- Delivery options (also known as qualities of service). See "Mapping of message delivery options flowing through the WebSphere MQ link."
- Inbound message conversion to JMS, and outbound message conversion to WebSphere MQ JMS or non-JMS messages. See "Mapping of messages flowing through the WebSphere MQ link" on page 636.
- Inbound message fields and properties conversion to JMS. See "Mapping of WebSphere MQ message fields and properties to JMS" on page 637.
- Inbound MQRFH2 header fields to JMS files and properties conversion. See "Mapping of MQRFH2 header fields to JMS" on page 638.
- Inbound MQ Message D Report fields conversion to JMS provider-specific properties. See "Mapping of MQMD Report fields to JMS provider-specific properties" on page 639.
- Data conversion. See "Conversion of data to and from WebSphere MQ" on page 640.

Mapping of message delivery options flowing through the WebSphere MQ link:

This topic shows the mapping of delivery options (qualities of service), when messages flow through the WebSphere MQ link, between WebSphere Application Server service integration and a WebSphere MQ network.

Delivery options (also called qualities of service) differ between service integration and WebSphere MQ: service integration offers a wider range of quality of service options.

When messages are received from a WebSphere MQ network, the default mapping of delivery options, carried out by the WebSphere MQ link receiver, is shown in the table below.

For details of delivery options definitions see Message reliability levels.

WebSphere MQ delivery option	WebSphere Application Server service-integration delivery option (default)
Persistent	Assured persistent
Nonpersistent	Express nonpersistent

Your administrator can select the attributes of the WebSphere MQ link receiver to alter the delivery option of inbound messages:

- Inbound persistent messages can be altered, with the advanced attribute ″inbound persistent message reliability,″ to *reliable* or *assured*.
- Inbound nonpersistent messages can be altered, with the advanced attribute ″inbound nonpersistent message reliability,″ to *best effort* or *express* or *reliable*.

When messages are sent to WebSphere MQ the mapping of the delivery options, carried out by the MQLinkSender, is shown in the table below.

WebSphere Application Server service-integration delivery option	WebSphere MQ delivery option
Reliable persistent	Persistent
Assured persistent	Persistent
Reliable nonpersistent	Nonpersistent
Express nonpersistent	Nonpersistent
Best effort nonpersistent	Nonpersistent

Mapping of messages flowing through the WebSphere MQ link:

This topic describes how messages sent from WebSphere MQ, through the WebSphere MQ link, are mapped to JMS messages, and messages sent to WebSphere MQ, through the WebSphere MQ link, are mapped to JMS messages or non-JMS messages.

Application messages received from a WebSphere MQ application are converted into WebSphere Application Server JMS messages as shown in the table below.

WebSphere MQ or MA88	WebSphere Application Server service integration
WebSphere MQ JMS text message	WebSphere Application Server JMS text message
WebSphere MQ JMS bytes message	WebSphere Application Server JMS bytes message
WebSphere MQ JMS stream message	WebSphere Application Server JMS stream message
WebSphere MQ JMS map message	WebSphere Application Server JMS map message
WebSphere MQ JMS object message	WebSphere Application Server JMS object message
WebSphere MQ text message	WebSphere Application Server JMS text message
Other WebSphere MQ message format	WebSphere Application Server JMS bytes message
WebSphere MQ broker control message	WebSphere Application Server broker control message
WebSphere MQ broker response message	WebSphere Application Server broker response message

When messages are sent by an application through the WebSphere MQ link to a WebSphere MQ network they are converted as shown in the table below. A destination setting on the WebSphere MQ link determines whether JMS messages are forwarded to WebSphere MQ as WebSphere MQ JMS messages which include an MQRFH2 header, or as non-JMS messages. For more information, see Point-to-point messaging with a WebSphere MQ network.

WebSphere Application Server service integration	WebSphere MQ or MA88 (choice depends on destination setting)
WebSphere Application Server JMS text message	WebSphere MQ JMS text message or WebSphere MQ text message (MQFMT_STRING)
WebSphere Application Server JMS bytes message	WebSphere MQ JMS bytes message or WebSphere MQ message (MQFMT_NONE)
WebSphere Application Server JMS stream message	WebSphere MQ JMS stream message or WebSphere MQ message (MQFMT_NONE)
WebSphere Application Server JMS map message	WebSphere MQ JMS map message or WebSphere MQ message (MQFMT_NONE)
WebSphere Application Server JMS object message	WebSphere MQ JMS object message or WebSphere MQ message (MQFMT_NONE)
WebSphere Application Server broker control message	WebSphere MQ broker control message
WebSphere Application Server broker response message	WebSphere MQ broker response message

Mapping of WebSphere MQ message fields and properties to JMS:

This topic describes how the WebSphere MQ message fields and properties map to JMS and are converted by the WebSphere MQ link.

The JMS API defines the set of fields and properties available on a JMS message. The message originating from WebSphere MQ is translated into a form used by the service integration bus. This content is accessed using the methods defined by the JMS *javax.jms.Message* class and subclasses. For example, the text body of a WebSphere MQ message received by the WebSphere MQ link engine is accessed using the *getText* method of the resulting *javax.jms.TextMessage* object. Additionally, a set of JMS provider-specific properties are present that reflect the message's underlying WebSphere MQ representation. These properties are relevant only to applications designed to be WebSphere MQ-aware.

The tables below show the mapping of MQMD V1 and V2 fields.

Table 24. Mapping between message descriptor field V1 and JMS fields and properties.

WebSphere MQ MQMD V1 field in original message	WebSphere Application Server JMS message field or property	Type
StrucId V1	-	
Version	-	
Report	JMS_IBM_Report_COA JMS_IBM_Report_COD JMS_IBM_Report_Expiration JMS_IBM_Report_Exception JMS_IBM_Report_PAN JMS_IBM_Report_NAN JMS_IBM_Report_Pass_Msg_ID JMS_IBM_Report_Pass_Correl_ID JMS_IBM_Report_Discard_Msg	s s s s s s s s s
MsgType	JMS_IBM_MsgType	s
Expiry	JMSExpiration	h

Table 24. Mapping between message descriptor field V1 and JMS fields and properties. (continued)

WebSphere MQ MQMD V1 field in original message	WebSphere Application Server JMS message field or property	Type
Feedback	JMS_IBM_Feedback	s
Encoding	JMS_IBM_Encoding	s
CodedCharSetId	JMS_IBM_Character_Set	s
Format	JMS_IBM_Format	s
Priority	JMSPriority	h
Persistence	JMSDeliveryMode	h
MsgId	JMSMessageID	h
CorrelId	JMSCorrelationID	h
BackoutCount	JMSXDeliveryCount	p
ReplyToQ	JMSReplyTo	h
ReplyToQMgr	JMSReplyTo	h
UserIdentifier	JMSXUserID	p
AccountingToken	-	
ApplIdentityData	-	
PutApplType	JMS_IBM_PutApplType	s
PutApplName	JMSXAppID	p
PutDate	JMSTimestamp JMS_IBM_PutDate	h s
PutTime	JMSTimestamp JMS_IBM_PutTime	h s
ApplOriginData	-	
Key: h=message header field p=message property s=provider-specific property		

Table 25. Mapping between message descriptor field V2 and JMS fields and properties.

WebSphere MQ MQMD V2 field in original message	WebSphere Application Server JMS message field or property	Type
GroupId	JMSXGroupID	p
MsgSeqNumber	JMSXGroupSeq	p
Offset	-	
MsgFlags	JMS_IBM_Last_Msg_In_Group	s
OriginalLength	-	
Key: p=message property s=provider-specific property		

Mapping of MQRFH2 header fields to JMS:

This topic describes how WebSphere MQ MQRFH2 header fields are mapped to WebSphere Application Server JMS fields and properties.

Where items appear in the MQRFH2 header as well as in the message descriptor, the MQRFH2 value takes precedence if present. See "Mapping of WebSphere MQ message fields and properties to JMS" on page 637.

MQRFH2 folder and field (jms folder)	JMS message field or property	Type
Dst	JMSDestination	h
Dlv	JMSDeliveryMode	h
Exp	JMSExpiration	h
Tms	JMSTimestamp	h
Cid	JMSCorrelationID	h
Rto	JMSReplyTo	h
Gid	JMSXGroupId	p
Seq	JMSXGroupSeq	p
Key: h=message header field p=message property		

Mapping of MQMD Report fields to JMS provider-specific properties:

This topic describes how a WebSphere MQ MQMD Report field can map to a number of JMS properties rather than a single property. The possible values for each are shown in the table below.

Table 26. MQMD flag values mapped to JMS properties.

WebSphere MQ MQMD Report option	JMS field or property name
MQRO_NONE MQRO_COA MQRO_COA_WITH_DATA MQRO_COA_WITH_FULL_DATA	JMS_IBM_Report_COA
MQRO_NONE MQRO_COD MQRO_COD_WITH_DATA MQRO_COD_WITH_FULL_DATA	JMS_IBM_Report_COD
MQRO_NONE MQRO_EXPIRATION MQRO_EXPIRATION_WITH_DATA MQRO_EXPIRATION_WITH_FULL_DATA	JMS_IBM_Report_Expiration
MQRO_NONE MQRO_EXCEPTION MQRO_EXCEPTION_WITH_DATA MQRO_EXCEPTION_WITH_FULL_DATA	JMS_IBM_Report_Exception
MQRO_NONE MQRO_PAN	JMS_IBM_Report_PAN
MQRO_NONE MQRO_NAN	JMS_IBM_Report_NAN
MQRO_NONE MQRO_PASS_MSG_ID	JMS_IBM_Report_Pass_Msg_ID
MQRO_NONE MQRO_PASS_CORREL_ID	JMS_IBM_Report_Pass_Correl_ID
MQRO_NONE MQRO_DISCARD_MSG	JMS_IBM_Report_Discard_Msg

Conversion of data to and from WebSphere MQ:

This topic describes how data and headers received from WebSphere MQ are converted by the WebSphere MQ link into service integration format, and how data is sent to WebSphere MQ.

Conversion of data sent from a WebSphere MQ network

The WebSphere MQ link is capable of automatically handling data in both Big and Little-Endian encoding and character sets, converting header and message content according to the WebSphere MQ formats and protocols (MQFAP) definition. Known message formats such as JMS messages and MQ string format are also automatically converted.

User defined formats are not converted and are treated solely as bytes messages. Any necessary data conversion must be performed in the receiving application.

Conversion of data sent to a WebSphere MQ network

Data and headers sent to the WebSphere MQ network are in Big Endian encoding and UTF8 format. User defined formats are not converted and are treated solely as bytes messages. Any necessary data conversion must be performed in the WebSphere MQ network.

WebSphere MQ functions not supported by service integration:

This topic describes WebSphere MQ functions that are not supported by a service integration bus
- Use this topic for functions not supported by service integration.
- Use this topic for differences in delivery options and qualities of service.

WebSphere MQ functions not available

There are various functions available in a WebSphere MQ network that are not available on a service integration bus that has a WebSphere MQ link or a WebSphere MQ client link. The following list helps you identify those functions but it is given as guidance rather than a complete definition. Functions not supported include:
1. Native MQ client (this includes client applications that make use of the base MQ classes for Java) attach.
2. Message segmentation.
3. Message grouping.
4. The MQMD Offset. Original length, MsgFlags, MsgSeqNumber, and GroupId fields are not supported because Message grouping and message segmentation are not supported.
5. Distribution lists.
6. Reference messages.
7. Triggering.
8. Alternate user authority.
9. Pass/set identity context.
10. In a program, setting the attributes of a queue (that is, the equivalent function of MQSET).
11. Confirmation of arrival/delivery.
12. Cluster sender/receiver channels (and cluster workload exits), because a messaging engine cannot participate in a WebSphere MQ cluster.
13. Server and requestor channels.
14. API crossing exits.

15. Data conversion exits.

16. Channel exits.

17. The equivalent to the MCAUSER and PUTAUTH fields of a channel.

18. Networks based on NetBIOS, SPX or SNA.

19. Message based command server.

20. PCF (Programmable Canonical Form messages).

21. Model queues. Service integration does not allow you to define model queues of a given name. Service integration technology supports only one model queue called the SYSTEM.DEFAULT.MODEL.QUEUE.

22. Dynamic queue name prefix length. Service integration all dynamic queue names with '_Q' and suffixes them with a unique id. This restricts the name specified in the dynamic queue name field of the Object Descriptor to up to 12 chars. If this name is greater than 12 characters, then it is truncated to 12 characters. In service integration, it is not possible to create a dynamic queue with the full name specified in the dynamic queue name field of the Object Descriptor.

