## Commands for the SPNEGO TAI group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SPNEGO TAI group of the AdminTask object:

| Command name:          | Description:                                                                                                                                                                                                            | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Commands for the AuthorizationGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the [Commands for the AdminTask object](#) article.

The following commands are available for the AuthorizationGroupCommands group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                                        |                                                                                                                                                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| listAuthorizationGroupsOfResource | The <b>listAuthorizationGroupsOfResource</b> command lists authorization groups for a given resource. If the value of the <code>traverseContainedObjects</code> parameter is false, only the authorization group of the resource is returned. If the value of the <code>traverseContainedObjects</code> parameter is true, it returns the authorization group of the resource and the authorization groups of all the parent resources in the containment tree. | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>resourceName</b><br/>The name of the resource. (String, required)</li> <li>The <code>resourceName</code> parameter must be in the following format:<br/>ResourceType=ResourceName</li> <li>where <code>ResourceType</code> can be any one of the following values: Application, Server, ServerCluster, Node, or NodeGroup.</li> <li><code>ResourceName</code> is the name of the resource instance, for example, <code>server1</code>.</li> <li>The following are examples of the <code>resourceName</code> parameter:<br/>Node=node1: Server=server</li> <li>This example uniquely identifies <code>server1</code>. The name of the node is required if a server on a different node uses the same server name.<br/>Application=app1</li> </ul> </li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask listAuthorizationGroupsOfResource {-resourceName Application=app1}</code></li> <li>Using Jython string:<br/><code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName Application=app1'])</code></li> <li>Using Jython list:<br/><code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName', 'Application=app1'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask listAuthorizationGroupsOfResource {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code></li> <li>Using Jython list:<br/><code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code></li> </ul> |

| removeUsersFromAdminRole | The <b>removeUsersFromAdminRole</b> command removes previously mapped user IDs from administrative roles in the authorization group. The name of the authorization group that you provide determines which authorization table is involved. If you do not specify an authorization group name, the user ID from the cell level authorization table will be used. The user ID can be a short name or a fully qualified domain name if a LDAP user registry is used. | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li><b>- authorizationGroupName</b><br/>The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional)</li> <li><b>- roleName</b><br/>The name of the administrative role. (String, required)</li> <li><b>- userids</b><br/>A list of user IDs that you want to remove from the administrative role. (String[], required)</li> </ul> </li> <li>Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask removeUsersFromAdminRole {-authorizationGroupName groupName - roleName administrator -userids user1}</code></li> <li>Using Jython string:<br/><code>AdminTask.removeUsersFromAdminRole('[-authorizationGroupName groupName -roleName administrator -userids user1]')</code></li> <li>Using Jython list:<br/><code>AdminTask.removeUsersFromAdminRole(['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-userids', 'user1'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask removeUsersFromAdminRole {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.removeUsersFromAdminRole ('[-interactive]')</code></li> <li>Using Jython list:<br/><code>AdminTask.removeUsersFromAdminRole (['-interactive'])</code></li> </ul> |

## Commands for the ChannelFrameworkManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ChannelFrameworkManagement group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

## Configuring data access with scripting

Use these topics to learn about using scripting to configure data access.

This topic contains the following tasks:

- “Configuring a JDBC provider using scripting”
- “Configuring new data sources using scripting” on page 548
- “Configuring new connection pools using scripting” on page 550
- “Changing connection pool settings with the wsadmin tool” on page 550
- “Configuring new data source custom properties using scripting” on page 557
- “Configuring new J2CAuthentication data entries using scripting” on page 558
- “Configuring new WAS40 data sources using scripting” on page 559
- “Configuring new WAS40 connection pools using scripting” on page 560
- “Configuring new WAS40 custom properties using scripting” on page 561
- “Configuring new J2C resource adapters using scripting” on page 562
- “Configuring custom properties for J2C resource adapters using scripting” on page 563
- “Configuring new J2C connection factories using scripting” on page 564
- “Configuring new J2C authentication data entries using scripting” on page 566
- “Configuring new J2C administrative objects using scripting” on page 568
- “Configuring new J2C activation specifications using scripting” on page 567
- “Testing data source connections using scripting” on page 570

## Configuring a JDBC provider using scripting

You can configure a JDBC provider using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

1. There are two ways to perform this task. Perform one of the following:

- Using the AdminTask object:
  - Using Jacl:  
\$AdminTask createJDBCProvider {-interactive}
  - Using Jython:  
AdminTask.createJDBCProvider (['-interactive'])
- Using the AdminConfig object:
  - a. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.

- Using Jacl:
 

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```
- Using Jython:
 

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

b. Identify the required attributes:

- Using Jacl:
 

```
$AdminConfig required JDBCProvider
```
- Using Jython:
 

```
print AdminConfig.required('JDBCProvider')
```

Example output:

```
Attribute      Type
name           String
implementationClassName  String
```

c. Set up the required attributes and assign it to the `jdbcAttrs` variable. You can modify the following example to setup non-required attributes for JDBC provider.

- Using Jacl:
 

```
set n1 [list name JDBC1]
set implCN [list implementationClassName myclass]
set jdbcAttrs [list $n1 $implCN]
```

Example output:

```
{name {JDBC1}} {implementationClassName {myclass}}
```

- Using Jython:
 

```
n1 = ['name', 'JDBC1']
implCN = ['implementationClassName', 'myclass']
jdbcAttrs = [n1, implCN]
print jdbcAttrs
```

Example output:

```
[['name', 'JDBC1'], ['implementationClassName', 'myclass']]
```

d. Create a new JDBC provider using `node` as the parent:

- Using Jacl:
 

```
$AdminConfig create JDBCProvider $node $jdbcAttrs
```
- Using Jython:
 

```
AdminConfig.create('JDBCProvider', node, jdbcAttrs)
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
```

2. Save the configuration changes. See the “Saving configuration changes with the `wsadmin` tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the `wsadmin` tool” on page 99 article for more information.

If you modify the class path or native library path of a JDBC provider: After saving your changes (and synchronizing the node in a network deployment environment), you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

## Configuring new data sources using scripting

You can configure new data sources using scripting and the `wsadmin` tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

In WebSphere Application Server, any JDBC driver properties that are required by your database vendor must be set as data source properties. Consult the article Vendor-specific data sources minimum required settings in the *Troubleshooting and support* PDF to see a list of these properties and setting options, ordered by JDBC provider type.

There are two ways to perform this task; use either of the following wsadmin scripting objects:

- AdminTask object
- AdminConfig object

AdminConfig gives you more configuration control than the AdminTask object. When you create a data source using AdminTask, you supply universally required properties only, such as a JNDI name for the data source. (Consult the article “Commands for the JDBCProviderManagement group of the AdminTask object” on page 616 for more information.) Other properties that are required by your JDBC driver are assigned default values by Application Server. You cannot use AdminTask commands to set or edit these properties; you must use AdminConfig commands.

- Using the AdminConfig object to configure a new data source:
  1. Identify the parent ID, which is the name and location of the JDBC provider that supports your data source.

– Using Jacl:

```
set newjdbc [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/]
```

– Using Jython:

```
newjdbc = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/')
print newjdbc
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
```

2. Obtain the required attributes.

**Tip:** If the database vendor-required properties (which are referenced in the article Vendor-specific data sources minimum required settings) are not displayed in the resulting list of required attributes, script these properties as data source *custom properties* after you create the data source.

– Using Jacl:

```
$AdminConfig required DataSource
```

– Using Jython:

```
print AdminConfig.required('DataSource')
```

Example output:

```
Attribute Type
name      String
```

3. Set up the required attributes.

– Using Jacl:

```
set name [list name DS1]
set dsAttrs [list $name]
```

– Using Jython:

```
name = ['name', 'DS1']
dsAttrs = [name]
```

4. Create the data source.

– Using Jacl:

```
set newds [$AdminConfig create DataSource $newjdbc $dsAttrs]
```

- Using Jython:

```
newds = AdminConfig.create('DataSource', newjdbc, dsAttrs)
print newds
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml#DataSource_1)
```

- Using the AdminTask object to configure a new data source:
  - Using Jacl:

```
$AdminTask createDatasource {-interactive}
```
  - Using Jython:

```
AdminTask.createDatasource (['-interactive'])
```
- Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
- Synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

Consult your database documentation to see if the vendor recommends setting additional properties. Script them as data source custom properties. See the article “Configuring new data source custom properties using scripting” on page 557.

## Configuring new connection pools using scripting

You can use scripting and the wsadmin tool to configure new connection pools.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps:

1. Identify the parent ID:

- Using Jacl:

```
set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
```

- Using Jython:

```
newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
```

2. Creating connection pool:

- Using Jacl:

```
$AdminConfig create ConnectionPool $newds {}
```

- Using Jython:

```
print AdminConfig.create('ConnectionPool', newds, [])
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#ConnectionPool_1)
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Changing connection pool settings with the wsadmin tool

You can use the wsadmin scripting tool to change connection pool settings.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages. To learn more about the wsadmin tool see Starting the wsadmin scripting client.

To use the wsadmin tool to change connection pool settings:

1. Launch a scripting command. There are several options for you to run scripting commands, ranging from running them interactively to running them in a profile.

To change connection pool settings, you use the *getAttribute* and *setAttribute* commands, run against the various settings objects.

For example, to change the connection timeout setting, the commands are:

```
$AdminControl getAttribute $objectname connectionTimeout
$AdminControl setAttribute $objectname connectionTimeout 200
```

where:

- \$ is a Jacl operator for substituting a variable name with its value
  - getAttribute and setAttribute are the commands
  - connectionTimeout is the object whose value you are resetting
2. For Jacl code examples of each of the connection pool settings, see “Example: Changing connection pool settings with the wsadmin tool”

### **Example: Changing connection pool settings with the wsadmin tool**

You can use the wsadmin tool to change connection pool settings.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. The WebSphere Application Server only supports the Jacl and Jython scripting languages.

You must start the wsadmin scripting client before you perform any other task using scripting.

### **Connection Timeout**

The Connection timeout can be changed at any time while the pool is active. All connection requests that are waiting for a connection are changed to the new value minus the time already waited, and are returned to the wait state if there are no available connections.

For example, if the connection timeout is changed to 300 seconds and a connection request has waited 100 seconds, the connection request waits for 200 more seconds if no connection becomes available.

```
$AdminControl getAttribute $objectname connectionTimeout
$AdminControl setAttribute $objectname connectionTimeout 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

### **Maximum Connections**

The maximum connections can be changed at any time except in the case where stuck connection support is active.

If stuck connection support is active, an attempt to change the maximum connections is made. If the attempt fails, an `IllegalState` exception occurs. See the Connection pool advanced settings topic in the *Administering applications and their environment* PDF for more information.

If stuck connection support is not active, the maximum connections are changed to the new value. If the new value is greater than the current value, the number of connections increases to the new value and any requests waiting are notified. If the new value is less than the current value and Aged Timeout or

Reap Time is used, the number of connections decreases to the new value depending on pool activity. If agedTimeout or Reap Time are not used, no automatic attempt will be made to reduce the total number of connections. To manually reduce the number of connections to the new maximum connections, use the Mbean function `purgePoolContents`.

```
$AdminControl getAttribute $objectname maxConnections  
$AdminControl setAttribute $objectname maxConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Minimum Connections

The minimum connections can be changed at any time

```
$AdminControl getAttribute $objectname minConnections  
$AdminControl setAttribute $objectname minConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Reap Time

The reap time can be changed at any time. The reap time interval is changed to the new value at the next interval.

```
$AdminControl getAttribute $objectname reapTime  
$AdminControl setAttribute $objectname reapTime 30
```

## Unused Timeout

The unused timeout can be changed at any time.

```
$AdminControl getAttribute $objectname unusedTimeout  
$AdminControl setAttribute $objectname unusedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Aged Timeout

The Aged Timeout can be changed at any time.

```
$AdminControl getAttribute $objectname agedTimeout  
$AdminControl setAttribute $objectname agedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Purge Policy

The purge policy can be changed at any time.

```
$AdminControl getAttribute $objectname purgePolicy  
$AdminControl setAttribute $objectname purgePolicy "Failing Connection Only"
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Surge Protection Support

Surge connection support starts if surgeThreshold is > -1 and surgeCreationInterval is > 0. The surge protection properties can be changed at any time.

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

## Stuck connection Support

An attempt is made to change the stuckTime, stuckTimerTime or stuckThreshold properties. If the attempt fails, an `IllegalStateException` occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, all three stuck property values must be greater than 0, and the maximum connections value must be > 0.

If the connection pool is stuck, you cannot change the stuck or the maximum connection properties. If you are stuck, there are active connections.

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerTime
$AdminControl setAttribute $objectname stuckTimerTime 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

## Test Connection Support (This is only supported for a DataSource)

The test connection support starts when the testConnection property is set to true, and the interval is > 0. The test connection properties can be changed at any time.

```
$AdminControl getAttribute $objectname testConnection
$AdminControl setAttribute $objectname testConnection 30
$AdminControl getAttribute $objectname testConnectionInterval
$AdminControl setAttribute $objectname testConnectionInterval 15
```

For more information about this setting, see the Test connection service topic in the *Administering applications and their environment* PDF.

## Connection Pool Partition Support

```
$AdminControl invoke $objectname freePoolDistributionTableSize
$AdminControl invoke $objectname numberOfFreePoolPartitions
$AdminControl invoke $objectname numberOfSharedPoolPartitions
$AdminControl invoke $objectname gatherPoolStatisticalData
$AdminControl invoke $objectname enablePoolStatisticalData
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

## Show Pool Information Support

The show pool operations can be changed at any time.

```
$AdminControl invoke $ObjectName showAllPoolContents
$AdminControl invoke $ObjectName showPoolContents
$AdminControl invoke $ObjectName showAllocationHandleList
```

## Purge Connection Support

PurgePool can be changed at any time.

```
$AdminControl invoke $ObjectName purgePoolContents normal
$AdminControl invoke $ObjectName purgePoolContents immediate
```

## Pool Control Support

Pause and resume can be changed at any time.

```
$AdminControl invoke $ObjectName pause
$AdminControl invoke $ObjectName resume
```

## Example: Connection factory and data source Mbean access using wsadmin

Wsadmin commands are used to access connection factory and data source MBeans. MBeans can retrieve or update properties for a connection factory or data source.

To get a list of J2C connection factory or data source Mbean object names, from the wsadmin command line use one of the following administrative control commands:

```
$AdminControl queryNames *:type=J2CConnectionFactory,*
$AdminControl queryNames *:type=DataSource, *
```

Example output from DataSource query:

```
wsadmin>$AdminControl queryNames *:type=DataSource,*
"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Cloudscape JDBC Provider,j2eeType=JDBCDataSource,J2EESe
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Cloudscape JDBC Provider,cell=system1Node01Cell"
```

By using the J2C connection factory or data source MBean object name, you can access the MBean. The name follows the webSphere:name= expression. In the following example, for the first set, the default data source name is set on variable name. For the second set, the object name is set on variable *objectName*.

Example using the Default Datasource

```
- wsadmin>set name [list Default Datasource]
```

Default Datasource

```
- wsadmin>set objectName [$AdminControl queryNames *:name=$name,*]
```

```
"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Cloudscape JDBC Provider,j2eeType=JDBCDataSource,J2EESe
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Cloudscape JDBC Provider,cell=system1Node01Cell"
```

Now you can use the objectName for getting help on attributes and operations available for this mbean.

```
$Help attributes $objectName
$Help operations $objectName
```

To get or set an attribute or to use an operation, use one of the following commands:

```

$AdminControl getAttribute $ObjectName "attribute name"
$AdminControl setAttribute $ObjectName "attribute name" value
$AdminControl invoke $ObjectName "operation"

```

#### Attribute, operation examples:

Get and set a attribute maxConnections (Note, if you get no value, a null value, or a java.lang.IllegalStateException, the connection factory or data source for this MBean has not been created. The connection factory or data source is created at first JNDI lookup. For this example, the Default Datasource needs to be used before get, set and invoke will work.)

```

wsadmin>$AdminControl getAttribute $ObjectName maxConnections
10

```

```

wsadmin>$AdminControl setAttribute $ObjectName maxConnections 20

```

```

wsadmin>$AdminControl getAttribute $ObjectName maxConnections
20

```

Using invoke

```

wsadmin>$AdminControl invoke $ObjectName showPoolContents

```

```

PoolManager name:DefaultDatasource
PoolManager object:746354514
Total number of connections: 3 (max/min 20/1, reap/unused/aged 180/1800/0,
connectiontimeout/purge 1800/EntirePool)
(testConnection/inteval false/0, stuck timer/time
/threshold 0/0/0, surge time/connections 0/-1)
Shared Connection information (shared partitions 200)
  No shared connections

Free Connection information (free distribution table/partitions 5/1)
  (2)(0)MCWrapper id 5c6af75b Managed connection WSRdbManagedConnectionImpl@4b5
a775b State:STATE_ACTIVE_FREE
  (2)(0)MCWrapper id 3394375a Managed connection WSRdbManagedConnectionImpl@328
5f75a State:STATE_ACTIVE_FREE
  (2)(0)MCWrapper id 4795b75a Managed connection WSRdbManagedConnectionImpl@46a
4b75a State:STATE_ACTIVE_FREE

Total number of connection in free pool: 3
UnShared Connection information
  No unshared connections

```

Here is an example Java program using the wsadmin tool to invoke showPoolContents: the Example: using wsadmin to invoke showPoolContents topic in the *Administering applications and their environment* PDF.

**Example: Invoking showPoolContents using the wsadmin tool:** The following example Java program uses the wsadmin tool to invoke showPoolContents:

```

/**
 * "This sample program is provided AS IS and may be used, executed, copied and modified without royalty payment
 * by customer (a) for its own instruction and study, (b) in order to develop applications designed to run with
 * an IBM WebSphere product, either for customer's own internal use or for redistribution by customer, as part
 * of such an application, in customer's own products. "
 *
 * Product 5724i63, (C) COPYRIGHT International Business Machines Corp., 2004
 *
 *
 * All Rights Reserved * Licensed Materials - Property of IBM
 *
 * This program will display an active mbean object name and the connection pool.
 *
 * To run this program

```

```

*
* 1. call "%WAS_HOME%/bin/setupCmdLine.bat"
*
* 2. "%JAVA_HOME%\bin\java" "%CLIENTSAS%" "-Dwas.install.root=%WAS_HOME%" "-Dwas.repository.root=%CONFIG_ROOT%"
* -Dcom.ibm.CORBA.BootstrapHost=%COMPUTERNAME% -classpath "%WAS_CLASSPATH%;%WAS_HOME%\lib\admin.jar;%WAS_HOME%
* \lib\wasjmx.jar;." ShowPoolContents DataSource_mbean_name
*/

import java.util.Properties;

        on[i] = (ObjectName) o[i];
    }

    return on;
}
}

```

## Configuring new data source custom properties using scripting

You can configure new data source custom properties using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new data source custom property:

### 1. Identify the parent ID:

- Using Jacl:

```
set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
```

- Using Jython:

```
newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
print newds
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
```

### 2. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newds propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newds, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_8)
```

### 3. Get required attribute:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |

4. Set up attributes:

- Using Jacl:

```
set name [list name RP4]  
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP4']  
rpAttrs = [name]
```

5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2CAuthentication data entries using scripting

You can configure new J2CAuthentication data entries with the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new J2CAuthentication data entry:

1. Identify the parent ID:

- Using Jacl:

```
set security [$AdminConfig getid /Cell:mycell/Security:/]
```

- Using Jython:

```
security = AdminConfig.getid('/Cell:mycell/Security:/')  
print security
```

Example output:

```
(cells/mycell|security.xml#Security_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required JAASAuthData
```

- Using Jython:

```
print AdminConfig.required('JAASAuthData')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| alias     | String |
| userId    | String |
| password  | String |

### 3. Set up required attributes:

- Using Jacl:

```
set alias [list alias myAlias]  
set userid [list userid myid]  
set password [list password secret]  
set jaasAttrs [list $alias $userid $password]
```

Example output:

```
{alias myAlias} {userid myid} {password secret}
```

- Using Jython:

```
alias = ['alias', 'myAlias']  
userid = ['userid', 'myid']  
password = ['password', 'secret']  
jaasAttrs = [alias, userid, password]  
print jaasAttrs
```

Example output:

```
[['alias', 'myAlias'], ['userid', 'myid'], ['password', 'secret']]
```

### 4. Create JAAS auth data:

- Using Jacl:

```
$AdminConfig create JAASAuthData $security $jaasAttrs
```

- Using Jython:

```
print AdminConfig.create('JAASAuthData', security, jaasAttrs)
```

Example output:

```
(cells/mycell|security.xml#JAASAuthData_2)
```

### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

### 6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WAS40 data sources using scripting

Use scripting to configure a new WAS40 data source.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps:

#### 1. Identify the parent ID:

- Using Jacl:

```
set newjdbc [$AdminConfig getid "/JDBCProvider:Cloudscape JDBC Provider/"]
```

- Using Jython:

```
newjdbc = AdminConfig.getid('/JDBCProvider:Cloudscape JDBC Provider/')  
print newjdbc
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml$JDBCProvider_1)
```

#### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WAS40DataSource
```

- Using Jython:

```
print AdminConfig.required('WAS40DataSource')
```

Example output:

```
Attribute  Type
name      String
```

### 3. Set up required attributes:

- Using Jacl:

```
set name [list name was4DS1]
set ds4Attrs [list $name]
```

- Using Jython:

```
name = ['name', 'was4DS1']
ds4Attrs = [name]
```

### 4. Create WAS40DataSource:

- Using Jacl:

```
set new40ds [$AdminConfig create WAS40DataSource $newjdbc $ds4Attrs]
```

- Using Jython:

```
new40ds = AdminConfig.create('WAS40DataSource', newjdbc, ds4Attrs)
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynode|resources.xml#WAS40DataSource_1)
```

### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

### 6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WAS40 connection pools using scripting

You can use scripting to configure a new WAS40 connection pool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WAS40 connection pool:

#### 1. Identify the parent ID:

- Using Jacl:

```
set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
```

- Using Jython:

```
new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynodes:resources.xml$WAS40DataSource_1)
```

#### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WAS40ConnectionPool
```

- Using Jython:

```
print AdminConfig.required('WAS40ConnectionPool')
```

Example output:

```
Attribute  Type
minimumPoolSize  Integer
maximumPoolSize  Integer
connectionTimeout Integer
idleTimeout      Integer
orphanTimeout    Integer
statementCacheSize Integer
```

### 3. Set up required attributes:

- Using Jacl:

```
set mps [list minimumPoolSize 5]
set minps [list minimumPoolSize 5]
set maxps [list maximumPoolSize 30]
set conn [list connectionTimeout 10]
set idle [list idleTimeout 5]
set orphan [list orphanTimeout 5]
set scs [list statementCacheSize 5]
set 40cpAttrs [list $minps $maxps $conn $idle $orphan $scs]
```

Example output:

```
{minimumPoolSize 5} {maximumPoolSize 30}
{connectionTimeout 10} {idleTimeout 5}
{orphanTimeout 5} {statementCacheSize 5}
```

- Using Jython:

```
minps = ['minimumPoolSize', 5]
maxps = ['maximumPoolSize', 30]
conn = ['connectionTimeout', 10]
idle = ['idleTimeout', 5]
orphan = ['orphanTimeout', 5]
scs = ['statementCacheSize', 5]
cpAttrs = [minps, maxps, conn, idle, orphan, scs]
print cpAttrs
```

Example output:

```
[[minimumPoolSize, 5], [maximumPoolSize, 30],
[connectionTimeout, 10], [idleTimeout, 5],
[orphanTimeout, 5], [statementCacheSize, 5]]
```

### 4. Create was40 connection pool:

- Using Jacl:

```
$AdminConfig create WAS40ConnectionPool $new40ds $40cpAttrs
```

- Using Jython:

```
print AdminConfig.create('WAS40ConnectionPool', new40ds, 40cpAttrs)
```

Example output:

```
(cells/mycell/nodes/mynode:resources.xml#WAS40ConnectionPool_1)
```

### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

### 6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WAS40 custom properties using scripting

You can use scripting and the wsadmin tool to configure a new WAS40 custom property.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WAS40 custom properties:

#### 1. Identify the parent ID:

- Using Jacl:

```
set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
```

- Using Jython:

```
new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynodes|resources.xml$WAS40DataSource_1)
```

2. Get required attributes:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newsds propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newds, 'propertySet')  
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_9)
```

3. Get required attribute:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |

4. Set up required attributes:

- Using Jacl:

```
set name [list name RP5]  
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP5']  
rpAttrs = [name]
```

5. Create J2EE Resource Property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP5(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_9)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2C resource adapters using scripting

Use scripting to configure new J2C resource adapters in WebSphere Application Server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new J2C resource adapter:

1. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:
 

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Identify the required attributes:

- Using Jacl:
 

```
$AdminConfig required J2CResourceAdapter
```
- Using Jython:
 

```
print AdminConfig.required('J2CResourceAdapter')
```

Example output:

| Attribute name | Type String |
|----------------|-------------|
|----------------|-------------|

3. Set up the required attributes:

- Using Jacl:
- Using Jython:

4. Create a resource adapter:

- Using Jacl:
 

```
set newra [$AdminConfig installResourceAdapter $rarFile mynode $option]
```
- Using Jython:
 

```
newra = AdminConfig.installResourceAdapter(rarFile, 'mynode', option)
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring custom properties for J2C resource adapters using scripting

You can configure custom properties for J2C resource adapters with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new custom property for a J2C resource adapters:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:
 

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```
- Using Jython:
 

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. Get the J2EE resource property set:

- Using Jacl:
 

```
set propSet [$AdminConfig showAttribute $newra propertySet]
```
- Using Jython:

```
propSet = AdminConfig.showAttribute(newra, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_8)
```

3. Identify the required attributes:

- Using Jacl:  
\$AdminConfig required J2EEResourceProperty
- Using Jython:  
print AdminConfig.required('J2EEResourceProperty')

Example output:

| Attribute name | Type   |
|----------------|--------|
|                | String |

4. Set up the required attributes:

- Using Jacl:  
set name [list name RP4]  
set rpAttrs [list \$name]
- Using Jython:  
name = ['name', 'RP4']  
rpAttrs = [name]

5. Create a J2EE resource property:

- Using Jacl:  
\$AdminConfig create J2EEResourceProperty \$propSet \$rpAttrs
- Using Jython:  
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)

Example output:

```
RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2C connection factories using scripting

Use scripting and the wsadmin tool to configure new J2C connection factories.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new J2C connection factory:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:  
set newra [\$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
- Using Jython:  
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')  
print newra

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C connection factory. Perform one of the following:

- Using the AdminTask object:
  - a. List the connection factory interfaces:

– Using Jacl:  
`$AdminTask listConnectionFactoryInterfaces $newra`

– Using Jacl:  
`AdminTask.listConnectionFactoryInterfaces(newra)`

Example output:

```
javax.sql.DataSource
```

b. Create a J2CConnectionFactory:

– Using Jacl:  
`$AdminTask createJ2CConnectionFactory $newra { -name cf1  
-jndiName eis/cf1 -connectionFactoryInterface  
avax.sql.DataSource`

– Using Jacl:  
`AdminTask.createJ2CConnectionFactory(newra, ['-name', 'cf1',  
'-jndiName', 'eis/cf1', '-connectionFactoryInterface',  
'avax.sql.DataSource'])`

• Using the AdminConfig object:

a. Identify the required attributes:

– Using Jacl:  
`$AdminConfig required J2CConnectionFactory`

– Using Jython:  
`print AdminConfig.required('J2CConnectionFactory')`

Example output:

```
Attribute Type  
connectionDefinition ConnectionDefinition@
```

b. If your resource adapter is JCA1.5 and you have multiple connection definitions defined, it is required that you specify the ConnectionDefinition attribute. If your resource adapter is JCA1.5 and you have only one connection definition defined, it will be picked up automatically. If your resource adapter is JCA1.0, you do not need to specify the ConnectionDefinition attribute. Perform the following command to list the connection definitions defined by the resource adapter:

– Using Jacl:  
`$AdminConfig list ConnectionDefinition $newra`

– Using Jython:  
`print AdminConfig.list('ConnectionDefinition', $newra)`

c. Set up the required attributes:

– Using Jacl:  
`set name [list name J2CCF1]  
set j2ccfAttrs [list $name]  
set jname [list jndiName eis/j2ccf1]`

– Using Jython:  
`name = ['name', 'J2CCF1']  
j2ccfAttrs = [name]  
jname = ['jndiName', eis/j2ccf1]`

d. If you are specifying the ConnectionDefinition attribute, also set up the following:

– Using Jacl:  
`set cdatr [list connectionDefinition $cd]`

– Using Jython:  
`cdattr = ['connectionDefinition', $cd]`

e. Create a J2C connection factory:

– Using Jacl:

```
$AdminConfig create J2CConnectionFactory $newra $j2ccfAttrs
- Using Jython:
  print AdminConfig.create('J2CConnectionFactory', newra, j2ccfAttrs)
```

Example output:

```
J2CCF1(cells/mycell/nodes/mynode|resources.xml#J2CConnectionFactory_1)
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2C authentication data entries using scripting

You can use scripting to configure a new J2C authentication data entry.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new J2C authentication data entry:

1. Identify the parent ID and assign it to the security variable.

- Using Jacl:
 

```
set security [$AdminConfig getid /Security:mysecurity/]
```
- Using Jython:
 

```
security = AdminConfig.getid('/Security:mysecurity/')
```

2. Identify the required attributes:

- Using Jacl:
 

```
$AdminConfig required JAASAuthData
```
- Using Jython:
 

```
print AdminConfig.required('JAASAuthData')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| alias     | String |
| userid    | String |
| password  | String |

3. Set up the required attributes:

- Using Jacl:
 

```
set alias [list alias myAlias]
set userid [list userid myid]
set password [list password secret]
set jaasAttrs [list $alias $userid $password]
```

Example output:

```
{alias myAlias} {userid myid} {password secret}
```

- Using Jython:
 

```
alias = ['alias', 'myAlias']
userid = ['userid', 'myid']
password = ['password', 'secret']
jaasAttrs = [alias, userid, password]
```

Example output:

```
[[alias, myAlias], [userid, myid], [password, secret]]
```

4. Create JAAS authentication data:

- Using Jacl:
 

```
$AdminConfig create JAASAuthData $security $jaasAttrs
```

- Using Jython:

```
print AdminConfig.create('JAASAuthData', security, jaasAttrs)
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#JAASAuthData_2)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2C activation specifications using scripting

You can configure new J2C activation specifications using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a J2C activation specifications:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:

- Using the AdminTask object:

- a. List the administrative object interfaces:

Using Jacl:

```
$AdminTask listMessageListenerTypes $newra
```

Using Jython:

```
AdminTask.listMessageListenerTypes(newra)
```

Example output:

```
javax.jms.MessageListener
```

- b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CActivationSpec $newra { -name ac1
-jndiName eis/ac1 -message ListenerType
javax.jms.MessageListener}
```

Using Jython:

```
AdminTask.createJ2CActivationSpec(newra, ['-name', 'ao1',
'-jndiName', 'eis/ao1', '-message', 'ListenerType',
'javax.jms.MessageListener'])
```

- Using the AdminConfig object:

- a. Using Jacl:

```
$AdminConfig required J2CActivationSpec
```

Using Jython:

```
print AdminConfig.required('J2CActivationSpec')
```

Example output:

Attribute Type  
activationSpec ActivationSpec@

- b. If your resource adapter is JCA V1.5 and you have multiple activation specifications defined, it is required that you specify the activation specification attribute. If your resource adapter is JCA V1.5 and you have only one activation specification defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the activationSpec attribute. Perform the following command to list the activation specifications defined by the resource adapter:

Using Jacl:

```
$AdminConfig list ActivationSpec $newra
```

Using Jython:

```
print AdminConfig.list('ActivationSpec', $newra)
```

- c. Set the administrative object that you need to a variable:

Using Jacl:

```
set ac ActivationSpecID  
set name [list name J2CAC1]  
set jname [jndiName eis/j2cac1]  
set j2cacAttrs [list $name $jname]
```

Using Jython:

```
ac = ActivationSpecID  
name = ['name', 'J2CAC1']  
jname = ['jndiName', 'eis/j2cac1']  
j2cacAttrs = [name, jname]
```

- d. If you are specifying the ActivationSpec attribute, also set up the following:

Using Jacl:

```
set cdcttr [list activationSpec $ac]
```

Using Jython:

```
cdattr = ['activationSpec', ac]
```

- e. Create a J2C activation specification object:

Using Jacl:

```
$AdminConfig create J2CActivationSpec $newra $j2cacAttrs
```

Using Jython:

```
print AdminConfig.create('J2CActivationSpec', newra, j2cacAttrs)
```

Example output:

```
J2CAC1(cells/mycell/nodes/mynode|resources.xml#J2CActivationSpec_1)
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new J2C administrative objects using scripting

You can use scripting and the wsadmin tool to configure new J2C administrative objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a J2C administrative object:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:

- Using the AdminTask object:

- a. List the administrative object interfaces:

Using Jacl:

```
$AdminTask listAdminObjectInterfaces $newra
```

Using Jython:

```
AdminTask.listAdminObjectInterfaces(newra)
```

Example output:

```
com.ibm.test.message.FVTMessageProvider
```

- b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CAdminObject $newra { -name ao1 -jndiName eis/ao1
-adminObjectInterface com.ibm.test.message.FVTMessageProvider }
```

Using Jython:

```
AdminTask.createJ2CAdminObject(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1',
'-adminObjectInterface', 'com.ibm.test.message.FVTMessageProvider'])
```

- Using the AdminConfig object:

- a. Using Jacl:

```
$AdminConfig required J2CAdminObject
```

Using Jython:

```
print AdminConfig.required('J2CAdminObject')
```

Example output:

```
Attribute Type
adminObject AdminObject@
```

- b. If your resource adapter is JCA V1.5 and you have multiple administrative objects defined, it is required that you specify the administrative object attribute. If your resource adapter is JCA V1.5 and you have only one administrative object defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the administrative object attribute. Perform the following command to list the administrative objects defined by the resource adapter:

Using Jacl:

```
$AdminConfig list AdminObject $newra
```

Using Jython:

```
print AdminConfig.list('AdminObject', $newra)
```

- c. Set the administrative objects that you need to a variable:

Using Jacl:

```
set ao AdminObjectId
set name [list name J2CA01]
set jname [jndiName eis/j2cao1]
set j2caoAttrs [list $name $jname]
```

Using Jython:

```
ao = AdminObjectId
name = ['name', 'J2CA01']
set jname = ['jndiName', 'eis/j2cao1']
j2caoAttrs = [name, jname]
```

- d. If you are specifying the AdminObject attribute, also set up the following:

Using Jacl:

```
set cdatr [list adminObject $ao]
```

Using Jython:

```
cdatr = ['adminObject', ao]
```

- e. Create a J2C administrative object:

Using Jacl:

```
$AdminConfig create J2CAdminObject $newra $j2caoAttrs
```

Using Jython:

```
print AdminConfig.create('J2CAdminObject', newra, j2caoAttrs)
```

Example output:

```
J2CA01(cells/mycell/nodes/mynode|resources.xml#J2CAdminObject_1)
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Testing data source connections using scripting

You can test connections for data sources with the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to test a data source to ensure a connection to the database.

1. Identify the DataSourceCfgHelper MBean and assign it to the ds helper variable.

- Using Jacl:

```
set ds [$AdminConfig getid /DataSource:DS1/]  
$AdminControl testConnection $ds
```

- Using Jython:

```
ds = AdminConfig.getid('/DataSource:DS1/')  
AdminControl.testConnection(ds)
```

Example output:

```
WASX7217I: Connection to provided datasource was successful.
```

2. Test the connection. The following example invokes the testConnectionToDataSource operation on the MBean, passing in the classname, userid, password, database name, JDBC driver class path, language, and country.

- Using Jacl:

- Using Jython:

Example output:

```
WASX7217I: Connection to provided data source was successful.
```

## Commands for the EventServiceDBCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the EventServiceDBCommands group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

## Commands for the JDBCProviderManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the JDBCProviderManagement group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

---

## Configuring messaging with scripting

Use these topics to learn about configuring messaging with scripting and the wsadmin tool.

This topic contains the following tasks:

### Configuring the message listener service using scripting

Use scripting to configure the message listener service.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure the message listener service for an application server:

1. Identify the application server and assign it to the server variable:

- Using Jacl:  
set server [\$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
- Using Jython:  
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')  
print server

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the message listener service belonging to the server and assign it to the mls variable:

- Using Jacl:

```
set mls [$AdminConfig list MessageListenerService $server]
```

- Using Jython:

```
mIs = AdminConfig.list('MessageListenerService', server)
print mIs
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)
```

3. Modify various attributes with one of the following examples:

- This example command changes the thread pool attributes:

- Using Jacl:

```
$AdminConfig modify $mIs {{threadPool {{inactivityTimeout 4000}
{isGrowable true} {maximumSize 100} {minimumSize 25}}}}
```

- Using Jython:

```
AdminConfig.modify(mIs, [['threadPool', [['inactivityTimeout', 4000],
['isGrowable', 'true'], ['maximumSize', 100], ['minimumSize', 25]]]])
```

- This example modifies the property of the first listener port:

- Using Jacl:

```
set lports [$AdminConfig showAttribute $mIs listenerPorts]
set lport [lindex $lports 0]
$AdminConfig modify $lport {{maxRetries 2}}
```

- Using Jython:

```
lports = AdminConfig.showAttribute(mIs, 'listenerPorts')
cleanLports = lports[1:len(lports)-1]
lport = cleanLports.split(" ")[0]
AdminConfig.modify(lport, [['maxRetries', 2]])
```

- This example adds a listener port:

- Using Jacl:

```
set new [$AdminConfig create ListenerPort $mIs {{name my}
{destinationJNDIName di} {connectionFactoryJNDIName jndi/fs}}]
$AdminConfig create StateManageable $new {{initialState START}}
```

- Using Jython:

```
new = AdminConfig.create('ListenerPort', mIs, [['name', 'my'],
['destinationJNDIName', 'di'], ['connectionFactoryJNDIName', 'jndi/fsi']])
print new
print AdminConfig.create('StateManageable', new, [['initialState', 'START']])
```

Example output:

```
my(cells/mycell/nodes/mynode/servers/server1:server.xml#ListenerPort_1079471940692)
(cells/mycell/nodes/mynode/servers/server1:server.xml#StateManageable_107947182623)
```

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new JMS providers using scripting

You can use the wsadmin tool and scripting to configure a new JMS provider.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new JMS provider:

1. Identify the parent ID:

- Using Jacl:
 

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```
- Using Jython:
 

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

## 2. Get required attributes:

- Using Jacl:
 

```
$AdminConfig required JMSPProvider
```
- Using Jython:
 

```
print AdminConfig.required('JMSPProvider')
```

Example output:

| Attribute                     | Type   |
|-------------------------------|--------|
| name                          | String |
| externalInitialContextFactory | String |
| externalProviderURL           | String |

## 3. Set up required attributes:

- Using Jacl:
 

```
set name [list name JMSP1]
set extICF [list externalInitialContextFactory
"Put the external initial context factory here"]
set extPURL [list externalProviderURL "Put the external provider URL here"]
set jmsAttrs [list $name $extICF $extPURL]
```
- Using Jython:
 

```
name = ['name', 'JMSP1']
extICF = ['externalInitialContextFactory',
"Put the external initial context factory here"]
extPURL = ['externalProviderURL', "Put the external provider URL here"]
jmsAttrs = [name, extICF, extPURL]
print jmsAttrs
```

Example output:

```
{name JMSP1} {externalInitialContextFactory {Put the external
initial context factory here }} {externalProviderURL
{Put the external provider URL here}}
```

## 4. Create the JMS provider:

- Using Jacl:
 

```
set newjmsp [$AdminConfig create JMSPProvider $node $jmsAttrs]
```
- Using Jython:
 

```
newjmsp = AdminConfig.create('JMSPProvider', node, jmsAttrs)
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSPProvider_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new JMS destinations using scripting

You can use scripting and the wsadmin tool to configure a new JMS destination.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new JMS destination:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required GenericJMSDestination
```

- Using Jython:

```
print AdminConfig.required('GenericJMSDestination')
```

Example output:

| Attribute        | Type   |
|------------------|--------|
| name             | String |
| jndiName         | String |
| externalJNDIName | String |

3. Set up required attributes:

- Using Jacl:

```
set name [list name JMSP1]
set jndi [list jndiName jms/JMSDestination1]
set extJndi [list externalJNDIName jms/extJMSP1]
set jmsdAttrs [list $name $jndi $extJndi]
```

- Using Jython:

```
name = ['name', 'JMSP1']
jndi = ['jndiName', 'jms/JMSDestination1']
extJndi = ['externalJNDIName', 'jms/extJMSP1']
jmsdAttrs = [name, jndi, extJndi]
print jmsdAttrs
```

Example output:

```
{name JMSP1} {jndiName jms/JMSDestination1} {externalJNDIName jms/extJMSP1}
```

4. Create generic JMS destination:

- Using Jacl:

```
$AdminConfig create GenericJMSDestination $newjmsp $jmsdAttrs
```

- Using Jython:

```
print AdminConfig.create('GenericJMSDestination', newjmsp, jmsdAttrs)
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#GenericJMSDestination_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new JMS connections using scripting

Use scripting and the wsadmin tool to configure a new JMS connection.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new JMS connection:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required GenericJMSConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('GenericJMSConnectionFactory')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
externalJNDIName String
```

3. Set up required attributes:

- Using Jacl:

```
set name [list name JMSCF1]
set jndi [list jndiName jms/JMSConnFact1]
set extJndi [list externalJNDIName jms/extJMSCF1]
set jmscfAttrs [list $name $jndi $extJndi]
```

Example output:

```
{name JMSCF1} {jndiName jms/JMSConnFact1} {externalJNDIName jms/extJMSCF1}
```

- Using Jython:

```
name = ['name', 'JMSCF1']
jndi = ['jndiName', 'jms/JMSConnFact1']
extJndi = ['externalJNDIName', 'jms/extJMSCF1']
jmscfAttrs = [name, jndi, extJndi]
print jmscfAttrs
```

Example output:

```
[[name, JMSCF1], [jndiName, jms/JMSConnFact1], [externalJNDIName, jms/extJMSCF1]]
```

4. Create generic JMS connection factory:

- Using Jacl:

```
$AdminConfig create GenericJMSConnectionFactory $newjmsp $jmscfAttrs
```

- Using Jython:

```
print AdminConfig.create('GenericJMSConnectionFactory', newjmsp, jmscfAttrs)
```

Example output:

```
JMSCF1(cells/mycell/nodes/mynode|resources.xml#GenericJMSConnectionFactory_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WebSphere queue connection factories using scripting

You can use scripting and the wsadmin tool to configure new queue connection factories in WebSphere Application Server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WebSphere queue connection factory:

### 1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASQueueConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('WASQueueConnectionFactory')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| jndiName  | String |

### 3. Set up required attributes:

- Using Jacl:

```
set name [list name WASQCF]
set jndi [list jndiName jms/WASQCF]
set mqcfAttrs [list $name $jndi]
```

Example output:

```
{name WASQCF} {jndiName jms/WASQCF}
```

- Using Jython:

```
name = ['name', 'WASQCF']
jndi = ['jndiName', 'jms/WASQCF']
mqcfAttrs = [name, jndi]
print mqcfAttrs
```

Example output:

```
[[name, WASQCF], [jndiName, jms/WASQCF]]
```

### 4. Create was queue connection factories:

- Using Jacl:

```
$AdminConfig create WASQueueConnectionFactory $newjmsp $mqcfAttrs
```

- Using Jython:

```
print AdminConfig.create('WASQueueConnectionFactory', newjmsp, mqcfAttrs)
```

Example output:

```
WASQCF(cells/mycell/nodes/mynode|resources.xml#WASQueueConnectionFactory_1)
```

### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WebSphere topic connection factories using scripting

Use scripting and the wsadmin tool to configure new WebSphere topic connection factories.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WebSphere topic connection factory:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASTopicConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('WASTopicConnectionFactory')
```

Example output:

| Attribute | Type                 |
|-----------|----------------------|
| name      | String               |
| jndiName  | String               |
| port      | ENUM(DIRECT, QUEUED) |

3. Set up required attributes:

- Using Jacl:

```
set name [list name WASTCF]
set jndi [list jndiName jms/WASTCF]
set port [list port QUEUED]
set mtcfAttrs [list $name $jndi $port]
```

Example output:

```
{name WASTCF} {jndiName jms/WASTCF} {port QUEUED}
```

- Using Jython:

```
name = ['name', 'WASTCF']
jndi = ['jndiName', 'jms/WASTCF']
port = ['port', 'QUEUED']
mtcfAttrs = [name, jndi, port]
print mtcfAttrs
```

Example output:

```
[[name, WASTCF], [jndiName, jms/WASTCF], [port, QUEUED]]
```

4. Create was topic connection factories:

- Using Jacl:

```
$AdminConfig create WASTopicConnectionFactory $newjmsp $mtcfAttrs
```

- Using Jython:

```
print AdminConfig.create('WASTopicConnectionFactory', newjmsp, mtcfAttrs)
```

Example output:

```
WASTCF(cells/mycell/nodes/mynode|resources.xml#WASTopicConnectionFactory_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WebSphere queues using scripting

You can use scripting to configure a new WebSphere queue.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WebSphere queue:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASQueue
```

- Using Jython:

```
print AdminConfig.required('WASQueue')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| jndiName  | String |

3. Set up required attributes:

- Using Jacl:

```
set name [list name WASQ1]
set jndi [list jndiName jms/WASQ1]
set wqAttrs [list $name $jndi]
```

Example output:

```
{name WASQ1} {jndiName jms/WASQ1}
```

- Using Jython:

```
name = ['name', 'WASQ1']
jndi = ['jndiName', 'jms/WASQ1']
wqAttrs = [name, jndi]
print wqAttrs
```

Example output:

```
[[name, WASQ1], [jndiName, jms/WASQ1]]
```

4. Create was queue:

- Using Jacl:

```
$AdminConfig create WASQueue $newjmsp $wqAttrs
```

- Using Jython:

```
print AdminConfig.create('WASQueue', newjmsp, wqAttrs)
```

Example output:

```
WASQ1(cells/mycell/nodes/mynode|resources.xml#WASQueue_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new WebSphere topics using scripting

You can configure new WebSphere topics using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new WebSphere topic:

### 1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1/')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASTopic
```

- Using Jython:

```
print AdminConfig.required('WASTopic')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| jndiName  | String |
| topic     | String |

### 3. Set up required attributes:

- Using Jacl:

```
set name [list name WAST1]
set jndi [list jndiName jms/WAST1]
set topic [list topic "Put your topic here"]
set wtAttrs [list $name $jndi $topic]
```

Example output:

```
{name WAST1} {jndiName jms/WAST1} {topic {Put your topic here}}
```

- Using Jython:

```
name = ['name', 'WAST1']
jndi = ['jndiName', 'jms/WAST1']
topic = ['topic', "Put your topic here"]
wtAttrs = [name, jndi, topic]
print wtAttrs
```

Example output:

```
[[name, WAST1], [jndiName, jms/WAST1], [topic, "Put your topic here"]]
```

### 4. Create was topic:

- Using Jacl:

```
$AdminConfig create WASTopic $newjmsp $wtAttrs
```

- Using Jython:

```
print AdminConfig.create('WASTopic', newjmsp, wtAttrs)
```

Example output:

```
WAST1(cells/mycell/nodes/mynode|resources.xml#WASTopic_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new MQ connection factories using scripting

You can use scripting to configure a new MQ connection factory.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new MQ connection factory:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:WebSphere MQ JMS Provider/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:WebSphere MQ JMS Provider')
print newjmsp
```

Example output:

```
WebSphere MQ JMS Provider(cells/mycell/nodes/mynode|resources.xml#builtin_mqprovider)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required MQConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('MQConnectionFactory')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
connectionPool ConnectionPool
```

3. Set up required attributes:

- Using Jacl:

```
set name [list name MQCF]
set jndi [list jndiName jms/MQCF]
set mqcfAttrs [list $name $jndi]
```

Example output:

```
{name MQCF} {jndiName jms/MQCF}
```

- Using Jython:

```
name = ['name', 'MQCF']
jndi = ['jndiName', 'jms/MQCF']
mqcfAttrs = [name, jndi]
print mqcfAttrs
```

Example output:

```
[[name, MQCF], [jndiName, jms/MQCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [index [$AdminConfig listTemplates MQConnectionFactory] 0]
```

- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQConnectionFactory').split(lineseparator)[0]
print template
```

Example output:

```
Example non-XA WMQ ConnectionFactory(templates/
system:JMS-resource-provider-templates.xml
#MQConnectionFactory_3)
```

#### 5. Create MQ connection factory:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQConnectionFactory
$newjmsp $mqcfAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQConnectionFactory',
newjmsp, mqcfAttrs, template)
```

Example output:

```
MQCF(cells/mycell/nodes/mynode:resources.xml#MQConnectionFactory_1)
```

#### 6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

#### 7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new MQ queue connection factories using scripting

You can use scripting to configure a new MQ queue connection factory.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new MQ queue connection factory:

#### 1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

#### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required MQQueueConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('MQQueueConnectionFactory')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| jndiName  | String |

#### 3. Set up required attributes:

- Using Jacl:

```
set name [list name MQQCF]
set jndi [list jndiName jms/MQQCF]
set mqcfAttrs [list $name $jndi]
```

Example output:

```
{name MQQCF} {jndiName jms/MQQCF}
```

- Using Jython:

```
name = ['name', 'MQQCF']
jndi = ['jndiName', 'jms/MQQCF']
mqqcAttrs = [name, jndi]
print mqqcAttrs
```

Example output:

```
[[name, MQQCF], [jndiName, jms/MQQCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQQueueConnectionFactory] 0]
```

- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQQueueConnectionFactory').split(lineseparator)[0]
print template
```

Example output:

```
Example non-XA WMQ QueueConnectionFactory(templates/
system:JMS-resource-provider-templates.xml
#MQQueueConnectionFactory_3)
```

5. Create MQ queue connection factory:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQQueueConnectionFactory
$newjmsp $mqqcAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQQueueConnectionFactory',
newjmsp, mqqcAttrs, template)
```

Example output:

```
MQQCF(cells/mycell/nodes/mynode:resources.xml#MQQueueConnectionFactory_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new MQ topic connection factories using scripting

Use scripting and the wsadmin tool to configure a new MQ topic connection factory.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new MQ topic connection factory:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode:resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:
 

```
$AdminConfig required MQTopicConnectionFactory
```

- Using Jython:
 

```
print AdminConfig.required('MQTopicConnectionFactory')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
```

### 3. Set up required attributes:

- Using Jacl:
 

```
set name [list name MQTCF]
set jndi [list jndiName jms/MQTCF]
set mqtcfAttrs [list $name $jndi]
```

Example output:

```
{name MQTCF} {jndiName jms/MQTCF}
```

- Using Jython:
 

```
name = ['name', 'MQTCF']
jndi = ['jndiName', 'jms/MQTCF']
mqtcfAttrs = [name, jndi]
print mqtcfAttrs
```

Example output:

```
[[name, MQTCF], [jndiName, jms/MQTCF]]
```

### 4. Set up a template:

- Using Jacl:
 

```
set template [lindex [$AdminConfig listTemplates MQTopicConnectionFactory] 0]
```

- Using Jython:
 

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQTopicConnectionFactory').split(lineseparator)[0]
print template
```

Example output:

```
Example non-XA WMQ TopicConnectionFactory(templates/system:
JMS-resource-provider-templates.xml
#MQTopicConnectionFactory_5)
```

### 5. Create mq topic connection factory:

- Using Jacl:
 

```
$AdminConfig create MQTopicConnectionFactory $newjmsp $mqtcfAttrs $template
```
- Using Jython:
 

```
print AdminConfig.create('MQTopicConnectionFactory', newjmsp, mqtcfAttrs, template)
```

Example output:

```
MQTCF(cells/mycell/nodes/mynode:resources.xml#MQTopicConnectionFactory_1)
```

### 6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

### 7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new MQ queues using scripting

You can use scripting and the wsadmin tool to configure a new MQ queue.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new MQ queue:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required MQQueue
```

- Using Jython:

```
print AdminConfig.required('MQQueue')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
baseQueueName String
```

3. Set up required attributes:

- Using Jacl:

```
set name [list name MQQ]
set jndi [list jndiName jms/MQQ]
set baseQN [list baseQueueName "Put the base queue name here"]
set mqqAttrs [list $name $jndi $baseQN]
```

Example output:

```
{name MQQ} {jndiName jms/MQQ} {baseQueueName {Put the base queue name here}}
```

- Using Jython:

```
name = ['name', 'MQQ']
jndi = ['jndiName', 'jms/MQQ']
baseQN = ['baseQueueName', "Put the base queue name here"]
mqqAttrs = [name, jndi, baseQN]
print mqqAttrs
```

Example output:

```
[[name, MQQ], [jndiName, jms/MQQ], [baseQueueName, "Put the base queue name here"]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQQueue] 0]
```

- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQQueue').split(lineseparator)[0]
print template
```

Example output:

```
Example.JMS.WMQ.Q1(templates/system:JMS-resource-provider-
templates.xml#MQQueue_1)
```

5. Create MQ queue factory:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQQueue $newjmsp $mqqAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQQueue', newjmsp, mqqAttrs, template)
```

Example output:

```
MQQ(cells/mycell/nodes/mynode|resources.xml#MQQueue_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new MQ topics using scripting

You can use scripting to configure a new MQ topic.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new MQ topic:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required MQTopic
```

- Using Jython:

```
print AdminConfig.required('MQTopic')
```

Example output:

| Attribute     | Type   |
|---------------|--------|
| name          | String |
| jndiName      | String |
| baseTopicName | String |

3. Set up required attributes:

- Using Jacl:

```
set name [list name MQT]
set jndi [list jndiName jms/MQT]
set baseTN [list baseTopicName "Put the base topic name here"]
set mqtAttrs [list $name $jndi $baseTN]
```

Example output:

```
{name MQT} {jndiName jms/MQT} {baseTopicName {Put the base topic name here}}
```

- Using Jython:

```
name = ['name', 'MQT']
jndi = ['jndiName', 'jms/MQT']
baseTN = ['baseTopicName', "Put the base topic name here"]
mqtAttrs = [name, jndi, baseTN]
print mqtAttrs
```

Example output:

```
[[name, MQT], [jndiName, jms/MQT], [baseTopicName, "Put the base topic name here"]]
```

4. Create MQ topic factory:

- Using Jacl:

```
$AdminConfig create MQTopic $newjmsp $mqtAttrs
```

- Using Jython:

```
print AdminConfig.create('MQTopic', newjmsp, mqtAttrs)
```

Example output:

```
MQT(cells/mycell/nodes/mynode|resources.xml#MQTopic_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Commands for the JCA management group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the JCA management group of the AdminTask object:

| Command name:       | Description:                                                                                                                     | Target object:                 | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Configuring mail, URLs, and resource environment entries with scripting

Use scripting to configure mail, URLs, and resource environment entries.

This topic contains the following tasks:

- “Configuring new mail providers using scripting”
- “Configuring new mail sessions using scripting” on page 643
- “Configuring new protocols using scripting” on page 644
- “Configuring new custom properties using scripting” on page 645
- “Configuring new resource environment providers using scripting” on page 646
- “Configuring custom properties for resource environment providers using scripting” on page 647
- “Configuring new referenceables using scripting” on page 648
- “Configuring new resource environment entries using scripting” on page 649
- “Configuring custom properties for resource environment entries using scripting” on page 650
- “Configuring new URL providers using scripting” on page 651
- “Configuring custom properties for URL providers using scripting” on page 652
- “Configuring new URLs using scripting” on page 653
- “Configuring custom properties for URLs using scripting” on page 654

### Configuring new mail providers using scripting

You can use scripting and the wsadmin tool to configure new mail providers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new mail provider:

1. Identify the parent ID:

- Using Jacl:  

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```
- Using Jython:  

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')  
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Get required attributes:

- Using Jacl:  

```
$AdminConfig required MailProvider
```
- Using Jython:  

```
print AdminConfig.required('MailProvider')
```

Example output:

```
Attribute      Type  
name          String
```

3. Set up required attributes:

- Using Jacl:  

```
set name [list name MP1]  
set mpAttrs [list $name]
```
- Using Jython:

```
name = ['name', 'MP1']
mpAttrs = [name]
```

4. Create the mail provider:

- Using Jacl:

```
set newmp [$AdminConfig create MailProvider $node $mpAttrs]
```

- Using Jython:

```
newmp = AdminConfig.create('MailProvider', node, mpAttrs)
print newmp
```

Example output:

```
MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new mail sessions using scripting

You can use scripting and the wsadmin tool to configure new mail sessions.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new mail session:

1. Identify the parent ID:

- Using Jacl:

```
set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
```

- Using Jython:

```
newmp = AdminConfig.create('MailProvider', node, mpAttrs)
print newmp
```

Example output:

```
MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required MailSession
```

- Using Jython:

```
print AdminConfig.required('MailSession')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| jndiName  | String |

3. Set up required attributes:

- Using Jacl:

```
set name [list name MS1]
set jndi [list jndiName mail/MS1]
set msAttrs [list $name $jndi]
```

Example output:

```
{name MS1} {jndiName mail/MS1}
```

- Using Jython:

```
name = ['name', 'MS1']
jndi = ['jndiName', 'mail/MS1']
msAttrs = [name, jndi]
print msAttrs
```

Example output:

```
[[name, MS1], [jndiName, mail/MS1]]
```

4. Create the mail session:

- Using Jacl:

```
$AdminConfig create MailSession $newmp $msAttrs
```

- Using Jython:

```
print AdminConfig.create('MailSession', newmp, msAttrs)
```

Example output:

```
MS1(cells/mycell/nodes/mynode|resources.xml#MailSession_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new protocols using scripting

You can configure new protocols with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new protocol:

1. Identify the parent ID:

- Using Jacl:

```
set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
```

- Using Jython:

```
newmp = AdminConfig.create('MailProvider', node, mpAttrs)
print newmp
```

Example output:

```
MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required ProtocolProvider
```

- Using Jython:

```
print AdminConfig.required('ProtocolProvider')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| protocol  | String |
| classname | String |

3. Set up required attributes:

- Using Jacl:

```
set protocol [list protocol "Put the protocol here"]
set classname [list classname "Put the class name here"]
set ppAttrs [list $protocol $classname]
```

Example output:

```
{protocol protocol1} {classname classname1}
```

- Using Jython:

```
protocol = ['protocol', "Put the protocol here"]
classname = ['classname', "Put the class name here"]
ppAttrs = [protocol, classname]
print ppAttrs
```

Example output:

```
[[protocol, protocol1], [classname, classname]]
```

4. Create the protocol provider:

- Using Jacl:

```
$AdminConfig create ProtocolProvider $newmp $ppAttrs
```

- Using Jython:

```
print AdminConfig.create('ProtocolProvider', newmp, ppAttrs)
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#ProtocolProvider_4)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new custom properties using scripting

You can use scripting and the wsadmin tool to configure new custom properties.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new custom property:

1. Identify the parent ID:

- Using Jacl:

```
set newmp [$AdminConfig getid /Cell:mycell/Node:mynode/MailProvider:MP1/]
```

- Using Jython:

```
newmp = AdminConfig.create('MailProvider', node, mpAttrs)
print newmp
```

Example output:

```
MP1(cells/mycell/nodes/mynode|resources.xml#MailProvider_1)
```

2. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newmp propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newmp, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_2)
```

3. Get required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |

4. Set up the required attributes:

- Using Jacl:

```
set name [list name CP1]
set cpAttrs [list $name]
```

Example output:

```
{name CP1}
```

- Using Jython:

```
name = ['name', 'CP1']
cpAttrs = [name]
print cpAttrs
```

Example output:

```
[[name, CP1]]
```

5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $cpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, cpAttrs)
```

Example output:

```
CP1(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_2)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new resource environment providers using scripting

You can use the wsadmin tool and scripting to configure new resources environment providers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new resource environment provider:

1. Identify the parent ID and assign it to the node variable.

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required ResourceEnvironmentProvider
```

- Using Jython:

```
print AdminConfig.required('ResourceEnvironmentProvider')
```

Example output:

```
Attribute      Type
name          String
```

3. Set up the required attributes and assign it to the repAttrs variable:

- Using Jacl:

```
set n1 [list name REP1]
set repAttrs [list $name]
```

- Using Jython:

```
n1 = ['name', 'REP1']
repAttrs = [n1]
```

4. Create a new resource environment provider:

- Using Jacl:

```
set newrep [$AdminConfig create ResourceEnvironmentProvider $node $repAttrs]
```

- Using Jython:

```
newrep = AdminConfig.create('ResourceEnvironmentProvider', node, repAttrs)
print newrep
```

Example output:

```
REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring custom properties for resource environment providers using scripting

You can use scripting to configure custom properties for a resource environment provider.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new custom property for a resource environment provider:

1. Identify the parent ID and assign it to the newrep variable.

- Using Jacl:

```
set newrep [$AdminConfig getid /Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/]
```

- Using Jython:

```
newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/')
print newrep
```

Example output:

```
REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
```

2. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

```
Attribute      Type
name           String
```

3. Set up the required attributes and assign it to the repAttrs variable:

- Using Jacl:

```
set name [list name RP]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP']
rpAttrs = [name]
```

4. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newrep propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newrep, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_1)
```

#### 5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
```

#### 6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

#### 7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new referenceables using scripting

You can use scripting and the wsadmin tool to configure new referenceables.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new referenceable:

#### 1. Identify the parent ID and assign it to the newrep variable.

- Using Jacl:

```
set newrep [$AdminConfig getid /Cell:mycell/Node:mynode/
ResourceEnvironmentProvider:REP1/]
```

- Using Jython:

```
newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/
ResourceEnvironmentProvider:REP1/')
print newrep
```

Example output:

```
REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
```

#### 2. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required Referenceable
```

- Using Jython:

```
print AdminConfig.required('Referenceable')
```

Example output:

```
Attribute      Type
factoryClassname String
classname      String
```

#### 3. Set up the required attributes:

- Using Jacl:

```
set fcn [list factoryClassname REP1]
set cn [list classname NM1]
set refAttrs [list $fcn $cn]
```

- Using Jython:

```

fcn = ['factoryClassname', 'REP1']
cn = ['classname', 'NM1']
refAttrs = [fcn, cn]
print refAttrs

```

Example output:

```
{factoryClassname {REP1}} {classname {NM1}}
```

#### 4. Create a new referenceable:

- Using Jacl:

```
set newref [$AdminConfig create Referenceable $newrep $refAttrs]
```

- Using Jython:

```
newref = AdminConfig.create('Referenceable', newrep, refAttrs)
print newref
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#Referenceable_1)
```

#### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

#### 6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new resource environment entries using scripting

You can use scripting and the wsadmin tool to configure a new resource environment entry.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new resource environment entry:

#### 1. Identify the parent ID and assign it to the newrep variable.

- Using Jacl:

```
set newrep [$AdminConfig getid /Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/]
```

- Using Jython:

```
newrep = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvironmentProvider:REP1/')
print newrep
```

Example output:

```
REP1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvironmentProvider_1)
```

#### 2. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required ResourceEnvEntry
```

- Using Jython:

```
print AdminConfig.required('ResourceEnvEntry')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
referenceable  Referenceable@
```

#### 3. Set up the required attributes:

- Using Jacl:

```
set name [list name REE1]
set jndiName [list jndiName myjndi]
set newref [$AdminConfig getid /Cell:mycell/Node:mynode/Referenceable:/]
set ref [list referenceable $newref]
set reeAttrs [list $name $jndiName $ref]
```

- Using Jython:

```
name = ['name', 'REE1']
jndiName = ['jndiName', 'myjndi']
newref = AdminConfig.getid('/Cell:mycell/Node:mynode/Referenceable:/')
ref = ['referenceable', newref]
reeAttrs = [name, jndiName, ref]
```

#### 4. Create the resource environment entry:

- Using Jacl:

```
$AdminConfig create ResourceEnvEntry $newrep $reeAttrs
```

- Using Jython:

```
print AdminConfig.create('ResourceEnvEntry', newrep, reeAttrs)
```

Example output:

```
REE1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvEntry_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring custom properties for resource environment entries using scripting

You can use scripting to configure a new custom property for a resource environment entry.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new custom property for a resource environment entry:

#### 1. Identify the parent ID and assign it to the newree variable.

- Using Jacl:

```
set newree [$AdminConfig getid /Cell:mycell/Node:mynode/ResourceEnvEntry:REE1/]
```

- Using Jython:

```
newree = AdminConfig.getid('/Cell:mycell/Node:mynode/ResourceEnvEntry:REE1/')
print newree
```

Example output:

```
REE1(cells/mycell/nodes/mynode|resources.xml#ResourceEnvEntry_1)
```

#### 2. Create the J2EE custom property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newree propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newree, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_5)
```

#### 3. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

```
Attribute      Type
name           String
```

4. Set up the required attributes:

- Using Jacl:

```
set name [list name RP1]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP1']
rpAttrs = [name]
```

5. Create the J2EE custom property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RPI(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new URL providers using scripting

You can use scripting and the wsadmin tool to configure new URL providers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new URL provider:

1. Identify the parent ID and assign it to the node variable.

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required URLProvider
```

- Using Jython:

```
print AdminConfig.required('URLProvider')
```

Example output:

| Attribute              | Type   |
|------------------------|--------|
| streamHandlerClassName | String |
| protocol               | String |
| name                   | String |

3. Set up the required attributes:

- Using Jacl:

```
set name [list name URLP1]
set shcn [list streamHandlerClassName "Put the stream handler classname here"]
set protocol [list protocol "Put the protocol here"]
set urlpAttrs [list $name $shcn $protocol]
```

Example output:

```
{name URLP1} {streamHandlerClassName {Put the stream handler classname here}}
{protocol {Put the protocol here}}
```

- Using Jython:

```
name = ['name', 'URLP1']
shcn = ['streamHandlerClassName', "Put the stream handler classname here"]
protocol = ['protocol', "Put the protocol here"]
urlpAttrs = [name, shcn, protocol]
print urlpAttrs
```

Example output:

```
[[name, URLP1], [streamHandlerClassName, "Put the stream handler classname here"],
[protocol, "Put the protocol here"]]
```

4. Create a URL provider:

- Using Jacl:

```
$AdminConfig create URLProvider $node $urlpAttrs
```

- Using Jython:

```
print AdminConfig.create('URLProvider', node, urlpAttrs)
```

Example output:

```
URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring custom properties for URL providers using scripting

You can use scripting to configure custom properties for URL providers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure custom properties for URL providers:

1. Identify the parent ID and assign it to the newurlp variable.

- Using Jacl:

```
set newurlp [$AdminConfig getid /Cell:mycell/Node:mynode/URLProvider:URLP1/]
```

- Using Jython:

```
newurlp = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/')
print newurlp
```

Example output:

```
URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
```

2. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newurlp propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newurlp, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_7)
```

3. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:
 

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |

4. Set up the required attributes:

- Using Jacl:
 

```
set name [list name RP2]
set rpAttrs [list $name]
```
- Using Jython:
 

```
name = ['name', 'RP2']
rpAttrs = [name]
```

5. Create a J2EE resource property:

- Using Jacl:
 

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```
- Using Jython:
 

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP2(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring new URLs using scripting

You can use scripting and the wsadmin tool to configure new URLs.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following example to configure a new URL:

1. Identify the parent ID and assign it to the newurlp variable.

- Using Jacl:
 

```
set newurlp [$AdminConfig getid /Cell:mycell/Node:mynode/URLProvider:URLP1/]
```
- Using Jython:
 

```
newurlp = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/')
print newurlp
```

Example output:

```
URLP1(cells/mycell/nodes/mynode|resources.xml#URLProvider_1)
```

2. Identify the required attributes:

- Using Jacl:
 

```
$AdminConfig required URL
```
- Using Jython:
 

```
print AdminConfig.required('URL')
```

Example output:

| Attribute | Type   |
|-----------|--------|
| name      | String |
| spec      | String |

3. Set up the required attributes:

- Using Jacl:

```
set name [list name URL1]
set spec [list spec "Put the spec here"]
set urlAttrs [list $name $spec]
```

Example output:

```
{name URL1} {spec {Put the spec here}}
```

- Using Jython:

```
name = ['name', 'URL1']
spec = ['spec', "Put the spec here"]
urlAttrs = [name, spec]
```

Example output:

```
[[name, URL1], [spec, "Put the spec here"]]
```

#### 4. Create a URL:

- Using Jacl:

```
$AdminConfig create URL $newurlp $urlAttrs
```

- Using Jython:

```
print AdminConfig.create('URL', newurlp, urlAttrs)
```

Example output:

```
URL1(cells/mycell/nodes/mynode|resources.xml#URL_1)
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring custom properties for URLs using scripting

Use the wsadmin tool and scripting to set custom properties for URLs.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a new custom property for a URL:

1. Identify the parent ID and assign it to the newurl variable.

- Using Jacl:

```
set newurl [$AdminConfig getid /Cell:mycell/Node:mynode/URLProvider:URLP1/URL:URL1/]
```

- Using Jython:

```
newurl = AdminConfig.getid('/Cell:mycell/Node:mynode/URLProvider:URLP1/URL:URL1/')
print newurl
```

Example output:

```
URL1(cells/mycell/nodes/mynode|resources.xml#URL_1)
```

2. Create a J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newurl propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newurl, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_7)
```

3. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

```
Attribute      Type
name           String
```

4. Set up the required attributes:

- Using Jacl:

```
set name [list name RP3]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP3']
rpAttrs = [name]
```

5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP3(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_7)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Commands for the provider group of the AdminTask object

Use the commands in the provider group to create or delete a provider. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the provider group of the AdminTask object:

Table 23.

| Command name:  | Description:                                                                              | Target object: | Parameters and return values:                                                                                                         | Examples:                                                                                                                                                                                                                                                                                                      |
|----------------|-------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createProvider | The <b>createProvider</b> command creates a provider in the model given the ProviderInfo. | None           | <ul style="list-style-type: none"><li>• Parameters: None</li><li>• Returns: true if the provider was created, false if not.</li></ul> | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"><li>• Using Jacl:<br/>\$AdminTask createProvider {-interactive}</li><li>• Using Jython string:<br/>AdminTask.createProvider ('[-interactive]')</li><li>• Using Jython list:<br/>AdminTask.createProvider (['-interactive'])</li></ul> |

Table 23. (continued)

| Command name:       | Description:                                                                                                  | Target object: | Parameters and return values:                                                                                                                           | Examples:                                                                                                                                                                                                                                                                                                                                              |
|---------------------|---------------------------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deleteProvider      | The <b>deleteProvider</b> command deletes a provider from the model given the providerName.                   | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: true if the provider was deleted, false if not.</li> </ul>                    | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask deleteProvider {-interactive}</pre> </li> <li>Using Jython string: <pre>AdminTask.deleteProvider ('[-interactive]')</pre> </li> <li>Using Jython list: <pre>AdminTask.deleteProvider (['-interactive'])</pre> </li> </ul>                   |
| getProviderInfo     | The <b>getProviderInfo</b> command returns a ProviderInfo object defined in the model given the providerName. | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A ProviderInfo object defined in the model given the providerName.</li> </ul> | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask getProviderInfo {-interactive}</pre> </li> <li>Using Jython string: <pre>AdminTask.getProviderInfo ('[-interactive]')</pre> </li> <li>Using Jython list: <pre>AdminTask.getProviderInfo (['-interactive'])</pre> </li> </ul>                |
| getProviderInstance | The <b>getProviderInstance</b> command returns a java.security.Provider for the providerName specified.       | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A java.security.Provider for the providerName specified.</li> </ul>           | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask getProviderInsta nce {-interactive}</pre> </li> <li>Using Jython string: <pre>AdminTask.getProviderInsta nce ('[-interactive]')</pre> </li> <li>Using Jython list: <pre>AdminTask.getProviderInsta nce (['-interactive'])</pre> </li> </ul> |

Table 23. (continued)

| Command name: | Description:                                                                           | Target object: | Parameters and return values:                                                                                                       | Examples:                                                                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| getProviders  | The <b>getProviders</b> command returns a List of ProviderInfo objects from the model. | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A list of ProviderInfo objects from the model.</li> </ul> | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"> <li>Using Jacl:           <pre>\$AdminTask getProviders {-interactive}</pre> </li> <li>Using Jython string:           <pre>AdminTask.getProviders ('[-interactive]')</pre> </li> <li>Using Jython list:           <pre>AdminTask.getProviders (['-interactive'])</pre> </li> </ul> |

## Using the thin administrative client with the wsadmin tool

With the thin administrative client, you can run the wsadmin tool or a standalone administrative Java program with only a couple of JAR files. This leads to a reduction in the amount of time that it takes for the wsadmin tool to start and improved performance.

For tracing and logging information for the thin administrative client, see the Enabling trace on client and standalone applications article in the *Troubleshooting and support* PDF.

1. Make the thin administrative client JAR files available by copying them from a WebSphere Application Server environment to an environment outside of WebSphere Application Server. The thin administrative client JAR files are located in one of the following locations:
  - The *AppServer/runtimes* directory.
  - The *AppClient/runtimes* directory, if you optionally selected the thin administrative client when you installed the application client.

You must have a special license agreement to download these JAR files.

2. Use the thin client JAR files to compile and test administration client programs. For Java applications, you can compile and run the JAR files within a standard Java 2 Platform, Standard Edition environment or pull them in as bundles for an OSGi environment. For more information see the “Compiling an application in an OSGi environment using scripting” and the “Compiling an application in a non-OSGi environment using scripting” on page 660 articles.
3. Launch the thin wsadmin client or run the wsadmin tool remotely in a Java 2 Platform, Standard Edition environment.
4. Deploy the stand alone JAR files and the administrative client applications and start the applications outside of a WebSphere Application Server environment.

## Compiling an application in an OSGi environment using scripting

To compile an application in an OSGi environment, the application must be contained in an OSGi bundle. Perform the following steps:

1. Create a `plugins` directory that includes the JAR files that you will need. Include the following JAR files in the CLASSPATH:

```

com.ibm.ws.admin.client_6.1.0.jar
org.eclipse.core.runtime_3.1.0.jar
org.eclipse.jdt.core_3.1.0.jar
org.eclipse.osgi_3.1.0.jar
org.eclipse.update.configurator_3.1.0.jar

```

By convention, all of the OSGi bundles are placed in the plugins directory.

2. Create an application class that implements the IPlatformRunnable interface. For example:

```

package ...

import org.eclipse.core.runtime.IPlatformRunnable;

public class ThinClientTest implements IPlatformRunnable
{

    public ThinClientTest () {

        System.out.println("ThinClientTest has been constructed");

    }

    public Object run(Object o) throws Exception
    {
        new ThinClientTest().executeUtility();
        return null;
    }

    private void executeUtility() throws Exception
    {

        . . .

    }
}

```

3. Create a bundle activator for the bundle. For example:

```

package com.ibm.ws;

import java.util.Set;
import java.util.List;

import org.osgi.framework.BundleActivator;
import org.osgi.framework.BundleContext;
import org.osgi.framework.ServiceListener;
import org.osgi.framework.ServiceEvent;

/**
 * This class implements a simple bundle that utilizes the OSGi
 * framework's event mechanism to listen for service events. Upon
 * receiving a service event, it prints out the event's details.
 */
public class JWSClientBundleActivator implements BundleActivator, ServiceListener
{
    /**
     * Implements BundleActivator.start(). Prints a message and adds itself to the bundle context
     * as a service listener.
     * @param context the framework context for the bundle.
     */
    public void start(BundleContext context) throws Exception
    {
        System.out.println("Starting");
        context.addServiceListener(this);
        System.out.println("Starting to listen for service events.");
    }

    /**
     * Implements BundleActivator.stop(). Prints
     * a message and removes itself from the bundle context as a

```

```

    * service listener.
    * @param context the framework context for the bundle.
    */
    public void stop(BundleContext context) throws Exception
    {
        context.removeServiceListener(this);
        System.out.println("Stopped listening for service events.");
        // Note: It is not required that we remove the listener here,
        // since the framework will do it automatically anyway.
    }

    /**
     * Implements ServiceListener.serviceChanged().
     * Prints the details of any service event from the framework.
     * @param event the fired service event.
     */
    public void serviceChanged(ServiceEvent event)
    {
        String[] objectClass = (String[])
            event.getServiceReference().getProperty("objectClass");

        if (event.getType() == ServiceEvent.REGISTERED)
        {
            System.out.println(
                "Ex1: Service of type " + objectClass[0] + " registered.");
        }
        else if (event.getType() == ServiceEvent.UNREGISTERING)
        {
            System.out.println(
                "Ex1: Service of type " + objectClass[0] + " unregistered.");
        }
        else if (event.getType() == ServiceEvent.MODIFIED)
        {
            System.out.println(
                "Ex1: Service of type " + objectClass[0] + " modified.");
        }
    }
}

```

4. Create the MANIFEST.MF application. For example:

```

Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: Client1
Bundle-SymbolicName: com.ibm.ws; singleton=true
Bundle-Version: 1.0.0
Bundle-Vendor: IBM
Bundle-Localization: plugin
Eclipse-AutoStart: true
Bundle-Activator: com.ibm.ws.JWSClientBundleActivator
DynamicImport-Package: *

```

5. Create the plugin.xml file. For example:

```

<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.0"?>
<plugin
  id="com.ibm.ws"
  name="Client1"
  version="1.0.0"
  provider-name="IBM"
>
  <extension id="Client1" name="Client1"
    point="org.eclipse.core.runtime.applications">
    <application>
      <run class="name_of_your_client_class" />
    </application>
  </extension>
</plugin>

```

6. Compile the application and the bundle activator. For example:
 

```
CLASSPATH=/opt/resources/com.ibm.ws.admin.client_6.1.0.jar:${CLASSPATH}
cd ${HOME}/com/ibm/ws
${JAVA_HOME}/bin/javac ThinClientTest.java
${JAVA_HOME}/bin/javac JWSCClientBundleActivator.java
```
7. Package the MANIFEST.MF application and the plugin.xml files into an OSGi bundle. You perform do this step using the JAR utility to turn the MANIFEST.MF application, the plugin.xml file, and the Java classes for the application into a JAR file.

## Compiling an application in a non-OSGi environment using scripting

To use the thin administrative client JAR files to compile an application, perform the following steps:

1. Include the com.ibm.ws.admin.client\_6.1.0.jar JAR file in the CLASSPATH.
2. Compile the application.

For example, the JAR file is located in the *app\_server\_root/opt/resources* directory and you want to compile the ThinAdminClientApplication.java file in the current directory. Use the following to compile the file:

```
export CLASSPATH=/opt/resources/com.ibm.ws.admin.client_6.1.0.jar:${CLASSPATH}
${JAVA_HOME}/bin/javac ThinAdminClientApplication.java
```

## Running the wsadmin tool remotely in a Java 2 Platform, Standard Edition environment

The thin administrative client adds JAR files that support administrative client functions that you can use with IBM Developer Kits For the Java Platform. For more information about thin administrative clients, see the Application client functions article in the *Developing and deploying applications* PDF.

For tracing and logging information for the thin administrative client, see the Enabling trace on client and standalone applications article in the *Troubleshooting and support* PDF.

1. Obtain the thin administrative client JAR files from the WebSphere Application Server Network Deployment installation from one of the following places:
  - The *app\_server\_root/runtimes* directory.
  - The *app\_client\_root/runtimes* directory, if you optionally installed this JAR file when you installed the application client.

Copy the JAR files into the environment from where you want to use them.

2. Set or export the classpath to include the *app\_server\_root/runtimes/com.ibm.ws.admin.client\_6.1.0.jar* file on the remote client machine.
3. Run the setupCmdLine.sh or the setupCmdLine.bat file.
4. Copy the wsadmin.sh or the wsadmin.bat file from the server machine. This file does not ship with the application client installation.
5. Start the wsadmin tool in either an OSGi or a non-OSGi environment.
  - a. Modify the wsadmin.sh or the wsadmin.bat file to include the following settings:

```
JAVA_HOME: location of the JDK/JRE installation
CLIENTSAS: location of the sas.client.props file
CLIENTSOAP: location of the soap.client.props file
JAASSOAP: location of the wsjaas_client.conf file
TAC_CLASSPATH: location of the thin administrative client JAR.
If you use the Jython language, use the jython.jar file.
If you use the Jacl file, use the jacl.jar and tcljava.jar files.
```

The additional JAR files are also located in the run time directory.

b. Use the startup.jar file to start the application. There are several properties that you can set. You can place these properties in environment variables which you can use on the command line to invoke the administrative client application. Then you can place these properties directly on the command line and invoke Java using the -D argument. For example:

- Using the SOAP connector. The SOAP connector settings, including the security settings, are stored in a file pointed to by the com.ibm.SOAP.ConfigURL property. Application code can override some of the settings through properties that you pass in to create the administrative client. The following example application code initializes the properties used to create the connector:

```
Properties props = new Properties();
props.setProperty(AdminClient.CONNECTOR_HOST, "host_name");
props.setProperty(AdminClient.CONNECTOR_PORT, "port");
props.setProperty(AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
props.setProperty(AdminClient.CONNECTOR_SECURITY_ENABLED, "false");
```

The following example starts the user program:

```
#!/bin/sh
CONNECTORPROPS=-Dcom.ibm.SOAP.ConfigURL=location of soap.client.props
JAVA_HOME=location of Java
TAC_CLASSPATH=location of the thin client JAR
```

```
"${JAVA_HOME}/bin/java" \
-Djava.ext.dirs="${JAVA_HOME}/jre/lib/ext" \
-classpath "${TAC_CLASSPATH}" ${CONNECTORPROPS} UserProgram
```

- Using the RMI connector. The RMI settings used by the connector, including security settings, are stored in a file pointed to by the com.ibm.CORBA.ConfigURL property. Application code can override some of the settings through properties that you pass in to create the administrative client. The following example application code initializes the properties used to create the administrative client:

```
Properties props = new Properties();
props.setProperty(AdminClient.CONNECTOR_HOST, "host_name");
props.setProperty(AdminClient.CONNECTOR_PORT, "port");
props.setProperty(AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_RMI);
props.setProperty(AdminClient.CONNECTOR_SECURITY_ENABLED, "false");
```

The following example starts the application:

```
#!/bin/sh
CONNECTORPROPS=-Dcom.ibm.CORBA.configURL=location of sas.client.props
JAVA_HOME=location of Java
TAC_CLASSPATH=location of thin client JAR
```

```
"${JAVA_HOME}/bin/java" \
-Djava.ext.dirs="${JAVA_HOME}/jre/lib/ext" \
-classpath "${TAC_CLASSPATH}" ${CONNECTORPROPS} UserProgram
```

- Launching an OSGI application. For example, assuming that the supporting JAR files are in the app\_server\_root/plugins directory and you put the startup.jar file in the app\_server\_root/lib/startup.jar directory, you can run the application in the bundle using the following:

```
#!/bin/bash
#
```

```
. setupCmdLine.bsh
#####
set -x
cd ${HOME}

trap ERR
set -x
"${JAVA_HOME}/bin/java" \
-Dosgi.install.area=${HOME} \
```

```

-Dosgi.configuration.area=${HOME}/configuration \
-Dosgi.debug=${HOME}/.options \
"-classpath" "${HOME}/lib/startup.jar" \
"-Dwas.install.root=${HOME}" \
org.eclipse.core.launcher.Main -nosplash -debug -clean \
-application \
<app name>
exit $?

```

## Auditing invocations of the wsadmin tool

In order to set up your application server environment, you must perform multiple tasks. For example, the following non-wsadmin scripts: create the persistent session database, install the JDBC driver for the database on the system, set up MQ and create MQ queues on the system, or place PDF files in specific locations that are required as part of the application structure. You must also run the following wsadmin scripts as part of the environment setup: create the cluster definition, create data sources and JMS object configuration, or install one or more EAR files that comprise the hosted software on WebSphere Application Server. Each of the scripts, wsadmin and non- wsadmin, need to support the ability to capture a log of the activity performed when you run the script. All of the logs from the scripts are written in a specific directory that archives each time you create an environment. Each time you set up an environment, the overall process is considered a job and each job has an associated identifier. The identifier is a string that includes the date, environment name, machine name, operator, and approval code as indicated by company policy. To examine the logs at a later time, after the environment provisioning is complete, and verify that all of the log files for the wsadmin and non-wsadmin scripts reflect the actual output of the script that you ran for a specific job, and that no other logs are mixed in with the ones from that job, perform the following steps:

1. Start the wsadmin tool using the `-jobid string`, `-appendTrace string`, or the `-tracefile string` option. For more information about these options, see the “Wsadmin tool” on page 678 article. For more information about starting the wsadmin tool, see the “Starting the wsadmin scripting client” on page 134 article. Use the `-tracefile` option to name the logs based on the activity performed by the script that you want to run and to locate the log files in the specific directory for the job. Uses the `-appendtrade true` option to append to an existing log file, if one already exists. Use the `-jobid` option to embed an identifier within the log file so that you can validate that all of the logs were the result of the same specific provisioning activity and not some other job.

You can change the name and location of a file. Modifying the contents of the log file can prove difficult. Also, different log files can have the same job ID and each log file needs a unique name. So the `-jobid` option provides an important audit and correlation function that the `-tracefile` option cannot provide.

2. Examine the log file for the job ID that you specified. Use the log files to audit or correlate the wsadmin tool.

The following example outputs to the log of the wsadmin tool when you use the `-jobid string` parameter:

```
[5/16/05 15:45:49:449 CDT] 0000000a AbstractShell A JobID= scriptTest1
```

---

## Troubleshooting with scripting

Use these topics to learn more about troubleshooting with scripting.

This topic contains the following tasks:

- “Tracing operations with the wsadmin tool” on page 663
- “Configuring traces using scripting” on page 664
- “Turning traces on and off in servers processes using scripting” on page 664
- “Dumping threads in server processes using scripting” on page 665
- “Setting up profile scripts to make tracing easier using scripting” on page 665

- “Enabling the Runtime Performance Advisor tool using scripting” on page 666

You can set the trace string using either of the following supported formats. For example:

```
$AdminControl trace com.ibm.*=all=enabled
```

or

```
$AdminControl trace com.ibm.*=all
```

For more information see the Tracing and logging configuration article and the Log level settings article in the *Troubleshooting and support* PDF.

## Tracing operations with the wsadmin tool

You can enable tracing with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to trace operations:

Enable wsadmin client tracing with the following command:

- Using Jacl:

```
$AdminControl trace com.ibm.*=all=enabled
```

- Using Jython:

```
AdminControl.trace('com.ibm.*=all=enabled')
```

where:

|                       |                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------|
| \$                    | is a Jacl operator for substituting a variable name with its value                         |
| AdminControl          | is an object that enables the manipulation of MBeans running in a WebSphere server process |
| trace                 | is an AdminControl command                                                                 |
| com.ibm.*=all=enabled | indicates to turn on tracing                                                               |

The following command disables tracing:

- Using Jacl:

```
$AdminControl trace com.ibm.*=all=disabled
```

- Using Jython:

```
AdminControl.trace('com.ibm.*=all=disabled')
```

where:

|                        |                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------|
| \$                     | is a Jacl operator for substituting a variable name with its value                         |
| AdminControl           | is an object that enables the manipulation of MBeans running in a WebSphere server process |
| trace                  | is an AdminControl command                                                                 |
| com.ibm.*=all=disabled | indicates to turn off tracing                                                              |

The trace command changes the trace settings for the current session. You can change this setting persistently by editing the wsadmin.properties file. The property com.ibm.ws.scripting.traceString is read by the launcher during initialization. If it has a value, the value is used to set the trace.

A related property, `com.ibm.ws.scripting.traceFile`, designates a file to receive all trace and logging information. The `wsadmin.properties` file contains a value for this property. Run the `wsadmin` tool with a value set for this property. It is possible to run without this property set, where all logging and tracing goes to the administrative console.

## Configuring traces using scripting

Use the `wsadmin` tool and scripting to configure traces for a configured server.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

Perform the following steps to set the trace for a configured server:

1. Identify the server and assign it to the server variable:

- Using Jacl:

```
set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print server
```

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the trace service belonging to the server and assign it to the tc variable:

- Using Jacl:

```
set tc [$AdminConfig list TraceService $server]
```

- Using Jython:

```
tc = AdminConfig.list('TraceService', server)
print tc
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#TraceService_1)
```

3. Set the trace string. The following example sets the trace string for a single component:

- Using Jacl:

```
$AdminConfig modify $tc {{startupTraceSpecification
com.ibm.websphere.management.*=all=enabled}}
```

- Using Jython:

```
AdminConfig.modify(tc, [['startupTraceSpecification',
'com.ibm.websphere.management.*=all=enabled']])
```

4. The following command sets the trace string for multiple components:

- Using Jacl:

```
$AdminConfig modify $tc {{startupTraceSpecification
com.ibm.websphere.management.*=all=enabled:com.ibm.ws.
management.*=all=enabled:com.ibm.ws.runtime.*=all=enabled}}
```

- Using Jython:

```
AdminConfig.modify(tc, [['startupTraceSpecification',
'com.ibm.websphere.management.*=all=enabled:com.ibm.ws.
management.*=all=enabled:com.ibm.ws.runtime.*=all=enabled']])
```

5. Save the configuration changes. See the “Saving configuration changes with the `wsadmin` tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the `wsadmin` tool” on page 99 article for more information.

## Turning traces on and off in servers processes using scripting

You can use scripting to turn traces on or off in server processes.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to turn traces on and off in server processes:

1. Identify the object name for the TraceService MBean running in the process:
  - Using Jacl:  
`$AdminControl completeObjectName type=TraceService,node=mynode,process=server1,*`
  - Using Jython:  
`AdminControl.completeObjectName('type=TraceService,node=mynode,process=server1,*')`
2. Obtain the name of the object and set it to a variable:
  - Using Jacl:  
`set ts [$AdminControl completeObjectName type=TraceService,process=server1,*]`
  - Using Jython:  
`ts = AdminControl.completeObjectName('type=TraceService,process=server1,*')`
3. Turn tracing on or off for the server. For example:
  - To turn tracing on, perform the following step:
    - Using Jacl:  
`$AdminControl setAttribute $ts traceSpecification com.ibm.*=all=enabled`
    - Using Jython:  
`AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=enabled')`
  - To turn tracing off, perform the following step:
    - Using Jacl:  
`$AdminControl setAttribute $ts traceSpecification com.ibm.*=all=disabled`
    - Using Jython:  
`AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=disabled')`

## Dumping threads in server processes using scripting

Use the AdminControl object to dump the Java threads of a running server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The following example produces a Java core file. You can use this file for problem determination.

- Using Jacl:  
`set jvm [$AdminControl completeObjectName type=JVM,process=server1,*]  
$AdminControl invoke $jvm dumpThreads`
- Using Jython:  
`jvm = AdminControl.completeObjectName('type=JVM,process=server1,*')  
AdminControl.invoke(jvm, 'dumpThreads')`

## Setting up profile scripts to make tracing easier using scripting

You can use scripting and the wsadmin tool to set up profile scripts to facilitate tracing.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Set up a profile script to make tracing easier. The following profile script example turns tracing on and off for server1:

- Using Jacl:

```

proc ton {} {
    global AdminControl
    set ts [$AdminControl queryNames type=TraceService,node=mynode,process=server1,*]
    $AdminControl setAttribute $ts traceSpecification com.ibm.*=all=enabled
}

proc toff {} {
    global AdminControl
    set ts [$AdminControl queryNames type=TraceService,node=mynode,process=server1,*]
    $AdminControl setAttribute $ts traceSpecification com.ibm.*=all=disabled
}

proc dt {} {
    global AdminControl
    set jvm [$AdminControl queryNames type=JVM,node=mynode,process=server1,*]
    $AdminControl invoke $jvm dumpThreads
}

```

- Using Jython:

```

def ton():
    global lineSeparator
    ts = AdminControl.queryNames('type=TraceService,node=mynode,process=server1,*')

    AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=enabled')

def toff():
    global lineSeparator
    ts = AdminControl.queryNames('type=TraceService,node=mynode,process=server1,*')

    AdminControl.setAttribute(ts, 'traceSpecification', 'com.ibm.*=all=disabled')

def dt():
    global lineSeparator
    jvm = AdminControl.queryNames('type=JVM,node=mynode,process=server1,*')
    AdminControl.invoke(jvm, 'dumpThreads')

```

If you start the wsadmin tool with this profile script, you can use the **ton** command to turn on tracing in the server, the **toff** command to turn off tracing, and the **dt** command to dump the Java threads. For more information about running scripting commands in a profile script, see the “Starting the wsadmin scripting client” on page 134 article.

## Enabling the Runtime Performance Advisor tool using scripting

You can configure the Runtime Performance Advisor using the wsadmin tool or the administrative console.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The Runtime Performance Advisor tool provides advice to help tune systems for optimal performance. See the Using the Runtime Performance Advisor article in the *Tuning guide* PDF for more information on how to enable this tool using the administrative console. The recommendations display as text in the SystemOut.log file.

The Runtime Performance Advisor (RPA) requires that the Performance Monitoring Service (PMI) is enabled. It does not require that individual counters be enabled. When a counter that is needed by the RPA is not enabled, the RPA will enable it automatically.

There is no MBean/object available for wsadmin to create a RPA configuration. You can use wsadmin to change the settings and make them effective at runtime. These changes will not be persisted. The changes remain until you stop the server. Since the RPA is disabled once you stop the server, you may want to disable the PMI Service or the counters that were enabled while it was active. You can enable the following counters using the Runtime Performance Advisor:

ThreadPools (module)  
 Web Container (module)  
 Pool Size  
 Active Threads  
 Object Request Broker (module)  
 Pool Size  
 Active Threads  
 JDBC Connection Pools (module)  
 Pool Size  
 Percent used  
 Prepared Statement Discards  
 Servlet Session Manager (module)  
 External Read Size  
 External Write Size  
 External Read Time  
 External Write Time  
 No Room For New Session  
 System Data (module)  
 CPU Utilization  
 Free Memory

The following provides an explanation for some of the settings that you can use:

- Calculation interval PMI data - This setting is taken over an interval of time and averaged to provide advice. The calculation interval specifies the length of the time over which data is taken for this advice. Details within the advice messages will appear as averages over this interval.
- Maximum warning sequence - This setting refers to the number of consecutive warnings issued before the threshold is relaxed. For example, if the maximum warning sequence is set to 3, then the advisor only sends three warnings to indicate that the prepared statement cache is overflowing. After that, a new alert is only issued if the rate of discards exceeds the new threshold setting.
- Number of processors - This setting specifies the number of processors on the server. It is critical in order to ensure accurate advice for the specific configuration of the system.

To enable the Runtime Performance Advisor tool using the wsadmin tool, perform the following steps:

Setup the Runtime Performance Advisor (RPA), for example:

- Using Jacl:

```

set perf [$AdminControl queryNames mbeanIdentifier=ServerRuleDriverMBean2,process=server1,*]
set enabledVal [java::new java.lang.Boolean true]
set attr [java::new javax.management.Attribute enabled $enabledVal]
set perfObject [$AdminControl makeObjectName $perf]
set ObjectArray [java::new {java.lang.Object[]} 1]
set sigArray [java::new {java.lang.String[]} 1]
$ObjectArray set 0 $attr
$sigArray set 0 "javax.management.Attribute"
$AdminControl invoke_jmx $perfObject setRPAAttribute $ObjectArray $sigArray

$AdminConfig save
  
```

After completing the previous steps, start the server and monitor RPA.

## Commands for the EventServiceCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the EventServiceCommands group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                            |                                                                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Commands for the AdministrationReports group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the AdministrationReports group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                             |                                                                                                                       |      |                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reportConfigInconsistencies | Use the <b>reportConfigInconsistencies</b> command to create a report of inconsistencies in the system configuration. | None | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A report that describes inconsistencies found in the system.</li> </ul> | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask reportConfigInconsistencies {-interactive}</li> <li>Using Jython string:<br/>AdminTask.reportConfigInconsistencies ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.reportConfigInconsistencies (['-interactive'])</li> </ul> <p><b>Example output:</b></p> <p>Configuration consistency report for cell yardbirdCell</p> <p>cells/yardbirdCell/test.xml is a zero length file.<br/>cells/yardbirdCell/nodes/DummyNode does not contain a serverindex.xml document.<br/>cells/yardbirdCell/applications/Test.ear/deployments/Test does not contain a deployment.xml document.</p> <p>3 consistency problems were found.</p>                                 |
| reportConfiguredPorts       | Use the <b>reportConfiguredPorts</b> command to create a report of all the ports configured in the cell.              | None | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A report that describes the port usage in the system.</li> </ul>        | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask reportConfiguredPorts {-interactive}</li> <li>Using Jython string:<br/>AdminTask.reportConfiguredPorts ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.reportConfiguredPorts (['-interactive'])</li> </ul> <p><b>Example output:</b></p> <p>Ports configured in cell yardbirdCell</p> <p>Node yardbirdCellMgr / Server dmgr<br/>yardbird:7283 CELL_DISCOVERY_ADDRESS<br/>yardbird:9809 BOOTSTRAP_ADDRESS<br/>...</p> <p>Node dizzyNode1 / Server server1<br/>dizzy:2813 BOOTSTRAP_ADDRESS<br/>dizzy:8880 SOAP_CONNECTOR_ADDRESS<br/>...</p> <p>Node dizzyNode1 / Server nodeagent<br/>dizzy:2814 BOOTSTRAP_ADDRESS<br/>dizzy:9904 ORB_LISTENER_ADDRESS</p> |

## Scripting reference material

The following tasks are reference material for the wsadmin tool and scripting.

This topic contains the following tasks:

- “Wsadmin tool”
- “Commands for the AdminConfig object” on page 695
- “Commands for the AdminControl object” on page 716
- “Commands for the AdminApp object” on page 741
- “Commands for the AdminTask object” on page 832
- “Administrative command invocation syntax” on page 843
- “Commands for the Help object” on page 682
- “Properties used by scripted administration” on page 845

### Wsadmin tool

The WebSphere Application Server wsadmin tool runs scripts. You can use the wsadmin tool to manage WebSphere Application Server as well as the configuration, application deployment, and server run-time operations.

The options for the wsadmin tool are case insensitive.

The command-line invocation syntax for the wsadmin scripting client is as follows:

```
wsadmin [-h(help)]
```

```
[-?]
```

```
[-c <commands>]
```

```
[-p <properties_file_name>]
```

```
[-profile <profile_script_name>]
```

```
[-profileName <profile_name>]
```

```
[-f <script_file_name>]
```

```
[-javaoption java_option]
```

```
[-lang language]
```

```
[-wsadmin_classpath classpath]
```

```
[-conntype SOAP [-host host_name]
```

```
[-port port_number] [-user userid] [-password password] |
```

```
RMI [-host host_name] [-port port_number] [-user userid] [-password password] | NONE]
```

```
[-jobid string]
```

```
[-tracefile trace_file]
```

```
[-appendtrace true/false]
```

```
[script parameters]
```

Where *script parameters* represent any arguments other than the ones listed previously. The `argc` variable contains the argument number, and the `argv` variable contains the contents.

## Options

**-c** Designates to run a single command.

Multiple **-c** options can exist on the command line. They run in the order that you designate. You must save after using this command.

**-f** Designates a script to run.

Only one **-f** option can exist on the command line.

### **-javaoption**

Specifies a valid Java standard or a non-standard option. Multiple **-javaoption** options can exist on the command line.

To shorten the length of the command, type it the following way:

```
wsadmin -javaoption java_option java_option
```

instead of the following:

```
wsadmin -javaoption java_option -javaoption java_option
```

### **-lang**

Specifies the language of the script file, the command, or an interactive shell. The possible languages include: Jacl and Jython. The options for the **-lang** argument include: `jacl` and `jython`.

This option overrides language determinations that are based on a script file name, a profile script file name, or the `com.ibm.ws.scripting.defaultLang` property. The **-lang** argument has no default value.

If you do not specify the **-lang** argument but you have the **-f** `<script_file_name>` argument specified, the `wsadmin` tool determines the language based on a target script file name. If you do not specify the **-lang** argument and the **-f** argument, the `wsadmin` tool determines the language based on a profile script file name if the **-profile** `<profile_script_name>` argument is specified. If the command line or the property does not supply the script language, and the `wsadmin` tool cannot determine it, an error message generates.

### **-p**

Specifies a properties file.

The file listed after **-p**, represents a Java properties file that the scripting process reads. Three levels of default properties files load before the properties file that you specify on the command line. The first level is the installation default, `wsadmin.properties`, which is located in the WebSphere Application Server properties directory. The second level is the user default, `wsadmin.properties`, which is located in your home directory. The third level is the properties file that the environment variable `WSADMIN_PROPERTIES` points to.

Multiple **-p** options can exist on the command line. They invoke in the order that you supply them.

### **-profile**

Specifies a profile script.

The profile script runs before other commands, or scripts. If you specify **-c**, the profile script runs before it invokes this command. If you specify **-f**, the profile script runs before it runs the script. In interactive mode, you can use the profile script to perform any standard initialization that you want. You can specify multiple **-profile** options on the command line, and they invoke in the order that you supply them.

### **-profileName**

Specifies the profile from which the `wsadmin` tool will run. Specify this option if one the following reasons apply:

- You run the `wsadmin` tool from the `WAS_HOME/bin` directory and you do not have a default profile or you want to run in a profile other than the default profile.
- You are currently in a profile `bin` directory but want to run the `wsadmin` tool from a different profile.

**Note:** WebSphere Application Server for z/OS does not support user-created profiles; only the default profile is used.

**-?**

Provides syntax help.

**-help**

Provides syntax help.

**-conntype**

Specifies the type of connection to use.

This argument consists of a string that determines the type, for example, SOAP, and the options that are specific to that connection type. Possible types include: SOAP, RMI, and NONE.

Use the `-conntype NONE` option to run in local mode. The result is that the scripting client is not connected to a running server. You can manage server configuration, the installation and the uninstallation of applications without the application server running.

**-wsadmin\_classpath**

Use this option to make additional classes available to your scripting process.

Follow this option with a class path string. For example:

```
/home/MyDir/Myjar.jar;/yourdir/yourdir.jar
```

The class path is then added to the class loader for the scripting process.

You can also specify this option in a properties file that is used by the `wsadmin` tool. The property is `com.ibm.ws.scripting.classpath`. If you specify `-wsadmin_classpath` on the command line, the value of this property overrides any value that is specified in a properties file. The class path property and the command-line options are not concatenated.

**-host**

Specify a hostname to which `wsadmin` should attempt to connect. The default `wsadmin.properties` file located in the properties directory of each WebSphere profile provides `localhost` as the value of the `host` property if this option is not specified.

**-password**

Specify a password to be used by the connector to connect to the server if security is enabled in the server.

Warning: On UNIX system, the use of `-password` option may result in security exposure as the password information becomes visible to the system status program such as `ps` command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere profile.

**-username**

Specify a user name to be used by the connector to connect to the server if security is enabled in the server.

**-port**

Specify a port to be used by the connector. The default `wsadmin.properties` file located in the properties directory of each WebSphere Application Server profile provides a value in the `port` property to connect to the local server.

**-jobid**

Specifies a jobID string so that you can keep track of each invocation of the `wsadmin` tool for auditing purposes. The jobID string (`jobID=xxxx`) displays at the beginning of the `wsadmin` log file.

### **-tracefile**

Specifies the name of the log file and location where the log output is directed. This option overrides the `com.ibm.ws.scripting.traceFile` property in the `wsadmin.properties` file.

### **-appendtrace**

Determines if a trace appends to or overrides the end of the existing log file. Specify `true` to append the trace to the end of a log file or specify `false` to override the log file for each `wsadmin` invocation.

The following example specifies the `jobID` option, log location and appends the trace to the log file.

```
wsadmin -jobid wsadmin_test_1 -tracefile /temp/wsadmin_test_1.log -appendtrace true
```

In the following syntax examples, *mymachine* is the name of the host in the `wsadmin.properties` file that is specified by the `com.ibm.ws.scripting.port` property:

### **SOAP connection to the local host**

Use the options that are defined in the `wsadmin.properties` file.

### **SOAP connection to the *mymachine* host**

Using Jacl:

```
wsadmin -f test1.jacl -profile setup.jacl -conntype SOAP  
-port mymachinesoapportnumber -host mymachine
```

Using Jython:

```
wsadmin -lang jython -f test1.py -profile setup.py -conntype  
SOAP -port mymachinesoapportnumber -host mymachine
```

### **Initial and maximum Java heap size**

Using Jacl:

```
wsadmin -javaoption -Xms128m -Xmx256m -f test.jacl
```

Using Jython:

```
wsadmin -lang jython -javaoption -Xms128m -Xmx256m -f test.py
```

### **RMI connection with security**

Using Jacl:

```
wsadmin -conntype RMI -port rmiportnumber -userid userid  
-password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port rmiportnumber -userid userid  
-password password
```

Warning: On UNIX system, the use of `-password` option may result in security exposure as the password information becomes visible to the system status program such as `ps` command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere profile.

### **Local mode of operation to perform a single command**

Using Jacl:

```
wsadmin -conntype NONE -c "$AdminApp uninstall app"
```

Using Jython:

```
wsadmin -lang jython -conntype NONE -c "AdminApp.uninstall('app')"
```

## **wsadmin tool performance tips**

Follow these tips to get the best performance from the `wsadmin` tool.

The following performance tips are for the `wsadmin` tool:

- If the deployment manager is running at a higher service maintenance level than that of the node agent, you must run the `wsadmin.sh` or the `wsadmin.bat` from the `bin` directory of the deployment manager. See the Installing maintenance packages topic in the *Troubleshooting and support* PDF for more information.
- When you launch a script using the `wsadmin` tool, a new process is created with a new Java virtual machine (JVM) API. If you use scripting with multiple `wsadmin -c` commands from a batch file or a shell script, these commands run slower than if you use a single `wsadmin -f` command. The `-f` option runs faster because only one process and JVM API are created for installation and the Java classes for the installation load only once.

The following example, illustrates running multiple application installation commands from a batch file:

Using Jacl:

```
wsadmin -c "$AdminApp install /home/myDir/myApps/App1.ear {-appname app1}"
wsadmin -c "$AdminApp install /home/myDir/myApps/App2.ear {-appname app2}"
wsadmin -c "$AdminApp install /home/myDir/myApps/App3.ear {-appname app3}"
```

Using Jython:

```
wsadmin -lang jython -c "AdminApp.install('/home/myDir/myApps/App1.ear', '[-appname app1]')"
wsadmin -lang jython -c "AdminApp.install('/home/myDir/myApps/App2.ear', '[-appname app2]')"
wsadmin -lang jython -c "AdminApp.install('/home/myDir/myApps/App3.ear', '[-appname app3]'"
```

Or, for example, using Jacl, you can create the `appinst.jacl` file that contains the commands:

```
$AdminApp install /home/myDir/myApps/App1.ear {-appname app1}
$AdminApp install /home/myDir/myApps/App2.ear {-appname app2}
$AdminApp install /home/myDir/myApps/App3.ear {-appname app3}
```

Invoke this file using the following command: `wsadmin -f appinst.jacl`

Or using Jython, you can create the `appinst.py` file, that contains the commands:

```
AdminApp.install('/home/myDir/myApps/App1.ear', '[-appname app1]')
AdminApp.install('/home/myDir/myApps/App2.ear', '[-appname app2]')
AdminApp.install('/home/myDir/myApps/App3.ear', '[-appname app3]')
```

Then invoke this file using the following command: `wsadmin -lang jython -f appinst.py`.

- Use the AdminControl **queryNames** and **completeObjectName** commands carefully with a large installation. For example, if only a few beans exist on a single machine, the `$AdminControl queryNames *` command performs well. If a scripting client connects to the deployment manager in a multiple machine environment, use a command only if it is necessary for the script to obtain a list of all the MBeans in the system. If you need the MBeans on a node, it is easier to invoke `"$AdminControl queryNames node=mynode,*"`. The JMX system management infrastructure forwards requests to the system to fulfill the first query, `*`. The second query, `node=mynode,*` is targeted to a specific machine.
- The WebSphere Application Server is a distributed system, and scripts perform better if you minimize remote requests. If some action or interrogation is required on several items, for example, servers, it is more efficient to obtain the list of items once and iterate locally. This procedure applies to the actions that the AdminControl object performs on running MBeans, and actions that the AdminConfig object performs on configuration objects.

## Commands for the Help object

The Help object provides general help and dynamic online information about the currently running MBeans. You can use the Help object as an aid in writing and running scripts with the AdminControl object.

The following commands are available for the Help object:

| Command name: | Description: | Parameters and return values: | Examples: |
|---------------|--------------|-------------------------------|-----------|
|               |              |                               |           |

|          |                                                                             |                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Related concepts

“Help object for scripted administration” on page 87

The Help object provides general help, online information about running MBeans, and help on messages.

## Commands for the AdminConfig object

Use the AdminConfig object to invoke configuration commands and to create or change elements of the WebSphere Application Server configuration, for example, creating a data source.

You can start the scripting client without a running server, if you only want to use local operations. To run in local mode, use the `-conntype NONE` option to start the scripting client. You receive a message that you are running in the local mode. If a server is currently running, running the AdminConfig tool in local mode is not recommended. This is because any configuration changes made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following commands are available for the AdminConfig object:

| Command name: | Description:                                                 | Parameters and return values:                                                                                                                                                                                                                                                                      | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Commands for the AdminControl object

Use the AdminControl object to invoke operational commands that deal with running objects in the WebSphere Application Server.

Many of the AdminControl commands have multiple signatures so that they can either invoke in a raw mode using parameters that are specified by Java Management Extensions (JMX), or by using strings for parameters. In addition to operational commands, the AdminControl object supports some utility commands for tracing, reconnecting with a server, and converting data types.

The following commands are available for the AdminControl object:

| Command name: | Description: | Parameters and return values: | Examples: |
|---------------|--------------|-------------------------------|-----------|
|---------------|--------------|-------------------------------|-----------|

|                        |                                                                                                                                                                                                                                                                           |                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| complete<br>ObjectName | Creates a string representation of a complete ObjectName value that is based on a fragment. This command does not communicate with the server to find a matching ObjectName value. If it finds several MBeans that match the fragment, the command returns the first one. | <ul style="list-style-type: none"> <li>Parameters:<br/>name-java.lang.String</li> <li>Returns: java.lang.String</li> </ul>                                 | <p>Example usage:</p> <p>Using Jacl:</p> <pre>set serverON [\$AdminControl completeObjectName node= mynode,type=Server,*]</pre> <p>Using Jython:</p> <pre>serverON = AdminControl. completeObjectName('node= mynode,type=Server,*')</pre>                                                                                                                          |
| getAttribute           | Returns the value of the attribute for the name that you provide.                                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>Parameters:<br/>name-java.lang.String;<br/>attribute-java.lang.String</li> <li>Returns: java.lang.String</li> </ul> | <p>Example usage:</p> <p>Using Jacl:</p> <pre>set objNameString [\$AdminControl complete ObjectName WebSphere: type=Server,*] \$AdminControl getAttribute \$objNameString processType</pre> <p>Using Jython:</p> <pre>objNameString = Admin Control.completeObject Name('WebSphere:type= Server,*') AdminControl.getAttribute (objNameString, 'processType')</pre> |

|                         |                                                                          |                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| help | Returns general help text for the AdminControl object. | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: java.lang.String</li> </ul> | <p>Example usage:</p> <p>Using Jacl:<br/>\$AdminControl help</p> <p>Using Jython:<br/>AdminControl.help()</p> <p>Example output:</p> <p>WASX7027I: The AdminControl object enables the manipulation of MBeans that run in a WebSphere Application Server process. The number and type of MBeans that are available to the scripting client depend on the server to which the client is connected. If the client is connected to a deployment manager, then all the MBeans running in the Deployment Manager are visible, as are all the MBeans running in the node agents that are connected to this deployment manager, and all the MBeans that run in the application servers on those nodes.</p> <p>The following commands are supported by the AdminControl object; more detailed information about each of these commands is available by using the "help" command of the AdminControl object and supplying the name of the command as an argument.</p> <p>Many of these commands support two different sets of signatures: one that accepts and returns strings, and one low-level set that works with JMX objects like ObjectName and AttributeList. In most situations, the string signatures are likely to be more useful, but JMX-object signature versions are supplied as well. Each of these JMX-object signature commands has "_jmx" appended to the command name, so an "invoke" command, as well as a "invoke_jmx" command are supported.</p> |

| <p>invoke</p> | <p>Invokes the object operation using the parameter list that you supply. The signature generates automatically. The types of parameters are supplied by examining the MBeanInfo that the MBean supplies. Returns the string result of the invocation. The string that is returned is controlled by the Mbean method that you invoked. If the Mbean method is synchronous, then control is returned back to the wsadmin tool only when the operation is complete. If the Mbean method is asynchronous, control is returned back to the wsadmin tool immediately even though the invoked task might not be complete.</p> | <ul style="list-style-type: none"> <li>• Parameters:<br/>name-java.lang.String;<br/>operationName-java.lang.String;<br/>params-java.lang.String</li> <li>• Returns: java.lang.String</li> </ul> | <p>Example usage:</p> <p>Using Jacl:</p> <pre>set objNameString [\$AdminControl completeObjectName WebSphere: type=Server,*] \$AdminControl invoke \$objNameString appendTraceString com.ibm.*=all=enabled</pre> <p>Using Jython:</p> <pre>objNameString = AdminControl. completeObjectName('WebSphere: type=Server,*') AdminControl.invoke(objName String, 'appendTraceString', 'com.ibm.*=all=enabled')</pre> |

## Commands for the AdminApp object

Use the AdminApp object to install, modify, and administer applications.

The AdminApp object interacts with the WebSphere Application Server management and configuration services to make application inquiries and changes. This interaction includes installing and uninstalling applications, listing modules, exporting, and so on.

You can start the scripting client when no server is running, if you want to use only local operations. To run in local mode, use the `-conntype NONE` option to start the scripting client. You receive a message that you are running in the local mode. Running the AdminApp object in local mode when a server is currently running is not recommended. This is because any configuration changes made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration. In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by

connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

The following commands are available for the AdminApp object:

| Command name:             | Description:                                                                                                                                                                                                                                             | Parameters and return values:                                                                                                                                                                                                                        | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|  |  | <ul style="list-style-type: none"> <li>•</li> <li>– <code>app</code> - Indicates that you want to update the entire application. This option is the same as indicating the update option with the <b>install</b> command. With the <code>app</code> value as the content type, you must specify the operation option with <code>update</code> as the value. Provide the new enterprise archive file (EAR) file using the <code>contents</code> option. You can also specify binding information and application options. By default, binding information for installed modules is merged with the binding information for updated modules. To change this default behavior, specify the <code>update.ignore.old</code> or the <code>update.ignore.new</code> options.</li> <li>– <code>file</code> - Indicates that you want to update a single file. You can add, remove, or update individual files at any scope within the deployed application. With the <code>file</code> value as the content type, you must perform operations on the file using the <code>operation</code> option. Depending on the type of operation, additional options are required. For file additions and updates, you must provide file content and the file URI relative to the root of the EAR file using the <code>contents</code> and <code>contenturi</code> options. For file deletion, you must provide the file URI relative to the root of the EAR file using the <code>contenturi</code> option which is the only required input. Any other options that you provide are ignored.</li> </ul> |  |

|  |  | <ul style="list-style-type: none"> <li>• - modulefile - Indicates that you want to update a module. You can add, remove, or update an individual application module. If you specify the modulefile value as the content type, you must indicate the operation that you want to perform on the module using the operation option. Depending on the type of operation, additional options are required. For installing new modules or updating existing modules in an application, you must indicate the file content and the file URI relative to the root of the EAR file using the contents and the contenturi options. You can also specify binding information and application options that pertain to the new or updated modules. For module updates, the binding information for the installed module is merged with the binding information for the input module by default. To change the default behavior, specify the update.ignore.old or the update.ignore.new options. To delete a module, indicate the file URI relative to the root of the EAR file.</li> </ul> | <p>Example output:</p> <pre>Getting tasks for: myApp WASX7266I: A was.policy file exists for this application; would you like to display it? [No]  Task[4]: Binding enterprise beans to JNDI names Each non message driven enterprise bean in your application or module must be bound to a JNDI name.  EJB Module: Increment Enterprise Java Bean EJB: Increment URI: Increment.jar,META-INF/ejb-jar.xml JNDI Name: [Inc]:  Task[10]: Specifying the default data source for EJB 2.x modules Specify the default data source for the EJB 2.x Module containing 2.x CMP beans.  WASX7349I: Possible value for resource authorization is container or per connection factory EJB Module: Increment Enterprise Java Bean URI: Increment.jar,META-INF/ejb-jar.xml JNDI Name: [DefaultDatasource]: Resource Authorization: [Per connection factory]:  Task[12]: Specifying data sources for individual 2.x CMP beans Specify an optional data source for each 2.x CMP bean. Mapping a specific data source to a CMP bean overrides the default data source for the module containing the enterprise bean. WASX7349I: Possible value for resource authorization is container or per connection factory EJB Module: Increment Enterprise Java Bean EJB: Increment URI: Increment.jar,META-INF/ejb-jar.xml JNDI Name: [DefaultDatasource]: Resource Authorization: [Per connection factory]: container Setting "Resource Authorization" to "cmpBinding.container"  Task[14]: Selecting Application Servers Specify the application server where you want to install modules that are contained in your application. Modules can be installed on the same server or dispersed among several servers. ## Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands

This article lists the available options for the **install**, **installInteractive**, **edit**, **editInteractive**, **update**, and **updateInteractive** commands of the AdminApp object.

The options listed in this article apply to all of these commands except where noted.

See Commands for the AdminApp object for more detailed information on how to use the commands. See Usage table for the options of the AdminApp object install, installInteractive, update, updateInteractive, edit, and editInteractive commands for a list of applicable commands for each option.

You can use pattern matching to simplify the task of supplying required values for certain complex options. Pattern matching only applies to fields that are required or read only. See “Pattern matching with the wsadmin tool” on page 831 for more information.

The following options are available for the **install**, **installInteractive**, **edit**, **editInteractive**, **update**, and **updateInteractive** commands:

| Option name: | Description: | Examples: |
|--------------|--------------|-----------|
|--------------|--------------|-----------|

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ActSpecJNDI | <p>Binds J2C activation specifications to destination JNDI names. You can bind J2C activation specifications in your application or module to a destination JNDI name. This option is optional. Each element of the ActSpecJNDI option consists of the following fields:</p> <ul style="list-style-type: none"> <li>RARModule, uri, j2cid, j2c.jndiName.</li> <li>j2c.jndiName field, can be assigned a value. The current contents of the option after running default bindings include:</li> </ul> <ul style="list-style-type: none"> <li>• RARModule: &lt;rar module name&gt;</li> <li>• uri: &lt;rar name&gt;,META-INF/ra.xml</li> <li>• Object identifier: &lt;messageListenerType&gt;</li> <li>• JNDI name: null</li> </ul> <p>You can only use this option if the activation specification has the Destination property defined in the ra.xml file and the introspected type of the Destination property is the following:</p> <pre>javax.jms.Destination</pre> | <p>Using Jacl:</p> <pre>\$AdminApp install \$embeddedEar {-ActSpecJNDI {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageListener jndi5} {"FVT Resource Adapter" jca15cmd.rar,META-INF/ra.xml javax.jms.MessageListener2 jndi6}}</pre> <p>Using Jacl with pattern matching:</p> <pre>\$AdminApp install \$embeddedEar {-ActSpecJNDI {.* *.rar,.* javax.jms.MessageListener jndi5} {.* *.rar,.* javax.jms.MessageListener2 jndi6}}</pre> <p>Using Jython:</p> <pre>AdminApp.install(embeddedEar, ['-ActSpecJNDI', [{"FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageListener', 'jndi5'}, {"FVT Resource Adapter", 'jca15cmd.rar,META-INF/ra.xml', 'javax.jms.MessageListener2', 'jndi6'}]])</pre> <p>Using Jython with pattern matching:</p> <pre>AdminApp.install(embeddedEar, ['-ActSpecJNDI', [['.*', '.*.rar,.*', 'javax.jms.MessageListener', 'jndi5'], ['.*', '.*.rar,.*', 'javax.jms.MessageListener2', 'jndi6']]])</pre> |

| <code>defaultbinding.cf.jndi</code>               | Specifies the Java Naming and Directory Interface (JNDI) name for the default connection factory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| <code>defaultbinding.cf.resauth</code>            | Specifies the RESAUTH for the connection factory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| <code>defaultbinding.datasourcesource.jndi</code> | Specifies the Java Naming and Directory Interface (JNDI) name for the default data source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |

|                                    |                                                                                                                                                                                                                                                                                                                |  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| defaultbinding.datasource.password | Specifies the password for the default data source.                                                                                                                                                                                                                                                            |  |
|                                    | Specifies the user name for the default data source.                                                                                                                                                                                                                                                           |  |
| defaultbinding.ejbjndi.prefix      | Specifies the prefix for the enterprise bean Java Naming and Directory Interface (JNDI) name.                                                                                                                                                                                                                  |  |
| defaultbinding.force               | Specifies that the default bindings override the current bindings.                                                                                                                                                                                                                                             |  |
| defaultbinding.strategy.file       | Specifies a custom default bindings strategy file.                                                                                                                                                                                                                                                             |  |
| defaultbinding.virtual.host        | Specifies the default name for a virtual host.                                                                                                                                                                                                                                                                 |  |
| depl.extension.reg                 | Deprecated. No replication option is available.                                                                                                                                                                                                                                                                |  |
| deployejb                          | <p>Specifies to run the EJBDeploy tool during installation. This option does not require a value.</p> <p>If you pre-deploy the application Enterprise Archive (EAR) file using the EJBDeploy tool then the default value is <code>nodeployejb</code>. If not, the default value is <code>deployejb</code>.</p> |  |
| deployejb.classpath                | Specifies an extra class path for the EJBDeploy tool.                                                                                                                                                                                                                                                          |  |
| hdeployejb.dbschema                | Specifies the database schema for the EJBDeploy tool.                                                                                                                                                                                                                                                          |  |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                    |  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| deployejb.dbtype   | <p>Specifies the database type for the EJBDeploy tool.</p> <p>Possible values include:</p> <p>CLOUDSCAPE_V5<br/> DB2UDB_V72<br/> DB2UDB0S390_V6<br/> DB2UDBISERIES<br/> INFORMIX_V73<br/> INFORMIX_V93<br/> MSSQLSERVER_V7<br/> MSSQLSERVER_2000<br/> ORACLE_V8<br/> ORACLE_V9I<br/> SYBASE_V1200</p> <p>For a list of current supported database vendor types, run <code>ejbdeploy -?</code>.</p> |  |
| deployejb.rmic     | <p>Specifies extra RMIC options to use for the EJBDeploy tool.</p>                                                                                                                                                                                                                                                                                                                                 |  |
| deployws           | <p>Specifies to deploy Web services during installation. This option does not require a value.</p> <p>The default value is: <code>nodeployws</code>.</p>                                                                                                                                                                                                                                           |  |
| deployws.classpath | <p>Specifies the extra class path to use when you deploy Web services.</p>                                                                                                                                                                                                                                                                                                                         |  |
| deployws.jardirs   | <p>Specifies the extra extension directories to use when you deploy Web services.</p>                                                                                                                                                                                                                                                                                                              |  |
| distributeApp      | <p>Specifies that the application management component distributes application binaries. This option does not require a value.</p> <p>This setting is the default.</p>                                                                                                                                                                                                                             |  |

| server | <p>Specifies the server name to install or update an entire application or to update an application in order to add a new module. If you want to update an application, this option only applies if the application contains a new module that does not exist in the installed application.</p> <p>You cannot use the <code>-cluster</code> and <code>-server</code> options together. If you want to deploy an application and specify the HTTP server during the deployment so that the application will appear in the generated <code>plugin-cfg.xml</code> file, you must first install the application with a target of <code>-cluster</code>. After you install the application and before you save, use <b>edit</b> command of the <code>AdminApp</code> object to add the additional mapping to the Web server.</p> |  |

| update | <p>Updates the installed application with a new version of the enterprise archive file (EAR) file. This option does not require a value.</p> <p>The application that is being updated, which is specified by the appname option, must already be installed in the WebSphere Application Server configuration. The update action merges bindings from the new version with the bindings from the old version, uninstalls the old version, and installs the new version. The binding information from new version of the EAR file is preferred over the corresponding one from the old version. If any element of binding is missing in the new version, the corresponding element from the old version is used.</p> |  |

**Usage table for the options of the AdminApp object install, installInteractive, update, updateInteractive, edit, and editInteractive commands:**

This table lists all of the options available for the **install**, **installInteractive**, **update**, **updateInteractive**, **edit**, and **editInteractive** commands of the AdminApp object.

The table indicates the applicable commands for each option.

| Option name                  | install and install Interactive commands - install an application | update and update Interactive commands - Update an application | update and update Interactive commands - Add a module | update and update Interactive commands - Update a module | edit and edit Interactive commands - Edit an application | edit and edit Interactive commands - Edit a module |

## Pattern matching with the wsadmin tool

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use pattern matching when you install, edit, or update an application. Pattern matching simplifies the task of supplying required values for certain complex options by allowing you to pass in asterisk (\*) to all of the required values that cannot be edited. For more information about installing, editing, or updating an application, see the “Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands” on page 768 article.

The following example uses pattern matching to install an application with the MapModulesToServers option:

- To install all WAR and JAR files to WebSphere Application Server:cell=myCell,node=myNode,server=myServer, use the following examples:
  - Using Jacl:
 

```
$AdminApp install DefaultApplication.ear {-appname TEST
-MapModulesToServers {{.* .* WebSphere:cell=myCell,node=myNode,server=myServer}}}
```
  - Using Jython:
 

```
AdminApp.install('DefaultApplication.ear', ['-appname', 'TEST',
'-MapModulesToServers', [['.*', '.*', 'WebSphere:cell=myCell,node=myNode,server=myServer']]])
```
- To install all WAR file to WebSphere Application Server :cell=myCell,node=myNode,server=myServer and all JAR files to WebSphere Application Server:cell=myCell,node=yourNode,server=yourServer, use the following examples:
  - Using Jacl:
 

```
$AdminApp install DefaultApplication.ear {-appname TEST -MapModulesToServers
{{.* .*war,.* WebSphere:cell=myCell,node=myNode,server=myServer}
{.* .*jar,.* WebSphere:cell=myCell,node=yourNode,server=yourServer}}}
```
  - Using Jython:
 

```
AdminApp.install('DefaultApplication.ear', ['-appname', 'TEST',
'-MapModulesToServers', [['.*', '.*war,.*', 'WebSphere:cell=myCell,
node=myNode,server=myServer'], ['.*', '.*jar,.*',
'WebSphere:cell=myCell,node=yourNode,server=yourServer']]])
```

Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

## Example: Obtaining option information for AdminApp object commands

Use the **taskInfo** command of the AdminApp object to obtain information about the data that is needed for your application.

You need to provide data for rows or entries that are either missing information, or require an update.

- You can use the **options** command to see the requirements for an enterprise archive file (EAR) file if you construct installation command lines. The **taskInfo** command provides detailed information for each task option with a default binding applied to the result.
- The options for the AdminApp **install** command can be complex if you specify various types of binding information, for example, Java Naming and Directory Interface (JNDI) name, data sources for enterprise bean modules, or virtual hosts for Web modules. An easy way to specify command-line installation options is to use a feature of the **installInteractive** command that generates the options for you. After you install the application interactively once and specify all the updates that you need, look for message WASX7278I in the wsadmin output log. The default output log for wsadmin is wsadmin.traceout. You can cut and paste the data in this message into a script, and modify it.

## Commands for the AdminTask object

Use the AdminTask object to run an administrative command.

Administrative commands are discovered dynamically when you start the wsadmin tool. The administrative commands that are available for you to use, and what you can do with them, depends on the edition of WebSphere Application Server that you have.

You can start the scripting client without having a server running by using the **-conntype NONE** option with the wsadmin tool. The AdminTask administrative commands are available in both connected and local modes. If a server is currently running, it is not recommended to run the AdminTask commands in local mode because any configuration changes made in local mode are not reflected in the running server configuration and vice versa. If you save a conflicting configuration, you can corrupt the configuration.

In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you cannot update the configuration because the configuration for these server processes are copies of the master configuration, which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. To change a configuration, do not run a scripting client in local mode on a node machine because this is not supported.

The following AdminTask commands are available but do not belong to a group:

Some of the information in the table is split on multiple lines for printing purposes.

| Command name: | Description: | Target object: | Parameters and return values: | Examples:                                                                                                                                                                                                                                                                                                |

### Service integration commands

The service integration functionality within the product provides a highly-flexible messaging system that supports a service-oriented architecture with a wide spectrum of quality of service options, supported protocols, and messaging patterns. It supports both message-oriented and service-oriented applications.

A variety of administrative commands are available for service integration, such as bus administrative commands, messaging engine administrative commands, mediation administrative commands, and so on. For information on the service integration commands, click on the administering applications section of the information center navigation, then click on Administering WebSphere applications, and then finally click on Service integration.

### Administrative command invocation syntax

The administrative command uses a specific syntax to invoke operations.

You can use an administrative command in batch mode or in interactive mode. The following syntax is used for an administrative command:

### Using Jacl:

```
$AdminTask cmdName [targetObject] [options]
```

where options include:

```
{  
  [-paramName paramValue] [-paramName] ...  
  [-stepName {{stepParamValue ...} ...} ...]  
  [-delete {-stepName {{stepKeyParamValue ...} ...} ...} ...]  
  [-interactive]  
}
```

or

```
{  
  [-paramName paramValue] [-paramName] ...  
  [-stepName {{stepParamName stepParamValue} {stepParamName stepParamValue} ...}]  
  [-delete {-stepName {{stepKeyParamValue ...} ...} ...} ...]  
  [-interactive]  
}
```

### Using Jython:

```
AdminTask.cmdName(['targetObject'], [options])
```

where options include:

```
'[  
  [-paramName paramValue] [-paramName ...]  
  [-stepName [[stepParamValue ...] ...] ...]  
  [-delete [-collectionStepName [[stepKeyParamValue ...] ...] ...] ...]  
  [-interactive]  
]'
```

or