23. Mark skip backout option.

24. Signal option on a get request.

25. Version 3 get message options structures.

26. All queue properties (the properties of a service integration destination do not map, one for one, to the properties of a WebSphere MQ local queue, for example).

27. Poisoned messages. Service integration bus local destination definitions have a maximum failed deliveries count (that is, the equivalent to the WebSphere MQ BackoutThreshold value) but there is no equivalent of the WebSphere MQ backout requeue queue name. In service integration technology, poisoned messages are instead backed out to an exception destination. Additionally, in service integration technology, when the number of times an application backs out a poisoned message is equal to the maximum failed deliveries count, the message is automatically backed out to an ExceptionDestination. If there is more than one message in the current unit of recovery, only the poisoned message is backed out to the ExceptionDestination. The remainder of the messages in the unit of recovery are backed out to the destination from which they were read.

28. A strict limitation of 48 bytes on the name of a queue. Service integration bus destination names can be greater than 48 bytes in length. If a destination name is to be returned to a WebSphere MQ JMS application, then it is important to use 48 byte destination lengths. Though, in some cases, it may be feasible to define an alias destination with a name length of up to 48 bytes) to map to a local destination with a name of length greater than 48 bytes.

Differences from WebSphere MQ delivery options

While WebSphere MQ supports persistent and nonpersistent messages, service integration supports five delivery options (also known as qualities of service (QoS).

* BEST_EFFORT_NONPERSISTENT
* RELIABLE_NONPERSISTENT
* EXPRESS_NONPERSISTENT
* RELIABLE_PERSISTENT
* ASSURED_PERSISTENT

Outbound BEST_EFFORT_NONPERSISTENT, RELIABLE_NONPERSISTENT, and EXPRESS_NONPERSISTENT messages sent to a WebSphere MQ network, are sent as nonpersistent messages in the WebSphere MQ network. Outbound RELIABLE_PERSISTENT and ASSURED_PERSISTENT messages, when sent to a WebSphere MQ network, are sent as persistent messages.

For inbound messages from a WebSphere MQ network, the inbound *nonpersistent* reliability (with possible values of BEST_EFFORT_NONPERSISTENT, RELIABLE_NONPERSISTENT, and EXPRESS_NONPERSISTENT) and the inbound *persistent* reliability (with possible values of RELIABLE_PERSISTENT and ASSURED_PERSISTENT), fields of the MQLinkReceiver channel can be set to specify the service integration delivery options to be used for nonpersistent and persistent messages.

Similarly, for inbound messages from WebSphere MQ JMS clients, the inbound nonpersistent reliability and the inbound persistent reliability fields of the MQ client link can be set to control the message persistence.

Designing for interoperation with WebSphere MQ using a WebSphere MQ server

This topic outlines the reference information you should consider when designing an application that will interoperate with WebSphere MQ using a WebSphere MQ server.

You should identify the WebSphere MQ queues that your applications will interoperate with.

Familiarize yourself with important reference information for the two interoperating environments, WebSphere MQ environment and the service integration bus. There are four types of reference material:
1. Read about "Mapping of additional MQRFH2 header fields in service integration when using a WebSphere MQ Server"
2. Read about "Mapping the JMS Destination property between service integration and WebSphere MQ when using a WebSphere MQ server" on page 643
3. Read about "Mapping the Message Reliability property between service integration and WebSphere MQ when using a WebSphere MQ server" on page 643
4. Read about "Reply to queue constraints when using a WebSphere MQ server" on page 644

Mapping of additional MQRFH2 header fields in service integration when using a WebSphere MQ Server

This topic describes additional fields that are added to the MQRFH2 header when interoperating with WebSphere MQ using a WebSphere MQ server. These additional fields allow for properties that can be used by service integration, but that are unavailable in WebSphere MQ, to be preserved.

A set of message fields specific to the service integration bus convey extra information not used in WebSphere MQ. These properties are inserted in the MQRFH2 header of application messages in the sib folder and are used to preserve key service integration message attributes when messages are sent to, then retrieved from, WebSphere MQ.

Table 27.

MQRFH2 header field	Equivalent SIBusMessage field or property	Description
JsApiUserId	Application user identifier (JMSXUserId)	The service integration application user identifier.
JsDst	Message format	The service integration JMS destination to which the message was sent.
JsFmt	JMS destination	The service integration message format.
JsSysMsgId	System message identifier	The service integration system message identifier assigned to the message.

When a message is sent to WebSphere MQ using a WebSphere MQ server, a sib folder is included in the MQRFH2 header of the message if both of the following are true:

- TheWebSphere MQ server definition is configured to use RFH2 headers.
- Fields corresponding to the sib folder content are set in the service integration message.

Mapping the JMS Destination property between service integration and WebSphere MQ when using a WebSphere MQ server

Service integration and WebSphere MQ JMS destinations are fundamentally different making it is impossible to map between the two representations of JMS destination property. Instead of mapping between the two JMS destination property representations, when a message leaves service integration and enters WebSphere MQ, an additional RFH2 property is introduced into the RFH2 header to store the service integration JMS destination.

The Service Integration JMS destination is serialized, then formatted as a hexadecimal string before being stored using the JsDst property of the sib RFH2 folder.

In an example where a service integration destination (SIQ1), that is localised on a WebSphere MQ queue (MQQ1), residing on queue manager QM1 has been configured, the following actions will be taken when a service integration JMS application sends a message to SIQ1:

- A serialised representation of PMQ1 will be placed into the sib RFH2 folder, using the JsDst property.
- The message will be stored on MQQ1.
- The string "queue://QM1/MQQ1" will also be placed into the jms RFH2 folder of the message using the Dst property.

This follows the convention used by the WebSphere MQ JMS to encode JMS destinations. If the message is retrieved by a service integration JMS application, then the JMS destination may be recovered from the contents of the sib folder RFH2 header. If the message is retrieved by a WebSphere MQ JMS application, then the JMS destination may be recovered from the contents of the jms folder in the RFH2 header.

Note: If the WebSphere MQ Server definition is configured not to use RFH2 headers, the JMS destination will not be preserved when the message enters WebSphere MQ. In this situation, a service integration JMS application is still able to retrieve the JMS message, however, any attempt to examine the JMS destination property will result in a JMS exception being thrown.

Mapping the Message Reliability property between service integration and WebSphere MQ when using a WebSphere MQ server
This topic describes the order in which message reliability mappings are applied.

There are several places where the reliability for a message can be set, overridden or mapped:

1. The reliability can be set when the message is created.
2. The message reliability can be mapped to a different level of reliability when it is sent to a destination. The settings which determine this mapping are a property of the service integration JMS Destination administer object.
3. If the message is sent to a service integration destination which is assigned to a WebSphere MQ queue, then the reliability is subject to the reliability mapping performed on all messages sent to WebSphere MQ. This process maps reliable persistent, or higher levels of reliability, to WebSphere MQ persistent reliability. All other levels of service integration reliability are mapped to WebSphere MQ non-persistent.
4. If a message is received from WebSphere MQ, then its WebSphere MQ persistence is mapped to a service integration reliability using the mappings defined as part of the WebSphere MQ Server Bus member from which the message is being retrieved.

Depending on whether a message is being sent to, or received by, a service integration destination assigned to a WebSphere MQ Server Bus member, the message reliability mappings listed above are applied in a different order.

For messages being sent to a service integration destination that is localized on a WebSphere MQ bus member, steps 1 to 3 (inclusive) apply in the order given.

For messages being received by a service integration destinations that are localized on a WebSphere MQ bus member, step 4 only applies.

Reply to queue constraints when using a WebSphere MQ server

This topic describes the behavior and restrictions of the reply to queue message property when using a WebSphere MQ Server. These restrictions apply when replying to a message using a WebSphere MQ application, such as an application developed using WebSphere MQ JMS.

When a message with a reply to destination is sent to a destination assigned to a WebSphere MQ Server Bus member, this is represented using the following WebSphere MQ MQMD fields:

- MQMD reply to queue name is set to the name of the service integration destination specified as a reply to queue.
- MQMD reply to queue manager name is set to the name of the service integration bus from which the message was sent.

In both cases, names which are not recognized by WebSphere MQ are truncated at the first character which is not a valid WebSphere MQ character, or at the WebSphere MQ limit on the field length.

This places the following restrictions on the situations in which a WebSphere MQ JMS application can successfully reply to a message sent from Service Integraton.

- The reply to destination name must be a valid WebSphere MQ queue name
- The bus in which the reply to destination resides must have a name which is a valid WebSphere MQ queue manager name.
- The reply to destination must reside in the same bus as the bus which originates the message.
- There must be an MQ Link between the service integration bus and the WebSphere MQ network, over which the reply can flow.
- The "virtual queue manager name" given to the MQ Link must match the service integration bus name to which the MQ Link leads.

Using durable subscriptions

This topic describes things to consider when using *durable subscriptions* for publish/subscribe messaging. A durable subscription can be used to preserve messages published on a topic while the subscriber is not active.

If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscriber, or until they expire, or until the durable subscription is deleted. This enables subscriber applications to operate disconnected from the JMS provider for periods of time, and then reconnect to the provider and process messages that were published during their absence.

Each JMS durable subscription is identified by a subscription name (*subName*), which is defined when the durable subscription is created. A JMS connection also has an associated client identifier (*clientID*), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client. The subName assigned to a durable subscription must be unique within a given client ID.

If an application needs to receive messages published on a topic while the subscriber is inactive, it uses a *durable subscriber*.

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, when running inside an application server it is possible to clone the application server for failover and load-balancing purposes. In this case, a cloned durable subscription can have multiple simultaneous consumers.

For information about durable subscriptions, see the JMS 1.1 Specification (for example, section 9.3.3 "Using Durable Subscriptions").

The following operations for durable subscriptions are in addition to the usual JMS operations, such as to first look up a connection factory and a JMS destination, and to create a connection and session.

The following are the main operations for using durable subscriptions:
- Creating a new durable subscription
- Reconnecting to an existing durable subscription
- Unsubscribing (deleting) a durable subscription
- Define the Durable Subscription Home This property must be set on the JMS connection factory if durable subscriptions are to be created using connections created from this connection factory. The value is the name of the messaging engine where all durable subscriptions accessed through this connection are managed.

    You can also set the Durable Subscription Home on the JMS topic destination, which enables a single connection to access durable subscriptions on more than one messaging engine.

    To be able to create durable subscriptions, the property on the connection factory must not be null (the default). Setting a value of null or empty string on the property of a destination indicates that the value specified on the connection factory should be inherited.
- Creating a new durable subscription A durable TopicSubscriber can be created by a Session or by a TopicSession.

    Having performed the normal setup, an application can create a durable subscriber to a destination. To do this, the client program creates a durable TopicSubscriber, using session.createDurableSubscriber. The name *subName* is used as an identifier of the durable subscription.

    ```
    session.createDurableSubscriber( Topic topic,
            java.lang.String subName,
            java.lang.String messageSelector,
            boolean noLocal);
    ```

    Alternatively, you can use the two-argument form of this operation, which takes only a topic and name (*subName*) as parameters. This alternative form invokes the four-argument operation with null as the messageSelector and false as the noLocal parameters.

    ```
    session.createDurableSubscriber( Topic topic, java.lang.String subName);
    ```

    A JMS durable subscription is created with a unique identifier of the form $clientID+"##"+subName$. The characters ## should not be used in the clientID or subName if the JMS connection is to use a durable subscription.

    Handling exceptions. The following JMS exceptions can be thrown for the reasons listed in the exception messages:
    - InvalidDestination - The name of this durable subscription ($clientID+"##"+subName$) clashes with an existing destination.
    - IllegalState - The method was invoked on a closed connection.
    - IllegalState - This destination is not accepting consumers. This probably means that there is already an active subscriber for this durable subscription.
    - InvalidDestination - The mediation named in the parameters cannot be found.
    - InvalidDestination - The destination cannot be found.
    - JMSSecurity - The user does not have authorization to perform this operation.
    - JMSException - Errors occurred in the MsgStore, Comms or Core layers.

- Reconnecting to an existing durable subscription To reconnect to a topic that has an existing durable subscription, the subscriber application calls `session.CreateDurableSubscriber` again, using the same parameters that it used to originally create the durable subscription. However, consider the following important restrictions:
    - The subscriber must be attached to the same connection.
    - The destination and subscription name must be the same as in the original method call.
    - If a message selector was specified, it must be the same as in the original method call.

    By calling createDurableSubscriber again, the subscriber application reconnects to the topic, and receives any messages that arrived while the subscriber was disconnected.
- Unsubscribing (deleting) a durable subscription To unsubscribe (delete) a durable subscription to a topic, the subscriber application calls `session.unsubscribe(java.lang.String name)`.

    Do not call the unsubscribe method to delete a durable subscription if there is a TopicConsumer currently consuming messages from the topic.

Sending Web service messages directly over the bus from a JAX-RPC client

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive Web service request and response messages. JAX-RPC client applications using the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see Getting Started with JAX-RPC.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:
- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by "retargeting" the JAX-RPC client application as described in this topic.

    Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:
- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:
- Create an outbound service. An outbound service represents an externally-provided Web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.
- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a

single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have Web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.
3. Use the administrative console to access the port information for your JAX-RPC client application, as described in Configuring Web service client bindings and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send Web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the SDOMessageContext subclass.

Associated reference information:
- "sib: URL syntax"

sib: URL syntax

The `sib:` URL has the following syntax:

`sib:/[destination|path]?property_1=value_1&property_2=value_2&...`

where:
- Square brackets ("[ ]") indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a "query string" that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax *bus:destination*. If a bus or destination name contains a colon or comma, wrap the name in double quotation marks (""). If it contains a double quotation mark, repeat the quotation mark.

destinationName
    The destination name.

path   The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName
    The name of the destination to be used for the reply.

inboundService
    The name of the inbound service that identifies the specific attachment that the requester

application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout
> The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the SIMessage interface.

reliability
> The reliability of the request message.

timeToLive
> The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

> **Note:** The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority
> The priority of the request message.

user
> The user ID required to access the request destination.

password
> The password required to access the request destination.

replyReliability
> The reliability of the reply message.

replyTimeToLive
> The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority
> The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a `user.` prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Writing a routing mediation

Use this topic to create a mediation that chooses a particular forward route for a message.

For an introduction to using mediations with the service integration bus, see Learning about mediations. For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see Working with mediations.

This topic assumes that you are familiar with using a Java 2 platform, Enterprise Edition (J2EE) session bean development environment such as the Application Server Toolkit (AST) or Rational Application Developer.

A routing mediation is a mediation application that contains a routing handler. You associate a routing mediation with a service integration bus destination, and use the mediation to choose a particular route from a range of available routes. For example when you create a new outbound service configuration or modify an existing outbound service configuration you can apply a port selection mediation to choose a particular outbound port from the range of ports that are available to the outbound service.

To create a routing mediation, use a Java 2 platform, Enterprise Edition (J2EE) session bean development environment to complete the following steps:

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see Writing the mediation handler.

2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

   Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the routing function to the handler. Before you begin, review Adding mediation function to handler code, in particular its subtopic Working with message context. Add import statements to your handler class, and modify the handle method by adding your routing code. Specify the routing destination by adding that destination to the front of the forward routing path list. The forward routing path list is available from the message context. For example:

```
import javax.xml.rpc.handler.MessageContext;
import com.ibm.websphere.sib.mediation.handler.MediationHandler;
import com.ibm.websphere.sib.mediation.handler.MessageContextException;
import com.ibm.websphere.sib.mediation.messagecontext.SIMessageContext;
import com.ibm.websphere.sib.SIMessage;
import com.ibm.websphere.sib.SIDestinationAddress;
import com.ibm.websphere.sib.SIDestinationAddressFactory;
import java.util.List;
public class RouteMediationHandler implements MediationHandler {

 public boolean handle(MessageContext ctx) throws MessageContextException {
  SIMessageContext siCtx = (SIMessageContext) ctx;
  SIMessage msg = siCtx.getSIMessage();
  List frp = msg.getForwardRoutingPath();
  try {
   SIDestinationAddress destination =
    SIDestinationAddressFactory
     .getInstance()
     .createSIDestinationAddress(
     "RoutingDestination", //this is the name of the target destination
     false);
   frp.add(0, destination);
  } catch (Exception e) {
   return false;
  }
  msg.setForwardRoutingPath(frp);
  return true;
 }

}
```

For more information on the service integration technologies classes, including the mediation handler and message context classes, see the generated API information.

4. Export the routing mediation enterprise application.

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Writing a mediation that maps between attachment encoding styles

Use this topic to create a mediation that maps from SOAP Messages with Attachments encoding style to WS-I Attachments Profile Version 1.0 encoding style.

For an introduction to using mediations with the service integration bus, see Learning about mediations. For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see Working with mediations.

This topic assumes that you are familiar with using a Java 2 platform, Enterprise Edition (J2EE) session bean development environment such as the Application Server Toolkit (AST) or Rational Application Developer.

The example mediation given in this topic is based upon the WSDL examples that are given in Supporting bound attachments: WSDL examples

You can use a mediation to map from a SOAP Messages with Attachments encoding of a message to WS-I Attachments Profile Version 1.0 encoding. The WSDL definition is the same in both cases, so if you create a mediation that rewrites the Content ID values to match the Version 1.0 conventions then the message is encoded by service integration technologies according to Version 1.0 rules.

To create a mapping mediation, use a Java 2 platform, Enterprise Edition (J2EE) session bean development environment to complete the following steps:

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see Writing the mediation handler.

2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

   Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the mapping function to the handler. Before you begin, review Adding mediation function to handler code. Here is an example of mediation handler code that rewrites the Content ID values to match the Version 1.0 conventions:

```
int uuidBase = 0;
DataObject root = SIMessage.getDataGraph().getRootObject();
List attachments = root.getList("info/attachments");
Iterator entries = attachments.iterator();
while(entries.hasNext()) {
  DataObject entry = (DataObject) entries.next();
  if(entry.getType().equals("BoundMIMEAttachmentEntryType")) {
    String newContentId = entry.getString("messagePart") + "=" +
                          Integer.toString(uuidBase++) +
                          "@some.domain";
  }
}
```

   Note: For messages that use a SOAP with attachments reference (swaref) or some other URI mechanism to refer to the attachments, the URI values might also need to be updated to match the new Content ID values. However such mechanisms are usually used to refer to unbound

attachments.

For more information on the service integration technologies classes, including the mediation handler classes, see the generated API information.

4. Export the mapping mediation enterprise application.

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Choosing a target service and port through a routing mediation

If you have migrated your gateway, and the configuration included a routing filter that used the routing bean that is supplied with IBM WebSphere Application Server Version 5, then your routing filter still works in this version. However, if you did not use the supplied routing bean, then you must write a routing mediation and configure it to select a target service and port.

One gateway service can map to one or more target services, and (for outbound target services) each target service can have one or more ports as defined in the outbound service WSDL. Without a routing mediation there is no point in mapping multiple targets because the gateway always picks the default destination. If you want to map multiple targets, you must write a routing mediation then configure it, for each gateway service, to select the target service and target port.

You associate routing mediations with service integration bus destinations. To pick a target service, you associate the mediation with the gateway service destination. To pick an outbound service port, you associate the mediation with the outbound service destination.

Use the steps described in Writing a routing mediation to help you write a mediation application that contains a routing handler, install it into WebSphere Application Server and associate it with a destination.

Writing a WS-Notification application that exposes a Web service endpoint

Write a J2EE application, containing a JSR109 Web service definition, that can be deployed to the application server and act as a NotificationProducer, NotificationConsumer or demand based publisher.

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- The WSDL file for the endpoint that is to be exposed.

To write a WS-Notification application that exposes a Web service endpoint, follow the method provided by your tooling for creating a Web service implementation from a WSDL file. For example in Rational Software Architect there is a wizard in the Tutorials Gallery under "Create and deploy a WS-I compliant Web service and an enterprise bean skeleton from a WSDL document using the WebSphere run-time environment". This wizard guides you through the following steps:

1. Create a Dynamic Web Project.

2. Import and validate the WSDL file.

3. Create the Web service. Select **File** → **New** → **Other** → **Web services** → **Web service wizard** → **Skeleton EJB Web service**.

4. Implement the business methods in the generated EJB class. (e) The methods you choose depend upon the type of endpoint that you are exposing (NotificationProducer, NotificationConsumer or demand based publisher).

5. Export the application.

You are now ready to deploy the application to WebSphere Application Server as described in Installing application files with the console. In the Select installation options panel, ensure that the **Deploy Web services** option is enabled.

Writing a WS-Notification application that does not expose a Web service endpoint

Write a J2EE application that can be run outside of the application server to make Web service invocations against an external Web service. This application acts as a lightweight publisher, or a pull type consumer by invoking Web service operations against another Web service such as the NotificationBroker provided by WebSphere Application Server.

This task assumes that you have the following resources:
- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- Knowledge of where to find the WSDL file for the service that is to be invoked.

To write a WS-Notification application that does not expose a Web service endpoint, follow the method provided by your tooling for creating a Web service implementation from a WSDL file. The following steps follow the method provided by Rational Software Architect:

1. Get the WSDL for the service that you wish to invoke. If the target service is the notification broker inbound service that was generated by WebSphere Application Server, use the administrative console to navigate to **Service integration** › **Web services** › **WS-Notification services** › **[Content Pane]** *service_name* › **[Related items] Notification broker inbound service settings** › **[Additional Properties] Publish WSDL files to ZIP file** or **Service integration** › **Buses** › **[Content Pane]** *bus_name* › **[Services] WS-Notification services** › **[Content Pane]** *service_name* › **[Related items] Notification broker inbound service settings** › **[Additional Properties] Publish WSDL files to ZIP file**, then use the publish WSDL files property to export the template WSDL for this inbound service to a ZIP file.
2. Create a Dynamic Web Project with a name of your choice.
3. Choose **File** › **New** › **Other** › **Web services** › **Web services Client**.
4. Select **Java Proxy**.
5. Enter or select the WSDL you obtained earlier.
6. Choose a Client Type of "Application Client" or "Java" depending upon your requirements.
7. Select your required security configuration.
8. Click **Finish**.
9. Use the generated proxy and stubs to make calls against the remote Web service. For detailed coding examples, see "Developing applications that use WS-Notification."

You are now ready to deploy the application for use in the J2EE application client container as described in Running application clients.

Developing applications that use WS-Notification

Example code for common tasks that your WS-Notification applications can perform.

For an overview of how applications can use the notification broker, see WS-Notification - how client applications interact at runtime.

WS-Notification applications divide into two broad types: those that expose a Web service endpoint, and those that do not expose a Web service endpoint. For broad guidance on the steps you take to develop each of these application types, see the following topics:
- "Writing a WS-Notification application that exposes a Web service endpoint" on page 651.

- "Writing a WS-Notification application that does not expose a Web service endpoint" on page 652.

The code examples listed in this topic use the following Websphere Application Server APIs and SPIs:

```
com.ibm.websphere.sib.wsn.AbsoluteOrRelativeTime;
com.ibm.websphere.sib.wsn.CreatePullPoint;
com.ibm.websphere.sib.wsn.CreatePullPointResponse;
com.ibm.websphere.sib.wsn.Filter;
com.ibm.websphere.sib.wsn.GetMessages;
com.ibm.websphere.sib.wsn.GetMessagesResponse;
com.ibm.websphere.sib.wsn.NotificationMessage;
com.ibm.websphere.sib.wsn.TopicExpression;
com.ibm.websphere.webservices.soap.IBMSOAPFactory;
com.ibm.websphere.wsaddressing.EndpointReference;
com.ibm.websphere.wsaddressing.WSAConstants;
com.ibm.wsspi.wsaddressing.EndpointReferenceManager;
```

A single application can be coded to perform several WS-Notification tasks. Use the following examples to help you code these tasks into your WS-Notification applications:

- "Example: Subscribing a WS-Notification consumer" on page 654.
- "Example: Pausing a WS-Notification subscription" on page 656.
- "Example: Publishing a WS-Notification message" on page 656.
- "Example: Creating a WS-Notification pull point" on page 657.
- "Example: Getting messages from a WS-Notification pull point" on page 658.
- "Example: Registering a WS-Notification publisher" on page 658.
- "Example: Notification consumer Web service skeleton" on page 659.

Your applications can also use WS-Notification to receive event notifications generated by other clients of the service integration bus such as JMS clients. This is described in Use pattern for WS-Notification as an entry or exit point to the SIBus and Providing access for WS-Notification applications to an existing bus topic space. For information about developing applications for a mixed clients solution, including cross-streaming from a JMS client, see "Sharing event notification messages with other bus client applications" on page 660.

Writing a WS-Notification application that exposes a Web service endpoint

Write a J2EE application, containing a JSR109 Web service definition, that can be deployed to the application server and act as a NotificationProducer, NotificationConsumer or demand based publisher.

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- The WSDL file for the endpoint that is to be exposed.