```
'[  
  [-paramName paramValue] [-paramName ...]  
  [-stepName [[stepParamName stepParamValue] [stepParamName stepParamValue] ...]]  
  [-delete [-collectionStepName [[stepKeyParamValue ...] ...] ...] ...]  
  [-interactive]  
]'
```

where:

|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cmdName      | represents the name of an administrative command to run.                                                                                                                                                                                                                                                                           |
| targetObject | represents the target object on which the command operates. Depending on the administrative command, this input can be required, optional, or nonexistent. This input corresponds to the Target object that is displayed in the command-specific help.                                                                             |
| paramName    | represents the parameter name of the command that was run. Depending on the administrative command, this input can be required, optional, or nonexistent. Each parameter name corresponds to an argument name that is displayed in the Arguments area of the command-specific help.                                                |
| paramValue   | represents the parameter value to set for the preceding parameter name. Parameters are specified as name-value pairs. The parameter value is not required if a parameter has Boolean as its value type. If you specify the parameter name only, without specifying a value for a Boolean type parameter, the value is set to true. |
| stepName     | represents the step name of the command. This input corresponds to a step name that is displayed in the Steps area of the command-specific help.                                                                                                                                                                                   |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>stepParamName</code>         | represents the parameter name for a step. Depending on the administrative command, this input can be required, optional, or nonexistent. Each parameter name corresponds to an argument name that displays in the step area of the command-specific help.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stepParamValue ...</code>    | represents the values of the parameters for a step. Provide all the parameter values of a step in the correct order, as displayed in the step-specific help. For any optional parameters that you do not want to specify a value, put "" instead of the value. If a command step is a collection type, for example, it contains multiple objects where each object has the same set of parameters. You can specify multiple objects with each object enclosed by a pair of braces. For collection type steps, each step parameter is a key or a non-key. Key parameters in a step are used to uniquely identify an object in the collection. If data exists in the step, key parameter values that are provided in the input are compared with key parameter values in the existing data. If a match is found, the existing data is updated. Otherwise, if the specified step supports the addition of new objects, the input values are added. |
| <code>delete</code>                | represents the option to delete existing data from a specified step that supports collection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>collectionStepName</code>    | represents the collection step name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>stepKeyParamValue ...</code> | represents the values of key parameters to uniquely identify an object to delete from a collection step. You must provide the key parameter values of an object in the order that they are displayed in the step specific help.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>interactive</code>           | represents the option to enter interactive mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>[ ]</code>                   | represents a Jython list bracket.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>[ ]</code>                   | indicates that the parameters or options inside the brackets are optional. Do not type these brackets as part of the syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Properties used by scripted administration

This article explains the Java properties that are used by scripted administration. Three levels of default property files load before any property file that is specified on the command line. The first level represents an installation default, located in the properties directory for each WebSphere Application Server profile called `wsadmin.properties`. The second level represents a user default, and is located in the Java user.home property. This properties file is also called `wsadmin.properties`. The third level is a properties file that is pointed to by the `WSADMIN_PROPERTIES` environment variable. This environment variable is defined in the environment where the `wsadmin` tool starts. If one or more of these property files is present, they are interpreted before any properties file that is present on the command line. These three levels of property files load in the order that they are specified. The properties file that is loaded last overrides the ones loaded earlier.

The following Java properties are used by scripting:

### **`com.ibm.ws.scripting.classpath`**

Searches for classes and resources, and is appended to the list of paths.

### **`com.ibm.ws.scripting.connectionType`**

Determines the connector to use. This value can either be SOAP, RMI, or NONE. The `wsadmin.properties` file specifies SOAP as the connector.

### **`com.ibm.ws.scripting.host`**

Determines the host to use when attempting a connection. If not specified, the default is the local machine.

### **`com.ibm.ws.scripting.port`**

Specifies the port to use when attempting a connection. The `wsadmin.properties` file specifies 8879 as the SOAP port for a single server installation.

### **com.ibm.ws.scripting.defaultLang**

Indicates the language to use when running scripts. The `wsadmin.properties` file specifies Jacl as the scripting language.

The supported scripting languages are Jacl and Jython.

### **com.ibm.ws.scripting.traceString**

Turns on tracing for the scripting process. The default has tracing turned off.

### **com.ibm.ws.scripting.traceFile**

Determines where trace and log output is directed. The `wsadmin.properties` file specifies the `wsadmin.traceout` file that is located in the `logs` directory of each WebSphere Application Server profile as the value of this property.

If multiple users work with the `wsadmin` tool simultaneously, set different `traceFile` properties in the user properties files. If the file name contains double-byte character set (DBCS) characters, use a unicode format, such as `\uxxxx`, where `xxxx` is a number.

### **com.ibm.ws.scripting.validationOutput**

Determines where the validation reports are directed. The default file is `wsadmin.valout` which is located in the `logs` directory of each WebSphere Application Server profile.

If multiple users work with the `wsadmin` tool simultaneously, set different `validationOutput` properties in the user properties files. If the file name contains double-byte character set (DBCS) characters, use unicode format, such as `\uxxxx`, where `xxxx` is a number.

### **com.ibm.ws.scripting.emitWarningForCustomSecurityPolicy**

Controls whether the `WASX7207W` message is emitted when custom permissions are found.

The possible values are `true` and `false`. The default value is `true`.

### **com.ibm.ws.scripting.tempdir**

Determines the directory to use for temporary files when installing applications.

The Java virtual machine API uses `java.io.tmp` as the default value.

### **com.ibm.ws.scripting.validationLevel**

Determines the level of validation to use when configuration changes are made from the scripting interface.

Possible values are: `NONE`, `LOW`, `MEDIUM`, `HIGH`, `HIGHEST`. The default is `HIGHEST`.

### **com.ibm.ws.scripting.crossDocumentValidationEnabled**

Determines whether the validation mechanism examines other documents when changes are made to one document.

Possible values are `true` and `false`. The default value is `true`.

### **com.ibm.ws.scripting.profiles**

Specifies a list of profile scripts to run automatically before running user commands, scripts, or an interactive shell.

The `wsadmin.properties` file specifies `securityProcs.jacl` and `LTPA_LDAPSecurityProcs.jacl` as the values of this property. If Jython is specified with the `wsadmin -lang` option, the `wsadmin` tool performs a

conversion to change the profile script names that are specified in this property to use the file extension that matches the language specified. Use the provided script procedures with the default settings to make security configuration easier.

**com.ibm.ws.scripting.echoparams**

Determines if the parameters or arguments output to STDOUT or to a wsadmin log file. The default setting, `true`, outputs the parameters or arguments to a log file.

**com.ibm.ws.scripting.appendTrace**

Determines if the trace file appends to the end of the existing log file. The default setting, `false`, overrides the log file on each invocation.

---

## Chapter 4. Using administrative programs (JMX)

This topic describes how to use Java application programming interfaces (APIs) to administer WebSphere Application Server and to manage your applications.

You can administer WebSphere Application Server and your applications through tools that come with the product or through programming with the Java APIs.

The wsadmin scripting tool, the administrative console, and the administrative command-line tools come with the product. These administrative tools provide most of the functions that you need to manage the product and the applications that run in WebSphere Application Server. You can use the command-line tools from automation scripts to control the servers. Scripts that are written for the wsadmin scripting tool offer a wide range of possible custom solutions that you can develop quickly.

Investigate these tools with the Java APIs to determine the best ways to administer WebSphere Application Server and your applications. For information on the Java APIs, view Java Management Extensions (JMX) API documentation.

WebSphere Application Server supports access to the administrative functions through a set of Java classes and methods. You can write a Java program that performs any of the administrative features of the WebSphere Application Server administrative tools. You can also extend the basic WebSphere Application Server administrative system to include your own managed resources.

You can prepare, install, uninstall, edit, and update applications through programming. Preparing an application for installation involves collecting various types of WebSphere Application Server-specific binding information to resolve references that are defined in the application deployment descriptors. This information can also be modified after installation by editing a deployed application. Updating consists of adding, removing or replacing a single file or a single module in an installed application, or supplying a partial application that manipulates an arbitrary set of files and modules in the deployed application. Updating the entire application uninstalls the old application and installs the new one. Uninstalling an application removes it entirely from the WebSphere Application Server configuration.

Perform any or all of the following tasks to manage WebSphere Application Server and your Java 2 Platform, Enterprise Edition (J2EE) applications through programming.

- Create a JMX remote client program by using the JMX remote API (JSR 160)..  
This topic describes how to develop a JMX remote program that uses the JMX remote API (JSR 160) to access the WebSphere Application Server administrative system.
- Create a custom Java administrative client program using the Java administrative APIs.  
This topic describes how to develop a Java program that uses the WebSphere Application Server administrative APIs to access the administrative system of WebSphere Application Server.
- Extend the WebSphere Application Server administrative system with custom MBeans.  
This topic describes how to extend the WebSphere Application Server administration system by supplying and registering new JMX MBeans in one of the Application Server processes. In this case, you can use the administrative classes and methods to add newly managed objects to the administrative system.
- Deploy and manage a custom Java administrative client program for use with multiple Java 2 Platform, Enterprise Edition application servers.  
This topic describes how to connect to a J2EE server, and how to manage multiple vendor servers.
- Manage applications through programming  
This topic describes how, through Java MBean programming, to install, update, and delete a J2EE application on WebSphere Application Server.
- Extend application management operations through programming

This topic describes how, through programming, to use the common deployment framework to add additional logic to application management operations.

Depending on which tasks you complete, you have created your own administrative program, extended the WebSphere Application Server administrative console, connected and managed vendor servers, or managed your applications through programming.

You can continue to administer WebSphere Application Server and your applications through programming or in combination with the tools that come with the WebSphere Application Server.

---

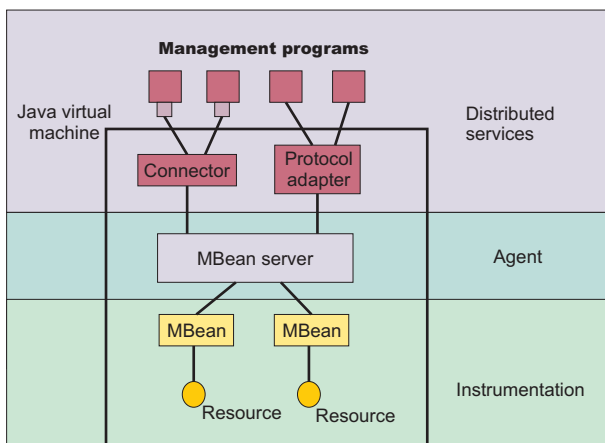

## Java Management Extensions

This topic gives an overview of Java Management Extensions (JMX) in general and how this standard applies to WebSphere Application Server.

### Java Management Extensions overview

Java Management Extensions (JMX) is the Java standard for managing application resources. The management architecture that is defined by JMX is divided into three levels:

- The bottom level is management instrumentation. Each manageable resource is described by an interface that specifies the attributes it has, the operations it supports, and the notifications it sends. This resource is a managed bean (MBean).
- The middle level is the management agent. Each managed process contains a JMX agent that includes an MBean server, which provides a registry and access point for MBeans. Management clients must use the MBean server to access the registered MBeans.
- The top level of the architecture is identified, but undefined in the current level of the JMX specification. It is the distributed services level, and its role is to facilitate remote access to JMX agents. This task is accomplished through connectors, which provide a protocol-independent, location-transparent, client-side interface to the MBean server (for example, a Remote Method Invocation (RMI) connector), or protocol adapters, which provide protocol-specific, server-side access to the MBean server (for example, an HTTP adapter).

### Java Management Extensions in WebSphere Application Server

Java Management Extensions (JMX) is at the core of Application Server administration capabilities. The application server contains a JMX agent. All of the system components are defined as MBeans. The JMX agent in Application Server supports three types of connectors, Remote Method Invocation/Internet Inter-ORB Protocol (RMI/IIOP), Simple Object Access Protocol/Hypertext Transfer Protocol (SOAP/HTTP),

and Simple Object Access Protocol/Hypertext Transfer Protocol Secure (SOAP/HTTPS), which provides remote access to the server resources. All of the administration tools included with Application Server use these JMX facilities to accomplish their functions.

In a stand-alone Application Server installation, servers exist and are administered individually. An administrative client connects directly to the Application Server in this environment.

In a Network Deployment installation, a hierarchical topology groups application servers within nodes and groups nodes within a cell. Administrative servers exist at the node level (node agents) and at the cell level (the deployment manager), and act as aggregation points for the administrative services in the subordinate servers.

MBeans in all servers on a node are visible through that node agent, and MBeans in all nodes are visible through the deployment manager. Therefore, by connecting to the deployment manager, you can invoke operations, can get and set attributes, and can receive notifications for any MBean in the cell. Application Server provides an AdminService class that reflects the standard JMX MBeanServer interface, and wraps the MBeanServer interface so that it takes part in implementing this distributed management functionality.

---

## Creating a custom Java administrative client program using WebSphere Application Server administrative Java APIs

This section describes how to develop a Java program for accessing the WebSphere Application Server administrative system by using the WebSphere Application Server administrative application programming interfaces (APIs).

This task assumes a basic familiarity with Java Management Extensions (JMX) API programming. See the JMX API documentation for information.

When you develop and run administrative clients that use various JMX connectors and that have security enabled, use the following guidelines. When you follow these guidelines, you guarantee the behavior among different implementations of JMX connectors. Any programming model that strays from these guidelines is unsupported.

1. Create and use a single administrative client before you create and use another administrative client.
2. Create and use an administrative client on the same thread.
3. Use one of the following ways to specify a user ID and password to create a new administrative client:

- Specify a default user ID and password in the property file.
- Specify a user ID and password other than the default. Once you create an administrative client with a nondefault user ID and password, specify the nondefault user ID and password when you create subsequent administrative clients.

1. Develop an administrative client program.
2. Build and run the administrative client program.

The steps required to build and run your program depends on the kind of application environment your code runs.

Refer to the Using application clients topic in the *Developing and deploying applications* PDF for details on how to build and run your administrative client program.

## Developing an administrative client program

This topic describes how to develop an administrative client program that utilizes WebSphere Application Server administrative application programming interfaces (APIs) and Java Management Extensions (JMX).

WebSphere Application Server administrative APIs provide control of the operational aspects of your distributed system as well as the ability to update your configuration. This topic also demonstrates examples of MBean operations. For information, view the JMX API documentation or the MBean API documentation.

1. Create an AdminClient instance.

An administrative client program needs to invoke methods on the AdminService object that is running in the deployment manager or the application server in the base installation. The AdminClient class provides a proxy to the remote AdminService object through one of the supported Java Management Extensions (JMX) connectors. The following example shows how to create an AdminClient instance:

```
Properties connectProps = new Properties();
connectProps.setProperty(
AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);

connectProps.setProperty(AdminClient.CONNECTOR_HOST, "localhost");
connectProps.setProperty(AdminClient.CONNECTOR_PORT, "8879");
AdminClient adminClient = null;
try
{
    adminClient = AdminClientFactory.createAdminClient(connectProps);
}
catch (ConnectorException e)
{
    System.out.println("Exception creating admin client: " + e);
}
```

- a. Set up a Properties object.

The example sets up a Properties object with the properties that are required to get to your server. In this case, you use the Simple Object Access Protocol (SOAP) connector to reach the server; for the connector type, use the value: AdminClient.CONNECTOR\_TYPE\_SOAP.

- b. For simplicity, run the client program on the same machine as the server; use localhost for the host name.

To access a remote host instead of a local host, use a network resolvable name for that host.

- c. Set the port number on which the server SOAP connector is listening.

In a single server installation, the default port number for the application server SOAP connector is 8880. In a Network Deployment installation, the default port number for the deployment manager SOAP connector is 8879.

- d. After the connection properties are set, use the AdminClientFactory class and the Properties object to create an AdminClient object that is connected to your chosen server.

Depending on factors such as your desired protocol and security environment, you might need to set other properties. For more detailed information about the AdminClient interface and additional creation examples, refer to the AdminClient interface in the JMX API documentation.

- Find an MBean. When you obtain an AdminClient instance, you can use it to access managed resources in the administration servers and application servers. Each managed resource registers an MBean with the AdminService through which you can access the resource. The MBean is represented by an ObjectName instance that identifies the MBean. An ObjectName instance consists of a domain name followed by an unordered set of one or more key properties. The syntax for the domain name follows:

```
[domainName]:property=value[,property=value]*
```

For WebSphere Application Server, the domain name is WebSphere and the key properties defined for administration are as follows:

|         |                                                                                   |
|---------|-----------------------------------------------------------------------------------|
| type    | The type of MBean. For example: Server, TraceService, Java virtual machine (JVM). |
| name    | The name identifier for the individual instance of the MBean.                     |
| cell    | The name of the cell that the MBean is running.                                   |
| node    | The name of the node that the MBean is running.                                   |
| process | The name of the process that the MBean is running.                                |

Some MBeans in WebSphere Application Server use additional key properties. An MBean without key properties can be registered with the MBean server in a WebSphere Application Server process. However, such an MBean cannot participate in the distributed enhancements that WebSphere Application Server adds, for example, request routing, distributed event notification, and so on.

If you know the complete set of key properties for an ObjectName instance, you can use it to find the MBean it identifies. However, finding MBeans without having to know all of their key properties is usually more practical and convenient. Use the wildcard character asterisk (\*) for any key properties that you do not need to match. The following table provides some examples of object names with wildcard key properties that match single or multiple MBeans.

|                                         |                                                      |
|-----------------------------------------|------------------------------------------------------|
| *:type=Server,*                         | All MBeans of type Server                            |
| *:node=Node1,type=Server,*              | All MBeans of type Server on Node1                   |
| *:type=JVM,process=server1,node=Node1,* | The JVM MBean in the server named server1 node Node1 |
| *:process=server1,*                     | All MBeans in all servers named server1              |
| *:process=server1,node=Node1,*          | All MBeans in the server named server1 on Node1      |

You can locate an MBean by querying for it with object names that match key properties. The following example shows how to find the MBean for the node agent of node, MyNode:

```
String nodeName = "MyNode";
String query = "WebSphere:type=NodeAgent,node=" + nodeName + ",*";
ObjectName queryName = new ObjectName(query);
ObjectName nodeAgent = null;
Set s = adminClient.queryNames(queryName, null);
if (!s.isEmpty())
    nodeAgent = (ObjectName)s.iterator().next();
else
    System.out.println("Node agent MBean was not found");
```

- Build an ObjectName instance with a query string that specifies the key properties of type and node.

By using a wildcard for the remaining key properties, this pattern matches the object names for all MBeans of the type `NodeAgent` on the node `MyNode`. Because only one node agent per node exists, this information is sufficient to identify the MBean that you want.

- b. Give this `ObjectName` instance to the `queryNames` method of the `AdminClient` interface.

The `AdminClient` interface performs the remote call to the `AdminService` interface to obtain the set of MBean object names that match the query. The null second parameter to this method is a query expression (`QueryExp`) object that you can use as an additional query over the MBeans that match the `ObjectName` pattern in the first parameter.

- c. Use the set iterator to get the first and, in this case, only element.

The element is the MBean `ObjectName` instance of the node agent.

3. Use the MBean. What a particular MBean can do depends on the management interface of that MBean. An MBean can declare:

- Attributes that you can obtain or set
- Operations that you can invoke
- Notifications for which you can register listeners
- 

For the MBeans provided by WebSphere Application Server, you can find information about the interfaces they support in the MBean API documentation. The following example invokes one of the operations available on the `NodeAgent` MBean that you located previously. The following example starts the *MyServer* application server:

```
String opName = "launchProcess";
String signature[] = { "java.lang.String" };
String params[] = { "MyServer" };
try
{
    adminClient.invoke(nodeAgent, opName, params, signature);
}
catch (Exception e)
{
    System.out.println("Exception invoking launchProcess: " + e);
}
```

The `AdminClient.invoke` method is a generic means of invoking any operation on any MBean. The parameters are:

- The object name of the target MBean, `nodeAgent`
- The name of the operation, `opName`
- An object array that contains the operation parameters, `params`
- A string array that contains the operation signature, `signature`

The `launchProcess` operation in the example has a single parameter which is a string that identifies the server to start.

The `invoke` method returns an object instance, which the calling code can use to cast to the correct return type for the invoked operation. The `launchProcess` operation is declared void so that you can ignore the return value in this example.

4. Register for events. In addition to managing resources, the JMX API also supports application monitoring for specific administrative events. Certain events produce notifications, for example, when a server starts. Administrative applications can register as listeners for these notifications. The WebSphere Application Server provides a full implementation of the JMX notification model, and provides additional function so you can receive notifications in a distributed environment. For a complete list of the notifications emitted from WebSphere Application Server MBeans, refer to the `com.ibm.websphere.management.NotificationConstants` class in the MBean API documentation. The following example shows how an object can register for event notifications that are emitted from an MBean using the `ObjectName` node agent:

```
adminClient.addNotificationListener(nodeAgent, this, null, null);
```

In this example, the first parameter is the `ObjectName` for the node agent MBean. The second parameter identifies the listener object, which must implement the `NotificationListener` interface. In this case, the calling object is the listener. The third parameter is a filter that you can use to indicate which notifications you want to receive. When you leave this value as `null`, you receive all notifications from this MBean. The final parameter is a handback object that you can use to set the JMX API to return to you when it emits a notification.

If your MBean is located on another server in the cell, you can receive its notifications even though your administrative client program might be connected to the deployment manager server. All notifications flow to the upstream server. For example, a notification from an application server first flows to the local node agent and then to the deployment manager.

Another enhanced feature that Application Server provides is the ability to register as a notification listener of multiple MBeans with one call. This registration is done through the `addNotificationListenerExtended` method of the `AdminClient` interface, an extension of the standard JMX `addNotificationListener` method. This extension method even lets you register for MBeans that are not currently active. This registration is important in situations where you want to monitor events from resources that can be stopped and restarted during the lifetime of your administrative client program.

5. Handle the events. Objects receive JMX event notifications through the `handleNotification` method, which is defined by the `NotificationListener` interface and which any event receiver must implement. The following example is an implementation of the `handleNotification` method that reports the notifications that it receives:

```
public void handleNotification(Notification n, Object handback)
{
    System.out.println("*****");
    System.out.println("* Notification received at " + new Date().toString());
    System.out.println("* type      = " + ntfyObj.getType());
    System.out.println("* message = " + ntfyObj.getMessage());
    System.out.println("* source  = " + ntfyObj.getSource());
    System.out.println(
        "* seqNum   = " + Long.toString(ntfyObj.getSequenceNumber());
    System.out.println("* timeStamp = " + new Date(ntfyObj.getTimeStamp()));
    System.out.println("* userData  = " + ntfyObj.getUserData());
    System.out.println("*****");
}
```

## Administrative client program example

This example is a complete administrative client program.

Copy the contents to a file named `MyAdminClient.java`. After changing the node name and server name to the appropriate values for your configuration, you can compile and run it using the instructions from [Creating a custom Java administrative client program using WebSphere Application Server administrative Java APIs](#)

```
import java.util.Date;
import java.util.Properties;
import java.util.Set;

import javax.management.InstanceNotFoundException;
import javax.management.MalformedObjectNameException;
import javax.management.Notification;
import javax.management.NotificationListener;
import javax.management.ObjectName;

import com.ibm.websphere.management.AdminClient;
import com.ibm.websphere.management.AdminClientFactory;
import com.ibm.websphere.management.exception.ConnectorException;

public class AdminClientExample implements NotificationListener
{
    private AdminClient adminClient;
    private ObjectName nodeAgent;
```

```

private long notifyCount = 0;

## Creating a Java Management Extensions client program using the Java Management Extensions Remote application programming interface

This topic describes how to develop and build a Java Management Extensions (JMX) client program that is compliant with JMX Remote application programming interface (JSR 160). After you have a working JMX client program, you can use it to manage WebSphere Application Server or non-WebSphere Application Server systems.

This task assumes a basic familiarity with JSR 160 and JMX application programming interface (API) programming. For information on JSR 160, see <http://www.jcp.org/en/jsr/detail?id=160>. For information on the JMX APIs, see the JMX API documentation.

When you develop and run JMX clients that use various JMX connectors and that have security enabled, use the following guidelines. When you follow these guidelines, you guarantee the behavior among different implementations of JMX connectors. Any programming model that strays from these guidelines is unsupported.

1. Create and use a single JMX client before you create and use another JMX client.
2. Create and use a JMX client on the same thread.
3. Use one of the following ways to specify a user ID and password to create a new JMX client:
  - Specify a default user ID and password in the property file.
  - Specify a user ID and password other than the default. After you create a JMX client with a nondefault user ID and password, specify the nondefault user ID and password when you create subsequent JMX clients.
1. Develop a JMX client program.
2. Build and run the JMX client program.

The steps that are required to build and run your program depend on the kind of application environment that your code runs. Refer to the Using application clients topic in the *Developing and deploying applications* PDF for details on how to build and run your JMX client program.

You have developed, built, and run a JMX client program that is JSR 160 compliant.

## Developing a Java Management Extensions client program using Java Management Extensions Remote application programming interface

This topic describes how to develop a Java Management Extensions (JMX) connector specification and JMX Remote application programming interface (API) (JSR 160). The program can communicate by Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP)

This topic assumes a basic understanding of JSR 160, JMX APIs, and managed beans (MBeans). For more information on JSR 160, see <http://www.jcp.org/en/jsr/detail?id=160>. For more information on the JMX APIs, see the JMX API documentation. For more information on MBeans, see the MBean API documentation.

You can administer your WebSphere Application Server environment through the administrative console, the wsadmin utility, or Java Management Extensions (JMX) programming. This topic discusses how to develop a JMX remote client program using the JMX remote API so that you can administer your WebSphere Application Server environment through JMX programming.

1. Specify the JMX connector address for the server through the JMXServiceURL class.  
The form of the JMXServiceURL class is `service:jmx:rmi://host name:port/jndi/JMXConnector`
2. Specify the user ID and password for the server, if security is enabled.
3. Establish the JMX connection.
4. Get the MBean server connection instance.

You have established a connection to WebSphere Application Server through an RMI connection and started the WebSphere Application Server through the node agent.

---

## Extending the WebSphere Application Server administrative system with custom MBeans

You can extend the WebSphere Application Server administration system by supplying and registering new Java Management Extensions (JMX) MBeans (see JMX 1.x Specification for details) in one of the WebSphere processes.

JMX MBeans represent the management interface for a particular piece of logic. All of the managed resources within the standard WebSphere infrastructure are represented as JMX MBeans. There are a variety of ways in which you can create your own MBeans and register them with the JMX MBeanServer running in any WebSphere process. For more information, view the MBean API documentation.

### 1. Create custom JMX MBeans.

You have some alternatives to select from, when creating MBeans to extend the WebSphere administrative system. You can use any existing JMX MBean from another application. You can register any MBean that you tested in a JMX MBean server outside of the WebSphere Application Server environment in a WebSphere Application Server process, including standard MBeans, dynamic MBeans, open MBeans, and model MBeans.

In addition to any existing JMX MBeans, and ones that were written and tested outside of the WebSphere Application Server environment, you can use the special distributed extensions provided by WebSphere and create a WebSphere ExtensionMBean provider. This alternative provides better integration with all of the distributed functions of the WebSphere administrative system. An ExtensionMBean provider implies that you supply an XML file that contains an MBean Descriptor based on the DTD shipped with the WebSphere Application Server. This descriptor tells the WebSphere system all of the attributes, operations, and notifications that your MBean supports. With this information, the WebSphere system can route remote requests to your MBean and register remote Listeners to receive your MBean event notifications.

All of the internal WebSphere MBeans follow the Model MBean pattern. Pure Java classes supply the real logic for management functions, and the WebSphere MBeanFactory class reads the description of these functions from the XML MBean Descriptor and creates an instance of a ModelMBean that matches the descriptor. This ModelMBean instance is bound to your Java classes and registered with the MBeanServer running in the same process as your classes. Your Java code now becomes callable from any WebSphere Application Server administrative client through the ModelMBean created and registered to represent it.

### 2. Optionally define an explicit MBean security policy.

If you do not define an MBean security policy, WebSphere Application Server uses the default security policy.

### 3. Register the new MBeans. There are various ways to register your MBean.

You can register your MBean with the WebSphere Application Server administrative service.

You can register your MBean with the MBeanServer in a WebSphere Application Server process. The following list describes the available options in order of preference:

- Go through the MBeanFactory class. If you want the greatest possible integration with the WebSphere Application Server system, then use the MBeanFactory class to manage the life cycle of your MBean through the activateMBean and deactivateMBean methods of the MBeanFactory class. Use these methods, by supplying a subclass of the RuntimeCollaborator abstract superclass and an XML MBean descriptor file. Using this approach, you supply a pure Java class that implements the management interface defined in the MBean descriptor. The MBeanFactory class creates the actual ModelMBean and registers it with the WebSphere Application Server administrative system on your behalf.

This option is recommended for registering model MBeans.

- Use the JMXManageable and CustomService interface. You can make the process of integrating with WebSphere administration even easier by implementing a CustomService interface that also implements the JMXManageable interface. Using this approach, you can avoid supplying the RuntimeCollaborator. When your CustomService interface is initialized, the WebSphere

MBeanFactory class reads your XML MBean descriptor file and creates, binds, and registers an MBean to your CustomService interface automatically. After the shutdown method of your CustomService is called, the WebSphere Application Server system automatically deactivates your MBean.

- Go through the AdminService interface. You can call the registerMBean() method on the AdminService interface and the invocation is delegated to the underlying MBeanServer for the process, after appropriate security checks. You can obtain a reference to the AdminService using the getAdminService() method of the AdminServiceFactory class.

This option is recommended for registering standard, dynamic, and open MBeans. Implement the UserCollaborator class to use the MBeans and to provide a consistent level of support for them across distributed and z/OS platforms.

- Get MBeanServer instances directly. You can get a direct reference to the JMX MBeanServer instance running in any WebSphere Application Server process, by calling the getMBeanServer() method of the MBeanFactory class. You get a reference to the MBeanFactory class by calling the getMBeanFactory() method of the AdminService interface.

When a custom MBean is registered directly with the MBean server, the MBean object name is enhanced with the cell, node and process name keys by default. This registration allows the MBean to participate in the distributed features of the WebSphere Application Server administrative system. You can turn off the default behavior by setting the com.ibm.websphere.mbeans.disableRouting custom property.

See the *Installing your application serving environment* PDF for more information on the com.ibm.websphere.mbeans.disableRouting custom property.

Regardless of the approach used to create and register your MBean, you must set up proper Java 2 security permissions for your new MBean code. The WebSphere AdminService and MBeanServer are tightly protected using Java 2 security permissions and if you do not explicitly grant your code base permissions, security exceptions are thrown when you attempt to invoke methods of these classes. If you are supplying your MBean as part of your application, you can set the permissions in the was.policy file that you supply as part of your application metadata. If you are using a CustomService interface or other code that is not delivered as an application, you can edit the library.policy file in the node configuration, or even the server.policy file in the properties directory for a specific installation.

## Best practices for standard, dynamic, and open MBeans

This article discusses recommended guidelines for standard, dynamic, and open MBeans.

The underlying interface for the WebSphere Application Server administrative service is AdminService. Remote access occurs through the AdminControl scripting object.

For WebSphere Application Server Version 5, the MBean registration and capabilities are as follows:

| MBean type                 | Registered with:                                    | Capabilities                                                                                                                                                                                                                      |
|----------------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Model                      | WebSphere Application Server administrative service | Local access is through the WebSphere Application Server administrative service or the MBean server. Remote access is through the WebSphere Application Server administrative service, and WebSphere Application Server security. |
| Standard, dynamic, or open | MBean server                                        | Local access is through the WebSphere Application Server administrative service or the MBean server on the distributed platform.                                                                                                  |

**best-practices:** For V6, you can optionally register standard, dynamic, and open custom MBeans with the WebSphere Application Server administrative service to take advantage of the capabilities that in V5 are available only to model MBeans.

V6 introduces a special run-time collaborator that you use with standard, dynamic or open custom MBeans to register the custom MBeans with the WebSphere Application Server administrative service. The standard, dynamic, and open MBeans display in the administrative service as model MBeans. The administrative service uses the capabilities available to MBeans that are registered with the administrative service.

For WebSphere Application Server Version 6, the MBean registration and capabilities are as follows:

| MBean type                                       | Registered with:                                    | Capabilities                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Model, and optionally standard, dynamic, or open | WebSphere Application Server administrative service | Local access is through the WebSphere Application Server administrative service or the MBean server. Remote access is through the WebSphere Application Server administrative service, and WebSphere Application Server security.                                                                                                                                        |
| Standard, dynamic, or open                       | MBean server                                        | Local access is through the WebSphere Application Server administrative service or the MBean server on the distributed platform. Remote access is through the WebSphere Application Server administrative service, the Java Management Extensions (JMX) Remote application programming interface (API) (JSR 160) client code, and WebSphere Application Server security. |

## Creating and registering standard, dynamic, and open custom MBeans

You can create standard, dynamic, and open custom MBeans and register them with the WebSphere Application Server administrative service.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Perform the following tasks to create and register a standard, dynamic, or open custom MBean.

1. Create your particular MBean class or classes.
2. Write an MBean descriptor in the XML language for your MBean.
3. Register your MBean by inserting code that uses the WebSphere Application Server run-time `com.ibm.websphere.management.UserMBeanCollaborator` collaborator class into your application code.
4. Package the class files for your MBean interface and implementation, the descriptor XML file, and your application Java archive (JAR) file.

After you successfully complete the steps, you have a standard, dynamic, or open custom MBean that is registered and activated with the WebSphere Application Server administrative service.

The following example shows how to create and register a standard MBean with the WebSphere Application Server administrative service:

SnoopMBean.java:

```
/**
 * Use the SnoopMBean MBean, which has a standard mbean interface.
 */
public interface SnoopMBean {
    public String getIdentification();
    public void snoopy(String parm1);
}
```

SnoopMBeanImpl.java:

```
/**
 * SnoopMBeanImpl - SnoopMBean implementation
 */
public class SnoopMBeanImpl implements SnoopMBean {
    public String getIdentification() {
        System.out.println(">>> getIdentification() called...");
        return "snoopy!";
    }

    public void snoopy(String parm1) {
        System.out.println(">>> snoopy(" + parm1 + ") called...");
    }
}
```

Define the following MBean descriptor for your MBean in an .xml file. The getIdentification method is set to run with the unicast option and the snoopy method is set to use the multicast option. These options are used only for z/OS platform applications. The WebSphere Application Server for z/OS options are not applicable to the distributed platforms, but they do not need to be removed. The options are ignored on the distributed platforms. . Some statements are split on multiple lines for printing purposes.

SnoopMBean.xml:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE MBean SYSTEM "MbeanDescriptor.dtd">
<MBean type="SnoopMBean"
    version="5.0"
    platform="dynamicproxy"
    description="Sample SnoopMBean to be initialized inside an EJB.">

    <attribute name="identification" getMethod="getIdentification"
    type="java.lang.String" proxyInvokeType="unicast"/>

    <operation name="snoopy" role="operation" type="void" targetObjectType="objectReference"
    impact="ACTION" proxyInvokeType="multicast">
        <signature>
            <parameter name="parm1" description="test parameter" type="java.lang.String"/>
        </signature>
    </operation>
</MBean>
```

Assume that your MBean is used in an enterprise bean. Register your MBean in the enterprise bean `ejbCreate` method and unregister it in the `ejbRemove` method.

```
//The method MBeanFactory.activateMBean() requires four parameters:
//String type: The type value that you put in this MBean's descriptor. For this example
//the string type is SnoopMBean.
//RuntimeCollaborator co: The UserMBeanCollaborator user MBean collaborator instance
//that you create
//String id: Unique name that you pick
//String descriptor: The MBean descriptor file name
```

```
import com.ibm.websphere.management.UserMBeanCollaborator;
```

```

//Import other classes here.
.
.
.
static private ObjectName snoopyON = null;
static private Object lockObj = "this is a lock";
.
.
.
/**
 * ejbCreate method: Register your MBean.
 */
public void ejbCreate() throws javax.ejb.CreateException {
    synchronized (lockObj) {
        System.out.println(">>> SnoopMBean activating for --|" + this + "|--");
        if (snoopyON != null) {
            return;
        }
        try {
            System.out.println(">>> SnoopMBean activating...");
            MBeanFactory mbfactory = AdminServiceFactory.getMBeanFactory();
            RuntimeCollaborator snoop = new UserMBeanCollaborator(new SnoopMBeanImpl());
            snoopyON = mbfactory.activateMBean("SnoopMBean", snoop, "snoopMBeanId",
"SnoopMBean.xml");
            System.out.println(">>> SnoopMBean activation COMPLETED! --|" + snoopyON + "|--");
        } catch (Exception e) {
            System.out.println(">>> SnoopMBean activation FAILED:");
            e.printStackTrace();
        }
    }
}
.
.
.
/**
 * ejbRemove method: Unregister your MBean.
 */
public void ejbRemove() {
    synchronized (lockObj) {
        System.out.println(">>> SnoopMBean Deactivating for --|" + this + "|--");
        if (snoopyON == null) {
            return;
        }
        try {
            System.out.println(">>> SnoopMBean Deactivating ==|" + snoopyON + "|== for --|"
+ this + "|--");
            MBeanFactory mbfactory = AdminServiceFactory.getMBeanFactory();
            mbfactory.deactivateMBean(snoopyON);
            System.out.println(">>> SnoopMBean Deactivation COMPLETED!");
        } catch (Exception e) {
            System.out.println(">>> SnoopMBean Deactivation FAILED:");
            e.printStackTrace();
        }
    }
}
}

```

Compile the MBean Java files and package the resulting class files with the descriptor .xml file, into the enterprise bean JAR file.

## Setting Java 2 security permissions

You must configure Java 2 security permissions to use Java Management Extension and WebSphere Application Server administrative methods.

When you enable Java 2 security, you must grant Java 2 security permissions to application-specific code for Java Management Extensions (JMX) and WebSphere Application Server administrative privileges. With these permissions, your application code can call WebSphere Application Server administrative methods and JMX methods.

If you are using Java 2 security then you need to verify that your extensions and application server can access the required resources. The following steps show how to configure access for JMX and the application server administrative methods.

- Use the following permission to invoke all the JMX class methods and interface methods:

```
permission javax.management.MBeanPermission "*", "*";
```

Consult the Java Management Extensions (JMX) API documentation for specific actions under the `MBeanPermission` class.

- Use the following permission for WebSphere Application Server administrative application programming interfaces (APIs):

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "AdminPermission";
```

## Administrative security

Access to the Java Management Extension (JMX) administrative subsystem requires role-based access control when administrative security is enabled.

Administrative security is also referred to as *administrative security*. A client, which can be a user or an administrative client program, can access an MBean method only if at least one of the required roles is granted to the client. WebSphere Application Server uses the declarative security approach to specify the security policy on the JMX MBean. This approach has the advantage of not requiring MBean developers to add security code. Moreover, WebSphere Application Server provides a default security policy for an MBean so in most case MBean developers do not need to specify a security policy at all. With WebSphere Application Server, you can define explicit security policy for your MBeans if the default security policy does not meet your specific security requirements.

## Default MBean security policy

This topic discusses the default managed bean (MBean) security policy. In most cases, MBean developers do not need to specify a security policy.

Three types of MBeans exist for the default MBean security policy:

- A configuration type MBean
- A runtime type MBean
- A deployer type MBean

An optional attribute in the MBean descriptor XML file defines the type of MBean.

The `ConfigRepository` MBean is an example of one of a few configuration types. In the `configRepository.xml` descriptor file, the `configureMBean="true"` attribute indicates that the MBean is a configuration type.

```
<MBean type="ConfigRepository"
  version="5.0"
  platform="common"
  description="Management interface for the configuration repository."
  configureMBean="true">
```

The `EJBModule` MBean is an example of deployer type MBeans. In the `EJBModule.xml` descriptor file, the `deployerMBean="true"` attribute indicates that the MBean is a deployer type.

```
<MBean type="EJBModule" j2eeType="EJBModule"
  version="5.0"
  platform="dynamicproxy"
```

```
resourceIdentifierKey="Application"
resourceType="Application"
deployerMBean="true"
description="Management interface for the EJBModule component.">
```

WebSphere Application Server extended role-based access control supports role inheritance. Five administrative roles of administrator, configurator, operator, deployer, and monitor exist. The monitor role is the least privileged administrative role. Users that are granted the monitor role can view the WebSphere Application Server configuration and the run-time status, but cannot make any changes. The other administrative roles each have their own unique set of privileges as well as the same privileges as the monitor role.

The configurator role has permission to modify WebSphere Application Server configuration data. The operator role has permission to change the runtime state, such as the start and stop of administrative resources. A configurator role cannot change the runtime status and conversely an operator role cannot change the WebSphere Application Server configuration. The administrator role includes configurator and operator role, but has more permissions than the union of configurator role and operator role. The administrator role can additionally change the administrative security configuration. A simple picture shows the administrative role inheritance relationship. The deployer role is a combination of the configurator and operator roles for application management. The deployer role has both configurator and operator permission for applications. A diagram shows the administrative role inheritance relationship.

Each MBean method or operation is assigned an impact attribute with a value of either INFO or ACTION. Here are some examples:

- A get method has an impact value of INFO and a write method has an impact value of ACTION.
- In the ConfigRepository MBean, the extract method does not change the configuration data and has an impact value of INFO, while the modify method has an impact value of ACTION.
- In the NodeAgent MBean, which is an operator type of MBean, the terminate method has an impact value of ACTION.

A configuration MBean method that has an impact value of INFO requires the monitor role. A configuration MBean method that has an impact value of ACTION requires the configurator role. A deployer MBean method that has an impact value of INFO requires the monitor role. A deployer MBean method that has an impact value of ACTION requires the deployer role. Because all administrative roles are monitor roles, any administrative role can access configuration MBean methods and deployer MBean methods that have an impact value of INFO. The administrator role is a configurator role and has access to the configuration MBean methods that have an impact value of ACTION.

The default security policy for the configuration MBean is summarized in the following table:

Method impact	Monitor role	Operator role	Configurator role	Deployer role	Administrator role
INFO	X	X	X	X	X

Method impact	Monitor role	Operator role	Configurator role	Deployer role	Administrator role
ACTION			X		X

The default security policy for the operation MBean is summarized in the following table:

Method impact	Monitor role	Operator role	Configurator role	Deployer role	Administrator role
INFO	X	X	X	X	X
ACTION		X			X

The default security policy for the deployer MBean is summarized in the following table:

Method impact	Monitor role	Operator role	Configurator role	Deployer role	Administrator role
INFO	X	X	X	X	X
ACTION		X		X	X

If an MBean has both the `configureMBean` attribute and the `deployerMBean` attribute set to `true`, the required role for all actions is either configurator or monitor. No such MBean is presently defined in the system. Users with the deployer role cannot log in to the administrative console unless that user is also granted the administrator, configurator, operator, or monitor role for the entire cell.

## Defining an explicit MBean security policy

You can explicitly define an MBean security policy for a particular MBean. Use this example to define an MBean security policy.

This task assumes a basic familiarity with MBean programming. For information on MBean programming, see *MBean Java application programming interface (API) documentation*.

Perform the following tasks to define an explicit security policy.

1. Assume that you have an MBean defined by the MBean `sample.xml` descriptor file.
2. Specify the explicit security policy for that MBean in the `sampleSecurity.xml` file. The naming convention is that you must append "Security" to the MBean descriptor file name as the name of the MBean security descriptor file.
3. Place the security policy descriptor file at the same directory where the MBean security descriptor file is so that the MBean loader can find it. This directory is the typical location for the security policy descriptor file. If no MBean security descriptor file is present, the default MBean security policy is used.
4. Specify the MBean name of `sample` in the resource element `resource-name` field of the `sampleSecurity.xml` file so that the MBean policy loader can associate the MBean security policy with the MBean. The MBean security descriptor definition is very similar to the security policy that is defined by the Java 2 Platform, Enterprise Edition (J2EE) deployment descriptor.

You now have an explicitly defined MBean security policy that you can run with an MBean.

The following example describes the MBean security descriptor file format for the `sampleSecurity.xml` file.

Line 2 specifies that an MBean security descriptor schema is defined by the `RolePermissionDescriptor.dtd` file, which is a document type definition (DTD) in WebSphere Application Server.