To write a WS-Notification application that exposes a Web service endpoint, follow the method provided by your tooling for creating a Web service implementation from a WSDL file. For example in Rational Software Architect there is a wizard in the Tutorials Gallery under "Create and deploy a WS-I compliant Web service and an enterprise bean skeleton from a WSDL document using the WebSphere run-time environment". This wizard guides you through the following steps:

1. Create a Dynamic Web Project.
2. Import and validate the WSDL file.
3. Create the Web service. Select **File** → **New** → **Other** → **Web services** → **Web service wizard** → **Skeleton EJB Web service**.
4. Implement the business methods in the generated EJB class. (e) The methods you choose depend upon the type of endpoint that you are exposing (NotificationProducer, NotificationConsumer or demand based publisher).

5. Export the application.

You are now ready to deploy the application to WebSphere Application Server as described in Installing application files with the console. In the Select installation options panel, ensure that the **Deploy Web services** option is enabled.

Writing a WS-Notification application that does not expose a Web service endpoint

Write a J2EE application that can be run outside of the application server to make Web service invocations against an external Web service. This application acts as a lightweight publisher, or a pull type consumer by invoking Web service operations against another Web service such as the NotificationBroker provided by WebSphere Application Server.

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- Knowledge of where to find the WSDL file for the service that is to be invoked.

To write a WS-Notification application that does not expose a Web service endpoint, follow the method provided by your tooling for creating a Web service implementation from a WSDL file. The following steps follow the method provided by Rational Software Architect:

1. Get the WSDL for the service that you wish to invoke. If the target service is the notification broker inbound service that was generated by WebSphere Application Server, use the administrative console to navigate to **Service integration** → **Web services** → **WS-Notification services** → **[Content Pane]** *service_name* → **[Related items] Notification broker inbound service settings** → **[Additional Properties] Publish WSDL files to ZIP file** or **Service integration** → **Buses** → **[Content Pane]** *bus_name* → **[Services] WS-Notification services** → **[Content Pane]** *service_name* → **[Related items] Notification broker inbound service settings** → **[Additional Properties] Publish WSDL files to ZIP file**, then use the publish WSDL files property to export the template WSDL for this inbound service to a ZIP file.

2. Create a Dynamic Web Project with a name of your choice.

3. Choose **File** → **New** → **Other** → **Web services** → **Web services Client**.

4. Select **Java Proxy**.

5. Enter or select the WSDL you obtained earlier.

6. Choose a Client Type of "Application Client" or "Java" depending upon your requirements.

7. Select your required security configuration.

8. Click **Finish**.

9. Use the generated proxy and stubs to make calls against the remote Web service. For detailed coding examples, see "Developing applications that use WS-Notification" on page 652.

You are now ready to deploy the application for use in the J2EE application client container as described in Running application clients.

Example: Subscribing a WS-Notification consumer

Example code that describes a client acting in the subscriber role, subscribing a consumer application with a broker.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in conjunction with code generated using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");
```

```
// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the ConsumerReference. This contains the address of the consumer Web service which is being
// subscribed
EndpointReference consumerEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mycom.com:9080/Consumer"));

// Create the Filter. This provides the name of the topic to which you want to subscribe the consumer
Filter filter = new Filter();

// Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace
// prefixes and their corresponding namespaces for prefixes used in the expression
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
filter.addTopicExpression(exp);

// Create the InitialTerminationTime. This is the time when you want the subscription to terminate.
// For this example we set a time of 1 year in the future.
Calendar cal = Calendar.getInstance();
cal.add(Calendar.YEAR, 1);
AbsoluteOrRelativeTime initialTerminationTime = new AbsoluteOrRelativeTime(cal);

// Create the Policy information
SOAPElement[] policyElements = null;

/*
Optional
--------
The following lines show how to construct a policy indicating that the consumer
wants to receive raw style notifications:

    javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
    SOAPElement useRawElement = null;

    if (soapFactory instanceof IBMSOAPFactory) {
        // We can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
        // from an XML string.
      String useRawElementXML = "<mno:UseRaw xmlns:mno=\"http://docs.oasis-open.org/wsn/b-2\"/>";
        useRawElement = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(useRawElementXML);
    } else {
        useRawElement = soapFactory.createElement("UseRaw", "mno", "http://docs.oasis-open.org/wsn/b-2");
    }

    policyElements =  new SOAPElement[] { useRawElement };
*/

// Create holders to hold the multiple values returned from the broker:
// The subscription reference
EndpointReferenceTypeHolder subscriptionRefHolder = new EndpointReferenceTypeHolder();

// The current time at the broker
CalendarHolder currentTimeHolder = new CalendarHolder();

// The termination time for the subscription
CalendarHolder terminationTimeHolder = new CalendarHolder();

// Any additional elements
AnyArrayHolder anyOtherElements = new AnyArrayHolder();

/*
Optional
--------
The following line causes the request to be targeted at a pull point. You must
```

do this if you want to subscribe a consumer to use pull-based notifications. The pullPointEPR
is the EndpointReference returned by the broker in relation to an invocation of the
CreatePullPoint operation.

```
    ((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, pullPointEPR);
*/

// Invoke the Subscribe operation by calling the associated method on the stub
stub.subscribe(consumerEPR,
                    filter,
                    initialTerminationTime,
                    policyElements,
                    anyOtherElements,
                    subscriptionRefHolder,
                    currentTimeHolder,
                    terminationTimeHolder);

// Get the returned values:
// An endpoint reference for the subscription that has been created. It is required for
// subsequent lifetime management of the subscription, for example pausing the subscription
com.ibm.websphere.wsaddressing.EndpointReference subscriptionRef = subscriptionRefHolder.value;

// The current time at the broker
Calendar currentTime = currentTimeHolder.value;

// The termination time of the subscription
Calendar terminationTime = terminationTimeHolder.value;

// Any other information
SOAPElement[] otherElements = anyOtherElements.value;
```

Example: Pausing a WS-Notification subscription

Example code that describes a client acting in the subscriber role, pausing a subscription for a consumer
application.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in
conjunction with code generated using the WSDL2Java tool (run against the Subscription Manager WSDL
generated as a result of creating your WS-Notification service point) and WebSphere Application Server
APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation.
// The PauseSubscription operation belongs to the SubscriptionManager service
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup("java:comp/env/services/SubscriptionManager");

// Get a stub for the port on which you want to invoke operations
SubscriptionManager stub = (SubscriptionManager) service.getPort(SubscriptionManager.class);

// Associate the request with the subscription you want to pause. The subscriptionEPR is the
// EndpointReference returned by the invocation of the Subscribe operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, subscriptionEPR);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Invoke the PauseSubscription operation by calling the associated method on the stub
SOAPElement[] additionalReturnedInformation = stub.pauseSubscription(optionalInformation);
```

Example: Publishing a WS-Notification message

Example code that describes a client acting in the producer role, publishing a message to a broker.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in
conjunction with code generated using the WSDL2Java tool (run against the Notification Broker WSDL
generated as a result of creating your WS-Notification service point) and WebSphere Application Server
APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the message contents for a notification message
SOAPElement messageContents = null;
javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
if (soapFactory instanceof IBMSOAPFactory) {
    // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
    // from an XML string.
    String messageContentsXML = "<xyz:MyData xmlns:xyz=\"uri:mynamespace\">Some data</xyz:MyData>";
    messageContents = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(messageContentsXML);
} else {
    // Build up the SOAPElement using the standard javax.xml.soap APIs
    messageContents = soapFactory.createElement("MyData", "xyz", "uri:mynamespace");
    messageContents.addTextNode("Some data");
}

// Create a notification message from the contents
NotificationMessage message = new NotificationMessage(messageContents);

// Add a topic expression to the notification message indicating to which topic or topics the
// message corresponds
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
message.setTopic(exp);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

/*
Optional
--------
The following line will cause the request to be associated with a particular publisher registration.
You must do this if the broker requires publishers to register. The registrationEPR is the
ConsumerReference EndpointReference returned by the broker in relation to an invocation of the
RegisterPublisher operation.

    ((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, consumerReferenceEPR);
*/

// Invoke the Notify operation by calling the associated method on the stub
stub.notify(new NotificationMessage[] { message }, optionalInformation);
```

Example: Creating a WS-Notification pull point

Example code that describes a client acting in the subscriber role, creating a pull point for use by a consumer application that wants to use pull style notifications.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in conjunction with code generated using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);
```

```
// Create the request information.
SOAPElement[] optionalInformation = null;
CreatePullPoint cpp = new CreatePullPoint(optionalInformation);

// Invoke the CreatePullPoint operation by calling the associated method on the stub
CreatePullPointResponse response = stub.createPullPoint(cpp);

// Retrieve the reference to the pull point from the response
EndpointReference pullPointEPR = response.getPullPoint();

// Retrieve any additional information from the response
SOAPElement[] additionalInformation = response.getElements();
```

Example: Getting messages from a WS-Notification pull point

Example code that describes a client acting in the pull style consumer role, requesting messages from a pull point.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in conjunction with code generated using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Associate the request with a pull point. The pullPointEPR is the EndpointReference returned
// from invoking the CreatePullPoint operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, pullPointEPR);

// Specify the number of messages you want to retrieve
Integer numberOfMessages = new Integer(2);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Create the request information
GetMessages request = new GetMessages(numberOfMessages, optionalInformation);

// Invoke the GetMessages operation by calling the associated method on the stub
GetMessagesResponse response = stub.getMessages(request);

// Get the messages returned from the response
NotificationMessage[] messages = response.getMessages();
```

Example: Registering a WS-Notification publisher

Example code that describes a client acting in the publisher registration role, registering a publisher (producer) application with a broker.

This example is based on using the Java API for XML-based remote procedure call (JAX-RPC) APIs in conjunction with code generated using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

```
// Look up the JAX-RPC service. The JNDI name is specific to your Web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
```

```
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create a reference for the publisher (producer) being registered. This contains the address of the
// producer Web service.
EndpointReference publisherEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mysom.com:9080/Producer"));

// Create a list (array) of topic expressions to describe the topics to which the producer publishes
// messages. For this example you simply add one topic
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:mytopicns");
TopicExpression topic =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:xyz", prefixMappings);
TopicExpression[] topics = new TopicExpression[] {topic};

// Indicate that you do not want the publisher to use demand based publishing
Boolean demand = Boolean.FALSE;

// Set a value for the initial termination time of the registration. For this example we use 1 year in
// the future
Calendar initialTerminationTime = Calendar.getInstance();
initialTerminationTime.add(Calendar.YEAR, 1);

// Create holders to hold the multiple values returned from the broker:
// PublisherRegistrationReference: An endpoint reference for use in lifetime management of
// the registration
EndpointReferenceTypeHolder pubRegMgrEPR = new EndpointReferenceTypeHolder();

// ConsumerReference: An endpoint reference for use in subsequent publishing of messages
EndpointReferenceTypeHolder consEPR = new EndpointReferenceTypeHolder();

// Invoke the RegisterPublisher operation by calling the associated method on the stub
stub.registerPublisher(publisherEPR, topics, demand, initialTerminationTime, null, pubRegMgrEPR, consEPR);

// Retrieve the PublisherRegistrationReference
EndpointReference registrationEPR = pubRegMgrEPR.value;

// Retrieve the ConsumerReference
EndpointReference consumerReferenceEPR = consEPR.value;
```

Example: Notification consumer Web service skeleton

This example WSDL document describes a Web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.

```
<?xml version="1.0" encoding="utf-8"?>

<wsdl:definitions xmlns=http://schemas.xmlsoap.org/wsdl/
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:wsn-bw="http://docs.oasis-open.org/wsn/bw-2"
    xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:tns="uri:example.wsn/consumer"
    targetNamespace="uri:example.wsn/consumer">

    <wsdl:import namespace="http://docs.oasis-open.org/wsn/bw-2"
                       location="http://docs.oasis-open.org/wsn/bw-2.wsdl" />

    <wsdl:binding name="NotificationConsumerBinding" type="wsn-bw:NotificationConsumer">
        <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
        <wsdl:operation name="Notify">
            <wsdlsoap:operation soapAction="" />
            <wsdl:input>
                <wsdlsoap:body use="literal" />
            </wsdl:input>
        </wsdl:operation>
    </wsdl:binding>
```

```
    <wsdl:service name="NotificationConsumerService">
        <wsdl:port name="NotificationConsumerPort" binding="tns:NotificationConsumerBinding">
            <wsdlsoap:address location="http://myserver.mycom.com:9080/Consumer" />
        </wsdl:port>
    </wsdl:service>

</wsdl:definitions>
```

The following example shows a basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool:

```
public class ConsumerExample implements NotificationConsumer {

    public void notify(NotificationMessage[] notificationMessage, SOAPElement[] any)
                                                    throws RemoteException {
        // Process each NotificationMessage
        for (int i=0; i<notificationMessage.length; i++) {
            NotificationMessage message = notificationMessage[i];

            // Get the contents of the message
            SOAPElement messageContent = message.getMessageContents();

            // Get the expression indicating which topic the message is associated with
            TopicExpression topic = message.getTopic();

            // Get a reference to the producer (this value is optional and so may be null)
            EndpointReference producerRef = message.getProducerReference();

            // Get a reference to the subscription (this value is optional and so may be null)
            EndpointReference subscriptionRef = message.getSubscriptionReference();

            // User defined processing ...

        }
    }
}
```

Sharing event notification messages with other bus client applications

How to create the JMS side of a mixed WS-Notification and JMS (bus) clients configuration, to enable cross-streaming of messages between WS-Notification applications and other clients of the service integration bus.

You can configure WS-Notification so that Web service applications receive event notifications generated by other clients of the service integration bus such as JMS clients. Similarly Web service applications can generate notifications to be received by other client types. This configuration is described in the Use pattern for WS-Notification as an entry or exit point to the SIBus. You achieve this configuration by creating a permanent topic namespace that allows messages to be shared between Web service and non Web service clients of the bus, as described in Providing access for WS-Notification applications to an existing bus topic space.

Interacting with JMS message types

The WS-Notification service is responsible for both inserting messages into the service integration bus (in response to Notify operations received from Web services) and receiving messages from the bus (in order to pass messages to a Web service as a result of a Subscribe operation).

Messages inserted by the WS-Notification service are of the JMS BytesMessage type, so when a Web service invokes the Notify operation against a WS-Notification service point the application content of the message is inserted into the body of a JMS BytesMessage using the UTF-8 encoding.

For messages received by the WS-Notification service in response to a subscription the reverse conversion is applied. The received message is converted to the appropriate JMS message type. If the appropriate type is determined to be a BytesMessage type, then the body of the message is converted to a string using the UTF-8 encoding and proceeds through the code for checking before being sent to the requesting Web service.

If the converted BytesMessage string does not contain an XML element when converted to a string then this message is ignored as having been originated by a non WS-Notification aware (JMS) application.

If the received message is determined to be a TextMessage then the body content of the message is extracted and processing proceeds in the same way as for the converted BytesMessage content. This means that JMS applications that want to provide event notifications to a WS-Notification application can choose to send the content as either a BytesMessage or a TextMessage depending upon which is more convenient to the application.

If the received message is neither a BytesMessage nor a TextMessage then it is discarded as having been originated by a non WS-Notification aware (JMS) application.

Data access resources

Task overview: Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases. IBM WebSphere Application Server provides several options for accessing an information system's backend data store:
- Programming directly to the database through the JDBC 2.0 optional package API or the JDBC 3.0 API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using embedded Structured Query Language in Java (SQLJ) support with applications that use DB2 as a backend database.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

For all of these options, *except for using the JCA 1.0 or 1.5 compliant connectors*, the prerequisite Web site details which databases and drivers are currently supported. Consult the IBM Web address: http://www.ibm.com/software/webservers/appserv/doc/latest/prereq.html .

1. Develop data access applications. Develop your application to access data using the various ways available through the WebSphere Application Server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
2. Assemble data access applications using the assembly tool. Assemble your application by creating and mapping resource references.
3. Prepare for deployment: Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.
4. Install the application on your application server.

Resource adapter

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS).

A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

An application server vendor extends its system once to support the J2EE Connector Architecture (JCA) and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

WebSphere Application Server provides the WebSphere Relational Resource Adapter implementation. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the JCA connection management architecture. It provides connection pooling, transaction, and security support. WebSphere Application Server supports JCA versions 1.0 and 1.5.

Data access for container-managed persistence (CMP) beans is managed by the WebSphere Persistence Manager indirectly. The JCA specification supports persistence manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, the persistence manager uses the relational resource adapter to access the data from the database.

You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

J2EE Connector Architecture resource adapters:

A J2EE Connector Architecture (JCA) resource adapter is any resource adapter conforming to the JCA Specification.

The product supports any resource adapter that implements version 1.0 or 1.5 of this specification. IBM supplies resource adapters for many enterprise systems separately from the WebSphere Application Server package, including (but not limited to): the Customer Information Control System (CICS), Host On-Demand (HOD), Information Management System (IMS), and Systems, Applications, and Products (SAP) R/3 .

The general approach to writing an application that uses a JCA resource adapter is to develop EJB session beans or services with tools such as Rational Application Developer. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

WebSphere relational resource adapter settings:

Use this page to view the settings of the WebSphere relational resource adapter. This adapter is preinstalled in the product to provide access to relational databases.

Restriction: Although the default relational resource adapter settings are viewable, you cannot make changes to them.

To view this administrative console page, click **Resources** > **Resource adapters** > **Resource adapters** > **WebSphere Relational Resource Adapter**.

Name:

Specifies the name of the resource provider.

Data type   String

Description:

Specifies a description of the relational resource adapter.

Data type   String

Archive path:

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

Data type   String

Class path:

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

Data type   String

Native path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Data type   String

WebSphere Relational Resource Adapter:

The WebSphere Relational Resource Adapter (RRA) provides enterprise applications deployed on WebSphere Application Server access to relational databases.

The WebSphere RRA is installed and runs as part of WebSphere Application Server, and needs no further administration.

The RRA supports both the configuration and use of JDBC data sources and J2EE Connection Architecture (JCA) connection factories. The RRA supports the configuration and use of data sources implemented as either JDBC data sources or J2EE Connector Architecture connection factories. Data sources can be used directly by applications, or they can be configured for use by container-managed persistence (CMP) entity beans.

For more information about the WebSphere Relational Resource Adapter, see the following topics:
- For information about resource adapters, see "Resource adapter" on page 662
- For information about resource adapters and data access, see "Data access portability features"
- For RRA settings, see "WebSphere relational resource adapter settings" on page 662
- For information about CMP connection factories, see "Connection factory" on page 667
- For information about enterprise beans, see EJB applications

Data access portability features: The WebSphere Application Server relational resource adapter (RRA) provides a portability feature that enables applications to access data from different databases without changing the application. In addition, WebSphere Application Server enables you to plug in a data source

that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* type or the *ConnectionPoolDataSource* type, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

DataStoreHelper interface

With this interface, each data store platform can plug in its own private data store specific functions that the relational resource adapter run time uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

In addition, the interface also provides a GenericDataStoreHelper class for unsupported data sources to use. You can subclass the GenericDataStoreHelper class or other WebSphere provided helpers to support any new data source.

Note: If you are configuring data access through a user-defined JDBC provider, do not implement the DataStoreHelper interface directly. Either subclass the GenericDataStoreHelper class or subclass one of the DataStoreHelper implementation classes provided by IBM (if your database behavior or SQL syntax is similar to one of these provided classes).

For more information, see the API documentation **DataStoreHelper** topic (as listed in the API documentation index).

The following code segment shows how a new data store helper is created to add new error mappings for an unsupported data source.

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

WSCallHelper class

This class provides two methods that enable you to use vendor-specific methods and classes that do not conform to the standard JDBC APIs (and are not part of WebSphere Application Server extension packages).

- **jdbcCall() method**

  By using the static jdbcCall() method, you can invoke vendor-specific, nonstandard JDBC methods on your JDBC objects. (For more information, see the API documentation **WSCallHelper** topic.) The following code segment illustrates using this method with a DB2 data source:

  ```
  Connection conn = ds.getConnection();
  // get connection attribute
  String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
   "getConnectionAttribute", null, null);
  // setAutoClose to false
  WSCallHelper.jdbcCall(java.sql.Connection.class,
  conn, "setAutoClose",
  new Object[] { new Boolean(false)},
  new Class[] { boolean.class });
  // get data store helper
  DataStoreHelper dshelper = WSCallHelper.getDataStoreHelper(ds);
  ```

- **jdbcPass() method**

Use this method to exploit the nonstandard JDBC classes that some database vendors provide. These classes contain methods that require vendors' proprietary JDBC objects to be passed as parameters.

In particular, implementations of Oracle can involve use of nonstandard classes furnished by the vendor. Methods contained within these classes include:

```
oracle.sql.ArrayDescriptor ArrayDescriptor.createDescriptor(java.lang.String, java.sql.Connection)
oracle.sql.ARRAY new ARRAY(oracle.sql.ArrayDescriptor, java.sql.Connection, java.lang.Object)
oracle.xml.sql.query.OracleXMLQuery(java.sql.Connection, java.lang.String)
oracle.sql.BLOB.createTemporary(java.sql.Connection, boolean, int)
oracle.sql.CLOB.createTemporary(java.sql.Connection, boolean, int)
oracle.xdb.XMLType.createXML(java.sql.Connection, java.lang.String)
```

The following code examples demonstrate the difference between a call to the XMLType.createXML() method over a direct connection to Oracle, and a call to the same method within WebSphere Application Server.

1. Over a direct connection:

```
XMLType poXML = XMLType.createXML(conn, poString);
```

2. Within Application Server, using the jdbcPass() method:

```
XMLType poXML (XMLType)(WSCallHelper.jdbcPass(XMLType.class,
"createXML", new Object[]{conn,poString},
 new Class[]{java.sql.Connection.class, java.lang.String.class},
 new int[]{WSCallHelper.CONNECTION,WSCallHelper.IGNORE}));
```

There are two different jdbcPass() methods available, one for use in invoking static methods, another for use when invoking non-static methods. See the API documentation **WSCallHelper** topic.

Note: Because of the possible problems that can occur by passing an underlying object to a method, WebSphere Application Server strictly controls which methods are allowed to be invoked using the jdbcPass() method support. If you require support for a method that is not listed previously in this document, please contact WebSphere Application Server support with information on the method you require.

WARNING: Use of the jdbcPass() method causes the JDBC object to be used outside of WebSphere's protective mechanisms. Performing certain operations (such as setting autoCommit, or transaction isolation settings, etc.) outside of these protective mechanisms will cause problems with the future use of these pooled connections. IBM does not guarantee stability of the object after invocation of this method; it is the user's responsibility to ensure that invocation of this method does not perform operations that harm the object. Use at your own risk.

Example: Developing your own DataStoreHelper class: The DataStoreHelper interface supports each data store platform plugging in its own private data store specific functions that are used by the Relational Resource Adapter run time.

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
* Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
* Implementation for each method is provided only as an example.  More detail would likely be
* required for any custom DataStoreHelper created for use by a real application.
*/
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{
    static final long serialVersionUID = 87889310901490908285L;
```

```
public ExampleDataStoreHelper(java.util.Properties props)
{
    super(props);

    // Update the DataStoreHelperMetaData values for this helper.
    getMetaData().setGetTypeMapSupport(false);

    // Update the exception mappings for this helper.
    java.util.Map xMap = new java.util.HashMap();

    // Add an Error Code mapping to StaleConnectionException.
    xMap.put(new Integer(2310),  StaleConnectionException.class);
    // Add an Error Code mapping to DuplicateKeyException.
    xMap.put(new Integer(1062),  DuplicateKeyException.class);
    // Add a SQL State mapping to the user-defined ColumnNotFoundException
    xMap.put("S0022",            ColumnNotFoundException.class);
    // Undo an inherited StaleConnection SQL State mapping.
    xMap.put("S1000",            Void.class);

    setUserDefinedMap(xMap);

    // If you are extending a helper class, it is
    // normally not necessary to issue 'getMetaData().setHelperType(...)'
    // because your custom helper will inherit the helper type from its
    //  parent class.

    }

public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
{
    // Clean up the statement so it may be cached and reused.

    stmt.setCursorName("");
    stmt.setEscapeProcessing(true);
    stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
    stmt.setMaxFieldSize(0);
    stmt.setMaxRows(0);
    stmt.setQueryTimeout(0);
}

public int getIsolationLevel(AccessIntent intent) throws ResourceException
{
    // Determine an isolation level based on the AccessIntent.

    if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

    return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
           java.sql.Connection.TRANSACTION_READ_COMMITTED :
           java.sql.Connection.TRANSACTION_REPEATABLE_READ;
}
    public int getLockType(AccessIntent intent) {
       if ( intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC) {
          if ( intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ) {
              return WSInteractionSpec.LOCKTYPE_SELECT;
          }
          else {
              return WSInteractionSpec.LOCKTYPE_SELECT_FOR_UPDATE;
          }
       }
       return WSInteractionSpec.LOCKTYPE_SELECT;
    }

public int getResultSetConcurrency(AccessIntent intent) throws ResourceException
```

```
    {
        // Determine a ResultSet concurrency based on the AccessIntent.

        return intent == null || intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ?
                java.sql.ResultSet.CONCUR_READ_ONLY :
                java.sql.ResultSet.CONCUR_UPDATABLE;
    }

    public int getResultSetType(AccessIntent intent) throws ResourceException
    {
        // Determine a ResultSet type based on the AccessIntent.

        if (intent == null) return java.sql.ResultSet.TYPE_SCROLL_INSENSITIVE;

        return intent.getCollectionAccess() == AccessIntent.COLLECTION_ACCESS_SERIAL ?
                java.sql.ResultSet.TYPE_FORWARD_ONLY :
                java.sql.ResultSet.TYPE_SCROLL_SENSITIVE;
    }
}
```