As shown on line 3, each MBean descriptor file contains a single role-permission element. The administrative security role hierarchy is defined in the security-role elements between line 9 and line 37. The administrative security role has an inheritance relationship.

As defined on line 14 through 21, the operator security role implies the monitor security role, which means that a user with the operator role has all the permissions of the monitor role. As defined between line 30 and line 38, an administrator security role implies both the configurator and operator security role. Every MBean security descriptor file typically has the same role relationship definition so that you can cut and paste this section to your MBean security descriptor file.

One or more method-permission elements are defined after the security-role element. Each method-permission element defines the required roles for one or more methods. Specify method parameters to avoid method name collision in case multiple methods have the same name.

```
1. <?xml version="1.0" encoding="UTF-8"?>
2. <!DOCTYPE role-permission SYSTEM "RolePermissionDescriptor.dtd" >
3. <role-permission>
4.   <resource>
5.     <resource-name>sample</resource-name>

91.     </method>
92. </method-permission>
93. </role-permission>

```

## Specifying fine-grained MBean security in the MBean descriptor

To implement fine-grained administrative security, your code must identify the resource instance that the managed bean (MBean) represents and assign the user the required role for that instance of the resource. This topic discusses what to do to identify the resource and assign the required role. This topic also discusses how to make an MBean method run under a different user identity so that the method can access other resource instances. Lastly, this topic discusses how to check if an MBean method has access to a resource instance by using programmatic interfaces.

This task assumes a basic familiarity with MBean programming. For information on MBean programming, see MBean Java application programming interface (API) documentation.

Perform the following task to ensure that an MBean or MBean method is protected. Identify the resource instance that the MBean or MBean method represents and assign required roles to access the MBean. Perform this task during the development of the MBean.

1. Determine the resource instance that the MBean represents and the required roles to invoke the MBean methods.

Every MBean method has a default MBean security policy. When the MBean method uses the default security policy, the resource instance that the MBean represents is assumed to be the server in which the MBean runs. If an MBean or MBean method represents a resource instance other than the server on which it runs, perform the following steps:

- a. Identify the resource instance that the MBean represents.
  - If an MBean, such as the Server MBean, accesses and modifies the server in which the MBean runs, do not specify a security policy to verify that the user invoking the MBean is granted access to the server because the default security policy is in force. In most cases, you use an MBean to access and modify the server.
  - If an MBean that runs inside a server can access and modify resources that do not directly belong to the server, check if the user invoking the MBean is granted access to the instance of the resource before allowing the MBean method to run.

In most cases, identify the resource instance by identifying the key-value pair in the object name of the MBean that represents the resource instance. The `resourceIdentifierKey` attribute defines the key.

For example, you can use the `EJBModule` MBean to access an Enterprise JavaBeans (EJB) module within an application that runs inside the server. In this case, the object name of the `EJBModule` MBean contains a key-value pair. The key is `Application`. The value represents the resource instance that the `EJBModule` MBean tries to access. The user that invokes this MBean method is verified to make sure that access is granted to this instance of the application before allowing the MBean method to run.

The following example shows how to describe the fine-grained administrative security for the `EJBModule` type of MBean in the MBean descriptor:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE MBean SYSTEM "MbeanDescriptor.dtd">
<MBean type="EJBModule" j2eeType="EJBModule"
  version="5.0"
  platform="dynamicproxy"
  resourceIdentifierKey="Application"
  resourceType="Application"
  deployerMBean="true"
  description="Management interface for the EJBModule component.">
```

- If you can determine the resource that the MBean accesses before the MBean is invoked, but you cannot use the MBean object name to determine the resource instance that the MBean accesses, use parameters that are passed to the MBean instead.

Identify the MBean method parameter name with a parameter value that represents the resource instance. Mark the corresponding parameter metadata in the MBean descriptor as the resource identifier. To mark a parameter as the resource identifier, add the `resourceType` attribute. The attribute specifies the type resource that the parameter value contains. When the `resourceType` attribute is present for any MBean method parameter, the parameter value determines the resource instance that the MBean method represents.

For example, one instance of the `ApplicationManager` MBean runs in each server. The same MBean can be used to start and stop all the applications in the server. The start and stop methods of this MBean each take the application name as a parameter. They use the parameter to determine the instance of the application that this MBean method tries to access.

The following example shows how to describe the fine-grained administrative security for this type of MBean in the MBean descriptor:

```
<operation
  description="Start Application"
  impact="ACTION" name="startApplication" role="operation"
  targetObjectType="objectReference" type="void" proxyInvokeType="spray">
  <signature>
    <parameter description="Application Name" resourceType="Application"
      name="applicationName" type="java.lang.String"/>
  </signature>
</operation>
```

- If the resource that an MBean accesses cannot be determined until the MBean is invoked, check if the user invoking the MBean is granted access to the instance of the resource by using application programming interfaces (APIs).

Mark the MBean or MBean method as excluded from access checking in the MBean descriptor by using the `excludeAccessCheck` attribute. When an MBean is marked as excluded from access checking, all its methods are also excluded from access checking.

For example, the `ConfigService` MBean that runs in the deployment manager is used to configure all the resources within a cell. Exclude this MBean from access checking before invoking the MBean methods. Check that the `ConfigService` MBean is granted access to the configuration resource when the MBean attempts to access the resource.

The following example shows how to describe the fine-grained administrative security for the `ConfigServices` type of MBean in the MBean descriptor:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE MBean SYSTEM "MbeanDescriptor.dtd">
<MBean
  version="5.0"
  platform="proxy"
  collaboratorClass="com.ibm.ws390.management.proxy.ConfigServiceManager"
  description="Config Service component provides service of
configuration related tasks on top of configuration repository service."
  type="ConfigService"
  excludeAccessCheck="true"
  configureMBean="true">
```

Some statements are split on multiple lines for printing purposes.

The following example shows how to invoke the MBean method logic to perform authorization checking programmatically:

```
// Get administration authorizer.
AdminAuthorizer aa = AdminAuthorizerFactory.getAdminAuthorizer();
// Set the role that is required for this operation.
String role = com.ibm.ws.security.util.Constants.CONFIG_ROLE;
// Set the resource name.
// cells/cellName is optional.
String resource = "/nodes/" + nodeName + "/servers/" + serverName;
// Check access
if ( aa != null && !aa.checkAccess(resource, role) )
  // Disallow access.
  else
    // Allow access.
```

- b. Assign required roles for the MBean and MBean methods.

The required roles are automatically assigned, based on the type of MBean and the impact of the MBean method, as described in the topic on the default MBean security policy.

## 2. Specify delegation mode.

In some cases, after performing the initial access check, the MBean method might need to run under a different user identity so that it can access other resource instances. For example the `syncNode` operation in the `CellSync` MBean grants the user the operator role to the instance of the node being synchronized. The `syncNode` operation tries to access resources under the cell scope. The user might not have access to open files under the cell directory. The MBean must run as `System` after the initial access check so that the operation completes without any access denied problems.

Set the `runAs` attribute to `System` to specify delegation mode for an MBean or MBean method. When you set the `runAs` attribute for an MBean, the value applies to all MBean methods for that MBean.

The following example shows how to describe fine-grained administrative security for the `CellSync` type of MBean in the MBean descriptor.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE MBean SYSTEM "MbeanDescriptor.dtd">
<MBean type="CellSync"
  version="5.0.1"
```

```

    platform="common"
    runAs="System"
    description="Management interface for the configuration synchronization logic
    performed at the central deployment manager for the cell.">
<operation
    description="Initiate a synchronization request for a given node" impact="ACTION"
    name="syncNode" role="operation" targetObjectType="objectReference" type="ja
va.lang.Boolean">
<signature>
<parameter resourceType="Node"
    description="The name of the node"
    name="nodeName" type="java.lang.String"/>
</signature>
</operation>

```

You have determined the type of resource a given MBean method is accessing and performed the necessary access check so that WebSphere Application Server can allow access to the resource.

---

## Administrative programs for multiple Java 2 Platform, Enterprise Edition application servers

You can develop an administrative client to manage multiple vendor application servers through existing MBean support in the WebSphere Application Server.

### Existence of MBeans for stopped components

**best-practices:** The WebSphere Application Server completely implements the Java 2 Platform, Enterprise Edition (J2EE) Management specification. However, some differences in details between the J2EE specification and the WebSphere Application Server implementation are important for you to understand when you access WebSphere Application Server components. These differences are important to you when you access application MBeans because you can use either the WebSphere Application Server programming model or the J2EE programming model.

In the WebSphere Application Server programming model, if an MBean exists, you can assume that it is running. If an MBean does not exist, you can assume that it is stopped. Transient states between the started state and the stopped state are the same as the stopped state, which means that no MBean exists.

In the J2EE programming model, the MBean always exists regardless of the state of the component.

You can determine the state of a component by querying the state attribute. However, the state attribute only exists for MBeans that are state manageable, meaning that they implement the StateManageable interface. State manageable MBeans have start(), startRecursive(), and stop() operations whether these MBeans are J2EE MBeans or WebSphere Application Server MBeans. Additionally, the WebSphere Application Server defines the stateful interface. The stateful interface means that the component has a state and emits the j2ee.state.notifications method, but that the component cannot directly manage the state. For example, a Web module cannot stop itself. However, the application that contains the Web module can stop it.

Not all MBeans that have a state are state-manageable. Servlets, J2EE modules and enterprise beans, for example, are all stateful, but are not state manageable. The J2EE server is not state-manageable because no start() operation is available on a server.

The J2EEApplication MBean is an example of a state manageable MBean. When the WebSphere Application Server starts, each application activates a J2EEApplication MBean for itself. A J2EEApplication MBean has a J2EE type of J2EEApplication (for example, ObjectName \*\*\*,j2eeType=J2EEApplication). If the application starts, it also activates an Application MBean with a type of Application (for example,

\*,\*,type=Application). When the application changes state, the Application MBean is activated or deactivated. However, the J2EEApplication MBean is always activated. You can retrieve the application state changes by getting the state attribute.

The modules attribute on the J2EEApplication component returns an array of object names, one for every module in the application. The Application Server activates an MBean for each of these modules only after the Application Server starts the application. The managed enterprise bean isRegistered(ObjectName) method returns false if the application, and therefore the module, is not running.

All of the attributes that are defined in the J2EE management specification return valid values when the managed object stops. Other attributes and operations, for example those that are specifically defined for the Application Server, use the com.ibm.websphere.management.exception.ObjectNotRunningException exception if they are accessed when the object is stopped.

If you install the application while the server runs, the application installs the J2EEApplication MBean when the installation completes. Conversely, when the application uninstalls the J2EEApplication MBean, the application deactivates the MBean.

## Mapping key properties

The following table lists the mapping from the J2EE management-defined j2eeType key property to the WebSphere Application Server type key property. You can use either key property to access MBeans. However, only use the j2eeType key property if you want to connect to application servers other than WebSphere Application Server.

<b>j2eeType key property</b>	<b>type key property</b>
J2EEDomain	J2EEDomain [new]
J2EEServer	Server
JVM	JVM
J2EEApplication	Application [separate MBean from j2eeType]
WebModule	WebModule
ResourceAdapterModule	ResourceAdapterModule
EJBModule	EJBModule
EJB and subtypes / Servlet / ResourceAdapter	EJB and subtypes / Servlet / ResourceAdapter
JavaMailResource	MailProvider
JNDIResource	NameServer
JMSResource	JMSProvider
JTAResource	TransactionService
RMI_IIOPResource	ORB
URLResource	URLProvider
JDBCResource	JDBCProvider
JDBCDataSource	DataSource
JDBCDriver	JDBCDriver [new]
JCAResource	J2CResourceAdapter
JCAConnectionFactory	J2CConnectionFactory
JCAManagedConnectionFactory	J2CManagedConnectionFactory [new]

## Optional WebSphere Application Server interfaces

The following table shows the optional J2EE management interfaces that WebSphere Application Server provides. Some `j2eeType` key properties are split on multiples lines for printing purposes.

<b>j2eeType key property</b>	<b>EventProvider interface</b>	<b>StateManageable interface</b>	<b>StatisticsProvider interface</b>
J2EEDomain	No	No	No
J2EEServer	Yes	Stateful	No
JVM	No	No	Yes
J2EEApplication	Yes	Yes	No
WebModule	Yes	Stateful	No
ResourceAdapterModule	Yes	Stateful	No
EJBModule	Yes	Stateful	No
AppClientModule	Yes	Stateful	No
EJB and subtypes / Servlet / ResourceAdapter	No	No	Yes
JavaMailResource	No	No	No
JNDIResource	No	No	No
JMSResource	No	No	No
JTAResource	Yes	No	Yes
RMI_IIOPResource	No	No	Yes
URLResource	No	No	No
JDBCResource	No	No	Yes
JDBCDataSource	No	No	No
JDBCDriver	No	No	No
JCAResource	Yes	No	Yes
JCAConnectionFactory	No	No	No
JCAManagedConnection Factory	No	No	No

---

## Deploying and managing a custom Java administrative client program with multiple Java 2 Platform, Enterprise Edition application servers

This section describes how to connect to a Java 2 Platform, Enterprise Edition (J2EE) server, and how to manage multiple vendor servers.

The WebSphere Application Server completely implements the J2EE Management specification, also known as JSR-77 (Java Specification Requests 77). However, some differences in details between the J2EE specification and the WebSphere Application Server implementation are important for you to understand when you develop a Java administrative client program to manage multiple vendor servers. For information, see the Java 2 Platform, Enterprise Edition (J2EE) Management Specification and the MBean Java application programming interface (API) documentation.

When your administrative client program accesses WebSphere Application Servers exclusively, you can use the Java APIs and WebSphere Application Server-defined MBeans to manage them. If your program needs to access both WebSphere Application Servers and other J2EE servers, use the API defined in the J2EE Management specification.

## 1. Connect to a J2EE server.

Connect to a server by looking up the Management enterprise bean from the Java Naming and Directory Interface (JNDI). The Management enterprise bean supplies a remote interface to the MBean server that runs in the application server. The Management enterprise bean works almost exactly like the WebSphere Application Server administrative client, except that it does not provide WebSphere Application Server specific functionality. The following example shows how to look up the Management enterprise bean.

```
import javax.management.j2ee.ManagementHome;
import javax.management.j2ee.Management;

Properties props = new Properties();

props.setProperty(Context.PROVIDER_URL, "iiop://myhost:2809");
Context ic = new InitialContext(props);
Object obj = ic.lookup("ejb/mgmt/MEJB");
ManagementHome mejbHome = (ManagementHome)
    PortableRemoteObject.narrow(obj, ManagementHome.class);
Management mejb = mejbHome.create();
```

The example gets an initial context to an application server by passing the host and port of the Remote Method Invocation (RMI) connector. You must explicitly code the RMI port, in this case 2809. The lookup method looks up the `ejb/mgmt/MEJB` path, which is the location of the Management enterprise bean home. The example then creates the `mejb` stateless session bean, which you use in the next step.

## 2. Manage multiple vendor application servers.

After you create the `mejb` stateless session bean, you can use it to manage your application servers. Components from the application servers appear as MBeans, which the specification defines. These MBeans all have the `j2eeType` key property. This key property is one of a set of types that the specification defines. All of these types have a set of exposed attributes.

Use the following example to guide you in managing multiple vendor application servers. The example uses the Java virtual machine (JVM) MBean to determine what the current heap size is for the application server.

```
ObjectName jvmQuery = new ObjectName("*:j2eeType=JVM,*");
Set s = mejb.queryNames(jvmQuery, null);
ObjectName jvmMBean = (ObjectName) s.iterator().next();
boolean hasStats = ((Boolean) mejb.getAttribute(jvmMBean,
    "statisticsProvider")).booleanValue();
if (hasStats) {
    JVMStats stats = (JVMStats) mejb.getAttribute(jvmMBean,
        "stats");
    String[] statisticNames = stats.getStatisticNames();
    if (Arrays.asList(statisticNames).contains("heapSize")) {
        System.out.println("Heap size: " + stats.getHeapSize());
    }
}
```

The `queryNames()` method first queries the JVM MBean. The `getAttribute` method gets the `statisticsProvider` attribute and determine if this MBean provides statistics. If the MBean does, the example accesses the `stats` attribute, and then invokes the `getHeapSize()` method to get the heap size.

The strength of this example is that the example can run on any vendor application server. It demonstrates that an MBean can optionally implement defined interfaces, in this case the `StatisticsProvider` interface. If an MBean implements the `StatisticsProvider` interface, you can see if an application server supports a particular statistic, in this case the heap size. The specification defines the heap size, although this value is optional. If the application server supports the heap size, you can display the heap size for the JVM.

---

## Java Management Extensions V1.0 to Java Management Extensions V1.2 migration

You might need to migrate custom MBeans that are supplied by products other than the Application Server from Version 5 to Version 6.x for full compatibility.

Each Java virtual machine (JVM) in WebSphere Application Server includes an embedded implementation of Java Management Extensions (JMX). In Application Server, Version 5, the JVMs contain an implementation of the JMX 1.0 specification. In Application Server, Version 6, the JVMs contain an implementation of the JMX 1.2 specification. The JMX 1.0 implementation used in Version 5 is the TMX4J package that IBM Tivoli products supply. The JMX 1.2 specification used in Version 6 is the open source mx4j package. The JMX implementation change across the releases does not affect the behavior of the JMX MBeans in the Application Server. No Application Server administrative application programming interfaces (APIs) are altered due to the change from the JMX V1.0 specification to the JMX V1.2 specification.

The JMX V1.2 specification is compatible with the earlier JMX V1.0 specification. However, you might need to migrate custom MBeans that are supplied by products other than the Application Server from Version 5 to Version 6. The primary concern for these custom MBeans is related to the values that are used in key properties of the JMX ObjectName class for the MBean. The open source mx4j implementation more stringently enforces property validation according to the JMX 1.2 specification. Test the custom MBeans that you deployed in Version 5 in Version 6.x, to ensure compatibility. Full details of the JMX V1.2 specification changes from the JMX V1.0 specification are available in the JMX 1.2 specification.

---

## Java Management Extensions interoperability

Starting with Version 6, WebSphere Application Server implements Java Management Extensions (JMX) Version 1.2, while WebSphere Application Server Version 5 implements JMX Version 1.0.

### Differences between Version 5 and Version 6

Due to the evolution of the JMX specification, the serialization format for JMX objects, such as the `javax.management.ObjectName` object, differs between the V5 implementation and the V6 and later implementation. The V6 and later JMX run time is enhanced to be aware of the version of the client with which it is communicating. The V6 and later run time makes appropriate transformations on these incompatible serialized formats to support communication between the different version run times.

A V5 `wsadmin` script or a V5 administrative client can call a V6 and later deployment manager, node, or server. A V6 and later `wsadmin` script or a V6 and later administrative client can call a V5 node or server.

When a V5 `wsadmin` script or a V5 administrative client calls a V6 and later MBean, the instances of classes that are new in V6 and later cannot be passed back to V5 because these classes are not present in the V5 environment. The problem occurs infrequently. However, it usually occurs when an exception embeds a nested exception that is new starting with V6. The symptom is usually a `SerializationException` or a `NoClassDefFoundException` exception.

Due to changes in the JMX implementation from V5 to V6, different exceptions are created when a method on an MBean is invoked for V5 than when a method on an MBean is invoked for V6 and later. For example, when a method gets or sets an unknown attribute for V5, the `MBeanRuntimeException` exception is created. When a method gets or sets an unknown attribute for V6 and later, the `MBeanException` exception that wraps a `ServiceNotFoundException` exception is created.

An instance of a user-defined class that implements the `Serializable` interface that is passed as a parameter or return value during MBean invocation, or sent as part of a notification, cannot contain a

non-transient instance variable that is in the `javax.management.package` package. If the instance does, it cannot be properly deserialized when passed between V5 and V6 or later run times.

Due to changes in the supported format for the `ObjectName` class from V5 to V6, the configuration ID in starting with V6 contains a vertical bar (`|`), whereas in V5, the ID contains a colon (`:`). This change is reflected in the output for `wsadmin` clients. For example, for a V5 client, the output is:

```
wsadmin> $AdminConfig list Cell
      DefaultCellNetwork(cells/DefaultCellNetwork:cell.xml#Cell_1)
```

whereas for a V6 and later client, the output is:

```
wsadmin> $AdminConfig list Cell
      DefaultCellNetwork(cells/DefaultCellNetwork|cell.xml#Cell_1)
```

The change to the configuration ID generally is not a problem because configuration IDs are generated dynamically. When a V5 client passes a configuration ID that contains a colon, the JMX run time, for upward compatibility, automatically transforms the configuration ID that contains a colon into a configuration ID that contains a vertical bar. Similarly, a reverse transformation is performed for backward compatibility.

Do not save the configuration ID and then try to use it later. Only query the ID and use it.

## Differences between Version 6.1 and Version 6.0.x

A serialization format mismatch exists between the JMX implementation in V6.1 and V6.0.x releases. When a V6.0.x `wsadmin` script or a V6.0.x administrative client tries to retrieve the `ModelMBeanInfo` interface of a V6.1 MBean, the expected field names are not found in the deserialized object because of the case difference between the versions. For example, the following `wsadmin` function does not work when a V6.0.x `wsadmin` script connects to a V6.1 server:

```
$Help attributes MBeanObjectName
$Help operations MBeanObjectName
$Help all MBeanObjectName
```

where `MBeanObjectName` is a string representation of a V6.1 MBean Object.

To avoid this problem, set the `jmx.serial.form` Java virtual machine (JVM) custom property on the JVM custom properties page in the administrative console. Create the custom property by specifying the name value-pair on the V6.1 Application Server that you are connecting to from a V6.0.x client. The field names are forced to lower case to be compatible with what the V6.0.x client expects. The lower case field names contradict the JMX specification and compromise interoperability with future versions. Therefore, the recommendation is that you set this property only when it is absolutely needed in a mixed version environment.

<b>Property name</b>	<code>jmx.serial.form</code>
<b>Data type</b>	string
<b>Value</b>	1.2.0 or 1.2.1

To access the JVM custom properties page, click:

**Servers > Application Servers > *server1* > Java and Process Management > Process Definition > Java Virtual Machine > Custom Properties**

---

## Managed object metadata

Information about a node, such as operating system platform and product features, is maintained in the configuration repository in the form of properties. As product features are installed on a node, new property settings are added.

WebSphere Application Server system management uses the managed object metadata properties as follows:

- To display the node version in the administrative console
- To ensure that new configuration types or attributes are not created or set on older release nodes
- To ensure that new resource types are not created on old release nodes
- To ensure that new applications are not installed on old release nodes because the old run time cannot support the new applications

## Base properties

The following base property keys are defined for WebSphere Application Server:

**com.ibm.websphere.baseProductVersion:** The version of WebSphere Application Server that is installed.

**com.ibm.websphere.nodeOperatingSystem:** The operating system platform on which the node runs.

**com.ibm.websphere.nodeSysplexName:** The sysplex name on a z/OS operating system. This property applies to the z/OS operating system only.

**com.ibm.websphere.deployed.features:** A list of features that extends a profile. An example of a feature is an administrative console plug-in.

Here are examples of metadata property values. The last item is split on multiple lines for printing purposes.

```
com.ibm.websphere.baseProductVersion=6.0.0.0
com.ibm.websphere.nodeOperatingSystem=os390
com.ibm.websphere.nodeSysplexName=PLEX1
com.ibm.websphere.deployed.features=
  com.ibm.ws.base_6.0.0.0,com.ibm.ws.j2ee_6.0.0.0,
  com.ibm.ws.uddi_6.0.0.0,com.ibm.ws.wsgateway_6.0.0.0
```

For detailed information on metadata properties, view the `ManagedObjectMetadataHelper` class in the Application Server API documentation.

## Accessing managed object metadata properties

An administrator can query managed object metadata through the `wsadmin` tool or Application Server APIs. They can additionally be viewed on the Node Installation properties administrative console panel. This article provides details on the Application Server API method.

An accessor class is used to obtain the managed object metadata properties. An accessor instance is created through its factory. A helper class, which uses the accessor instance, makes it easy to query the base metadata properties. These classes are all part of the `com.ibm.websphere.management.metadata` package in the Application Server API documentation. The specific names of these classes are:

- `com.ibm.websphere.management.metadata.ManagedObjectMetadataHelper`
- `com.ibm.websphere.management.metadata.ManagedObjectMetadataAccessor`
- `com.ibm.websphere.management.metadata.ManagedObjectMetadataAccessorFactory`

---

## Managing applications through programming

Through Java MBean programming, you can install, update, and delete a Java 2 Platform, Enterprise Edition (J2EE) application on WebSphere Application Server.

This task assumes a basic familiarity with MBean programming. For information on MBean programming, see MBean Java application programming interface (API) documentation.

For information on the restarting of updated applications, refer to Fine-grained recycle behavior in *IBM WebSphere Developer Technical Journal: System management for WebSphere Application Server V6 -- Part 5 Flexible options for updating deployed applications*.

Before you can install or change an application on WebSphere Application Server, you must first create or update your application and assemble it using an assembly tool.

Besides installing, uninstalling, and updating applications through programming, you can additionally install, uninstall, and update J2EE applications through the administrative console or the wsadmin tool. All three ways provide identical updating capabilities.

1. Perform any or all of the following tasks to manage your J2EE applications through programming.

- Access the application management function.  
This topic provides examples to access the application management functionality:
  - From WebSphere Application Server code
  - From outside WebSphere Application Server
  - When WebSphere Application Server is not running
- Install an application.  
This topic provides an example for initially installing an application on WebSphere Application Server.
- Uninstall an application.  
This topic provides an example for uninstalling an application that resides on WebSphere Application Server.
- Manipulate additional attributes for a deployed application.  
This topic provides an example for manipulating attributes that are not exposed through the `AppDeploymentTask` object.
- Share sessions for application management.  
This topic provides an example for saving application-specific updates for a deployed application to a session, and then to the configuration repository.
- Update an application.  
This topic provides an example for updating the installed application on WebSphere Application Server with a new application. When you completely update an application, the deployed application is uninstalled and the new enterprise archive (EAR) file is installed.
- Add to, update, or delete part of an application.  
This topic provides an example that you can use to add, update, or delete part of an application on WebSphere Application Server.
- Edit an application.  
This topic provides an example that you can use to edit an application on WebSphere Application Server.
- Add a module.  
This topic provides an example for adding a module to an application that resides on WebSphere Application Server.
- Update a module.  
This topic provides an example for updating a module that resides on WebSphere Application Server. When you update a module, the deployed module is uninstalled and the updated module is installed.
- Delete a module.  
This topic provides an example for deleting a module that resides on WebSphere Application Server. When you delete a module, the deployed module is uninstalled.
- Add a file.

This topic provides an example for adding a file to an application that resides on WebSphere Application Server.

- Update a file.

This topic provides an example for updating a file on WebSphere Application Server. When you update a file, the deployed file is uninstalled and the updated file is installed.

- Delete a file.

This topic provides an example for deleting a file on WebSphere Application Server. When you delete a file, the deployed file is uninstalled.

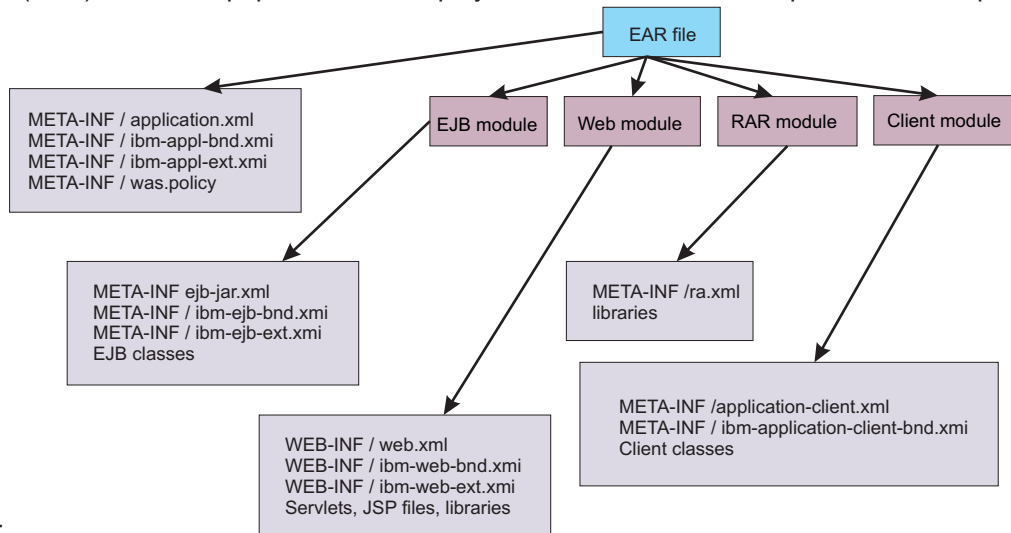

2. Save your changes to the master configuration repository.
3. Synchronize changes to the master configuration across the nodes for the changes to take effect.

If you have further application updates, you can do the updates through programming, the administrative console, or the wsadmin tool.

## Application management

Java 2 Platform, Enterprise Edition (J2EE) applications and modules include an Extensible Markup Language (XML)-based deployment descriptor that specifies various J2EE artifacts that pertain to applications or modules. The J2EE artifacts include Enterprise JavaBeans (EJB) definitions, security role definitions, EJB references, resource references, and so on. These artifacts define various unresolved references that the application logic uses. The J2EE specification requires that these artifacts map to J2EE platform-specific information, such as that found in WebSphere Application Server, during deployment of J2EE applications.

The application assembly tools that WebSphere Application Server supports, as well as the application management support that is provided with the product, facilitate collection of certain WebSphere Application Server information. The collected information is used to resolve references that are defined in various deployment descriptors in a J2EE application. This information is stored in the application EAR file in conjunction with the deployment descriptors. The following diagram shows the structure of an Enterprise Archive (EAR) file that is populated with deployment information that is specific to WebSphere Application

Server.

The application management architecture provides a set of classes with which deployers can collect WebSphere Application Server deployment information. This information is also referred to as *binding information*, and is stored in the application EAR file. The deployer can install the EAR file into a WebSphere Application Server configuration by using the AppManagement interface.

The application management support in WebSphere Application Server provides functions such as installing and uninstalling applications, editing binding information for installed applications, updating the entire application or part of the application, exporting the application, and so on. The `com.ibm.websphere.management.application.AppManagement` interface, which is exposed as a Java Management Extensions (JMX)-based `AppManagement` MBean in WebSphere Application Server, provides this functionality. Code that runs on the server or in a stand-alone administrative client program can access the interface. Access to the application management functions is also possible in the absence of WebSphere Application Server. This mode, known as *local mode*, is particularly useful for installing J2EE applications as part of product installation. For WebSphere Application Server Network Deployment, the `AppManagement` MBean is present in the deployment manager only, which facilitates centralized configuration and administration.

## Application deployment in a Network Deployment configuration

The following diagram explains application deployment for the Network Deployment product:

1. The application EAR file that you install is stored in the master configuration repository of the deployment manager, with the application metadata.
2. The configuration synchronization operation replicates the application in the master repository into the repository of the target node.
3. The application EAR file is extracted to the installation destination of the target node at the end of the synchronization operation.
4. The WebSphere Application Server run time reads the application business logic such as EJB classes, servlets, and JavaServer Pages (JSP) from the installation destination while serving application client requests.
5. WebSphere Application Server reads the application metadata, such as deployment descriptors and WebSphere Application Server bindings during application startup from the configuration repository or the installation destination only, depending on the option that is specified during application installation.

## Accessing the application management function

The `com.ibm.websphere.management.application.AppManagementProxy` class provides uniform access to application management functionality, regardless of whether the functionality is accessed from the server process, administrative client process, or a stand-alone Java program in the absence of WebSphere Application Server. This topic provides code excerpts that demonstrate how to obtain an `AppManagementProxy` instance in a variety of cases.

This task assumes a basic familiarity with WebSphere Application Server programming interfaces and MBean programming. For information on WebSphere Application Server programming interfaces, see application programming interface (API) documentation. For information on MBean programming, see MBean Java application programming interface (API) documentation.

Perform any of the following tasks to access application management functionality through programming.

- To access application management functionality from WebSphere Application Server code, for example, as a custom service, create the `AppManagementProxy` class.

```
AppManagement appMgmt =  
    AppManagementProxy. getJMXProxyForServer();
```

- To access application management functionality from outside WebSphere Application Server through the `AppManagement` MBean, create an administrative client to establish a connection to WebSphere Application Server and then create the `AppManagementProxy` class.

```
AdminClient adminClient = ....
```

```
// create AppManagement proxy object  
AppManagement appMgmt = AppManagementProxy. getJMXProxyForClient (adminClient);
```

- To access application management functionality when WebSphere Application Server is not running (local mode), create the `AppManagementProxy` class.

```
AppManagement appMgmt = AppManagementProxy. getLocalProxy ();
```

- When running in local mode set the `com.ibm.ws.management.standalone` system property to `true`. If you want to modify configuration documents in a non-default location, set the location of the configuration directory through the `was.repository.root` system property.
- Although you can use application management functions with or without WebSphere Application Server running, do not access application management functions concurrently through local mode and the `AppManagement` MBean. Otherwise, updates that are made using these modes can collide and break the integrity of the WebSphere Application Server configuration.

After you successfully create the `AppManagementProxy` class, you have access to application management functionality.

You can perform various management tasks such as installing, uninstalling, editing, and so on.

## Installing an application through programming

You can install an application through the administrative console, the `wsadmin` tool, or programming. Use this example to install an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can install an application on WebSphere Application Server, you must first create or update your application and assemble it using an assembly tool.

Perform the following tasks to install an application through programming.

1. Populate the enterprise archive (EAR) file with WebSphere Application Server-specific binding information.

- a. Create the controller and populate the EAR file with appropriate options.
  - b. Optionally run the default binding generator.
  - c. Save and close the EAR file.
  - d. Retrieve the saved options table that will be passed to the installApplication MBean (API).
2. Connect to WebSphere Application Server.
  3. Create the application management proxy.
  4. If the preparation phase (population of the EAR file) is not performed, then do the following actions:
    - a. Create an options table to be passed to the installApplication MBean API.
    - b. Create a table for module to server relations and add the table to the options table.  
 Refer to the `com.ibm.websphere.management.application.AppManagement` class in the Application Server API documentation to understand various options that can be passed to the installApplication MBean API.
  5. Create the notification filter for listening to installation events.
  6. Add the listener.
  7. Install the application.
  8. Wait for some timeout so that the program does not end.
  9. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
  10. When the installation is done, remove the listener and quit.

After you successfully run the code, the application is installed.

The following example shows how to install an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class Install {

    public static void main (String [] args) {

        try {
            String earFile = "C:/test/test.ear";
            String appName = "MyApp";

            // Preparation phase: Begin
            // Through the preparation phase you populate the enterprise archive (EAR) file with
            // WebSphere Application Server-specific binding information. For example, you can specify
            // Java Naming and Directory Interface (JNDI) names for enterprise beans, or virtual hosts
            // for Web modules, and so on.

            // First, create the controller and populate the EAR file with the appropriate options.
            Hashtable prefs = new Hashtable();
            prefs.put(AppConstants.APPDEPL_LOCALE, Locale.getDefault());

            // You can optionally run the default binding generator by using the following options.
            // Refer to Java documentation for the AppDeploymentController class to see all the
            // options that you can set.
            Properties defaultBnd = new Properties();
            prefs.put (AppConstants.APPDEPL_DFLTBNDDG, defaultBnd);
            defaultBnd.put (AppConstants.APPDEPL_DFLTBNDDG_VHOST, "default_host");
```

```

// Create the controller.
AppDeploymentController controller = AppDeploymentController
    .readArchive(earFile, prefs);
AppDeploymentTask task = controller.getFirstTask();
while (task != null)
{
// Populate the task data.
String[][] data = task.getTaskData();
// Manipulate task data which is a table of stringtask.
setTaskData (data);
task = controller.getNextTask();
}
controller.saveAndClose();

Hashtable options = controller.getAppDeploymentSavedResults();
// The previous options table contains the module-to-server relationship if it was set by
// using tasks.
//Preparation phase: End

// Get a connection to WebSphere Application Server.
String host = "localhost";
String port = "8880";
String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

Properties config = new Properties();
config.put (AdminClient.CONNECTOR_HOST, host);
config.put (AdminClient.CONNECTOR_PORT, port);
config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
System.out.println ("Config: " + config);
AdminClient_soapClient = AdminClientFactory.createAdminClient(config);

// Create the application management proxy, AppManagement.
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

// If code for the preparation phase has been run, then you already have the options table.
// If not, create a new table and add the module-to-server relationship to it by uncommenting
// the next statement.
//Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());

// Uncomment the following statements to add the module to the server relationship table if
// the preparation phase does not collect it.
//Hashtable module2server = new Hashtable();
//module2server.put ("*", target);
//options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, module2server);

//Create the notification filter for listening to installation events.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (AppConstants.NotificationType);

//Add the listener.
NotificationListener listener = new AListener(_soapClient,
myFilter, "Install: " + appName, AppNotification.INSTALL);

// Install the application.
proxy.installApplication (earFile, appName, options, null);
System.out.println ("After install App is called..");

// Wait for some timeout. The installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.

}
catch (Exception e) {
    e.printStackTrace();
}

```

```

    }
}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit.

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
             ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)
            {
                System.out.println ("Error removing listener: " + th);
            }
            System.exit (0);
        }
    }
}

```

Once you install the application, you must explicitly start the application or you must stop and restart the server. For information on starting an application, see the Starting an application through programming topic in the *Using the administrative clients* PDF. For information on stopping or restarting the server, see the Stopping an application server topic or the Starting an application server topic, respectively, in the *Setting up the application serving environment* PDF.

## Starting an application through programming

You can start an application through the administrative console, the wsadmin tool, or programming. Use this example to start an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can start an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to start an application through programming.

1. Connect the administrative client to WebSphere Application Server.
2. Create the application management proxy.
3. Call the startApplication method on the proxy by passing the application name and optionally the list of targets on which to start the application.

After you successfully run the code, the application is started.

The following example shows how to start an application following the previously listed steps. Some statements are split on multiple lines for printing purposes.

```
//Do a get of the administrative client to connect to
//WebSphere Application Server.

AdminClient client = ...;
String appName = "myApp";
Hashtable prefs = new Hashtable();
// Use the AppManagement MBean to start and stop applications on all or some targets.
// The AppManagement MBean is on the deployment manager in the Network Deployment product.

// Query and get the AppManagement MBean.
ObjectName on = new ObjectName ("WebSphere:type=AppManagement,*");
Iterator iter = client.queryNames (on, null).iterator();
ObjectName appmgmtON = (ObjectName)iter.next();

//Start the application on all targets.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient(client);
String started = proxy.startApplication(appName, prefs, null);
System.out.println("Application started on folloing servers: " + started);

//Start the application on some targets.
//String targets = "WebSphere:cell=cellname,node=nodename,
server=servername+WebSphere:cell=cellname,cluster=clusterName";
//String started1 = proxy.startApplication(appName, targets, prefs, null);
//System.out.println("Application started on following servers: " + started1)
```

## Uninstalling an application through programming

You can uninstall an application through the administrative console, the wsadmin tool, or programming. Use this example to uninstall an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can uninstall an application on WebSphere Application Server, you must first install it.

Perform the following tasks to uninstall an application through programming.

1. Get a connection to WebSphere Application Server.
2. Get the application management proxy.
3. Create the notification filter for listening to uninstallation events.
4. Add the listener.
5. Uninstall the application.
6. Wait for some timeout so that the program does not end.

7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the uninstallation is done, remove the listener and quit.

After you successfully run the code, the application is uninstalled.

The following example shows how to uninstall an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class Uninstall {

    public static void main (String [] args) {

        try {

// Get a connection to the server.
String host = "localhost";
String port = "8880";
String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

Properties config = new Properties();
config.put (AdminClient.CONNECTOR_HOST, host);
config.put (AdminClient.CONNECTOR_PORT, port);
config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
System.out.println ("Config: " + config);
    AdminClient _soapClient = AdminClientFactory.createAdminClient(config);

// Get the application management proxy.
AppManagement proxy = AppManagementProxy. getJMXProxyForClient (_soapClient);

String appName = "MyApp";
Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (AppConstants.NotificationType);

//Add the listener.
NotificationListener listener = new AListener(_soapClient,
myFilter, "Install: " + appName, AppNotification.UNINSTALL);

// Uninstall the application.
proxy.uninstallApplication (appName, options, null);
System.out.println ("After uninstall App is called..");

// Wait for some timeout. The installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

```

    }
}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the uninstallation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)
            {
                System.out.println ("Error removing listener: " + th);
            }
            System.exit (0);
        }
    }
}
}

```

## Manipulating additional attributes for a deployed application

You can manipulate attributes for a deployed application through the administrative console, the wsadmin tool, or by programming. Use this example to manipulate attributes that are not exposed during or after application installation through the AppDeploymentTask object.

This task assumes a basic familiarity with MBean programming and the ConfigService interfaces. For information on MBean programming, see MBean Java application programming interface (API) documentation. For information on ConfigService interfaces, see Java application programming interface (API) .

Before you can manipulate additional attributes for your deployed application on WebSphere Application Server, you must first install your application.

Perform the following tasks for your deployed application to manipulate attributes that are not exposed through the `AppDeploymentTask` object. The attributes are saved in the `deployment.xml` file that is created in the configuration repository for each deployed application.

1. Create a session.
2. Connect to WebSphere Application Server.
3. Locate the `ApplicationDeployment` object.
4. Manipulate the attributes.
5. Save your changes.
6. Clean up the session.

After you successfully run the code, the attributes are updated in the `deployment.xml` file for the deployed application.

The following example shows how to manipulate the `startingWeight`, `warClassLoaderPolicy`, and `classloader` attributes based on the previous steps.

```
import java.util.Properties;

import javax.management.Attribute;
import javax.management.AttributeList;
import javax.management.ObjectName;

import com.ibm.websphere.management.AdminClient;
import com.ibm.websphere.management.AdminClientFactory;
import com.ibm.websphere.management.Session;
import com.ibm.websphere.management.configservice.ConfigService;
import com.ibm.websphere.management.configservice.ConfigServiceHelper;
import com.ibm.websphere.management.configservice.ConfigServiceProxy;
import com.ibm.websphere.management.exception.ConfigServiceException;
import com.ibm.websphere.management.exception.ConnectorException;

public class AppManagementSample1 {

    public static void main(String[] args) {
        String hostName = "localhost";
        String port = "8880";
        String appName = "ivtApp";

        ConfigService configService = null;

        // create a session.
        Session session = new Session();

        // establish connection to the server.
        try {
            Properties props = new Properties();
            props.setProperty(AdminClient.CONNECTOR_TYPE,
                AdminClient.CONNECTOR_TYPE_SOAP);
            props.setProperty(AdminClient.CONNECTOR_HOST, hostName);
            props.setProperty(AdminClient.CONNECTOR_PORT, port);
            AdminClient adminClient =
                AdminClientFactory.createAdminClient(props);

            // create a config service proxy object.
            configService = new ConfigServiceProxy(adminClient);

            // Locate the application object.
            ObjectName rootID = configService.resolve(session,
                "Deployment="+appName)[0];
```

```

System.out.println ("rootID is: " + rootID);

// Locate the ApplicationDeployment object from the root.
ObjectName appDeplPattern = ConfigServiceHelper.createObjectName
    (null, "ApplicationDeployment");
/*
ObjectName appDeplID = configService.queryConfigObjects(session,
    rootID, appDeplPattern, null)[0];
*/
AttributeList list1 = configService.getAttributes(session,
    rootID, new String[]{"deployedObject"}, false);
ObjectName appDeplID = (ObjectName)
    ConfigServiceHelper.getAttributeValue(list1, "deployedObject");
System.out.println ("appDeplID: " + appDeplID);

// Locate the class loader.

// Change the starting weight through the startingWeight attribute. The starting weight
// affects the order in which applications start.
AttributeList attrList = new AttributeList();
Integer newWeight = new Integer (10);
attrList.add(new Attribute("startingWeight", newWeight));

// Change the WAR class loader policy through the warClassLoaderPolicy attribute by
// specifying SINGLE or MULTIPLE.
// SINGLE=one classloader for all WAR modules
attrList.add(new Attribute("warClassLoaderPolicy", "SINGLE"));

// Set the class loader mode to PARENT_FIRST or PARENT_LAST.
AttributeList clList = (AttributeList) configService.getAttribute
    (session, appDeplID, "classloader");
ConfigServiceHelper.setAttributeValue (clList, "mode",
    "PARENT_LAST");
attrList.add (new Attribute ("classloader", clList));

// Set the new values.
configService.setAttributes(session, appDeplID, attrList);

// Save your changes.
configService.save(session, false);

} catch (Exception ex) {
    ex.printStackTrace();
} finally {
    // Clean up the session.
    try {
        configService.discard(session);
    }
    catch (ConfigServiceException csEx)
    {
        csEx.printStackTrace();
    }
    catch (ConnectorException cnEx)
    {
        cnEx.printStackTrace();
    }
}
}
}

```

## Sharing sessions for application management

With the configuration service interface, `ConfigService`, you can create a session that is a temporary staging area, where you can save all the configuration modifications. Saving the session saves all the updates from the session into the WebSphere Application Server configuration repository. The application management logic supports session sharing with the configuration service. You can perform all the

application management functions in the same session as the one that the configuration service creates. Saving such a session saves all the updates, including the ones that are application-specific.