ColumnNotFoundException

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import com.ibm.websphere.ce.cm.PortableSQLException;

/**
* Example PortableSQLException subclass, which demonstrates how to create a user-defined
* exception for exception mapping.
*/
public class ColumnNotFoundException extends PortableSQLException
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}
```

Connection factory

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS).

Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

CMP connection factories collection:

Use this page to view existing CMP connection factories settings.

These connection factories are used by a container-managed persistence (CMP) bean to access any backend data store. A CMP connection factory is used by EJB model 2.x Entities with CMP version 2.x. Connection factories listed on this page are created automatically under the WebSphere Relational Resource Adapter when you check the box *Use this Data Source in container managed persistence (CMP)* in the General Properties area on the Data Source page. You cannot modify the settings for a CMP connection factory, and you cannot delete CMP connection factories from this collection. To remove the CMP connection factory object, you must navigate to the data source associated with the CMP connection factory and uncheck the *Use this Data Source for CMP* check box.

To view this administrative console page, click **Resources** > **Resource Adapters** > **Resource Adapters** >*WebSphere Relational Resource Adapter* > **CMP connection factories**.

Name:

Specifies a list of the display names for the resources.

Data type   String

JNDI Name:

Specifies the JNDI name of the resource.

Data type   String

Description:

Specifies a description for the resource.

Data type   String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type   String

CMP connection factory settings:

Use this page to view the settings of a connection factory that is used by a CMP bean to access any backend data store. This connection factory is only in ″read″ mode. It cannot be modified or deleted.

To view this administrative console page, click **Resources** >**Resource Adapters** > **Resource Adapters** > *WebSphere Relational Resource Adapter*> **CMP Connection Factories** > *connection_factory*

Name:

Specifies the display name for the resource.

Data type   String

JNDI name:

Specifies the JNDI name of the resource.

Data type   String

Description:

Specifies a description for the resource.

Data type   String

Category:

Specifies a category string which can be used to classify or group the resource.

Data type   String

Authentication Preference:

Specifies which of the authentication mechanisms that are defined for the corresponding resource adapter applies to this connection factory. This property is deprecated starting with version 6.0.

For example, if two authentication mechanism entries are defined for a resource adapter (*KerbV5* and *Basic Password*), this specifies one of those two types. If the authentication mechanism preference specified is not an authentication mechanism available on the corresponding resource adapter, it is ignored.

Data type   String

Component-managed authentication alias:

References authentication data for component-managed signon to the resource.

Data type   Drop-down list

Container-managed authentication alias:

References authentication data for container-managed signon to the resource. This property is deprecated starting with version 6.0.

Data type   Drop-down list

JDBC providers

Installed applications use JDBC providers to interact with relational databases.

The JDBC provider object supplies the specific JDBC driver implementation class for access to a specific vendor database. To create a pool of connections to that database, you associate a data source with the JDBC provider. Together, the JDBC provider and the data source objects are functionally equivalent to the J2EE Connector Architecture (JCA) connection factory, which provides connectivity with a non-relational database.

For a current list of supported providers, see the WebSphere Application Server prerequisite Web site.

See also Hardware and software requirements for more information. For detailed descriptions of the providers, including the supported data source classes and their required properties, refer to Vendor-specific data sources minimum required settings .

Data sources

Installed applications use a *data source* to obtain connections to a relational database. A data source is analogous to the J2EE Connector Architecture (JCA) connection factory, which provides connectivity to other types of enterprise information systems (EIS).

A data source is associated with a JDBC provider, which supplies the driver implementation classes that are required for JDBC connectivity with your specific vendor database. Application components transact directly with the data source to obtain connection instances to your database. The connection pool that corresponds to each data source provides connection management.

You can create multiple data sources with different settings, and associate them with the same JDBC provider. For example, you might use multiple data sources to access different databases within the same

vendor database application. WebSphere Application Server requires JDBC providers to implement one or both of the following data source interfaces, which are defined by Sun Microsystems. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

*   *ConnectionPoolDataSource* - a data source that supports application participation in local and global transactions, excepting two-phase commit transactions.

    Note: In two cases, a connection pool data source does support two-phase commit transactions: when the JDBC provider is DB2 for z/OS Local JDBC provider (RRS), or when the data source is making use of *Last participant* support. Last participant support enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources. For more information, consult the article "Using one-phase and two-phase commit resources in the same transaction" on page 1116.

    When a connection pool data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.
*   *XADataSource* - a data source that supports application participation in any single-phase or two-phase transaction environment. When this data source is involved in a global transaction, the WebSphere Application Server transaction manager provides transaction recovery.

In WebSphere Application Server releases prior to version 5.0, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available to support J2EE 1.2 applications, but another connection manager architecture is provided, based on the JCA architecture supporting the new J2EE 1.3 application style (also for J2EE 1.4 applications).

These two separate architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.

*   Data source (WebSphere Application Server V4) - This data source runs under the original CM architecture. Applications using this data source behave as if they were running in Version 4.0.
*   Data source - This data source uses the JCA standard architecture to provide support for J2EE version 1.3 and 1.4 applications. It runs under the JCA connection manager and the relational resource adapter.

Choice of data source

*   J2EE 1.2 application - all EJB 1.1 enterprise beans, JDBC applications, or Servlet 2.2 components must use the **4.0** data source.
*   J2EE 1.3 (and subsequent releases) application -
    *   EJB 1.1 Module - all EJB 1.x beans must use the **4.0** data source.
    *   EJB 2.0 (and subsequent releases) Module - enterprise beans that include container-managed persistence (CMP) Version 1.x, 2.0, and beyond must use the **new** data source.
    *   JDBC applications and Servlet 2.3+ components - must use the **new** data source.

Data access beans

Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the Enterprise JavaBeans specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *Rational Application Developer*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

Feature
> **Details**

Caching query results

You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

Updating through result cache

Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

Querying parameter support

The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

Supporting metadata

A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatyped parameters are automatically converted to SQL data types as specified in the metadata mapping.

When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the Java Database Connectivity (JDBC) 2.0 (and later) Extensions specification.

To make data source connections manageable by the CM, the WebSphere Application Server provides a resource adapter (the WebSphere Relational Resource Adapter) that enables JDBC data sources to be managed by the same CM that manages JCA connections. From the CM point of view, JDBC data sources and JCA connection factories look the same. Users of data sources do not experience any programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the specification changes from various J2EE requirements levels. These differences are not related to the adoption of the JCA architecture.

If you have J2EE 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 6.0 and later, the JDBC CM from Application Server version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 6.0 or later, using the latest migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.x modules in J2EE 1.3 (or later versions) applications cannot use the JDBC CM from WebSphere Application Server Version 4.0.

Connection pooling:

Each time an application attempts to access a backend store (such as a database), it requires resources to create, maintain, and release a connection to that datastore. To mitigate the strain this process can

place on overall application resources, WebSphere Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. *Connection pooling* spreads the connection overhead across several user requests, thereby conserving application resources for future requests.

WebSphere Application Server supports JDBC 3.0 APIs for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

Benefits of connection pooling

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. Because users connect and disconnect frequently with applications on the Internet, the application requests for data access can surge to considerable volume. Consequently, the total datastore overhead quickly becomes high for Web-based applications, and performance deteriorates. When connection pooling capabilities are used, however, Web applications can realize performance improvements of up to 20 times the normal results.

With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnection is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

When to use connection pooling

Use WebSphere connection pooling in an application that meets any of the following criteria:
* It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
* It requires Java Transaction API (JTA) transactions within WebSphere Application Server.
* It needs to share connections among multiple users within the same transaction.
* It needs to take advantage of product features for managing local transactions within the application server.
* It does not manage the pooling of its own connections.
* It does not manage the specifics of creating a connection, such as the database name, user name, or password

How connections are pooled together

Whenever you configure a unique data source or connection factory, you are required to give it a unique Java Naming and Directory Interface (JNDI) name. This JNDI name, along with its configuration information, is used to create the connection pool. A separate connection pool exists for each configured data source or connection factory.

A separate instance of a given configured connection pool is created on each application server that uses that data source or connection factory. For example, if you run a three server cluster in which all of the servers use *myDataSource*, and *myDataSource* has a maximum connections setting of 10, then you can generate up to 30 connections (three servers times 10 connections). Be sure to consider this fact when determining how many connections to your backend resource you can support.

Other considerations for determining the maximum connections setting:
* Each entity bean transaction requires an additional database connection, dedicated to handling the transaction.

- On UNIX platforms, a separate DB2 process is created for each connection; these processes quickly affect performance on systems with low memory and cause errors.
- If clones are used, one data pool exists for each clone.

It is also important to note that when using *connection sharing*, it is only possible to share connections obtained from the same connection pool.

Avoiding a deadlock

Deadlock can occur if the application requires more than one concurrent connection per thread, and the database connection pool is not large enough for the number of threads. Suppose each of the application threads requires two concurrent database connections and the number of threads is equal to the maximum connection pool size. Deadlock can occur when both of the following are true:
- Each thread has its first database connection, and all are in use.
- Each thread is waiting for a second database connection, and none would become available since all threads are blocked.

To prevent the deadlock in this case, the maximum connections value for the database connection pool should be increased by at least one. Doing this allows for at least one of the waiting threads to obtain its second database connection and to avoid a deadlock.

To avoid deadlock, code the application to use, at most, one connection per thread. If the application is coded to require C concurrent database connections per thread, the connection pool must support at least the following number of connections, where T is the maximum number of threads.

```
T * (C - 1) + 1
```

The connection pool settings are directly related to the number of connections that the database server is configured to support.

If the maximum number of connections in the pool is raised, and the corresponding settings in the database are not raised, the application fails and SQL exception errors are displayed in the `stderr.log` file.

Deferred Enlistment: In the WebSphere Application Server environment, *deferred enlistment* is a term used to refer to the technique of waiting until a connection is first used to enlist it in its unit of work (UOW) scope.

In one example, the technique works like this: a component calls getConnection() from within a global transaction, and at some point later in time, the component uses the connection. The call that uses the connection is intercepted, and the XA resource for that connection is enlisted with the transaction service (which in turn calls XAResource.start()). Next, the actual call is sent to the resource manager.

In contrast, if a component gets a connection within a global transaction without deferred enlistment, then the connection is enlisted in the transaction and has all the overhead associated with that transaction. For XA connections, this includes the two phase commit (2PC) protocol to the resource manager. Deferred enlistment offers better performance in the case where a connection is obtained, but not used within the UOW scope. This saves all the overhead of participating in the UOW when it is not needed.

The WebSphere Application Server relational resource adapter automatically supports deferred enlistment without any additional configuration needed.

Lazy Transaction Enlistment Optimization: The J2EE Connector Architecture (JCA) Version 1.5 specification calls the deferred enlistment technique *lazy transaction enlistment optimization*. This support comes through a marker interface (LazyEnlistableManagedConnection) and a new method on the connection manager (LazyEnlistableConnectionManager()):

```
package javax.resource.spi;
import javax.resource.ResourceException;
import javax.transaction.xa.Xid;

interface LazyEnlistableConnectionManager { // application server
    void lazyEnlist(ManagedConnection) throws ResourceException;
}

interface LazyEnlistableManagedConnection { // resource adapter
}
```

A resource adapter is not required to support this functionality. Check with the resource adapter provider if you need to know if the resource adapter provides this functionality.

Connection and connection pool statistics: Performance Monitoring Infrastructure (PMI) method calls that are supported in the two existing Connection Managers (JDBC and J2C) are still supported in this version of WebSphere Application Server. The calls include:
- ManagedConnectionsCreated
- ManagedConnectionsAllocated
- ManagedConnectionFreed
- ManagedConnectionDestroyed
- BeginWaitForConnection
- EndWaitForConnection
- ConnectionFaults
- Average number of ManagedConnections in the pool
- Percentage of the time that the connection pool is using the maximum number of ManagedConnections
- Average number of threads waiting for a ManagedConnection
- Average percent of the pool that is in use
- Average time spent waiting on a request
- Number of ManagedConnections that are in use
- Number of Connection Handles
- FreePoolSize
- UseTime

Java Specification Request (JSR) 77 requires statistical data to be accessed through managed beans (Mbeans) to facilitate this. The Connection Manager passes the ObjectNames of the Mbeans created for this pool. In the case of Java Message Service (JMS) *null* is passed in. The interface used is:

```
PmiFactory.createJ2CPerf(
    String pmiName, // a unique Identifier for JCA /JDBC.  This is the
                    // ConnectionFactory name.

    ObjectName providerName,// the ObjectName of the J2CResourceAdapter
                            // or JDBCProvider Mbean

    ObjectName factoryName // the ObjectName of the J2CConnectionFactory
                           // or DataSourceMbean.
)
```

The following Unified Modeling Language (UML) diagram shows how JSR 77 requires statistics to be reported:

In WebSphere Application Server Version 5.x, the JCAStats interface was implemented by the J2CResourceAdapter Mbean, and the JDBCStats interface was implemented by the JDBCProvider Mbean. The JCAConnectionStats and JDBCConnectionStats interfaces are not implemented because they collect statistics for nonpooled connections, which are not present in the JCA 1.0 Specification. JCAConnectionPoolStats, and JDBCConnectionPoolStats do not have a direct implementing Mbean; those statistics are gathered through a call to PMI. A J2C resource adapter, and JDBC provider each contain a list of ConnectionFactory or DataSource ObjectNames, respectively. The ObjectNames are used by PMI to find the appropriate connection pool in the list of PMI modules.

The JCA 1.5 Specification allows an exception from the matchManagedConnection() method that indicates that the resource adapter requests that the connection not be pooled. In that case, statistics for that connection are provided separately from the statistics for the connection pool.

Connection life cycle:

A ManagedConnection object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the DoesNotExist state. After a connection is created, it can be in either the InUse or the InFreePool state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the InFreePool state to InUse state only if:
- the application has called the data source or connection factory getConnection() method (the *getConnection* condition)
- a free connection is available in the pool with matching properties (the *freeConnectionAvailable* condition)
- and one of the two following conditions are true:
  - the getConnection() request is on behalf of a resource reference that is marked unsharable

– the getConnection() request is on behalf of a resource reference that is marked shareable but no shareable connection in use has the same properties.

This transition description follows:

```
InFreePool > InUse:
getConnection  AND
freeConnectionAvailable  AND
NOT(shareableConnectionAvailable)
```

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older then its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on a data source or connection factory object.
markedStale	Connection is marked as stale, typically in response to a fatal error notification.
noOtherReferences	There is only one connection handle to the managed connection, and the Transaction Service is not holding a reference to the managed connection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection() request is for a shareable connection, and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection() request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

Getting connections

The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
unshareableConnectionRequest)
```

This transition specifies that a connection object is not created unless the following conditions occur:
- The application calls the getConnection() method on the data source or connection factory
- No connections are available in the free pool (NOT(freeConnectionAvailable))
- The pool size is less than the maximum pool size (poolSizeLTMax)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (NOT(shareableConnectionAvailable)) OR the request is for an unsharable connection (unshareableConnectionRequest)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:
- the application has issued a getConnection() call
- a connection is available for use in the connection pool (freeConnectionAvailable),
- and one of the following is true:
  - the request is for an unsharable connection (unsharableConnectionRequest)
  - no connection with the same sharing properties is already in use in the transaction. (NOT(sharableConnectionAvailable)).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition indicates that if an application requests a shareable connection (getConnection) with the **same** sharing properties as a connection that is already in use (ShareableConnectionAvailable), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolation level*, which is configurable on the resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the ConnectionSpec object. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

Note: It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

Returning connections

All of the transitions discussed previously involve getting a connection for application use. With that goal, the transitions result in a connection closing, and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling close() on the connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:
* If the application or the container calls close() (producing the close condition) and there are no references (the noOtherReferences condition) either by the application (in the application sharing condition) or by the transaction manager (in the NoTx condition, meaning that the transaction manager holds a reference when the connection is enlisted in a transaction), the connection object returns to the free pool.
* If the connection was enlisted in a transaction but the transaction manager ends the transaction (the txEnds condition), and the connection was a shareable connection (the ShareableConnection condition), the connection closes and returns to the pool.

When the application calls close() on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls close() on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool, making it impossible for any application running on the server to get a connection.

When the application calls close() on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling close() can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data

store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently InUse connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to close() when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls close() on the connection and the connection is marked as stale during the pool cleansing step (markedStale), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.
1. If a fatal error notification is received from the resource adapter (or data source). A fatal error notification (FatalErrorNotification) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (UnusedTimeoutExpired) and the pool size is greater than the minimum number of connections (poolSizeGTMin), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.
3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

Unshareable and shareable connections:

WebSphere Application Server supports both *unshareable* and *shareable* connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

You can share a shareable connection with other components within the same transaction as long as each *getConnection()* request has the same connection properties. To enable connection sharing for data sources, the following connection properties must be the same:
- Java Naming and Directory Interface (JNDI) name. While not actually a connection property, this requirement simply means that you can only share connections from the same data source in the same server.
- Resource authentication
- In relational databases:
  - Isolation level (corresponds to access intent policies applied to CMP beans)
  - Readonly
  - Catalog
  - TypeMap

To enable connection sharing for resource adapters within the same transaction, the following connection properties must be the same:
- JNDI name. While not actually a connection property, this requirement simply means that you can only share connections from the same resource adapter in the same server.
- Resource authentication

In addition, the *ConnectionSpec* object used to get the connection must also be the same. For more information on sharing a connection with a CMP bean, see Sharing a connection with a CMP bean.

Java Message Service (JMS) connections cannot be shared with non-JMS connections.

Access to a resource marked as unshareable means that there is a one-to-one relationship between the connection handle a component is using and the physical connection with which the handle is associated. This access implies that every call to the getConnection() method returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring in another application that is sharing the connection (for example, unexpectedly changing the isolation level).

Marking a resource as shareable allows for greater scalability. Instead of creating new physical connections on every getConnection() invocation, the physical connection (that is, managed connection) is shared through multiple connection handles, as long as each getConnection request has the same connection properties. However, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application that assumes sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

For WebSphere Application Server, all sharing of connections is relative to the current Unit of Work (UOW) boundary. Anyone within a specific transaction, when getting a connection from a specific connection pool, gets a handle to the same physical connection (if the sharing properties are the same).

Sharing a connection with a CMP bean

WebSphere Application Server allows you to share a physical connection between a CMP bean, a BMP bean, and a JDBC application to reduce the resource allocation or deadlock scenarios. There are several ways to ensure that all of these entity beans and the JDBC applications are sharing the same physical connection.

- **Sharing a connection between CMP beans or methods**

  When all CMP bean methods use the same access intent, they all share the same physical connection. A different access intent policy triggers the allocation of a different physical connection. For example, a CMP bean has two methods; method 1 is associated with `wsPessimisticUpdate` intent, whereas method 2 has `wsOptimisticUpdate` access intent. Method 1 and method 2 cannot share the same physical connection within a transaction. In other words, an XA data source is required to run in a global transaction.

  You can experience some deadlocks from a database if both methods try to access the same table. Therefore, sharing a connection is determined by the access intents that are defined in the CMP methods.

- **Sharing a connection between CMP and BMP beans**

  There are two options to ensure that both CMP and BMP beans share the same physical connection:

  – Define the same access intent on both CMP and BMP bean methods. Because both use the same access intent, they share the same physical connection. The advantage to using this option is that the backend is transparent to a BMP bean; however, this BMP is not portable because it uses the WebSphere extended API to handle the isolation level. For more information, refer to the code example in Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans.

  – Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level that is specified on the resource reference to look up a data source and a connection. This option is more of a manual process, and the isolation level might be different from database to database. For more information refer to the isolation level and access intent mapping table: Access intent isolation levels and update locks and the Isolation level and resource reference section.

- **Sharing a connection between CMP and a JDBC application that is used by a servlet or a session bean**

Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level specified on the resource reference to look up a data source and a connection. For more information refer to Access intent isolation levels and update locks and Isolation level and resource reference.

Factors that determine sharing

The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref) that specifies the res-sharing-scope as shareable are candidates for sharing. The resource reference properties of res-sharing-scope and res-auth and the IBM extension isolationLevel help determine if it is possible to share a connection. IBM extension isolationLevel is stored in IBM deployment descriptor extension file; for example: ibm-ejb-jar-ext.xmi.
- You can only share connections that are requested with the same properties.
- Connection Sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection Sharing only occurs within a sharing boundary. Current sharing boundaries include *Transactions* and *LocalTransactionContainment* (LTC) boundaries.
- Connection Sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.

    The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true connection sharing does not take place. The term ″*reuse*″ is more accurate.

    More importantly, the *LocalTransactionContainment* boundary enclosing both *get* actions is not complete; no cleanUp() method is invoked on the ManagedConnection object. Therefore the second *get* action inherits all of the connection properties set during the first getConnection() call.
- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the J2EE 1.3 standard.
  - General users of resource adapters can set the connection properties on the connection factory getConnection() call by passing them in a *ConnectionSpec*.

    However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the *isolation level* specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.
  - For JDBC users, WebSphere Application Server provides an extension to enable passing the connection properties through the ConnectionSpec.

    Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.
- You cannot set the isolation level on a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to

enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

Connection sharing violations

There is a new exception, the `SharingViolation` exception, that the resource adapter can issue whenever an operation violates sharing requirements. Possible violations include changing connection attributes, security settings, or isolation levels, among others. When such a mutable operation is performed against a managed connection, the `SharingViolation` exception can occur when both of the following conditions are true:
* The number of connection handles associated with the managed connection is more than one.
* The managed connection is associated with a transaction, either local or XA.

Both the component and the J2C run time might need to detect this `SharingViolation` exception, depending on when and how the managed connection becomes unshareable. If the managed connection becomes unshareable because of an operation through the connection handle (for example, you change the isolation level), then the component needs to process the exception. If the managed connection becomes unshareable without being recognized by the application server (due to some component interaction with the connection handle), then the resource adapter can reject the creation of a connection handle by issuing the `SharingViolation` exception.

Connection handles:

A connection handle is a representation of a physical connection.

To use a backend resource (such as a relational database) in WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. It is used within a single method and without calling another method that might get a connection from the same data source or connection factory. An application using this pattern does the following:
1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:
1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Keep in mind the following considerations for using cached handles:

- Cached handle support requires some additional connection handle management across these boundaries, which can impact performance. For example, in a JDBC application, *Statements*, *PreparedStatements*, and *ResultSets* are closed implicitly after a transaction ends, but the connection remains valid.
- You are encouraged **not** to cache the connection across the transaction boundary for shareable connections; the get/use/close pattern is preferred.
- Caching of connection handles across servlet methods is limited to JDBC and Java Message Service (JMS) resources. Other non-relational resources, such as Customer Information Control System (CICS) or IMS objects, currently cannot have their connection handles cached in a servlet; you need to get, use, and close the connection handle within each method invocation. (This limitation only applies to single-threaded servlets because multithreaded servlets do not allow caching of connection handles.)
- You **cannot** pass a cached connection handle from one instance of a data access client to another client instance. Transferring between client instances creates the problematic contingency of one instance using a connection handle that is referenced by another. This relationship can only cause problems because connection handle management code processes tasks for each client instance *separately*. Hence, connection handle transfers result in run-time scenarios that trigger exceptions. For example:
  1. The application code of a client instance that receives a transferred handle closes the handle.
  2. If the client instance that retains the original reference to the handle tries to reclaim it, the application server issues an exception.