This task assumes a basic familiarity with MBean programming. For information on MBean programming, see MBean Java application programming interface (API) documentation.

Perform the following tasks for your deployed application to share and save application-specific updates through the `configService` configuration service.

1. Create a configuration service proxy object.
2. Create a session.
3. Pass the session information to the `AppManagement` MBean.

Every method on the `AppManagement` interface takes session ID (workspace ID) as the last parameter. If the session information is passed in this parameter, the application management function uses the session. If you set the parameter to a null value:

- No session sharing occurs
- The configuration changes are always saved in the configuration repository if the operation succeeds.

4. Save the session after all the necessary changes are made.

The following example outlines the general steps for session sharing through the `configService` configuration service. For a detailed example, see “Manipulating additional attributes for a deployed application” on page 890.

```
public void installApplication (String localEarPath,
                               String appName, Hashtable properties, String workspaceID)
    throws AdminException;

AdminClient adminClient = ....;

// Create a configuration service proxy object.
ConfigService configService = new ConfigServiceProxy(adminClient);

// Create a session.
Session session = new Session();

// Pass the session information to AppManagement MBean.
appMgmt = ...
appMgmt.installApplication
    (earPath, appName, properties, session.toString());
//Save the session after all necessary changes are made.
configService.save(session, false);
```

After you successfully complete the steps, you have saved application-specific updates for a deployed application to a session, and then to the configuration repository.

## Updating an application through programming

You can update an existing application through the administrative console, the `wsadmin` tool, or programming. Use this example to completely update an application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to completely update an application through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.

3. Create the notification filter for listening to events.
4. Add the listener.
5. Prepare the enterprise archive (EAR) file by populating it with binding information.
6. Update the application.
7. Wait for some timeout so that the program does not end.
8. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
9. When the update is done, remove the listener and quit.

After you successfully run the code, the application is updated.

The following example shows how to update an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```
import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;
import com.ibm.websphere.management.*;

import javax.management.*;

public class aa {

    public static void main (String [] args) {

        try {

            // Connect to WebSphere Application Server.
            String host = "localhost";
            String port = "8880";
            String target = "WebSphere:cell=cellName,node=nodeName,server=server1";

            Properties config = new Properties();
            config.put (AdminClient.CONNECTOR_HOST, host);
            config.put (AdminClient.CONNECTOR_PORT, port);
            config.put (AdminClient.CONNECTOR_TYPE, AdminClient.CONNECTOR_TYPE_SOAP);
            System.out.println ("Config: " + config);
            AdminClient_soapClient = AdminClientFactory.createAdminClient(config);

            // Create the application management proxy, AppManagement.
            AppManagement proxy = AppManagementProxy.getJMXProxyForClient (_soapClient);

            String appName = "MyApp";
            String fileContents = "C:/test/test.ear";

            // Create the notification filter.
            NotificationFilterSupport myFilter = new NotificationFilterSupport();
            myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
            //Add the listener.
            NotificationListener listener = new AListener(_soapClient, myFilter,
            "Install: " + appName, AppNotification.INSTALL);

            // Refer to the installation example to see how you can prepare the enterprise archive (EAR)
            // file by populating it with binding information.
            // If code for the preparation phase has started, then you already have the options table.
            // If not, create a new table and add the module-to-server relationship to it by uncommenting
            // the next statement.
            //Hashtable options = new Hashtable();
            options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
            options.put ((AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_APP);

            // Uncomment the following statements to add the module to the server relationship table if
```

```

// the preparation phase does not collect it
//Hashtable module2server = new Hashtable();
//module2server.put ("*", target);
//options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, module2server);
// Update the application.
    proxy.updateApplication (    appName,
                                null,
                                fileContents,
                                AppConstants.APPUPDATE_UPDATE,
                                options,
                                null);

// Wait for some timeout. The installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
    Thread.sleep(300000); // Wait so that the program does not end.

        }
        catch (Exception e) {
            e.printStackTrace();
        }
    }
}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
             ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)

```

```

        {
            System.out.println ("Error removing listener: " + th);
        }
        System.exit (0);
    }
}

```

## Adding to, updating, or deleting part of an application through programming

You can add to, update, or delete part of an existing application through the administrative console, the wsadmin tool, or programming. This example changes part of an application through programming. You can use this example whether you add to, update, or delete part of an existing application. Multiple changes to an application can be packaged in a single .zip file.

To learn about the structure of the .zip file, see the Updating applications topic in the *Developing and deploying applications* PDF.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can add to, update, or delete part of an application on WebSphere Application Server, you must first install your application.

Perform the following tasks to add to, update, or delete part of an application through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter.
4. Add the listener.
5. Partially change the existing application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the update is done, remove the listener and quit.

After you successfully run the code, you have changed the application.

The following example shows how to add to, update, or delete part of an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```

//Inputs:
//partialApp specifies the location of the partial application.
//appName specifies the name of the application.

String partialApp = "C:/apps/partial.zip";
String appName = "MyApp";

//Do a get of the administrative client to connect to
//WebSphere Application Server.

AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient (client);

// Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.

```

```

NotificationListener listener = new AListener(_soapClient, myFilter,
"Install: " + appName, AppNotification.UPDATE);
//Partially change the existing application, MyApp.

Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_PARTIALAPP);

proxy.updateApplication ( appName,
    null,
    partialApp,
    null,
    options,
    null);

// Wait for some timeout. The installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
    Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }
    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
        }
    }
}

```

```

        catch (Throwable th)
        {
            System.out.println ("Error removing listener: " + th);
        }
        System.exit (0);
    }
}
}

```

## Editing applications

You can edit deployed applications through the administrative console, the wsadmin tool, or by programming. Use this example to edit a deployed application through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming, see MBean Java application programming interface (API) documentation.

Before you can edit an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to edit your deployed application.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Get information about an installed application.
4. Manipulate task data as necessary.
5. Save changes for the installed application.

After you successfully run the code, the application is edited.

The following example shows how to edit an application, based on the previous steps.

```

import java.lang.*;
import java.io.*;
import java.util.*;
import java.lang.reflect.*;
import com.ibm.websphere.management.application.*;
import com.ibm.websphere.management.application.client.*;

## Preparing a module and adding it to an existing application through programming

You can add a module to an existing application through the administrative console, the wsadmin tool, or programming. Use this example to add a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can add a module to an application on WebSphere Application Server, you must install the application.

Perform the following tasks to add a module to an application through programming.

1. Create an application deployment controller instance to populate the module file with binding information.
2. Save the binding information in the module.
3. Get the installation options.
4. If the preparation phase (population of the EAR file) is not performed, then do the following actions:
  - a. Create an options table to be passed to the updateApplication MBean API.
  - b. Create a table for module to server relations and add the table to the options table.
5. Connect to WebSphere Application Server.
6. Create the application management proxy.
7. Create the notification filter.
8. Add the listener.
9. Add the module to the application.
10. Specify the target for the new module.
11. Wait for some timeout so that the program does not end.
12. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
13. When the module addition is done, remove the listener and quit.

After you successfully run the code, the module is added to the application.

The following example shows how to add a module to an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```
//Inputs:
//moduleName specifies the name of the module that you add to the application.
//moduleURI specifies a URI that gives the target location of the module
// archive contents on a file system. The URI provides the location of the new
// module after installation. The URI is relative to the application URL.
//uniquemoduleURI specifies the URI that gives the target location of the
// deployment descriptor file. The URI is relative to the application URL.
//target specifies the cell, node, and server on which the module is installed.

String moduleName = "C:/apps/foo.jar";
String moduleURI = "Increment.jar";
String uniquemoduleURI = "Increment.jar+META-INF/ejb-jar.xml";
String target = "WebSphere:cell=cellname,node=nodename,server=servername";

//Create an application deployment controller instance, AppDeploymentController,
//to populate the Java aArchive (JAR) file with binding information.
//The binding information is WebSphere Application Server-specific deployment information.

Hashtable preferences = new Hashtable();
preferences.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
preferences.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_MODULEFILE);
AppDeploymentController controller = AppManagementFactory.readArchiveForUpdate(
    moduleName,
    moduleURI,
    AppConstants.APPUPDATE_ADD,
    preferences,
    null);
```

If the module that you add to the application lacks any bindings, add the bindings so that the module addition works. Collect and add the bindings by using the public APIs provided with WebSphere Application Server. Refer to Java documentation for the `com.ibm.websphere.management.application.client.AppDeploymentController` instance to learn more about how to collect and populate tasks with WebSphere Application Server specific-binding information.

```

//After you collect all the binding information, save it in the module.
controller.saveAndClose();

//Get the installation options.
Hashtable options = controller.getAppDeploymentSavedResults();

//Connect the administrative client, AdminClient, to WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient (client);

//Update the existing application, MyApp, by adding the module.
String appName = "MyApp";

options.put (AppConstants.APPUPDATE_CONTENTTYPE,
    AppConstants. APPUPDATE_CONTENT_MODULEFILE);

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
    "Install: " + appName, AppNotification.UPDATE);

//Specify the target for the new module.
Hashtable mod2svr = new Hashtable();
options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, mod2svr);
mod2svr.put (uniquemoduleURI, target);
proxy.updateApplication ( appName,
    moduleURI,
    moduleName,
    AppConstants.APPUPDATE_ADD,
    options,
    null);

// Wait for some timeout. The installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
    Thread.sleep(300000); // Wait so that the program does not end.
        }
        catch (Exception e) {
            e.printStackTrace();
        }
    }

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient c1, NotificationFilterSupport f1,
Object h, String eType) throws Exception
    {
        _soapClient = c1;
        myFilter = f1;
        handback = h;
        eventTypeToCheck = eType;
    }
}

```

```

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)
            {
                System.out.println ("Error removing listener: " + th);
            }
            System.exit (0);
        }
    }
}

```

## Preparing and updating a module through programming

You can update a module for an existing application through the administrative console, the wsadmin tool, or programming. When you update a module, you replace the existing module with a new version. Use this example to update a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update a module on WebSphere Application Server, you must first install the application.

Perform the following tasks to update a module through programming.

1. Create an application deployment controller instance to populate the Java archive file with binding information.
2. Save the binding information in the module.
3. Get the installation options.
4. If the preparation phase (population of the EAR file) is not performed, the do the following actions:
  - a. Create an options table to be passed to the updateApplication MBean API.
  - b. Create a table for module to server relations and add the table to the options table.
5. Connect to WebSphere Application Server.
6. Create the application management proxy.
7. Create the notification filter.
8. Add the listener.
9. Replace the module in the application.
10. Specify the target for the new module.
11. Wait for some timeout so that the program does not end.

12. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
13. When the module addition is done, remove the listener and quit.

After you successfully run the code, the existing module is replaced with the new one.

The following example shows how to add a module to an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```
//Inputs:
//moduleName specifies the name of the module that you add to the application.
//moduleURI specifies a URI that gives the target location of the module
// archive contents on a file system. The URI provides the location of the new
// module after installation. The URI is relative to the application URL.
//uniquemoduleURI specifies the URI that gives the target location of the
// deployment descriptor file. The URI is relative to the application URL.
//target specifies the cell, node, and server on which the module is installed.
//appName specifies the name of the application to update.
String moduleName = "C:/apps/foo.jar";
String moduleURI = "Increment.jar";
String uniquemoduleURI = "Increment.jar+META-INF/ejb-jar.xml";
String target = "WebSphere:cell=cellname,node=nodename,server=servername";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;
AppManagement proxy = AppManagementProxy.getJMXProxyForClient (client);

Vector tasks = proxy.getApplicationInfo (appName, new Hashtable(), null);

//Create an application deployment controller instance, AppDeploymentController,
//to populate the Java archive (JAR) file with binding information.
//The binding information is WebSphere Application Server-specific deployment information.

Hashtable preferences = new Hashtable();
preferences.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
preferences.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_MODULEFILE);
AppDeploymentController controller = AppManagementFactory.readArchiveForUpdate(
    moduleName,
    moduleURI,
    AppConstants.APPUPDATE_UPDATE,
    preferences,
    tasks);
```

If the module that you update for the application lacks any bindings, add the bindings so that the module update works. Collect and add the bindings by using the public APIs that are provided with WebSphere Application Server. Refer to Java documentation for the AppDeploymentController instance to learn more about how to collect and populate tasks with WebSphere Application Server-specific binding information.

```
//After you collect all the binding information, save it in the module.
controller.saveAndClose();

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
"Install: " + appName, AppNotification.UPDATE);

//Get the installation options.
Hashtable options = controller.getAppDeploymentSavedResults();

//Update the existing application by adding the module.

options.put (AppConstants.APPUPDATE_CONTENTTYPE,
```

```

AppConstants.APPUPDATE_CONTENT_MODULEFILE);

//Specify the target for the new module
Hashtable mod2svr = new Hashtable();
options.put (AppConstants.APPDEPL_MODULE_TO_SERVER, mod2svr);
mod2svr.put (uniquemoduleURI, target);

proxy.updateApplication ( appName,
    moduleURI,
    moduleName,
    AppConstants.APPUPDATE_UPDATE,
    options,
    null);
// Wait; the installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,

        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)
            {

```

```

        System.out.println ("Error removing listener: " + th);
    }
    System.exit (0);
}
}
}

```

## Deleting a module through programming

You can delete a module from an existing application through the administrative console, the wsadmin tool, or programming. Use this example to delete a module through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can delete a module from an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to delete a module through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Delete the module.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the module is deleted, remove the listener and quit.

After you successfully run the code, the existing module is deleted from the application.

The following example shows how to delete a module from an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```

//moduleURI specifies a URI that gives the target location of the module.
//appName specifies the name of the application to update.
String moduleURI = "Increment.jar";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.

AppManagement proxy = AppManagementProxy. getJMXProxyForClient (client);

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
"Install: " + appName, AppNotification.UPDATE);

//Update the existing application, MyApp, by deleting the module.
Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_MODULEFILE);

proxy.updateApplication ( appName,
    moduleURI,
    null,

```

```

AppConstants.APPUPDATE_DELETE,
options,
null);

// Wait; the installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

}
// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;

## Updating a file through programming

You can update a file for an existing application through the administrative console, the wsadmin tool, or programming. This example describes how to update a file through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can update a file for an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to update a file through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Update the file in the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the installation is done, remove the listener and quit.

After you successfully run the code, the file is updated for the application.

The following example shows how to add a file to an application based on the previous steps. Some statements are split on multiple lines for printing purposes.

```

//Inputs:
//fileContents specifies the name of the file that you add to the application.
//appName specifies the name of the application.
//fileURI specifies a URI that gives the target location of the file. The URI
// provides the location of the new module after installation. The URI is
// relative to the application URL.

String fileContents = "C:/apps/test.jsp";
String appName = "MyApp";
String fileURI = "SomeWebMod.war/com/foo/abc.jsp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient (client);

```

```

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
"Install: " + appName, AppNotification.UPDATE);

Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_FILE);

proxy.updateApplication ( appName,
    fileURI,
    fileContents,
    AppConstants.APPUPDATE_UPDATE,
    options,
    null);

// Wait; the installation application programming interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //When the installation is done, remove the listener and quit.

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try

```

```

        {
            _soapClient.removeNotificationListener (on, this);
        }
    catch (Throwable th)
    {
        System.out.println ("Error removing listener: " + th);
    }
    System.exit (0);
}
}
}

```

## Deleting a file through programming

You can delete a file from an existing application through the administrative console, the wsadmin tool, or programming. Use this example to delete a file through programming.

This task assumes a basic familiarity with MBean programming. For information on MBean programming see MBean Java application programming interface (API) documentation.

Before you can delete a file from an application on WebSphere Application Server, you must first install the application.

Perform the following tasks to delete a file through programming.

1. Connect to WebSphere Application Server.
2. Create the application management proxy.
3. Create the notification filter for listening to events.
4. Add the listener.
5. Delete the file from the application.
6. Wait for some timeout so that the program does not end.
7. Listen to Java Management Extensions (JMX) notifications to understand completion of the operation.
8. When the file is deleted from the application, remove the listener and quit.

After you successfully run the code, the file is deleted from the application.

The following example shows how to delete a file based on the previous steps. Some statements are split on multiple lines for printing purposes.

```

//Inputs:
//fileURI specifies a URI that gives the target location of the file. The URI
// provides the location of the new module after installation. The URI is
// relative to the application URL.
//appName specifies the name of the application.

String fileURI = "Increment.jar/com/acme/Foo.class";
String appName = "MyApp";

//Get the administrative client to connect to
//WebSphere Application Server.
AdminClient client = ...;

//Create the application management proxy.
AppManagement proxy = AppManagementProxy.getJMXProxyForClient (client);

//Create the notification filter.
NotificationFilterSupport myFilter = new NotificationFilterSupport();
myFilter.enableType (NotificationConstants.TYPE_APPMANAGEMENT);
//Add the listener.
NotificationListener listener = new AListener(_soapClient, myFilter,
"Install: " + appName, AppNotification.UPDATE);

```

```

//Update the existing application, MyApp, by deleting the file.
Hashtable options = new Hashtable();
options.put (AppConstants.APPDEPL_LOCALE, Locale.getDefault());
options.put (AppConstants.APPUPDATE_CONTENTTYPE, AppConstants.APPUPDATE_CONTENT_FILE);

proxy.updateApplication ( appName,
    fileURI,
    null,
    AppConstants.APPUPDATE_DELETE,
    options,
    null);

// Wait for some timeout. The installation Application Programming Interface (API) is
// asynchronous and so returns immediately.
// If the program does not wait here, the program ends.
Thread.sleep(300000); // Wait so that the program does not end.
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

}

// Specify the Java Management Extensions (JMX) notification listener for JMX events.
class AListener implements NotificationListener
{
    AdminClient _soapClient;
    NotificationFilterSupport myFilter;
    Object handback;
    ObjectName on;
    String eventTypeToCheck;

    public AListener(AdminClient cl, NotificationFilterSupport fl,
Object h, String eType) throws Exception
    {
        _soapClient = cl;
        myFilter = fl;
        handback = h;
        eventTypeToCheck = eType;

        Iterator iter = _soapClient.queryNames (new ObjectName(
"WebSphere:type=AppManagement,*"), null).iterator();
        on = (ObjectName)iter.next();
        System.out.println ("ObjectName: " + on);
        _soapClient.addNotificationListener (on, this, myFilter, handback);
    }

    public void handleNotification (Notification notf, Object handback)
    {
        AppNotification ev = (AppNotification) notf.getUserData();
        System.out.println ("!! JMX event Recd: (handback obj= " + handback+ "): " + ev);

        //Once the installation is done, remove the listener and quit

        if (ev.taskName.equals (eventTypeToCheck) &&
            (ev.taskStatus.equals (AppNotification.STATUS_COMPLETED) ||
            ev.taskStatus.equals (AppNotification.STATUS_FAILED)))
        {
            try
            {
                _soapClient.removeNotificationListener (on, this);
            }
            catch (Throwable th)
            {
                System.out.println ("Error removing listener: " + th);
            }
        }
    }
}

```

```

        }
        System.exit (0);
    }
}

```

## Extending application management operations through programming

You can use the common deployment framework to add additional logic to application management operations. The additional logic can do such tasks as code generation, configuration operations, additional validation, and so on. This topic demonstrates, through programming, how to plug into the *common deployment framework* to extend application management operations.

This task assumes a basic familiarity with Java application programming interfaces (APIs). For information on the Java APIs, see Java Management Extensions (JMX) API documentation.

Before you can extend application management operations, you must first install WebSphere Application Server.

Use this example to extend application management through programming. The tasks that the extensions provide are available through all the administrative clients, such as the wsadmin tool, the administrative console, or through programmatic APIs that the AppManagement MBean provides.

1. Define your extension as an Eclipse plug-in and add a `plugin.xml` file to register your extension provider with the deployment framework.
  - a. In the `plugin.xml` file, provide an extension provider implementation class for the `common-deployment-framework-extensionprovider` extension point.
  - b. Put the plug-in Java archive (JAR) file in the `plugins` directory of your WebSphere Application Server installation.

```

<?xml version="1.0" encoding="UTF-8"?>
<plugin
  id="com.ibm.myproduct.MyExtensionProvider"
  name="My Extension"
  version="1.0.0">

  <extension point="common-deployment-framework-extensionprovider">
    <action class="com.acme.MyExtendProviderImpl"/>
  </extension>
</plugin>

```

2. Provide an extension provider.

An extension provider class provides steps for a given operation on an application Enterprise archive (EAR) file. Before an operation runs, the deployment framework queries all the registered extension providers for additional steps. A single list of steps is passed to each provider. Each provider can add steps to the list. The default provider that the deployment framework provides is called first to populate the list with default steps. Other extension providers are called next.

Various operations that you can extend through the common deployment framework are defined as constants in the `DeploymentConstants` class. These operations are described in the following table. Some operations are split on multiple lines for printing purposes.

Table 24.

Operation	Description
<code>DeploymentConstants.CDF_OP_INSTALLJ2EE</code>	Installs a Java 2 Platform, Enterprise Edition (J2EE) EAR file
<code>DeploymentConstants.CDF_OP_EDITJ2EE</code>	Edits a deployment application configuration

Table 24. (continued)

Operation	Description
DeploymentConstants.CDF_OP_UPDATEJ2EE	Applies a fine-grained update to an application such as addition, removal, or update of a file or a module; or partial update of an application
DeploymentConstants.CDF_OP_UNINSTALLJ2EE	Uninstalls a J2EE application
DeploymentConstants. CDF_OP_CREATE_EAR_WRAPPERJ2EE	Wraps the contents input to the application installation into an EAR file

The AppManagement MBean, which is responsible for deploying and managing J2EE applications on WebSphere Application Server, runs all the operations except the CDF\_OP\_CREATE\_EAR\_WRAPPERJ2EE operation. Deploy the extensions that extend these operations in the plugins directory of the deployment manager.

Either the wsadmin utility or the administrative console runs the CDF\_OP\_CREATE\_EAR\_WRAPPERJ2EE operation when the input contents that are supplied to the CDF\_OP\_INSTALLJ2EE operation are not packaged as an EAR file. Deploy an extension that extends the CDF\_OP\_CREATE\_EAR\_WRAPPERJ2EE operation in the plugins directory of the wsadmin installation.

The following example provides an extension provider that does the following tasks:

- a. Adds two additional steps for the application installation operation
- b. Adds one step for wrapping input contents into an EAR file

package com.acme;

```
import com.ibm.websphere.management.deployment.registry.ExtensionProvider;
import com.ibm.websphere.management.deployment.core.DeploymentConstants;
```

```
public class MyExtensionProviderImpl extends ExtensionProvider {
    public void addSteps (String type, String op, String phase,
        List steps)
    {
        if (op.equals (DeploymentConstants.CDF_OP_INSTALLJ2EE))
        {
            // Add a code generation step.
            steps.add (0, new com.acme.CodeGenStep());
            // Add a configuration step.
            steps.add (new com.acme.ConfigStep());
        }
        else if (op.equals (DeploymentConstants.CDF_OP_CREATE_EAR_WRAPPERJ2EE))
        {
            // Add an ear-wrapper step.
            steps.add (new com.acme.EarWrapperStep());
        }
    }
}
```

### 3. Provide the deployment step implementation.

An extension provider adds a deployment step. The step contains logic that performs additional processing in an application management operation. The logic provides the step access to the deployment context and the deployable object. The deployment context provides information, such as the name of the operation, the configuration session ID, a temporary location for creating temporary files, operation parameters, and so on. The deployable object wraps the deployment content input to the operation. For example, the deployable object wraps the J2EE EAR file for the installation operation or a file, a module, or a partial application for the update operation.

- The following example illustrates how an extension during installation entirely changes an EAR file that is input to the installation operation. The example provides a deployment step during the installation operation that does the following tasks:
  - a. Runs code generation to generate a new EAR file.

- b. Calls the `setContentPath` method in the `DeployableObject` class to set the new EAR file path. The default installation logic, such as steps that the default installation logic adds, uses this new EAR file for installation in the configuration repository.

```
package com.acme;

import com.ibm.websphere.management.deployment.core.DeploymentStep;
import com.ibm.websphere.management.deployment.core.DeployableObject;

public class CodeGenStep extends DeploymentStep
{
    public void execute (DeployableObject dObject)
    {
        EARFile earFile = (EARFile)dObject.getHandle();
        String newEARPath = null;
        // Use step specific logic to create another EAR file after code generation.
        ...
        newEARPath = _context.getTempDir() + "new.ear";

        dObject.setContentPath (newEARPath);
    }
}
```

- The following example provides a deployment step that:
  - a. Reads the contents of the input EAR file.
  - b. Manipulates the configuration session accessed through the context instance, `_context`.

```
package com.acme;

public class ConfigStep extends DeploymentStep
{
    public void execute (DeployableObject dObject)
    {
        EARFile earFile = (EARFile) dObject.getHandle();

        // Use the following example code to perform the configuration.
        String sessionID = _context.getSessionID();
        com.ibm.websphere.management.Session session = new
            com.ibm.websphere.management.Session (sessionID, true);
        // Use the configuration service to perform the configuration steps.
        ...

        // Read the application configuration.
        Application appDD = earFile.getDeploymentDescriptor();
        ...

        String newEARPath = null;
    }
}
```

- The following example provides a deployment step to wrap arbitrary content around an EAR file. Application management logic accepts only the EAR file for deployment. An extension is required if you want to input anything other than an EAR file to the deployment process.

```
package com.acme;

import com.ibm.websphere.management.deployment.core.DeploymentStep;
import com.ibm.websphere.management.deployment.core.DeployableObject;

public class EarWrapperStep extends DeploymentStep
{
    public void execute (DeployableObject dObject)
    {
        Archive archive = (Archive) dObject.getHandle();
        String newEARPath = null;
        // provide your logic to wrap the jar with the ear
        ...
        newEARPath = //;
    }
}
```

```
// Set the new ear path back into DeploymentContext
this.getContext().getContextData()
    .put(DeploymentContext.RETURN_Object_key, newEARPath);

    }
}
```

Through programming, you have plugged into the common deployment framework to extend application management operations.

You can extend other application management operations, or do any other administrative operations you choose.

---

## Chapter 5. Using command line tools

WebSphere Application Server Network Deployment provides many tools that you can call from a command line.

There are several command line tools that you can use to start, stop, and monitor WebSphere Application Server Network Deployment processes and nodes. These tools only work on local servers and nodes. They cannot operate on a remote server or node.

To administer a remote server, you can use the wsadmin scripting program connected to the deployment manager for the cell in which the target server or node is configured. See *Deploying and managing using scripting* for more information about using the wsadmin scripting program. You can also use the V6 administrative console which runs in the deployment manager for the cell. For more information about using the administrative console, see *Deploying and managing with the GUI*.

Unless otherwise specified, all of the WebSphere Application Server Network Deployment for i5/OS commands are located in the *app\_server\_root/bin* directory.

Parameter values that specify a server name, a node name or a cell name are case sensitive. For example, if you want to start the application server MyServer for the profile test, invoke `startServer MyServer -profileName test`. If you specify `myserver` for the server name, the `startServer` script fails.

Most command line tools function relative to a particular profile. To determine if a script requires the `-profileName` parameter, refer to the documentation for that script. If you run a command from the *app\_server\_root/bin* directory and do not specify the `-profileName` parameter, the default profile for the product sets profile-specific variables.

For more information about using profiles, including how to obtain a list of profiles, see the *manageprofiles* command article.

To use the command line tools, perform the following steps:

1. From the i5/OS command line, start a Qshell session by issuing the **STRQSH CL** command.
2. Change directories to the *app\_server\_root/bin* directory.
3. Run the command.

The command runs the requested function and displays the results on the screen.

Some scripts also log additional information to a log file. Refer to the documentation for the script for more information on whether additional information is logged.

---

### Configuring Qshell to run WebSphere Application Server scripts

You can configure Qshell to run WebSphere Application Server Network Deployment for i5/OS scripts.

In a default installation, unless otherwise specified, all WebSphere Application Server scripts are in the *app\_server\_root/bin* directory.

The scripts must be run from Qshell. To ensure that you use the correct version and directory, run QShell commands using one of the following methods:

- Invoke the fully qualified path name of the script:  
*app\_server\_root/bin/script\_name parameters*

where *script\_name* is the name of the script and *parameters* represents the parameters that are passed to the script.

- Invoke the script from the i5/OS command line or from an i5/OS CL program. To use this method, run the STRQSH command and specify the fully qualified path name of the script:

```
STRQSH CMD('app_server_root/bin/script_name parameters')
```

where *script\_name* is the name of the script and *parameters* represents the parameters that are passed to the script.

- Change directories to the *app\_server\_root/bin* directory and run the following script:

```
cd app_server_root/bin
script_name parameters
```

where *script\_name* is the name of the script, and *parameters* represents the parameters that are passed to the script.

- You can update the PATH environment variable to automatically locate the script when you run it. After you update the PATH variable, you can run these scripts from any directory. To update the PATH environment variable, perform the following steps:

1. Edit the *.profile* file in the */home/user\_profile\_name* directory, where *user\_profile\_name* is the name of your iSeries user profile.

If this file does not exist, create it in this directory. You can use the EDTF command from an i5/OS command line or use any editor from a workstation. Also note that *.profile* is the full name of the file. When you start Qshell, it searches for the *.profile* file, and runs the commands listed in it. You can use the *.profile* file to set persistent environment variables for your Qshell session.

2. Add the following line to the *.profile* file:

```
export PATH=app_server_root/bin:$PATH
```

3. Save the file.

The updates to *.profile* do not take effect until you restart Qshell (if you had a session open) or source *.profile* (command: *./home/user\_profile\_name/.profile*)

To change the path for a single Qshell session instead of changing the default path for all Qshell sessions, run the **export** commands shown in the last step during the Qshell session, but do not edit the *.profile*.

---

## Qshell environment variables

WebSphere Application Server provides these Qshell environment variables that affect the WebSphere Application Server scripts.

To set these variables, run the following command:

```
export variableName=value
```

To unset these variables, run the following command:

```
unset variableName
```

- **WAS\_ADDL\_JVM\_ARGS**

If you set this variable, its value is appended to the Java virtual machine (JVM) arguments for all of the scripts that run a JVM. (All of the scripts except *crtwasinst*, *dltwasinst*, *updwashost*, *enbprfwas*, *startServer*, *startNode*, *startManager*, *lstwasinst*, *grtwasaut*, and *rvkwasaut* run a JVM.) For example, this command:

```
export WAS_ADDL_JVM_ARGS="-Dtrace=com.ibm.*=all=enabled -Xms256m"
```

enables tracing for the JVM that a script starts, and sets the minimum heap size for the JVM to 256 megabytes.

- **WAS\_USER\_SCRIPT**

This variable specifies the path to a script that runs before a WebSphere Application Server Qshell script runs. For example, if you want to append a `/home/QSYS/classes.jar` to the classpath for every script, you might create a script called `/home/myDir/classpath.script`. The script file contains this command:

```
WAS_CLASSPATH=${WAS_CLASSPATH}:/home/QSYS/classes.jar
```

After you create the script file, run this command to set the environment variable:

```
export WAS_USER_SCRIPT=/home/myDir/classpath.script
```

---

## Example: Security and the command line tools

If you want to enable WebSphere Application Server security, you need to provide the command line tools with authentication information.

Without authentication information, the command line tools receive an `AccessDenied` exception when you attempt to use them with security enabled. There are multiple ways to provide authentication data:

- Most command line tools support a `-username` and `-password` option for providing basic authentication data. Specify the user ID and password for an administrative user. For example, you can use a member of the administrative console users with operator or administrator privileges, or the administrative user ID configured in the user registry. The following example demonstrates the `stopNode` command, which specifies command line parameters:

```
stopNode -username adminuser -password adminpw
```

- You can place the authentication data in a properties file that the command line tools read. The default file for this data is the `sas.client.props` file in the `properties` directory for the WebSphere Application Server.

---

## manageprofiles command

The **manageprofiles** command line tool creates all application server run-time environments. The command creates a profile, which is the set of files that define the run-time environment for a deployment manager, a custom profile, or a stand-alone application server.

The **manageprofiles** command creates the run-time environment for a WebSphere Application Server process in a set of files called a *profile*. The profile defines the run-time environment and includes all of the files that the server processes in the run-time environment can change.

The command file is located in the `app_server_root/bin` directory. The command file is a script named `manageprofiles`.

The **manageprofiles** command creates a log for every profile that it creates.

- The logs are in the `profile_root/profileRegistry/logs/manageprofiles` directory. The files are named in this pattern: `manageprofiles_create_profile_name.log`.
- The command also creates a log for every profile that it deletes. The logs are in the `profile_root/profileRegistry/logs/manageprofiles` directory. The files are named in this pattern: `manageprofiles_delete_profile_name.log`.

For more information about where to run this command, see [Using command line tools](#).

## Syntax

The **manageprofiles** command is used to perform the following:

- create a profile (`-create`)
- delete a profile (`-delete`)
- augment a profile (`-augment`)

- unaugment a profile (-unaugment)
- delete all profiles (-deleteAll)
- list all profiles (-listProfiles)
- get a profile name (-getName)
- get a profile path (-getPath)
- validate a profile registry (-validateRegistry)
- validate and update a profile registry (-validateAndUpdateRegistry)
- get the default profile name (-getDefaultName)
- set the default profile name (-setDefaultName)
- backup a profile (-backupProfile)
- restore a profile (-restoreProfile)

For detailed help including the required parameters for each of the tasks accomplished with the **manageprofiles** command, use the `-help` parameter. The following is an example of using the help parameter with the **manageprofiles** -augment command on Windows operating systems:

```
app_server_root\bin\manageprofiles.bat -augment -help
```

The output from the help command will specify which parameters are required and which are optional.

Depending on the operation that you want to perform with the **manageprofiles** command, you will need to provide one or more of the following parameters. The command line profile management tool validates that the required parameters are provided and the values entered for those parameters are valid. Be sure to type the name of the parameters with the correct upper and lower case as the command line profile management tool does not validate the case of the parameter name. Incorrect results can occur when the parameter case is not typed correctly.

- `-profileName` *profile\_name*
- `-profilePath` *profile\_root*
- `-templatePath` *template\_path*
- `-nodeName` *node\_name*
- `-cellName` *cell\_name*
- `-hostName` *host\_name*
- `-serverName` *server\_name*
- `-adminUserName` *adminUser\_ID*
- `-adminPassword` *adminPassword*
- `-backupFile` *backupFile\_name*
- `-dmgrProfilePath` *dmgr\_profile\_path*
- `-dmgrHost` *dmgr\_host\_name*
- `-dmgrPort` *dmgr\_port\_number*
- `-debug`
- `-enableAdminSecurity` true | false
- `-federateLater` true | false
- `-isDefault`
- `-isDeveloperServer`
- `-omitAction` *feature1 feature2... featureN*
- `-response` *reponse\_file*
- `-samplesPassword` *samplesPassword*
- `-startingPort` *starting\_port* | `-portsFile` *file\_path* | `-defaultPorts`
- `-validatePorts`

- `-webServerCheck true | false`
- `-webServerHostname webserver_host_name`
- `-webServerInstallPath webserver_installpath_name`
- `-webServerName webserver_name`
- `-webServerOS webserver_operating_system`
- `-webServerPluginPath webserver_plugin_path`
- `-webServerPort webserver_port`
- `-webServerType webserver_type`

The following is an example of using the **manageprofiles** `-create` command on operating systems such as AIX or Linux:

```
app_server_root/bin/manageprofiles.sh -create
    -profileName profile_name
    -profilePath profile_root
    -templatePath template_path
```

## Parameters

The following options are available for the **manageprofiles** command:

### **-adminUserName** *adminUser\_ID*

Specify the user ID that is used for administrative security.

### **-adminPassword** *adminPassword*

Specify the password for the administrative security user ID specified with the `-adminUserName` parameter.

### **-augment**

Augmentation is the ability to apply a changed template to an existing profile. The `augment` parameter causes **manageprofiles** to refresh or augment the profile identified in the `-profileName` parameter using the template in the `-templatePath` parameter.

Specify the fully qualified file path for `-templatePath`. For example:

```
manageprofiles.bat(sh) -augment -profileName profile_name -templatePath fully_qualified_template_path
```

Specifying a relative file path for the `-templatePath` parameter results in the specified profile not being fully augmented.

See also the `-unaugment` parameter.

### **-backupProfile**

Performs a file system back up of a profile folder and the profile metadata from the profile registry file. Any servers using the profile that you want to back up must first be stopped prior to invoking the **manageprofiles** command with the `-backupProfile` option. The `-backupProfile` parameter must be used with the `-backupFile` and `-profileName` parameters, for example:

```
manageprofiles.bat(sh) -backupProfile -profileName profile_name -backupFile backupFile_name
```

### **-backupFile** *backupFile\_name*

Backs up the profile registry file to the specified file.

### **-cellName** *cell\_name*

Specifies the cell name of the profile. Use a unique cell name for each profile.

Use a unique name even though you plan to federate the custom profile or stand alone profile into a deployment manager cell. Federation requires unique cell names before it can make the node part of the deployment manager cell. A cell name must be unique in any circumstance in which the product is running on the same physical machine or cluster of machines, such as a sysplex. Additionally, a cell name must be unique in any circumstance in which network connectivity between entities is required

either between the cells or from a client that must communicate with each of the cells. Cell names also must be unique if their name spaces are going to be federated. Otherwise, you might encounter symptoms such as a `javax.naming.NameNotFoundException` exception, in which case, you need to create uniquely named cells. The default value for this parameter is based on a combination of the short host name, the constant cell, and a trailing number, for example:

```
if (DMgr)
  shortHostNameCellCellNumber
else
  shortHostNameNodeNodeNumberCell
```

where *CellNumber* is a sequential number starting at 01 and *NodeNumber* is the node number that you used to define the node name.

The default node names are as follows:

- dmgr template: *profilenameNetwork*
- default template: *shorthostname\_profilename*
- managed template: *shorthostname\_profilename*
- cell template: Same as the previous dmgr example for the two profiles that are created.

The value for this parameter must not contain spaces or any characters that are not valid such as the following: \*, ?, ", <, >, ,, /, \, |, and so on.

#### **-create**

Creates the profile.

Specify `manageprofiles -create -templatePath fully_qualified_file_path_to_template -help` for specific information about creating a profile. Available templates include:

- **cell** - Deployment manager cell (dmgr and default)
- **dmgr** - Deployment manager
- **default** - Application server
- **managed** - Custom

#### **-debug**

Turns on the debug function of the Ant utility, which the **manageprofiles** command uses.

#### **-defaultPorts**

Assigns the default or base port values.

Do not use this parameter when using the `-startingPort` or `-portsFile` parameter.

During profile creation, the **manageprofiles** command uses an automatically generated set of recommended ports if you do not specify the `-startingPort` parameter, the `-defaultPorts` parameter or the `-portsFile` parameter. The recommended port values can be different than the default port values based on the availability of the default ports.

#### **-delete**

Deletes the profile. Deleting a profile does not delete the profile directory. For example, suppose that you create a profile in the `/usr/WebSphere/AppServer/profiles/managedProfile` directory. The directory remains after you delete the profile.

You can delete or leave the directory. However, the `profile_root/logs` directory contains information about uninstalling the profile. For example, you might retain the `_nodeuninst.log` file to determine the cause of any problem during the uninstall procedure.

If you delete a profile that has augmenting templates registered to it in the profile registry, then unaugmentation actions are performed automatically.

### **-deleteAll**

Deletes all registered profiles. Deleting a profile does not delete the profile directory. For example, suppose that you create a profile in the `/usr/WebSphere/AppServer/profiles/managedProfile` directory. The directory remains after you delete the profile.

You can delete or leave the directory. However, the `profile_root/logs` directory contains information about uninstalling the profile. For example, you might retain the `_nodeuninst.log` file to determine the cause of any problem during the uninstall procedure.

If you delete a profile that has augmenting templates registered to it in the profile registry, then unaugment actions are performed automatically.

### **-dmgrHost** *dmgr\_host\_name*

Identifies the machine where the deployment manager is running. Specify this parameter and the `dmgrPort` parameter to federate a custom profile as it is created.

The host name can be the long or short DNS name or the IP address of the deployment manager machine.

Specifying this optional parameter directs the **manageprofiles** command to attempt to federate the custom node into the deployment manager cell as it creates the custom profile. This parameter is ignored when creating a deployment manager profile or an Application Server profile.

If you federate a custom node when the deployment manager is not running or is not available because of security being enabled or for other reasons, the installation indicator in the logs is `INSTCONFFAIL` to indicate a complete failure. The resulting custom profile is unusable. You must move the custom profile directory out of the profile repository (the profiles installation root directory) before creating another custom profile with the same profile name.

If you have enabled security or changed the default JMX connector type, you cannot federate with the **manageprofiles** command. Use the **addNode** command instead.

The default value for this parameter is `localhost`. The value for this parameter must be a properly formed host name and must not contain spaces or characters that are not valid such as the following: `*`, `?`, `"`, `<`, `>`, `,`, `/`, `\`, `|`, and so on. A connection to the deployment manager must also be available in conjunction with the `dmgrPort` parameter.

### **-dmgrPort** *dmgr\_port\_number*

Identifies the SOAP port of the deployment manager. Specify this parameter and the `dmgrHost` parameter to federate a custom profile as it is created. The deployment manager must be running and accessible.

If you have enabled security or changed the default JMX connector type, you cannot federate with the **manageprofiles** command. Use the **addNode** command instead.

The default value for this parameter is `8879`. The port that you indicate must be a positive integer and a connection to the deployment manager must be available in conjunction with the `dmgrHost` parameter.

### **-dmgrProfilePath** *dmgr\_profile\_path*

Specifies the profile path to the deployment manager portion of the cell. Specify this parameter when you create the application server portion of the cell.

### **-enableAdminSecurity** **true** | **false**

Enables administrative security. Valid values include `true` or `false`. The default value is `false`.

When `enableAdminSecurity` is set to `true`, you must also specify the parameters `-adminUserName` and `-adminPassword` along with the values for these parameters. If samples were installed during the application server install, you must also specify the `-samplesPassword` parameter when creating a profile for which administrative security is enabled. If the `-samplesPassword` parameter is not specified when administrative security is enabled, the profile is created successfully, but when you attempt to run the samples, exceptions and failures will be put in the server system out log.

**-federateLater true | false**

Indicates if the managed profile will be federated during profile creation or if you will federate it later using the **addNode** command. If the `dmgrHost`, `dmgrPort`, `dmgrAdminUserName` and `dmgrAdminPassword` parameters have values, the default value for this parameter is true. Valid values include true or false.

**-getDefaultName**

Returns the name of the default profile.

**-getName**

Gets the name for a profile registered at a given `-profilePath` parameter.

**-getPath**

Gets the file system location for a profile of a given name. Requires the `-profileName` parameter.

**-help**

Displays command syntax.

**-hostName *host\_name***

Specifies the host name where you are creating the profile. This should match the host name that you specified during installation of the initial product. The default value for this parameter is the long form of the domain name system. The value for this parameter must be a valid IPv6 host name and must not contain spaces or any characters that are not valid such as the following: \*, ?, ", <, >, ,, /, \, |, and so on.

**-isDefault**

Specifies that the profile identified by the accompanying `-profileName` parameter is to be the default profile once it is registered. When issuing commands that address the default profile, it is not necessary to use the `-profileName` attribute of the command.

**-isDeveloperServer**

Specifies whether the server is intended for development purposes only. This parameter is useful when creating profiles to test applications on a non-production server prior to deploying the applications on their production application servers.

**-listProfiles**

Lists all defined profiles.

**-nodeName *node\_name***

Specifies the node name for the node that is created with the new profile. Use a unique value within the cell or on the machine. Each profile that shares the same set of product binaries must have a unique node name. The default value for this parameter is based on the short host name, profile type, and a trailing number, for example:

```
if (DMgr)
  shortHostNameCellManagerNodeNumber
else
  shortHostNameNodeNodeNumber
```

where *NodeNumber* is a sequential number starting at 01.

The default node names are as follows:

- dmgr template: *profilenameManager*
- default template: *shorthostname\_profilename*
- managed template: *shorthostname\_profilename*
- cell: See the previous dmgr and default template examples and apply as appropriate to the two profiles that are created.

The value for this parameter must not contain spaces or any characters that are not valid such as the following: \*, ?, ", <, >, ,, /, \, |, and so on.

**-omitAction** *feature1 feature2... featureN*

An optional parameter that excludes profile features.

Each profile template comes predefined with certain optional features. The `samplesInstallAndConfig` option is only available when WebSphere Application Server is installed with samples applications selected. The following optional features can be used with the `-omitAction` parameter for the following profile templates:

- **default** - Application server
  - `deployAdminConsole`
  - `samplesInstallAndConfig`
  - `defaultAppDeployAndConfig`
- **dmgr** - Deployment manager
  - `deployAdminConsole`
- **cell** - Deployment manager cell which is composed of both a dmgr and a default profile template
  - `cell_dmgr` (dmgr created during cell profile creation)
    - `deployAdminConsole`
    - `samplesInstallAndConfig`
    - `defaultAppDeployAndConfig`

**-portsFile** *file\_path*

An optional parameter that specifies the path to a file that defines port settings for the new profile.

Do not use this parameter when using the `-startingPort` or `-defaultPorts` parameter.

During profile creation, the **manageprofiles** command uses an automatically generated set of recommended ports if you do not specify the `-startingPort` parameter, the `-defaultPorts` parameter or the `-portsFile` parameter. The recommended port values can be different than the default port values based on the availability of the default ports.

**-profileName** *profile\_name*

Specifies the name of the profile. Use a unique value when creating a profile. Each profile that shares the same set of product binaries must have a unique name. The default profile name is based on the profile type and a trailing number, for example:

*profileType ProfileNumber*

where *profileType* is a value such as `AppSrv`, `Dmgr`, or `Custom` and *ProfileNumber* is a sequential number that creates a unique profile name.

The value for this parameter must not contain spaces or characters that are not valid such as the following: `*`, `?`, `"`, `<`, `>`, `,`, `/`, `\`, `|`, and so on. The profile name that you choose must not be in use.

**-profilePath** *profile\_root*

Specifies the fully qualified path to the profile, which is referred to throughout the information center as the *profile\_root*.

Specify the full path to avoid an ANT scripting limitation that can cause a failure when federating the profile into a cell. For example:

`-profilePath profile_root`

The default value is based on the location of the WebSphere Application Server installation, the profiles subdirectory, and the name of the file, for example:

`WS_WSPROFILE_DEFAULT_PROFILE_HOME/profiles/profileName`

where `WS_WSPROFILE_DEFAULT_PROFILE_HOME` is defined in the `manageprofile.properties` file.

The value for this parameter must be a valid path for the target system and must not be currently in use. You must have permissions to write to the directory.

**-response** *response\_file*

Accesses all API functions from the command line using the **manageprofiles** command.

The command line interface can be driven by a response file that contains the input arguments for a given command in the properties file in key and value format. The following is an example response file for a create operation:

```
create
profileName=testResponseFileCreate
profilePath=profile_root
templatePath=app_server_root/profileTemplates/default
nodeName=myNodeName
cellName=myCellName
hostName=myHostName
omitAction=myOptionalAction1, myOptionalAction2
```

**-restoreProfile**

Restores a profile backup. Must be used with the **-backupFile** parameter, for example:

```
manageprofiles.bat(sh) -restoreProfile -backupFile file_name
```

**-samplesPassword** *samplesPassword*

Creates a password to be used for samples. The password is used to restrict access to web application samples installed during the install of the application server.

**-serverName** *server\_name*

Specifies the name of the application server. If you do not specify this parameter, the default application server name is server1. The default value for this parameter is the profile name for the profile that contains the server for the dmgr, default, and cell templates.

**-setDefaultName**

Sets the default profile to one of the existing profiles. Must be used with the **-profileName** parameter, for example:

```
manageprofiles.bat(sh) -setDefaultName -profileName profile_name
```

**-startingPort** *startingPort*

Specifies the starting port number for generating all ports for the profile.

Port values are assigned sequentially from the **-startingPort** value.

Do not use this parameter with the **-defaultPorts** or **-portsFile** parameters.

During profile creation, the **manageprofiles** command uses an automatically generated set of recommended ports if you do not specify the **-startingPort** parameter, the **-defaultPorts** parameter or the **-portsFile** parameter. The recommended port values can be different than the default port values based on the availability of the default ports.

**-templatePath** *template\_path*

Specifies the directory path to the template files in the installation root directory. Within the **profileTemplates** directory are various directories that correspond to different profile types and that vary with the type of product installed. The profile directories are the paths that you indicate while using the **-templatePath** option. You can specify profile templates that lie outside the installation root, if you happen to have any.

Use absolute paths. This parameter must exist as a directory and point to a valid template directory.

**-unaugment**

Augmentation is the ability to apply a changed template to an existing profile. When you unaugment an existing profile that has been augmented, the changes are backed out according to the previously specified profile template. If a series of **manageprofiles** augmentations were performed, then the unaugment action will undo the last augment action first.

When the `unaugment` action is invoked, the **manageprofiles** command attempts to access the `deleteRegistry.xml` file in the template path that was specified in the `augment` command. The operations defined in the Config Actions stanza in the delete registry file are then applied against the specified profile.

Specify the fully qualified file path for `-templatePath`.

See also the `augment` parameter.

**-validateAndUpdateRegistry**

Checks all of the profiles that are listed in the profile registry to see if the profiles are present on the file system. Removes any missing profiles from the registry. Returns a list of the missing profiles that were deleted from the registry.

**-validateRegistry**

Checks all of the profiles that are listed in the profile registry to see if the profiles are present on the file system. Returns a list of missing profiles.

**-validatePorts**

Specifies the ports should be validated to ensure they are not reserved or in use. This parameter helps you to identify ports that are not being used. If a port is determined to be in use, the profile creation stops and an error message displays. You can use this parameter at any time on the `create` command line. It is recommended to use this parameter with the `-portsFile` parameter.

**-webServerCheck true | false**

Indicates if you want to set up Web server definitions. Valid values include `true` or `false`. The default value for this parameter is `false`.

**-webServerHostname** *webserver\_host\_name*

The host name of the server. The default value for this parameter is the long host name of the local machine.

**-webServerInstallPath** *webserver\_installpath\_name*

The installation path of the Web server, local or remote. The default value for this parameter is dependent on the operating system of the local machine and the value of the `webServerType` parameter. For example:

**-webServerName** *webserver\_name*

The name of the Web server. The default value for this parameter is `webserver1`.

**-webServerOS** *webserver\_operating\_system*

The operating system from where the Web server resides. Valid values include: `windows`, `linux`, `solaris`, `aix`, `hpux`, `os390`, and `os400`. Use this parameter with the `webServerType` parameter.

**-webServerPluginPath** *webserver\_pluginpath*

The path to the plug-ins that the Web server uses. The default value for this parameter is `WAS_HOME/plugins`.

**-webServerPort** *webserver\_port*

Indicates the port from where the Web server will be accessed. The default value for this parameter is `80`.

**-webServerType** *webserver\_type*

The type of the Web server. Valid values include: `IHS`, `SUNJAVASYSTEM`, `IIS`, `DOMINO`, `APACHE`, and `HTTPSERVER_ZOS`. Use this parameter with the `webServerOS` parameter.

## Usage scenario

The following examples demonstrate correct syntax. Issue the command in any of the following examples on one line. Each example shows the command on more than one line to increase clarity.

### Creating a deployment manager profile

The following example uses the dmgr template to create a deployment manager profile named Dmgr001. The deployment manager ports start at port 20000.

```
manageprofiles -create
  -profileName Dmgr001
  -profilePath profile_root
  -templatePath dmgr
  -startingPort 20000
```

## Creating a custom profile

Federate a custom profile to customize the profile with the deployment manager.

Create a custom profile for federating into a deployment manager cell with the following command:

```
manageprofiles -create
  -profileName Custom01
  -templatePath managed
  -startingPort 22000
```

## Creating an application server profile

Create an application server profile named Default01 with the following command:

```
manageprofiles -create
  -profileName Default01
  -templatePath default
  -startingPort 21000
```

## Creating a cell profile

Creating a cell profile requires the creation of both the deployment manager and the application server portion of the cell profile. The two profiles are linked and some parameters must match between the creation parameters of the deployment manager and the application server portion of the cell profile. For more detailed information regarding creating a cell profile, see “Example: Creating a cell profile with the manageprofiles command” on page 929.

The following example shows the creation of a cell profile named *Dmgr001* having a cell name of *Default01Cell* and a node name of *Default01Node*. To create a full working cell, the `-nodeProfilePath`, `-cellName`, `-appServerNodeName`, `-nodeName` parameters are required to match between the `cell_dmgr` profile and the `cell_node` profile.

1. Create the deployment manager portion of the cell profile.

```
app_server_root/bin/manageprofiles -create
  -templatePath app_server_root/profileTemplates/cell/dmgr
  -nodeProfilePath app_server_root/profiles/AppSrv01
  -profileName Dmgr001
  -cellName Default01Cell
  -nodeName Default01Node
  -appServerNodeName Default01Node
```

2. Create the application server portion of the cell profile.

```
app_server_root/bin/manageprofiles -create
  -templatePath app_server_root/profileTemplates/cell/default
  -dmgrProfilePath app_server_root/profiles/Dmgr001
  -portsFile app_server_root/profiles/Dmgr001/properties/portdef.props
  -nodePortsFile app_server_root/profiles/Dmgr001/properties/nodeportdef.props
  -profileName AppSrv01
  -cellName Default01Cell
  -nodeName Default01Node
  -appServerNodeName Default01Node
```

## Example: Creating a deployment manager profile

To create a deployment manager profile for user shasti:

```
manageprofiles.bat -create
    -profileName shasti
    -profilePath /shasti/WebSphere
    -templatePath /opt/IBM/WebSphere/AppServer/profileTemplates/dmgr
    -cellName cell1
    -hostName planetaix
    -nodeName dmgr1
```

The command creates a deployment manager profile named shasti in a cell named cell1 in location /shasti/WebSphere with a node name of dmgr1.

If you do not specify one of the port options during profile creation, a recommended set of port values will be used. The port conflict resolution algorithm determines these ports. The recommended set of ports must be free of conflict. If you want to use the IBM default ports, use the `-defaultPorts` option when you create a profile.

## Example: Creating a cell profile with the manageprofiles command

Cell profiles are created using two different manageprofiles command-line invocations.

To create the cell profile using the **manageprofiles** command, you must create both the cell deployment manager profile and the cell node profile using two different **manageprofiles** command-line invocations. The combination of these two profiles is the cell profile. Two templates are used to create the cell profile: `cell_dmgr` and `cell_node`. The templates are linked and some parameters must match between the creation parameters in these two invocations. Verify that the invocations match.

From the command line, you can create the two halves of the cell in any order or at any time. It is a best practice to create the deployment manager portion of the profile first. On a distributed system, the `cell_dmgr` profile and the `cell_node` profile are created with a `app_server_root` path unless the `-profilePath` parameter is specified when the `cell_dmgr` profile and the `cell_node` profile are created. The deployment manager portion and the node portion are in separate directories.

The two templates that compose a cell profile have dependencies between one another which requires some parameter values to match between the two create invocations. To create a full working cell, the `-nodeProfilePath`, `-cellName`, `-appServerNodeName`, `-nodeName` parameters are required to have the same values for both the `cell_dmgr` profile and the `cell_node` profile. In the case of ports, and especially in the case of dynamically allocated ports, the creation of the second half of the cell must reference the ports that are used in the first half of the cell. Use the `-portsFile` and `-nodePortsFile` arguments with references to the `properties/portdef.props` and `properties/nodeportdef.props` files of the profile that represents the first half of the cell. This approach ensures that the ports in the second half of the cell are created with the correct correlation to the first half of the cell. Additional information regarding the required and default values for both `cell_dmgr` and `cell_node` is located at `app_server_root/profiles/profile_name/logs/AboutThisProfile.txt`.

For detailed help in creating a cell profile, use

```
app_server_root\bin\manageprofiles.bat(sh) -create
    -templatePath app_server_root\profileTemplates\cell\dmgr
    -help
```

or

```
app_server_root\bin\manageprofiles.bat(sh) -create
    -templatePath app_server_root\profileTemplates\cell\default
    -help
```

The output from the `-help` parameter specifies which parameters are required and which are optional when creating the cell deployment manager profile and the cell node profile.

The following example creates a cell profile named *Dmgr001* having a cell name of *Default01Cell* and a node name of *Default01Node*.

1. Create the deployment manager portion of the cell profile.

```
app_server_root\bin\manageprofiles.bat(sh) -create
  -templatePath app_server_root\profileTemplates\cell\dmgr
  -nodeProfilePath app_server_root\profiles\AppSrv01
  -profileName Dmgr001
  -cellName Default01Cell
  -nodeName Default01Node
  -appServerNodeName federated_node_name
```

2. Create the application server portion of the cell profile.

```
app_server_root\bin\manageprofiles.bat(sh) -create
  -templatePath app_server_root\profileTemplates\cell\default
  -dmgrProfilePath app_server_root\profiles\Dmgr001
  -portsFile app_server_root\profiles\Dmgr001\properties\portdef.props
  -nodePortsFile app_server_root\profiles\Dmgr001\properties\nodeportdef.props
  -profileName AppSrv01
  -cellName Default01Cell
  -nodeName Default01Node
  -appServerNodeName federated_node_name
```

You must either use the `portsFile` or the `nodePortsFile` parameter and the `startingPort` or the `nodeStartingPort` parameter.

If you use the **manageprofiles** command, you can choose the profile that you want to be the default.

## Example: Deleting profiles

The following command deletes the profile named *shasti*:

```
manageprofiles.sh -delete -profileName shasti
```

## Example: Using predefined port numbers

The `manageprofiles` command recommends initial port values when you do not explicitly set port values. You can use predefined port values instead.

The `manageprofiles` command recommends port values when the options of `-defaultPorts`, `-startingPort`, or `-portFile` are not specified. The default port values are located in the `app_server_root/profileTemplates/template_type/actions/portsUpdate/portdef.props` file.

To customize the port values in the `portdef.props` file before creating your profile, perform the following steps. The following example creates the default profile. For other types of profiles, you must substitute all instances of the word *default* in the example with the type of profile that you want to create.

1. Copy the `app_server_root/profileTemplates/default/actions/portsUpdate/portdef.props` file from the default profile template path and place a copy of the file in an arbitrary temporary directory such as `\temp\ports`.
2. In the new file, modify the port settings to specify your port values.
3. Create your profile using the modified port values. Use the **manageprofiles** command and specify the `-portsFile` parameter to the location of your modified `portdef.props` file as shown in the following example:

Suppose that the `portdef.props` file has the following values:

```
WC_defaulthost=39080
WC_adminhost=39060
WC_defaulthost_secure=39443
```

```
WC_adminhost_secure=39043
BOOTSTRAP_ADDRESS=32809
SOAP_CONNECTOR_ADDRESS=38880
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=39401
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=39403
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=39402
ORB_LISTENER_ADDRESS=39100
DCS_UNICAST_ADDRESS=39353
SIB_ENDPOINT_ADDRESS=37276
SIB_ENDPOINT_SECURE_ADDRESS=37286
SIB_MQ_ENDPOINT_ADDRESS=35558
SIB_MQ_ENDPOINT_SECURE_ADDRESS=35578
SIP_DEFAULTHOST=35060
SIP_DEFAULTHOST_SECURE=35061
```

After running the `manageprofiles` command to create your profile with the user defined port values, a success or fail result displays.

The `manageprofiles` command creates a copy of the current `portdefs.props` file in the `profile_root\properties` directory.

Use only one of the three port values parameters, `-startingPort`, `-defaultPorts`, or `-portsFile` with the `manageprofiles` command. The three parameters are mutually exclusive.

## Example: Incrementing default port numbers from a starting point

The `manageprofiles` command can assign port numbers based on a starting port value that you give on the command line, using the `-startingPort` parameter. The tool assigns port numbers sequentially from the starting port number value.

The order of port assignments is arbitrary. Predicting assignments is not possible.

For example, ports created with `-startingPort 20002` would appear similar to the following example:

### Assigned ports for an Application Server profile

```
WC_defaulthost=20002
WC_adminhost=20003
WC_defaulthost_secure=20004
WC_adminhost_secure=20005
BOOTSTRAP_ADDRESS=20006
SOAP_CONNECTOR_ADDRESS=20007
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=20008
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=20009
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=20010
ORB_LISTENER_ADDRESS=20011
CELL_DISCOVERY_ADDRESS=20012
NODE_MULTICAST_DISCOVERY_ADDRESS=20013
NODE_IPV6_MULTICAST_DISCOVERY_ADDRESS=20014
NODE_DISCOVERY_ADDRESS=20015
DCS_UNICAST_ADDRESS=20016
SIB_ENDPOINT_ADDRESS=20017
SIB_ENDPOINT_SECURE_ADDRESS=20018
SIB_MQ_ENDPOINT_ADDRESS=20019
SIB_MQ_ENDPOINT_SECURE_ADDRESS=20018
SIP_DEFAULTHOST=20013
SIP_DEFAULTHOST_SECURE=20014
```

### Assigned ports for a custom profile

```
WC_defaulthost=20002
WC_adminhost=20003
WC_defaulthost_secure=20004
WC_adminhost_secure=20005
```

```
BOOTSTRAP_ADDRESS=20006
SOAP_CONNECTOR_ADDRESS=20007
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=20008
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=20009
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=20010
ORB_LISTENER_ADDRESS=20011
CELL_DISCOVERY_ADDRESS=20012
DCS_UNICAST_ADDRESS=20013
```

### Assigned ports for a deployment manager profile

```
CELL_DISCOVERY_ADDRESS=20010
BOOTSTRAP_ADDRESS=20004
DRS_CLIENT_ADDRESS=7989
SOAP_CONNECTOR_ADDRESS=20005
ORB_LISTENER_ADDRESS=20009
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS=20006
CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS=20008
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS=20007
WC_adminhost=20002
DCS_UNICAST_ADDRESS=20011
WC_adminhost_secure=20003
```

The following example uses the `startingPort` parameter of the `manageprofiles` command and creates ports from an initial value of 20002, with the content shown in the previous example:

```
manageprofiles.bat -create
    -profileName shasti
    -profilePath G:\shasti\WebSphere
    -templatePath G:\shasti\WebSphere\profileTemplates\default
    -nodeName W2K03
    -cellName W2K03_Cell01
    -hostName planetnt
    -startingPort 20002
```

---

## startServer command

The **startServer** command reads the configuration file for the specified application server and starts the server.

Depending on the options you specify, you can launch a new Java virtual machine (JVM) API to run the server process, or write the launch command data to a file.

You do not have to use a user name and password with the **startServer** command because this command launches a server process but does not invoke an MBean method.

For more information about where to run this command, see the [Using command line tools](#) article.

### Syntax

The command syntax is as follows:

```
startServer <server> [options]
```

where `server` is the name of the application server you want to start.

This argument is optional. If the default profile is being used, the server defaults to `server1`. If the profile name is not default, the server defaults to the profile name.

### Parameters

The following options are available for the **startServer** command:

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile.

**-trace**

Enables tracing of the native process code that starts the application server. The trace output is written to the `was_jobname-jobuser-jobnum.log` file which is located in the `profile_root/logs` directory.

**-timeout <seconds>**

Specifies the waiting time before server initialization times out and returns an error.

**-recovery**

Specifies that the server will start in recovery mode, perform a transactional recovery, and shut down. The server will not accept any new transactions while it is in recovery mode. When you start the server again, resources that were unavailable due to questionable transactions will be available.

Use this option if a server fails and you do not want to accept new transactions during the recovery process.

**-cpyenvvar**

Tells the `startServer` command to set the environment variables that are currently defined for the application server process. The default is to not set the currently defined environment variables.

**-help**

Prints a usage statement.

`-?` Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
startServer server1 (starts the server1 server for the default profile)
```

```
startServer server1 -trace (starts the server1 server for  
the default profile and produces trace files under the  
profile_root/logs directory)
```

```
startServer -profileName mytest (starts server mytest  
configured under profile mytest)
```

---

## stopServer command

The `stopServer` command reads the configuration file for the specified server process. This command sends a Java Management Extensions (JMX) command to the server telling it to shut down.

By default, the `stopServer` command does not return control to the command line until the server completes the shut down process. There is a `-nowait` option to return immediately, as well as other options to control the behavior of the `stopServer` command. For more information about where to run this command, see the Using command tools article.

Although the `stopServer` command returns control when the server completes shut down, it can return before the OS/400 process has terminated. Depending upon the amount of memory which the Java Virtual Machine must return to the memory pool, the process may take several seconds or minutes to completely end. You should not attempt to start the server again until the process has terminated. Use the `WRKACTJOB SBS(subsystem) CL` command to determine if the process has terminated completely. By default, subsystem is QWAS61.

If security is enabled, you must use a user name and password with the `stopServer` command because the command invokes an MBean method on the server.

## Syntax

The command syntax is as follows:

```
stopServer <server> [options]
```

where *server* is the name of the configuration directory of the server you want to stop.

This argument is optional. If the default profile is being used, server defaults to server1. If the profile name is not default, then server defaults to the profile name.

## Parameters

The following options are available for the **stopServer** command:

### **-nowait**

Tells the **stopServer** command not to wait for successful shutdown of the server process.

### **-quiet**

Suppresses the progress information that the **stopServer** command prints in normal mode.

### **-logfile <fileName>**

Specifies the location of the log file to which information is written.

### **-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

### **-replacelog**

Replaces the log file instead of appending to the current log.

### **-trace**

Generates trace information into a file for debugging purposes. The trace output is written to the stopServer.log file which is located in the *profile\_root/logs/server* directory.

### **-timeout <seconds>**

Specifies the time to wait for server shutdown before timing out and returning an error.

### **-statusport <portNumber>**

Supports an administrator in setting the port number for server status callback.

### **-conntype <type>**

Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are SOAP or Remote Method Invocation (RMI).

### **-port <portNumber>**

Specifies the server Java Management Extensions (JMX) port to use explicitly, so that you can avoid reading the configuration files to obtain the information.

### **-username <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the **-user** option.

### **-user <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the **-username** option.

### **-password <password>**

Specifies the password for authentication if security is enabled in the server.

**Note:** If you are running in a secure environment but have not provided a user ID and password, you will receive the following error message:

ADMN0022E: Access denied for the stop operation on Server MBean due to insufficient or empty credentials.

To solve this problem, provide the user ID and password information.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
stopServer server1
```

```
stopServer server1 -nowait
```

```
stopServer server1 -trace (produces the stopserver.log file)
```

```
stopServer -profileName mytest (stops server mytest  
configured for profile mytest)
```

---

## startManager command

Use the `startManager` command to manipulate a deployment manager with scripting.

You must run this command from the `profile_root/bin` directory of a Network Deployment installation.

The **startManager** command reads the configuration file for the deployment manager profile and starts the server.

You do not have to use a user name and password with the **startManager** command because this command launches a server process but does not invoke an MBean method.

For more information about where to run this command, see the [Using command line tools](#) article.

## Syntax

The command syntax is as follows:

```
startManager [server] [options]
```

where *server* is an optional parameter that specifies the name of the deployment manager server. If you do not specify this option and you use the deployment manager profile, *server* defaults to the deployment manager. If you do not specify this option and you specify a profile other than the deployment manager, *server* defaults to the name of the profile.

Because the deployment manager profile is not the default profile, you must specify the `-profileName` option when using the **startManager** command.

## Parameters

The following options are available for the **startManager** command:

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile.

**-trace**

Enables tracing of the native process code that starts the deployment manager server. The trace output is written to the `was_jobname-jobuser-jobnum.log` file which is located in the `profile_root/logs` directory.

**-timeout <seconds>**

Specifies the waiting time before deployment manager initialization times out and returns an error.

**-cpyenvvar**

Tells the **startServer** command to set the environment variables that are currently defined for the application server process. The default is to not set the currently defined environment variables.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
startManager -profileName dmgr (starts the deployment manager for the dmgr profile)
```

```
startManager -trace (produces trace files in the profile_root/logs directory)
```

---

## stopManager command

The **stopManager** command reads the configuration file for the Network Deployment manager process.

It sends a Java Management Extensions (JMX) command to the manager telling it to shut down. By default, the **stopManager** command waits for the manager to complete the shutdown process before it returns control to the command line. There is a `-nowait` option to return immediately, as well as other options to control the behavior of the **stopManager** command. For more information about where to run this command, see the Using command tools article.

Although the **stopServer** command returns control when the server completes shut down, it can return before the OS/400 process has terminated. Depending upon the amount of memory which the Java virtual machine must return to the memory pool, the process may take several seconds or minutes to completely end. You should not attempt to start the server again until the process has terminated. Use the `WRKACTJOB SBS(subsystem) CL` command to determine if the process has terminated completely. By default, the subsystem is QWAS61.

## Syntax

The command syntax is as follows:

```
stopManager [<server>] [options]
```

## Parameters

The following options are available for the **stopManager** command:

**-nowait**

Tells the **stopManager** command not to wait for successful shutdown of the deployment manager process.

**-quiet**

Suppresses the progress information that the **stopManager** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information is written.

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information to a file for debugging purposes. The trace output is written to the `stopmanager.log` file which is located in the `profile_root/logs` directory.

**-timeout <seconds>**

Specifies the waiting time for the manager to complete shutdown before timing out and returning an error.

**-statusport <portNumber>**

Specifies that an administrator can set the port number for server status callback.

**-conntype <type>**

Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are SOAP or Remote Method Invocation (RMI).

**-port <portNumber>**

Specifies the deployment manager JMX port to use explicitly, so that you can avoid reading the configuration files to obtain information.

**-username <name>**

Specifies the user name for authentication if security is enabled in the deployment manager. Acts the same as the `-user` option.

**-user <name>**

Specifies the user name for authentication if security is enabled in the deployment manager. Acts the same as the `-username` option.

**-password <password>**

Specifies the password for authentication if security is enabled in the deployment manager.

**Note:** If you are running in a secure environment but have not provided a user ID and password, you receive the following error message:

```
ADMN0022E: Access denied for the stop operation on Server MBean due
to insufficient or empty credentials.
```

To solve this problem, provide the user ID and password information.

**-help**

Prints a usage statement.

`-?` Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
stopManager
```

```
stopManager -nowait
```

```
stopManager -trace (produces the stopmanager.log file)
```

---

## startNode command

The **startNode** command reads the configuration file for the node agent process and constructs a **launch** command.

**startNode** command reads the configuration file for the node agent process for a profile that has been added to the Network Deployment cell and starts the server.

You do not have to use a user name and password with the **startNode** command because this command launches a server process but does not invoke an MBean method.

For more information about where to run this command, see the Using command line tools article.

### Syntax

The command syntax is as follows:

```
startNode [options]
```

### Parameters

The following options are available for the **startNode** command:

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-trace**

Enables tracing of the native process code that starts the node agent process. The trace output is written to the *was\_jobname-jobuser-jobnum.log* file which is located in the *profile\_root/logs* directory.

**-timeout <seconds>**

Specifies the waiting time before node agent initialization times out and returns an error.

**-statusport <portNumber>**

Specifies that an administrator can set the port number for node agent status callback.

**-cpyenvvar**

Tells the **startServer** command to set the environment variables that are currently defined for the application server process. The default is to not set the currently defines environment variables.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

### Usage scenario

The following examples demonstrate correct syntax:

```
startNode (Starts the node agent process for the default profile.  
The default profile must belong to a Network Deployment cell.)
```

```
startNode profileName mynode (Starts the node agent for the mynode profile  
which belongs to a Network Deployment cell.)
```

```
startNode -trace (produces trace files in the profile_root/logs directory)
```

---

## stopNode command

The **stopNode** command reads the configuration file for the Network Deployment node agent process and sends a Java Management Extensions (JMX) command telling the node agent to shut down.

By default, the **stopNode** command waits for the node agent to complete shutdown before it returns control to the command line. There is a `-nowait` option to return immediately, as well as other options to control the behavior of the **stopNode** command. For more information about where to run this command, see the Using command tools article.

Although the **stopServer** command returns control when the server completes shut down, it can return before the OS/400 process has terminated. Depending upon the amount of memory which the Java Virtual Machine must return to the memory pool, the process may take several seconds or minutes to completely end. You should not attempt to start the server again until the process has terminated. Use the `WRKACTJOB SBS(subsystem) CL` command to determine if the process has terminated completely. By default, subsystem is `QWAS61`.

### Syntax

The command syntax is as follows:

```
stopNode [options]
```

### Parameters

The following options are available for the **stopNode** command:

**-nowait**

Tells the **stopNode** command not to wait for successful shutdown of the node agent process.

**-quiet**

Suppresses the progress information that the **stopNode** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information gets written.

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into a file for debugging purposes.

**-timeout <seconds>**

Specifies the waiting time for the agent to shut down before timing out and returning an error.

**-statusport <portNumber>**

Specifies that an administrator can set the port number for server status callback.

**-stopservers**

Stops all application servers on the node before stopping the node agent.

**-conntype <type>**

Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are SOAP or Remote Method Invocation (RMI).

**-port <portNumber>**

Specifies the node agent JMX port to use explicitly, so that you can avoid reading configuration files to obtain the information.

**-username <name>**

Specifies the user name for authentication if security is enabled in the node agent. Acts the same as the `-user` option.

**-user <name>**

Specifies the user name for authentication if security is enabled in the node agent. Acts the same as the `-username` option.

**-password <password>**

Specifies the password for authentication if security is enabled in the node agent.

**Note:** If you are running in a secure environment but have not provided a user ID and password, you receive the following error message:

```
ADMN0022E: Access denied for the stop operation on Server MBean due
to insufficient or empty credentials.
```

To solve this problem, provide the user ID and password information.

**-help**

Prints a usage statement.

**Note:** When requesting help for the usage statement for the **stopNode** command, a reference to the **stopServer** command displays. All of the options displayed for this usage statement apply to the **stopNode** command.

**-?** Prints a usage statement.

**Note:** When requesting help for the usage statement for the **stopNode** command, a reference to the **stopServer** command displays. All of the options displayed for this usage statement apply to the **stopNode** command.

## Usage scenario

The following examples demonstrate correct syntax:

```
stopNode
```

```
stopNode -profileName mynode
```

```
stopNode -nowait
```

```
stopNode -trace (produces trace files under
the profile_root/logs directory.)
```

---

## addNode command

The **addNode** command incorporates a WebSphere Application Server installation into a cell.

For more information about where to run this command, see the Using command line tools article. Depending on the size and location of the new node you incorporate into the cell, this command can take a few minutes to complete. You must have Administrator privileges to use the **addNode** function.

The node agent server is automatically started as part of the **addNode** command unless you specify the `-noagent` option. If you recycle the system that hosts an application server node, and did not set up the node agent to act as an operating system daemon, you must issue a **startNode** command to start the node agent before starting any application servers.

The following items are new in V6.1:

- Ports generated for the node agent are unique for all the profiles in the installation. For development purposes, you can create multiple profiles on the same installation and add them to one or more cells without worrying about ports conflicts.
- If you want to specify the ports that the node agent uses, specify it in a file with the file name passed with the `-portprops` option. The format of the file is `key=value` pairs, one on each line, with the key being the same as the port name in the `serverindex.xml` file.
- If you want to use a number of sequential ports, the `-startingport` option works the same as it does in V5.x. This means that port conflicts with other profiles will not be detected.

## Syntax

The command syntax is as follows:

```
addNode dmgr_host [dmgr_port] [-profileName profilename]
[-conntype type] [-includeapps] [-startingport portnumber]
[-portprops qualified_filename] [-nodeagentshortname name]
[-nodegroupname name] [-includebuses name]
[-registerservice] [-servicename name] [-servicepassword password]
[-coregroupname name] [-noagent] [-statusport port] [-quiet] [-nowait]
[-logfile filename] [-replacelog] [-trace] [-username uid]
[-password pwd] [-localusername localuid]
[-localpassword localpwd] [-help]
```

The `dmgr_host` argument is required. All of the other arguments are optional. The default port number is 8879 for the default SOAP port of the deployment manager. SOAP is the default Java Management Extensions (JMX) connector type for the command. If you have multiple WebSphere Application Server installations or multiple profiles, the SOAP port may be different than 8879. Examine the deployment manager `SystemOut.log` to see the current ports in use.

## Parameters

The following options are available for the **addNode** command:

### **-conntype <type>**

Specifies the JMX connector type to use for connecting to the deployment manager. Valid types are SOAP or RMI, which stands for Remote Method Invocation.

### **-includeapps**

By default the **addNode** command does not carry over applications from the stand-alone servers on the new node to the cell. In general, you should install applications using the deployment manager. The `-includeapps` option tells the **addNode** command to carry over the applications from a node. If the application already exists in the cell, a warning is printed and the application does not install in the cell.

The applications will be mapped to the server that you federated using the **addNode** command. When the **addNode** command operation completes, the applications will run on that server when the server is started. Since these applications are part of the network deployment cell, you can map them to other servers and clusters in the cell using the administrative console. See the Mapping modules to servers article in the *Developing and deploying applications* PDF for more information.

You should not use the `-includeapps` option if your node to be federated includes WebSphere Application Server supplied applications, such as the samples. If you do, the second node to be federated that includes these applications will be rejected because the applications already exist in the cell and application merge is not supported.

If you use the `-includeapps` option on a node that includes a large number of applications, the timeout for the administrative connector needs to be extended to account for the additional time required to

transfer all of the applications to the deployment manager during `addNode` and to remotely install them into the cell. The `-includeapps` option is not a recommended approach unless only a few unique applications exist on the node.

By default, during application installation, application binaries are extracted in the `profile_root/installedApps/cellName` directory. After the `addNode` command, the cell name of the configuration on the node that you added changes from the base cell name to the deployment manager cell name. The application binaries are located where they were before the `addNode` command ran, for example, `profile_root/installedApps/old_cellName`.

If the application was installed by explicitly specifying the location for binaries as the following example:

```
${app_server_root}/${CELL}
```

where the variable `${CELL}`, specifies the current cell name, then when the **addNode** command runs, the binaries are moved to the following directory:

```
${app_server_root}/currentCellName
```

Federating the node to a cell using the **addNode** command does not merge any cell level configuration, including virtual host information. If the virtual host and aliases for the new cell do not match WebSphere Application Server, you cannot access the applications running on the servers. You have to manually add all the virtual host and host aliases to the new cell, using the administrative console running on the deployment manager.

#### **-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile. If you are adding a non-default profile to the deployment manager cell, this parameter is required.

#### **-user <name> or -username <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the `-user` option. The user name that you choose must be a pre-existing user name.

#### **-nowait**

Tells the **addNode** command not to wait for successful initialization of the launched node agent process.

#### **-quiet**

Suppresses the progress information that the **addNode** command prints in normal mode.

#### **-logfile <filename>**

Specifies the location of the log file to which information gets written. By default, the log file is called `addNode.log` and is created in the `logs` directory of the profile for the node being added.

#### **-trace**

Generates additional trace information in the log file for debugging purposes.

#### **-replacelog**

Replaces the log file instead of appending to the current log. By default, the **addNode** command appends to the existing trace file. This option causes the **addNode** command to overwrite the trace file.

#### **-noagent**

Tells the **addNode** command not to launch the node agent process for the new node.

#### **-password <password>**

Specifies the password for authentication if security is enabled. The password that you choose must be one that is associated with a pre-existing user name.

#### **-startingport <portNumber>**

Supports the specification of a port number to use as the base port number for all node agent and

Java Messaging Service (JMS) server ports created during the **addNode** command. With this support you can control which ports are defined for these servers, rather than using the default port values. The starting port number is incremented by one to calculate the port number for every node agent port and JMS server port configured during the **addNode** command.

If multiple node agents exist on the same physical server, you can define the base port number for each by using the `-startingport` parameter prior to federation, or by modifying the ports in the node agent section of `serverindex.xml`.

**-registerservice**

(Windows only) Registers the node agent as a Windows service.

**-servicename <user>**

(Windows only) Use the given user name as the Windows service user.

**-servicepassword <password>**

(Windows password) Use the given password as the Windows service password.

**-portprops <filename>**

Passes the name of the file that contains key-value pairs of explicit ports that you want the new node agent to use. For example, to set your SOAP and RMI ports to 3000 and 3001, create a file with the following two lines and pass it as the parameter:

```
SOAP_CONNECTOR_ADDRESS=3000
BOOTSTRAP_ADDRESS=3001
```

**-coregroupname <name>**

The name of the core group in which to add this node. If you do not specify this option, the node will be added to the DefaultCoreGroup.

**-nodegroupname <name>**

The name of the node group in which to add this node. If you do not specify, the node is added to the DefaultNodeGroup.

**-includebuses**

Copies the buses from the node to be federated to the cell. This parameter will also attempt to copy the service integration bus configuration of the remote node into the cell. If the destination cell already contains a bus with the same name as any bus at the remote node, the add node will fail. To prevent this problem, there are actions you can take before using the **addNode** command. You can delete the bus with that name in the destination cell, rename the bus to be added to the cell, or manually configure the bus already located in the cell.

**-nodeagentshortname <name>**

The shortname to use for the new node agent.

**-localusername <name>**

Specifies the user name for authentication for existing application servers on the node that you want to federate. This parameter is only applicable if security is enabled for the application server.

**-localpassword <password>**

Specifies the password for authentication for existing application servers on the node that you want to federate. The password that you choose must be one that is associated with a preexisting user name. This parameter is only applicable if security is enabled for the application server.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

`addNode testhost 8879` (adds an application server to the deployment manager)

`addNode deploymgr 8879 -trace` (produces the `addNode.log` file)

`addNode host25 8879 -nowait` (does not wait for a node agent process)

where 8879 is the default port.

`addNode mydmgr 11383 -profileName mynode` (adds profile `mynode` to the Network Deployment cell managed by profile `mydmgr`, which listens on SOAP port 11383)

## Best practices for adding nodes using command line tools

Use the **addNode** command to add a standalone node into a cell.

The **addNode** command does the following:

- Copies the base WebSphere Application Server cell configuration to a new cell structure. This new cell structure matches the structure of deployment manager.
- Creates a new node agent definition for the node that the cell incorporates.
- Sends commands to the deployment manager to add the documents from the new node to the cell repository.
- Performs the first configuration synchronization for the new node, and verifies that this node is synchronized with the cell.
- Launches the node agent process for the new node.
- Updates the `setupCmdLine.bat` or `setupCmdline.sh` files and the `wsadmin.properties` file to point to the new cell.
- After federating the node, the **addNode** command backs up the `plugin-cfg.xml` file from the `app_server_root/config/cells` directory to the `config/backup/base/cells` directory. The **addNode** command regenerates a new `plugin-cfg.xml` file at the Deployment Manager and the `nodeSync` operation copies the files to the node level.

Tips for using the **addNode** command:

- Verify that the deployment manager and nodes are updated to the same revision level within the WebSphere Application Server. For example, a deployment manager at level 6.0.1 will be unable to federate with nodes at 6.0.2.
- Do not put WebSphere Application Server `.jar` files on the generic `CLASSPATH` variable (default class path) for the overall system.
- By default, applications that are installed on the node will not copy to the cell. If you install an application after using the **addNode** command, the application will install on the cell. By specifying the `-includeapps` option, you force the **addNode** command to copy applications from the node to the cell. Applications with duplicate names will not copy to the cell.
- Cell-level documents are not merged. Any changes that you make to the standalone cell-level documents before using the **addNode** command must be repeated on the new cell. For example, virtual hosts.
- If you receive an `OutOfMemory` exception while using the **addNode** command, you may need to increase the heap size of the deployment manager. To increase the heap size of the deployment manager, adjust the `Maximum Heap Size` parameter using the administrative console. In the administrative console, go to `System Administration > Deployment Manager > Java and Process Management > Process Definition > Java Virtual Machine > Maximum Heap Size`.
- In some instances it may take longer than anticipated for the deployment manager to respond to the **addNode** command. The default timeout value, which determines how long the client will wait for a server response, is appropriate in the majority of cases. However, you may require more time for the server to respond under heavier processing conditions. For example, if you include the `-includeapps` option and have a large number of applications, or the applications are very large, the default value of 180 seconds may be insufficient. To change the default timeout value, open the file

`$WAS_HOME/profiles/<profile name>/properties/soap.client.props` in any ASCII text editor and find the following line (shown here with default value of 180 seconds):

```
com.ibm.SOAP.requestTimeout=180
```

If you need to change the default you can edit this line to set the timeout to a value more appropriate for your situation (**Note:** setting the above value to 0 will disable the timeout check altogether). If the timeout value is set too high you will have to wait a long time to determine if the **addNode** command will successfully complete its request to the deployment manager. If the value is set too short the deployment manager will not have sufficient time to complete the request before the **addNode** command concludes that the deployment manager is not responding and will respond with an error. Other factors that may affect server timeouts include the processing load or excessive paging on the deployment manager and network latency. Some of these conditions may be transient.

---

## serverStatus command

Use the **serverStatus** command to obtain the status of one or all of the servers configured on a node.

For more information about where to run this command, see the Using command line tools article.

### Syntax

The command syntax is as follows:

```
serverStatus <server>|-all [options]
```

The first argument is required. The argument is either the name of the server for which status is desired, or the **-all** keyword which requests status for all servers defined on the node.

### Parameters

The following options are available for the **serverStatus** command:

**-quiet**

Suppresses the progress information that the **serverStatus** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information gets written.

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into a file for debugging purposes.

**-username <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-user** option.

**-user <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-username** option.

**-password <password>**

Specifies the password for authentication if security is enabled.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
serverStatus server1
```

```
serverStatus -all (returns status for all defined servers)
```

```
serverStatus -trace (produces the serverStatus.log file)
```

---

## removeNode command

The **removeNode** command returns a node from a Network Deployment distributed administration cell to a standalone WebSphere Application Server installation.

For more information about where to run this command, see the Using command tools article. You must have Administrator privileges to use the **removeNode** function.