The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
ut.begin();
conn.prepareStatement("......"); --> Connection runs in global transaction mode
...
ut.commit();
conn.prepareStatement("......");   ---> Connection still valid but runs in autoCommit(True);
...
```

Unshareable connections

Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

- **The possible benefits of unshared connections**
  - Your application always maintains a direct link with a physical connection (managed connection).
  - The connection always has a one-to-one relationship between the connection handle and the managed connection.
  - In most cases, the connection does not close until the application closes it.
  - You can use a cached unshared connection handle across multiple transactions.
  - The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.
- **The possible drawbacks of unshared connections**
  - Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
  - Wasted connections. It is important not to keep the connection handle open (that is, your application does not call the *close()* method) any longer then it is needed. As long as an unshareable connection is open, the physical connection is unavailable to any other component, even if your application is not currently using that connection. Unlike a shareable connection, an ushareable connection is not closed at the end of a transaction or servlet call.

– Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlock in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

In the same scenario, but with a *shared* connection, deadlock does not occur because all the work is done on the same connection. It is worth noting that when writing code that uses shared connections, you use a strategy that calls for multiple work items to be performed on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception might occur for waiting connection requests if you exceed the maximum connections value, and unshareable connections are not being closed before the connection wait time-out is exceeded.

Shareable connections

Some characteristics of connection handles that are retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

- **The possible benefits of shared connections**
  - Within an instance of connection sharing, application components can share a managed connection with one or more connection handles, depending on how the handle is retrieved and which connection properties are used.
  - They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as a transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

    If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time ensures that the handle is reassociated with a managed connection that is appropriate for the current sharing scope, and has the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Futhermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.

- **The possible drawbacks of shared connections**
  - Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

    If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) that gets a connection handle to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle is not valid and triggers an exception at any attempt to use it.

    Note: This exception occurs only when calling a utility object (a Java object).

    Not all resource adapters have this limitation; it occurs only in certain implementations. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any data source used through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another (or close your handle before calling code that gets

another handle), and before returning from a method, you can allow two pieces of code to share the same managed connection. You simply cannot use the connection for both events at the same time.

– Trying to change the *isolation level* on a shareable JDBC-based connection in a global transaction (that is supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.

– Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

Lazy connection association optimization

In WebSphere Application Server Version 5.0, the Java 2 Platform, Enterprise Edition (J2EE) Connector (J2C) connection manager implemented *smart handle* support. This technology enables allocation of a connection handle to an application while the managed connection associated with that connection handle is used by other applications (assuming that the connection is not being used by the original application). This concept is part of the J2EE Connector Architecture (JCA) 1.5 specification. (You can find it in the JCA 1.5 specification document in the section entitled ″Lazy Connection Association Optimization.″) Smart handle support introduces use a method on the ConnectionManager object, the *LazyAssociatableConnectionManager()* method, and a new marker interface, the *DissociatableManagedConnection* class. You must configure the provider of the resource adapter to make this functionality available in your environment. (In the case of the RRA, WebSphere Application Server itself is the provider.) The following code snippet shows how to include smart handle support:

```
package javax.resource.spi;
import javax.resource.ResourceException;

interface LazyAssociatableConnectionManager { // application server
    void associateConnection(
        Object connection, ManagedConnectionFactory mcf,
        ConnectionRequestInfo info) throws ResourceException;
}

interface DissociatableManagedConnection { // resource adapter
    void dissociateConnections() throws ResourceException;
}
```

This DissociatableManagedConnection interface introduces another state to the Connection object: *inactive*. A Connection can now be active, closed, and inactive. The connection object enters the inactive state when a corresponding ManagedConnection object is cleaned up. The connection stays inactive until an application component attempts to re-use it. Then the resource adapter calls back to the connection manager to re-associate the connection with an active ManagedConnection object.

Transaction type and connection behavior:

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC) boundary. Each transaction type places different requirements on connections and impacts connection settings differently.

Connection sharing and reuse

You can only share connections within a global transaction scope (assuming other sharing rules are met). However, you can *serially reuse* connections within an LTC scope. A get/use/close connection pattern followed by another instance of get/use/close (to the same data source or connection factory) enables you to reuse the same connection. See the "Unshareable and shareable connections" on page 679 topic for more details.

JDBC AutoCommit behavior

All JDBC connections, when first obtained through a getConnection() call, contain the setting AutoCommit = TRUE by default. However, different transaction scope and settings can result in changing, or simply overriding, the AutoCommit value.

- If you operate within an LTC and have its resolution-control set to *Application*, then AutoCommit remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, then the application should **not** touch the AutoCommit setting. The WebSphere Application Server run time sets the AutoCommit value to *FALSE* before work begins, then commits or rolls back the work as appropriate at the end of the LTC scope.
- If you use a connection within a global transaction, the database ignores the AutoCommit setting so that the transaction service that controls the commit and rollback processing can manage the transaction. This action takes place upon first use of the connection to do work, regardless of the user changing the AutoCommit setting. After the transaction completes, the AutoCommit value returns to the value it had before the first use of the connection. So even if the AutoCommit value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* since the value is ignored by the database. In this example, after the transaction completes, the AutoCommit value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

One-phase commit and two-phase commit connections

The type and number of resource managers, such as a database server, that must be accessed by an application often determines the application transaction requirements. Consequently each type of resource manager places different requirements on connection behavior.

- A two-phase commit resource manager can support two-phase coordination of a transaction. That support is necessary for transactions that involve other resource managers; these transactions are global transactions. See "Transaction support in WebSphere Application Server" on page 1084 for further explanation.
- A one-phase commit resource manager supports only one-phase transactions, or LTC transactions, in which that resource is the sole participating datastore. Again, see "Transaction support in WebSphere Application Server" on page 1084 for further explanation.

One-phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done on all of the connections completes or fails atomically. The product does not allow more than one one-phase commit connection in a global transaction. Futhermore, it does not allow a one-phase commit connection in a global transaction with one or more two-phase commit connections. You can coordinate only multiple two-phase commit connections within a global transaction.

WebSphere Application Server provides *last participant support* that enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

Note that any time you do multiple getConnection() calls using a resource reference that specifies res-sharing-scope=Unshareable, then you get multiple physical connections. This situation also occurs when res-sharing-scope=Shareable, but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two-phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an XA exception that logs the following message:

```
WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources
 has occurred.
```

Application scoped resources:

Use this page to view brief descriptions of the resources that are bundled with your application. You can view individual resource settings by clicking on the resource name.

To view this administrative console page, click **Applications** > **Enterprise Applications** > *application_name* > **Application scoped resources**.

Each table row corresponds to a resource that is bundled with your application. Click a resource name or the corresponding provider name to view an administrative console page where you can edit the object configuration settings.

Name:

Specifies the administrative name that was assigned to this resource.

Click this name to view a page where you can edit the configuration settings.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the resource.

Data type   String

Resource type:

Specifies the type of resource, such as a data source or a J2C connection factory.

Provider:

Specifies the resource provider that supplies the class information for this resource object.

Click the provider name to view a page where you can edit the configuration settings.

Description:

Specifies a text description of the resource.

Cache instances

An application uses a cache instance to store, retrieve, and share data objects within the dynamic cache.

Each cache instance can be configured independently for Java Naming and Directory Interface (JNDI) name, cache size, priority, and disk offload. Objects that are stored in a particular cache instance are not affected by other cache instances. This means that if you store an object named **object_1** with a value of `object_data` in *cache_instance_x*, you can also store an object with the same name, but different value in *cache_instance_y*.

Objects that are stored in a particular cache instance are available to applications on other servers by accessing a cache instance of the same name. The two servers must be within the same replication domain to share data.

There are two types of cache instances, object cache instances and servlet cache instances.

An object cache instance is a location in addition to the default shared dynamic cache where Java 2 Platform, Enterprise Edition (J2EE) applications can store, distribute, and share objects. After configuring object cache instances, you can use the DistributedMap or DistributedObjectCache interfaces in the `com.ibm.websphere.cache` package to programmatically access your cache instances.

See the "Reference: Generated API documentation" on page 26 for more information about the DistributedMap or DistributedObjectCache interfaces.

Servlet cache instances are locations in addition to the default dynamic cache where dynamic cache can store, distribute, and share the output and the side effects of an invoked servlet. By configuring a servlet cache instance, your applications have greater flexibility and better tuning of cache resources. The Java Naming and Directory Interface (JNDI) name that is specified for the cache instance in the administrative console maps to the <cache-instance> element in the `cachespec.xml` configuration file. Any <cache-entry> elements that are specified within a <cache-instance> element are created in that specific cache instance. Any <cache-entry> elements that are specified outside of a <cache-instance> element are stored in the default dynamic cache instance.

See Using servlet cache instances for more information.

Data access: Resources for learning

Use the following links to find relevant supplemental information about data access. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Developing data access applications

You can access data in various ways:
- using standard or extended APIs
- using container-managed persistence beans
- using bean-managed persistence beans, session beans, or Web components.
- using Service Data Objects (SDO)

1. Decide how to implement data access.

   The Enterprise JavaBeans (EJB) programming model provides several distinct server-side component types: entity, session, and message-driven beans, and servlets. Of these types, entity beans are typically used to model business components in an application. Entity beans have both *state* and *behavior*.

   The state of entity beans is persistent and is stored in a database. As changes are made to an entity bean, its state is kept in synchronization with the database record representing the bean. There are two types of entity beans provided by the EJB model and these two types differ in the mechanism used to provide persistence. These two types of entity beans are *container-managed persistence* (CMP) beans and *bean-managed persistence* (BMP) beans.

   - With BMP beans, the developer manually produces code to manage the persistent state of the bean.

   - With CMP beans, the EJB container manages the persistent state of the bean. Persistent state management is a complex and difficult task; using CMP beans allows the developer to concentrate on business logic by delegating persistence behavior to the container.

   Typical examples of CMP beans are *Customer*, *Account*, and so on. Because CMP beans are objects, their data (state) is accessed using field accessors. For example, a *Customer* entity bean is

likely to have fields such as *name* and *phoneNumber*. These pieces of data are accessed using the accessor methods *getName()/setName()* and *getPhoneNumber()/setPhoneNumber()*. As a developer, you are not concerned with how this data is eventually stored and retrieved from the backend database and can assume that the integrity of the data is maintained by the container.

See the "Developing enterprise beans" on page 154 article for information on developing entity beans.

Tips:
- To maximize the efficiency of application requests to relational databases, consider using Structured Query Language in Java (SQLJ) when developing BMP and CMP beans. This option is available for applications that use the DB2 JDBC Universal Driver to access DB2 databases.
- Also consider using cursor holdability for potential performance gains; see the "Cursor holdability support for JDBC applications" on page 714 article for details.

An alternative to developing entity beans is using the Service Data Objects (SDO) framework, which is a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and utilize data. You need to know only one API, the SDO API, which lets you work with data from multiple sources, including relational databases, entity EJB components, XML pages, Web services, the Java Connector Architecture, JavaServer Pages, and more.

2. Look up a data source or connection factory using a resource reference (Looking up data sources with resource references for relational access). *Do not perform this step if you work with CMP beans, however; the EJB container handles this process for CMP beans.*

To run applications on WebSphere Application Server, your code must use resource references to logically name data sources or connection factories. Mapping the resource references to actual resources is usually done at assembly time. The Application Server administrator configures those resources.

- For relational database access, administrators configure a JDBC provider and associated data sources, which work with the embedded WebSphere Relational Resource Adapter.
- For non-relational database access, administrators install a J2EE Connector Architecture (JCA) resource adapter onto an application server and configure associated connection factories.

3. Get a connection to a data source or a connection factory. (See the "Getting connections" section of Connection life cycle for details.) *Do not perform this step if you work with CMP beans, however; the EJB container handles this process for CMP beans.*

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the JDBC Extensions Specification.

Extensions to data access APIs

Applications can access the backend data through the standard J2EE 1.4 defined application programming interfaces (APIs). The standard APIs, however, do not always provide a complete solution for an application that runs in an application server. In some cases the JDBC programming model does not completely integrate with the J2EE Connector Architecture (JCA) (even though full integration is a foundation of the JCA specification). These inconsistencies can limit data access options for an application that uses both APIs. WebSphere Application Server provides API extensions to resolve the compatibility issues.

For example:

Without the benefit of an extension, applications using both APIs cannot modify the properties of a shareable connection after making the connection request, if other handles exist for that connection. (If no other handles are associated with the connection, then the connection properties can be altered.) This limitation stems from an incompatibility between the connection-configuration policies of the APIs:

The J2EE Connector Architecture (JCA) specification supports relaying to the resource adapter the specific properties settings at the time you request the connection (using the getConnection() method) by passing in a *ConnectionSpec* object. The ConnectionSpec object contains the necessary connection properties used to get a connection. After you obtain a connection from this environment, your application does not need to alter the properties. The JDBC programming model, however, does not have the same interface to specify the connection properties. Instead, it gets the connection first, then sets the properties on the connection.

WebSphere Application Server provides the following extensions to fill in such gaps between the JDBC and JCA specifications:
- WSDataSource interface - this interface extends the *javax.sql.DataSource* class, and enables a component or an application to specify the connection properties through the WebSphere Application Server *JDBCConnectionSpec* class to get a connection.
  - getConnection(JDBCConnectionSpec) - this method returns a connection with the properties specified in the JDBCConnectionSpec class.
  - For more information see the **WSDataSource** API documentation topic (as listed in the API documentation index).