The **removeNode** command only removes the node-specific configuration from the cell. This command does not uninstall any applications that were installed as the result of executing an **addNode** command. Such applications can subsequently deploy on additional servers in the Network Deployment cell. As a consequence, an **addNode** command with the **-includeapps** option ran after a **removeNode** command does not move the applications into the cell because they already exist from the first **addNode** command. The resulting application servers added on the node do not contain any applications. To deal with this situation, add the node and use the deployment manager to manage the applications. Add the applications to the servers on the node after it is incorporated into the cell.

The **removeNode** command does the following:

- Stops all of the running server processes in the node, including the node agent process.
- Removes the configuration documents for the node from the cell repository by sending commands to the deployment manager.
- Copies the original application server cell configuration into the active configuration.

Depending on the size and location of the new node you remove from the cell, this command can take a few minutes to complete.

**Note:**

An application server node that is built as part of a cell profile creation does not have an original configuration. Therefore, the **removeNode** command is not able to restore the node to a usable base configuration. When removing a node that was federated as part of a cell profile creation, the **removeNode** command indicates that removing a node of this type causes the node to be unusable and the node cannot be federated again. To delete the profile for this node, run the **cleanupNode** command. A new profile can be created using the Profile Management Tool or the **manageprofiles** command.

## Syntax

The command syntax is as follows:

```
removeNode [options]
```

All arguments are optional.

## Parameters

The following options are available for the **removeNode** command:

**-quiet**

Suppresses the progress information that the **removeNode** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information is written.

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into a file for debugging purposes.

**-statusport <portNumber>**

Specifies that an administrator can set the port number for the node agent status callback.

**-username <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-user** option.

**-user <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-username** option.

**-password <password>**

Specifies the password for authentication if security is enabled.

**-force**

Cleans up the local node configuration regardless of whether you can reach the deployment manager for cell repository cleanup. After using the **-force** parameter, you may need to use the **cleanupNode** command on the deployment manager.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
removeNode -quiet
```

```
removeNode -profileName mynode
```

```
removeNode -trace (produces the removeNode.log file)
```

---

## cleanupNode command

The **cleanupNode** command cleans up a node configuration from the cell repository.

Only use this command to clean up a node if you have a node defined in the cell configuration, but the node no longer exists. For more information about where to run this command, see the Using command tools article.

## Syntax

The command syntax is as follows:

```
cleanupNode <node name> <deploymgr host> <deploymgr port> [options]
```

where the first argument is required.

## Parameters

The following options are available for the **cleanupNode** command:

### -quiet

Suppresses the progress information that the **cleanupNode** command prints in normal mode.

### -trace

Generates trace information into a file for debugging purposes.

### -profileName

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile. The `-profileName` parameter specifies the deployment manager profile to run the command against. Because the `dmgr` profile is not the default profile, you must specify this parameter.

## Usage scenario

The following examples demonstrate correct syntax:

```
cleanupNode myNode -profileName dmgr
```

```
cleanupNode myNode -trace -profileName mydmgr
```

---

## syncNode command

The **syncNode** command forces a configuration synchronization to occur between the node and the deployment manager for the cell in which the node is configured.

The node agent server runs a configuration synchronization service that keeps the node configuration synchronized with the master cell configuration. If the node agent is unable to run because of a problem in the node configuration, you can use the **syncNode** command to perform a synchronization when the deployment manager is not running in order to force the node configuration back in sync with the cell configuration.

The `syncNode.log` file is located in the `app_server_root/profile_name/logs` directory.

For more information about where to run this command, see the [Using command tools](#) article.

## Syntax

The command syntax is as follows:

```
syncNode <deploymgr host> <deploymgr port> [options]
```

where the `<deploymgr host>` argument is required.

## Parameters

The following options are available for the **syncNode** command:

**-stopservers**

Tells the **syncNode** command to stop all servers on the node, including the node agent, before performing configuration synchronization with the cell.

**-restart**

Tells the **syncNode** command to launch the node agent process after configuration synchronization completes.

**-nowait**

Tells the **syncNode** command not to wait for successful initialization of the launched node agent process.

**-quiet**

Suppresses the progress information that the **syncNode** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information gets written.

**-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into a file for debugging purposes.

**-timeout <seconds>**

Specifies the waiting time before node agent initialization times out and returns an error.

**-statusport <portnumber>**

Specifies that an administrator can set the port number for node agent status callback.

**-username <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-user** option.

**-user <name>**

Specifies the user name for authentication if security is enabled. Acts the same as the **-username** option.

**-password <password>**

Specifies the password for authentication if security is enabled.

**-conntype <type>**

Specifies the Java Management Extensions (JMX) connector type to use for connecting to the deployment manager. Valid types are SOAP or Remote Method Invocation (RMI).

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax:

```
syncNode testhost 8879
```

```
syncNode deploymgr 8879 -trace (produces the syncNode.log file)
```

```
syncNode host25 4444 -stopservers -restart  
(assumes that the deployment manager JMX port is 4444)
```

---

## renameNode command

Use the **renameNode** command to modify the node name of a federated server. Launch this command from the node whose name you want to modify. When you issue this command the following occurs:

1. Connects to the deployment manager.
2. Stops all servers.
3. Changes the node configuration on the deployment manager.
4. Synchronizes the node.

For more information about where to run this command, see the Using command line tools article.

### Syntax

The command syntax is as follows:

```
renameNode.sh dmgr_host dmgr_port node_name  
[-nodeshortname name][-trace][-conntype type][-username uid]  
[-password pwd][-logfile filename] [-help]
```

### Parameters

The following options are available for the **renameNode** command:

**-nodeshortname <name>**

The short name of the node.

**-trace**

Generates additional trace information in the log file for debugging purposes.

**-conntype <type>**

Specifies the JMX connector type to use for connecting to the deployment manager. Valid types are SOAP or RMI, which stands for Remote Method Invocation.

**-username <uid>**

Specifies the user name for authentication if security is enabled. Acts the same as the `-user` option. The user name that you choose must be a pre-existing user name.

**-password <pwd>**

Specifies the password for authentication if security is enabled. The password that you choose must be one that is associated with a pre-existing user name.

**-logfile <filename>**

Specifies the location of the log file to which information gets written. By default, the log file is called `renameNode.log` and is created in the logs directory of the profile for the node being renamed.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

### Usage scenario

The following examples demonstrate correct syntax:

Using Windows platforms:

```
renameNode.bat localhost 8879 newnode
```

Using UNIX platforms:

```
renameNode.sh localhost 8879 newnode
```

---

## backupConfig command

The **backupConfig** command is a simple utility to back up the configuration of your node to a file.

By default, all servers on the node stop before the backup is made so that partially synchronized information is not saved. For more information about where to run this command, see the Using command line tools article. If you do not have root authority, you must specify a path for the backup file in a location where you have write permission. The backup file will be in zip format and a .zip extension is recommended.

In a UNIX or Linux environment, the **backupConfig** command does not save file permissions or ownership information. The **restoreConfig** command uses the current umask and effective user ID (EUID) to set the permissions and ownership when restoring a file. If it is required that the restored files have the original permissions and ownership, use the **tar** command (available on all UNIX or Linux systems) to back up and restore the configuration.

The **backupConfig** command does not save authorities that were granted to the configuration directory structure of the profile. The **restoreConfig** command sets the owner of the directory structure and its contents to QEJBSVR and restores private authorities to the QTMHHTTP and QNOTES user profiles (if they exist). It does not restore any other private authorities that were granted.

### Syntax

The command syntax is as follows:

```
backupConfig <backup_file> [options]
```

where *backup\_file* specifies the file to which the backup is written. If you do not specify one, a unique name is generated.

The QEJBSVR user profile must have \*WX authority to the directory path specified in *backup\_file*. If no path is specified, the QEJBSVR user profile must have \*WX authority to the current working directory.

### Parameters

The following options are available for the **backupConfig** command:

**-nostop**

Tells the **backupConfig** command not to stop the servers before backing up the configuration.

**-quiet**

Suppresses the progress information that the **backupConfig** command prints in normal mode.

**-logfile <fileName>**

Specifies the location of the log file to which information gets written.

**-profileName <profileName>**

Defines the profile of the Application Server process in a multi-profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into the log file for debugging purposes.

**-username <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the **-user** option.

**-user <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the `-username` option.

**-password <password>**

Specifies the password for authentication if security is enabled in the server.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following example creates a new file that includes the current date:

```
backupConfig WebSphereConfig_2003-04-22.zip
```

The following example creates a file called `myprofileBackup.zip` under the `/home/mydir` directory for the `myprofile` profile.

```
backupConfig /home/mydir/myprofileBackup.zip -profileName myprofile
```

The following example creates a file called `myBackup.zip` and does not stop any servers before beginning the backup process.

```
backupConfig myBackup.zip -nostop
```

---

## restoreConfig command

Use the `restoreConfig` command to restore the configuration of your node after backing up the configuration using the `backupConfig` command.

The **restoreConfig** command is a simple utility to restore the configuration of your node after backing up the configuration using the **backupConfig** command. By default, all servers on the node stop before the configuration restores so that a node synchronization does not occur during the restoration. If the configuration directory already exists, it is renamed before the restoration occurs. For more information about where to run this command, see the [Using command line tools](#) article.

The **backupConfig** command does not save authorities that may have been granted to the configuration directory structure of the profile. The **restoreConfig** command sets the owner of the directory structure and its contents to `QEJBSVR` and restores private authorities to the `QTMHHTTP` and `QNOTES` user profiles (if they exist). It does not restore any other private authorities which may have been granted.

The `QEJBSVR` user profile must have `*R` authority to the directory path specified in `backup_file`. If no path is specified, `QEJBSVR` must have `*R` authority to the current working directory.

## Syntax

The command syntax is as follows:

```
restoreConfig <backup_file> [options]
```

where *backup\_file* specifies the file to be restored. If you do not specify one, the command will not run.

## Parameters

The following options are available for the **restoreConfig** command:

**-nowait**

Tells the **restoreConfig** command not to stop the servers before restoring the configuration.

**-quiet**

Suppresses the progress information that the **restoreConfig** command prints in normal mode.

**-location <directory\_name>**

Specifies the directory where the backup file is restored. The location defaults to the *profile\_root/config* directory.

**-logfile <fileName>**

Specifies the location of the log file to which information gets written.

**-profileName**

Defines the profile of the Application Server process in a multiple profile installation. The **-profileName** option is not required for running in a single profile environment. The default for this option is the default profile.

**-replacelog**

Replaces the log file instead of appending to the current log.

**-trace**

Generates trace information into the log file for debugging purposes.

**-username <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the **-user** option.

**-user <name>**

Specifies the user name for authentication if security is enabled in the server. Acts the same as the **-username** option.

**-password <password>**

Specifies the password for authentication if security is enabled in the server.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following example demonstrates correct syntax:

```
restoreConfig WebSphereConfig_2006-04-22.zip
```

The following example restores the configuration stored in */home/mydir/myprofileBackup.zip* to the configuration for profile *myprofile*:

```
restoreConfig /home/mydir/myprofileBackup.zip -profileName myprofile
```

The following example restores the given file to the */tmp* directory and does not stop any servers before beginning the restoration:

```
restoreConfig WebSphereConfig_2006-04-22.zip -location /tmp -nostop
```

Be aware that if you restore the configuration to a directory that is different from the directory that was backed up when you performed the **backupConfig** command, you may need to manually update some of the paths in the configuration directory.

---

## EARExpander command

Use the **EARExpander** command to expand an enterprise archive file (EAR) into a directory to run the application in that EAR file.

You can collapse a directory containing application files into a single EAR file. You can type `EARExpander` with no arguments to learn more about its options. For more information about where to run this command, see the [Using command tools](#) article.

## Syntax

The command syntax is as follows:

```
EarExpander -ear earName -operationDir dirName -operation  
<expand | collapse> [-expansionFlags <all|war>]
```

## Parameters

The following options are available for the **EARExpander** command:

### **-ear**

Specifies the name of the input EAR file for the expand operation or the name of the output EAR file for the collapse operation.

### **-operationDir**

Specifies the directory where the EAR file is expanded or specifies the directory from where files are collapsed.

### **-operation <expand | collapse>**

The `expand` value expands an EAR file into a directory structure required by the WebSphere Application Server run time. The `collapse` value creates an EAR file from an expanded directory structure.

### **-expansionFlags <all | war>**

(Optional) The `all` value expands all files from all of the modules. The `war` value only expands the files from Web archive file (WAR) modules.

### **-profileName**

Defines the profile of the Application Server process in a multi-profile installation. The `-profileName` option is not required for running in a single profile environment. The default for this option is the default profile.

## Usage scenario

The following examples demonstrate correct syntax:

```
EARExpander -ear C:\WebSphere\AppServer\installableApps\DefaultApplication.ear  
-operationDir C:\MyApps -operation expand -expansionFlags war
```

```
EARExpander -ear C:\backup\DefaultApplication.ear  
-operationDir C:\MyAppsDefaultApplication.ear -operation collapse
```

---

## versionInfo command

The **versionInfo** command generates a report from data extracted from XML files in the `properties/version` folder. The report includes a list of changed components and installed or uninstalled maintenance packages.

## Product version information

The `versionInfo` tool displays important data about the product and its installed components, such as the build version and build date. History information for installation and removal of maintenance packages also displays in the report. This tool is particularly useful when working with support personnel to determine the cause of any problem.

## Product version reports

The following report generation scripts extract data from XML data files in the properties/version folder:

- **versionInfo** script  
Lets you use parameters to create a version report.
- **genVersionReport** script  
Generates the versionReport.html report file in the current working directory, which is usually the bin directory.

## Location of the command file

The versionInfo command is a script.

The command file is a script named versionInfo in the *app\_server\_root/bin* directory.

## Syntax for the versionInfo command

The command syntax is:

```
versionInfo [ -format text | html ]  
            [ -file file_name ]  
            [ -long ]  
            [ -maintenancePackages ]  
            [ -maintenancePackageDetail ]  
            [ -components ]  
            [ -componentDetail ]
```

```
versionInfo [ -help | /help | -? | /? | -usage ]
```

Issue the command from the *app\_server\_root/bin* directory.

## Parameters

### **-? or /?**

Displays command syntax.

### **-components**

Adds a list of installed components to the report.

### **-componentDetail**

Adds details about installed components to the report.

### **-file *file\_name***

Specifies the output file name. The report goes to standard output (stdout) by default.

### **-format text | html**

Selects the format of the report. The default is "text".

### **-help or /help**

Displays command syntax.

### **-long**

Creates the long version of the report.

### **-maintenancePackages**

Adds a list of applied maintenance packages to the report.

### **-maintenancePackageDetail**

Adds details about an applied maintenance package to the report.

### **-usage**

Displays command syntax.

## Report description

The versionInfo command reports the following information:

### Installation information

Displays the following general information about the current installation:

- Report date and time - The date and time that the report was generated. The timestamp is formatted according to the current locale.
- Product directory - The file path to the installation root directory defined by the WAS\_HOME environment variable.
- Version directory - The file path of the version directory of the current IBM WebSphere Application Server - ND installation.
- DTD directory - The file path of the DTD directory of the current IBM WebSphere Application Server - ND installation.
- Log directory - The file path of the log directory of the current IBM WebSphere Application Server - ND installation. The maintenance package log files are in the directory.
- Backup directory - The file path of the backup directory of the current IBM WebSphere Application Server - ND installation. The backup files generated during the installation of maintenance packages are in this directory.
- TMP directory - The file path of the temporary directory of the current machine.

### Product list information

Displays a list of installed WebSphere products:

- Product ID - The product ID of the installed product.
- Status - The status of the product, either installed or uninstalled.

### Installed product information

This information and the other information topic descriptions are hierarchal for each installed product, component, component update, installed maintenance package, included APARs, and component updates.

This section of the report displays the following information:

- Name - The name of the installed product.
- Version - The current version of the product. Installing or uninstalling fix packs or refresh packs modifies this version.
- ID - The product ID of the product installed, such as BASE, BASETRIAL, ND, EXPRESS, EXPRESSTRIAL, embeddedEXPRESS, IHS, XD, PLG, or CLIENT.
- Build level - The build level of the installed product.
- Build date - The build date of the installed product.

**Installed component information:** Displays the following component-level information of the installed component from the .component file under the /properties/version directory:

- Component name - The name of the installed component
- Spec version - The spec version of the current component
- Build level - The build level of the current component
- Build date - The build date of the current component

**Installed component update information:** Displays the general maintenance package information:

- Component name - the name of the installed component
- Update type - All interim fixes, fix packs and refresh packs are maintenance packages. The update type field is always set to *maintenance package*.
- Maintenance package ID - The ID of the maintenance package that is responsible for the current maintenance level of the product.

- Update effect - The updated action taken on a particular component. The default effect is *replace*.
- Log file name - The file path of the log file that records the maintenance actions for the current maintenance level.
- Backup file name - The file path of the backup file generated during the installation of the maintenance package. Not applicable if the component is restored as a result of an uninstall of a maintenance package.
- Timestamp - The time at which the component is updated. The timestamp is stated in GMT offset values.

*Installed maintenance package information:* Displays the general maintenance package information:

- Maintenance Package ID - the maintenance package ID
- Description - the description of the maintenance package
- Build Date - the build date of this maintenance package

*Included APARs information:* Displays the list of APARs fixed by this maintenance package.

*Component updates information:* Displays the following information about each component that is updated by the installed maintenance package:

- Component name - The name of the installed component.
- Updated effect - The update action taken on the component by the maintenance package. The default action is *replace*.
- Timestamp - The time at which the component update is installed (GMT offset).

---

## genVersionReport command

The **genVersionReport** command uses the **versionInfo** command to generate the `versionReport.html` report file in the current working directory, which is usually the `bin` directory. The report includes a list of changed components and installed or uninstalled maintenance packages. The `genVersionReport` script invokes the `versionInfo` script specifying the correct parameters to place the information generated into an HTML file in the current working directory.

## Product version information

The `versionInfo` tool displays important data about the product and its installed components, such as the build version and build date. History information for installation and removal of maintenance packages also displays in the report. This tool is particularly useful when working with support personnel to determine the cause of any problem.

### Product version reports

The following report generation scripts extract data from XML data files in the `properties/version` folder:

- `versionInfo` script  
Use the `versionInfo` command to specify your own report parameters when creating a customized version report.
- `genVersionReport` script  
Use the `genVersionReport` command to generate the `versionReport.html` report file in the current working directory, which is usually the `bin` directory. The report includes the list of components, fixes, fix packs, and refresh packs.

## Location of the command file

The `genVersionReport` command is a script.

The command file is named `genVersionReport` in the `bin` directory of the `app_server_root` directory.

## Syntax for the `genVersionReport` command

The command syntax is:

```
genVersionReport
```

Issue the command from the `bin` directory of the `app_server_root` directory.

## Report description

The `versionInfo` command reports the following information:

### Installation information

Displays the following general information about the current installation:

- Report date and time - The date and time that the report was generated. The timestamp is formatted according to the current locale.
- Product directory - The file path to the installation root directory defined by the `WAS_HOME` environment variable.
- Version directory - The file path of the version directory of the current IBM WebSphere Application Server - ND installation.
- DTD directory - The file path of the DTD directory of the current IBM WebSphere Application Server - ND installation.
- Log directory - The file path of the log directory of the current IBM WebSphere Application Server - ND installation. The maintenance package log files are in the directory.
- Backup directory - The file path of the backup directory of the current IBM WebSphere Application Server - ND installation. The backup files generated during the installation of maintenance packages are in this directory.
- TMP directory - The file path of the system temporary directory.

### Product list information

Displays a list of installed WebSphere products:

- Product ID - The product ID of the installed product.
- Status - The status of the product, either installed or uninstalled.

### Installed product information

This information and the other information topic descriptions are hierarchal for each installed product, component, component update, installed maintenance package, included APARs, and component updates.

This section of the report displays the following information:

- Name - The name of the installed product.
- Version - The current version of the product. Installing or uninstalling fix packs or refresh packs modifies this version.
- ID - The product ID of the product installed, such as `BASE`, `BASETRIAL`, `ND`, `EXPRESS`, `EXPRESSTRIAL`, `embeddedEXPRESS`, `IHS`, `XD`, `PLG`, or `CLIENT`.
- Build level - The build level of the installed product.
- Build date - The build date of the installed product.

**Installed component information:** Displays the following component-level information of the installed component from the `.component` file in the `app_server_root/properties/version` directory:

- Component name - The name of the installed component
- Spec version - The spec version of the current component
- Build level - The build level of the current component
- Build date - The build date of the current component

*Installed component update information:* Displays the general maintenance package information:

- Component name - the name of the installed component
- Update type - All interim fixes, fix packs and refresh packs are maintenance packages. The update type field is always set to *maintenance package*.
- Maintenance package ID - The ID of the maintenance package that is responsible for the current maintenance level of the product.
- Update effect - The updated action taken on a particular component. The default effect is *replace*.
- Log file name - The file path of the log file that records the maintenance actions for the current maintenance level.
- Backup file name - The file path of the backup file generated during the installation of the maintenance package. Not applicable if the component is restored as a result of an uninstall of a maintenance package.
- Timestamp - The time at which the component is updated. The timestamp is stated in GMT offset values.

*Installed maintenance package information:* Displays the general maintenance package information:

- Maintenance Package ID - the maintenance package ID
- Description - the description of the maintenance package
- Build Date - the build date of this maintenance package

*Included APARs information:* Displays the list of APARs fixed by this maintenance package.

*Component updates information:* Displays the following information about each component that is updated by the installed maintenance package:

- Component name - The name of the installed component.
- Updated effect - The update action taken on the component by the maintenance package. The default action is *replace*.
- Timestamp - The time at which the component update is installed (GMT offset).

---

## historyInfo command

The **historyInfo** command generates a report from data extracted from XML files in the properties/version folder and the properties/version/history folder. The report includes a list of changed components and a history of installed or uninstalled maintenance packages.

### Product history information

The historyInfo tool displays important data about the product and its installed components, such as the build version and build date. History information for installation and removal of maintenance packages also displays in the report. This tool is particularly useful when working with support personnel to determine the cause of any problem.

### Product history reports

The following report generation scripts extract data from XML data files in the properties/version folder and the properties/version/history folder:

- historyInfo script

Lets you use parameters to create a history report.

- genHistoryReport script

Generates the historyReport.html report file in the current working directory, which is usually the bin directory.

## Location of the command file

The historyInfo command is a script.

The command file is a script named genHistoryReport in the *app\_server\_root/bin* directory.

## Syntax for the historyInfo command

The command syntax is:

```
historyInfo [ -format text | html ]  
            [ -file file_name ]  
            [ -maintenancePackageID ID_of_maintenance_package ]  
            [ -component component_name ]
```

```
historyInfo [ -help | /help | -? | /? | -usage ]
```

Issue the command from the *app\_server\_root/bin* directory.

## Parameters

### -? or /?

Displays command syntax.

### -component *component\_name*

Specifies the name of a component. When specified, the product history report displays events for only the named component. When not specified, the report displays events for all components.

### -file *file\_name*

Specifies the output file name. The report goes to standard output (stdout) by default.

### -format text | html

Selects the format of the report. The default is "text".

### -help or /help

Displays command syntax.

### -maintenancePackageID *ID\_of\_maintenance\_package*

Specifies the ID of the interim fix, fix pack, or refresh pack. When specified, the product history report displays events for only the named maintenance package. When not specified, the report displays events for all maintenance packages.

### -usage

Displays command syntax.

## Report description

The historyInfo command reports the following information:

### Installation information

Displays the following general information about the current installation:

- Report date and time - The date and time that the report was generated. The timestamp is formatted according to the current locale.
- Product directory - The file path to the installation root directory of the product.

- Version directory - The file path of the version directory of the current WAS installation.
- DTD directory - The file path of the DTD directory of the current installation.
- Log directory - The file path of the log directory of the current installation. The maintenance package log files are in the directory.
- Backup directory - The file path of the backup directory of the current WAS installation. The backup files generated during the installation of maintenance packages are in this directory.
- TMP directory - The file path of the temporary directory of the current machine.
- History directory - The file path of the history directory of the current installation. The history files are in the directory.
- History File - The file path of the event.history file.

### Installation event information

Displays the list of installed maintenance packages (interim fix, fix pack, and refresh pack) and the following related information:

- Maintenance package ID - The ID of the maintenance package.
- Action - The action taken with this maintenance package, which is either *install* or *uninstall*.
- Package file name - The file name of the maintenance package that was installed.
- Log file name - The file path of the log file generated during the installation or removal of the maintenance package.
- Backup file name - The file path of the backup file generated during the installation of the maintenance package. This field does not apply for an uninstall action.
- Timestamp - The time when the maintenance action (install or uninstall) occurs. The time is stated in relation to GMT.
- Result - The result of the installation or removal action. The result is either success, partial success, or failure.

### Component installation event information

Displays the following component-level information of the event for the current maintenance package:

- Maintenance package ID - The ID of the maintenance package to which this particular installation event belongs.
- Component name - The name of the current component.
- Action - The action taken on this component due to the action of the current maintenance package, either install or uninstall
- Update action - The updated action taken on this component. By default, the update action for an installation action is *replace*.
- Timestamp - The time at which the action occurs for the maintenance package (GMT offset values).
- Result - The result of the install or uninstall action. The result is either success, partial success or failure.

---

## genHistoryReport command

The **genHistoryReport** command generates the historyReport.html report file in the current working directory, which is usually the bin directory. The report includes a list of changed components and installed or uninstalled maintenance packages. The genHistoryReport script invokes the historyInfo script specifying the correct parameters to place the information generated into an HTML file in the current directory.

### Product history information

The historyInfo tool displays historical data about the product and the installation and removal of maintenance packages for the product. This tool is particularly useful when working with support personnel to determine the cause of any problem.

## Product history reports

The following report generation scripts extract data from XML data files in the properties/version folder and the properties/version/history folder:

- historyInfo script  
Lets you use parameters to create a history report.
- genHistoryReport script  
Generates the historyReport.html report file in the current working directory, which is usually the bin directory. The report includes a list of components, fixes, fix packs, and refresh packs.

## Location of the command file

The command file is a script.

The command file is named genHistoryReport in the *app\_server\_root/bin* directory.

## Syntax for the genHistoryReport command

The command syntax is:

```
genHistoryReport
```

Issue the command from the *app\_server\_root/bin* directory.

## Report description

The historyInfo command generates the report. The genHistoryReport command calls the historyInfo command with a set of report parameters that reports the following information:

### Installation information

Installation information displays the following general information about the current installation:

- Report date and time - The date and time that the report was generated. The timestamp is formatted according to the current locale.
- Product directory - The file path to the installation root directory of the product.
- Version directory - The file path of the version directory of the current WAS installation.
- DTD directory - The file path of the DTD directory of the current installation.
- Log directory - The file path of the log directory of the current installation. The maintenance package log files are in the directory.
- Backup directory - The file path of the backup directory of the current WAS installation. The backup files generated during the installation of maintenance packages are in this directory.
- TMP directory - The file path of the temporary directory of the current machine.
- History directory - The file path of the history directory of the current installation. The history files are in the directory.
- History File - The file path of the event.history file.

### Installation event information

Installation event information displays the list of installed maintenance packages (interim fix, fix pack, and refresh pack) and the following related information:

- Maintenance package ID - The ID of the maintenance package.
- Action - The action taken with this maintenance package, which is either *install* or *uninstall*.
- Package file name - The file name of the maintenance package that was installed.
- Log file name - The file path of the log file generated during the installation or removal of the maintenance package.

- Backup file name - The file path of the backup file generated during the installation of the maintenance package. This field does not apply for an uninstall action.
- Timestamp - The time when the maintenance action (install or uninstall) occurs. The time is stated in relation to GMT.
- Result - The result of the installation or removal action. The result is either success, partial success, or failure.

## Component installation event information

Component installation event information displays the following component-level information of the event for the current maintenance package:

- Maintenance package ID - The ID of the maintenance package to which this particular installation event belongs.
- Component name - The name of the current component.
- Action - The action taken on this component due to the action of the current maintenance package, either install or uninstall
- Update action - The updated action taken on this component. By default, the update action for an installation action is *replace*.
- Timestamp - The time at which the action occurs for the maintenance package (GMT offset values).
- Result - The result of the install or uninstall action. The result is either success, partial success or failure.

---

## ivt command

The install verification (ivt) script verifies that the application server for an instance is functioning correctly.

For a WebSphere Application Server instance, the ivt script verifies that a JavaServer page, a servlet and an enterprise bean can be successfully invoked. For a WebSphere Application Server Network Deployment instance, the ivt script verifies that the deployment manager can be contacted successfully. If the application server is not running, the ivt script attempts to start it before verification begins. For WebSphere Application Server instances, the ivtApp application must be installed in the server. By default, this application is installed in the default server that is created when you create an instance. To run this script, your user profile must have \*ALLOBJ authority.

## Syntax

The command syntax is as follows:

```
ivt [-instance instance]
```

## Parameters

The following options are available for the **ivt** command:

### -instance

This is an optional parameter. The value *instance* specifies the name of the instance for which you want to verify the installation. The default value is *default* (or the instance specified by the WAS\_OS400\_INSTANCE variable). For information about the WAS\_OS400\_INSTANCE variable, see the Qshell environment variables article.

## Usage scenario

The following example verifies the default instance:

```
ivt
```

The following example verifies the devinst instance:

ivt -instance devinst

---

## Displaying profile properties with the i5/OS command line

To display information for a profile and for the application servers in that profile, run the **dspwasinst** command from the Qshell command line.

To run the **dspwasinst** command, perform the following steps:

1. On the i5/OS command line, run the STRQSH (Start Qshell) command.
2. On the Qshell command line, use the cd command to change to the directory that contains the script:

```
cd app_server_root/bin
```

3. Run the **dspwasinst** command:

```
dspwasinst -profileName profile
```

where *profile* is the name of the profile that you want to display. For more information on the **dspwasinst** command and additional parameters, see “dspwasinst command” on page 975.

In the following example, the script displays information about the default profile for the WebSphere Application Server edition.

```
dspwasinst
```

```
Display WAS instance:
Instance name: default
Profile path: profile_root
Template path: app_server_root/profileTemplates/default
Instance type: Application Server
Cell: MYISERIES
Node: MYISERIES
Virtual hosts:
  default_host
    *:9080
    *:80
    *:9443
  admin_host
    *:9060
    *:9043
Information for server: server1
Installed applications:
  DefaultApplication
  ivtApp
  query
  SamplesGallery
  PlantsByWebSphere
  ManagementEJB.ear
  filetransfer.ear
  adminconsole.ear
  SchedulerCalendars.ear
Server status: Server is started. Job is 042628/QEJBSVR/SERVER1.
Web container tranports:
  None
Additional ports:
  2809  BOOTSTRAP_ADDRESS port
  8880  SOAP_CONNECTOR_ADDRESS port
  9501  SAS_SSL_SERVERAUTH_LISTENER_ADDRESS port
  9503  CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS port
  9502  CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS port
  9060  WC_adminhost port
  9080  WC_defaulthost port
  9353  DCS_UNICAST_ADDRESS port
  9043  WC_adminhost_secure port
  9443  WC_defaulthost_secure port
  7276  SIB_ENDPOINT_ADDRESS port
```

```
7286 SIB_ENDPOINT_SECURE_ADDRESS port
5558 SIB_MQ_ENDPOINT_ADDRESS port
5578 SIB_MQ_ENDPOINT_SECURE_ADDRESS port
9100 ORB_LISTENER_ADDRESS port
```

---

## Granting authority to a profile using the i5/OS command line

To grant authority to objects and directories in a profile, run the **grtwasaut** command from the Qshell command line.

To run the script, perform the following steps:

1. On the i5/OS command line, run the STRQSH (Start Qshell) command.
2. On the Qshell command line, use the cd command to change to the directory that contains the script:

```
cd app_server_root/bin
```

3. Run the **grtwasaut** command:

```
grtwasaut -profileName profile [ -user usrprf | -authlist authlist ]
-dtaaut dataAuth -objaut objAuth
```

where *profile* is the profile to which you are granting authority, *usrprf* is the user profile to which you are granting authority, *authlist* is the authorization list to which you are granting authority, *dataAuth* specifies the data authorities that you are granting to the user specified by the *-user* parameter and *objAuth* specifies the object authorities that you are granting to the user specified by the *-user* parameter. You do not need to specify both the *-user* and *-authlist* parameters, but you must specify at least one of them. For more information on the **grtwasaut** command and additional parameters, see the **grtwasaut** command article. Examples

In the following example, the user profiles johndoe and jsmith are granted rwx authority to the profile devinst and the associated objects.

```
grtwasaut -profileName devinst -user "johndoe jsmith" -dtaaut rwx -recursive
```

In the following example, the user profiles johndoe and jsmith are granted rwx authority to the installedApps subdirectory and all nested objects in the installedApps subdirectory.

```
grtwasaut -profileName devinst -object installedApps -user "johndoe jsmith" -dtaaut rwx -recursive
```

---

## Revoking authority to a profile using the i5/OS command line

To revoke authority to objects and directories in a profile, run the **rvkwasaut** script from the Qshell command line.

To run the script, follow these steps:

1. On the i5/OS command line, run the STRQSH (Start Qshell) command.
2. On the Qshell command line, use the cd command to change to the directory that contains the script:

```
cd app_server_root/bin
```

3. Run the **rvkwasaut** script:

```
rvkwasaut -profileName profile [-user usrprf | -authlist authlist]
```

where *profile* is the *profile* to which you want are revoking authority, *usrprf* is the user profile from which you are revoking authority, and *authlist* is the authorization list from which you are revoking authority. You do not need to specify both the *-user* and *-authlist* parameters, but you must specify at least one of them. For more information on the **rvkwasaut** script and additional parameters, see the “**rvkwasaut** command” on page 966 article.

In the following example, the user profile jsmith no longer has authority to the profile devinst:

```
rvkwasaut -profileName devinst -user jsmith -recursive
```

In the example, the user profile `jsmith` no longer has authority to the `installedApps` subdirectory and all nested objects in the `installedApps` subdirectory.

```
rvkwasaut -profileName devinst -object installedApps -user jsmith -recursive
```

---

## rvkwasaut command

The **rvkwasaut** command revokes user authority to a profile and the objects associated with it.

For usage instructions and examples, see the [Revoke authority to a profile](#) article. To run this script, your user profile must have `*ALLOBJ` authority.

### Syntax

The command syntax is as follows:

```
rvkwasaut [-profileName profile] [-user usrprf | -authlist none]
[-object path] [-recursive] [-verbose] [-help]
```

### Parameters

The following options are available for the **rvkwasaut** command:

#### **-profileName**

This is an optional parameter. The value `profile` specifies the name of the profile to which you are revoking authority. The default value is *default*.

#### **-user**

The value `usrprf` specifies the OS/400 user profile from which you are revoking authority. To revoke authority from multiple user profiles, specify all of the user profiles with a single `-user` parameter. Enclose the list of profiles in double quotation marks (`"`). For example, to revoke authority from `usrprf1` and `usrprf2`, specify `-user "usrprf1 usrprf2"`. You must specify `-user`, `-authlist`, or both.

#### **-authlist**

The value `none` specifies that the current authorization list associated with the object should be removed. If you use the `-authlist` parameter, you must specify the value *none*. You must specify either `-user`, `-authlist`, or both.

#### **-object**

This is an optional parameter. The value `path` specifies the subdirectory or partially qualified object name to which you are revoking authority. The profile root is prepended to the value to get the fully-qualified path. If you do not specify this parameter, the default value is the profile root. To revoke authority to multiple objects, you must run the script for each object.

#### **-recursive**

This optional parameter specifies whether to revoke authority to all subdirectories. If you do not specify this parameter, authority is revoked only to the object specified with the `-object` parameter, or the profile root directory if the `-object` parameter is not specified. This parameter applies to all objects specified with `-object` parameters.

#### **-verbose**

This optional parameter turns on verbose messages, which can be helpful if you need to debug the script.

#### **-help**

This optional parameter displays the help message. If you specify this parameter, the script ignores all other parameters.

---

## enbprfwas command

The **enbprfwas** command enables a profile to allow an application server to run under it and optionally changes the group profile to QEJBSVR.

It is an alternative to using iSeries Navigator to do the same thing. To run this script, your user profile must have \*ALLOBJ authority.

### Syntax

The command syntax is as follows:

```
enbprfwas -profile usrprf [-chggrpprf]
```

### Parameters

The following options are available for the **enbprfwas** command:

#### -profile

This is a required parameter. The value *usrprf* specifies the name of the profile that you want to enable to run application servers.

#### -chggrp*prf*

This is an optional parameter. If you specify this parameter, the command changes the group profile of *usrprf* to *QEJBSVR*.

---

## enbprfwas command

The **enbprfwas** command enables a profile to allow an application server to run under it and optionally changes the group profile to QEJBSVR.

It is an alternative to using iSeries Navigator to do the same thing. To run this script, your user profile must have \*ALLOBJ authority.

### Syntax

The command syntax is as follows:

```
enbprfwas -profile usrprf [-chggrpprf]
```

### Parameters

The following options are available for the **enbprfwas** command:

#### -profile

This is a required parameter. The value *usrprf* specifies the name of the profile that you want to enable to run application servers.

#### -chggrp*prf*

This is an optional parameter. If you specify this parameter, the command changes the group profile of *usrprf* to *QEJBSVR*.

---

## upwashost command

The upwashost script updates a profile if the host name of the server is changed.

To run this script, your user profile must have \*ALLOBJ authority.

## Syntax

The command syntax is as follows:

```
updwashost -profileName profile [-newhost new_host]  
[-changenode -oldhost old_host] [-regenplugin] [-verbose] [-help]
```

## Parameters

The following options are available for the **updwashost** command:

### -profileName

This is a required parameter. The value *profile* specifies the name of the profile that you want to update. To update the host name for all profiles, specify ALL.

### -newhost

This is an optional parameter. The value *new\_host* specifies the new host name to use for the profile. The default value is the current host name of the server.

### -changenode

This is an optional parameter. If you specify this parameter, the script changes the node name in the profile. If you specify this parameter, the -oldhost parameter is required.

If the node of the profile node is federated into a deployment manager, it is recommended that you not include this parameter, as it might break references to the node name.

### -oldhost

This parameter is required if the -changenode parameter is specified, and not valid otherwise. The value specifies the old host name to use when changing the node name for the profile. The value specified will be replaced in the node name with the value specified in the -newhost parameter.

### -regenplugin

This optional parameter will call the **GenPluginCfg** command after updating the host for the profile to regenerate the HTTP server plug-in configuration.

### -verbose

This optional parameter turns on verbose messages, which can be helpful if you need to debug the script.

### -help

This optional parameter displays the help message. If you specify this parameter, the script ignores all other parameters.

---

## checkprereqs command

The **checkprereqs** command runs the prerequisite validator tool.

This tool verifies your WebSphere Application Server installation, ensures that you have the appropriate prerequisite software and PTFs installed, and verifies certain configuration settings that the product requires. To run this script, your user profile must have \*ALLOBJ authority.

## Syntax

The command syntax is as follows:

```
checkprereqs [-xmlinput xml_input_file] [-xmloutput xml_output_file]  
[-output output_file] [-trace trace_file] [-help]
```

## Parameters

The following options are available for the **checkprereqs** command:

**-xmlinput**

This is an optional parameter. The value *xml\_input\_file* specifies the fully qualified path of an XML file that the script uses. If you do not specify this parameter, the script uses the CheckPrereqs.xml file that is included in the ServiceTools.jar file.

**-xmloutput**

This is an optional parameter. The value *xml\_output\_file* specifies the fully qualified path of an XML file to which the script writes its results. If you do not specify this parameter, the script writes its output to the display.

**-output**

This is an optional parameter. The value *output\_file* specifies the fully qualified path of a file to which the script writes its standard output. If you do not specify this parameter, the script does not generate standard output.

**-trace**

This is an optional parameter. The value *trace\_file* specifies the fully qualified path of a file to contain trace information. If you do not specify this parameter, the script does not generate trace information.

**-verbose**

This is an optional parameter. If you specify this parameter, the script displays all result information. If you do not specify this parameter, the script does not display successful result information.

**-help**

This optional parameter displays the usage statement for the script.

---

## servicetools command

The **servicetools** command includes serviceability tools that you can use to troubleshoot WebSphere Application Server.

To run this script, your user profile must have \*ALLOBJ authority.

### Syntax

The command syntax is as follows:

```
servicetools [-products product_list [-profiles profile_list]]  
  [-input input_file] [-output output_file] [-trace trace_file]  
  [-tools tool_options]
```

### Parameters

The following options are available for the **servicetools** command:

**-products**

This is an optional parameter. The value *product\_list* specifies the list of products for which you want to run the tools. If you specify multiple products, separate them with a colon (:). Valid products are WAS60Base, WAS60ND, WAS60Express, WAS51Base, WAS51ND, WAS51Express, WAS51PME, WAS51PMEND, WAS50Base, WAS50ND, WAS50Express, WAS40Adv, WAS40AEs, and ALL. If you do not specify this parameter, you must specify the -products parameter for each tool as appropriate.

Not all tools require that you specify a product. This parameter applies only to those tools that require that you specify a product.

**-profiles**

This is an optional parameter. The value *profile\_list* specifies the profile or profiles for which you want to run the tools. If you specify multiple profiles, separate them with a colon (:). If you do not specify this parameter, the tools run for all of the profiles in the products specified by the -products parameter.

**-input**

This is an optional parameter. The value `input_file` specifies an alternate XML Configuration file for the service tools. By default, the `servicetools` script uses the `validator.xml` file that is included in the `ServiceTools.jar` file.

**-output**

This is an optional parameter. The value `output_file` specifies a file to which the script writes standard output. If this value is not specified, the script writes the standard output to the display.

**-trace**

This is an optional parameter. The value `trace_file` specifies a file to which the script writes trace information. If you do not specify this parameter, the script does not generate trace information.

**-tools**

This parameter specifies the tool or tools that you want to run. The value `tools` specifies the tool that you want to run. The value `tool_options` specifies the parameters for the tool. These are the valid values for `-tools`:

- **-checkprereqs** If you specify this parameter, the script starts the prerequisite validator tool. For information about this tool and its parameters, see [The prerequisite validator tool](#).
- **-portconflict** If you specify this parameter, the script starts the port validator tool. For information about this tool and its parameters, see [The port validator tool](#).

You must specify all other parameters before you specify the `tools` parameter. You must specify the options for each tool after its parameter. You can specify more than one tool when you run the `servicetools` script. To run multiple tools, use this format:

```
servicetools parameters -tool1 tool1_options -tool2 tool2_options
```

**-help**

This optional parameter displays the usage statement for the script.

## port validator tool

The port validator tool verifies your WebSphere Application Server configuration to ensure that you do not have port conflicts between WebSphere Application Server profiles and products.

The port validator tool is one of the tools available with the `servicetools` script. For descriptions of the syntax and parameters that apply to the `servicetools` script, see [The servicetools script](#).

### Syntax

The syntax to run the port validator tool is:

```
servicetools [ parameters ] -portconflict [ -products product_list ]
[ -profiles profile_list ] [ -ports port_list ]
[ -comparetoproduct compare_prod ] [ -comparetoprofile compare_inst ]
[ -xmloutput output_file ]
```

### Parameters

The parameters for the port validator tool are:

***parameters***

This optional parameter list specifies parameters for the `servicetools` script. See [The servicetools script](#) for more information. The `servicetools` parameters must be specified before the `-portconflict` parameter.

**-portconflict**

Specify this parameter to invoke the port validator tool.

**-products**

This is an optional parameter. The value `product_list` specifies the product or products for which you want to check for port conflicts. If you specify multiple products, separate them with a colon (:). Valid

products are WAS60Base, WAS60ND, WAS60Express, WAS51Base, WAS51ND, WAS51Express, WAS51PME, WAS51PMEND, WAS50Base, WAS50ND, WAS50Express, WAS40Adv, WAS40AEs, and ALL.

The port validator tool uses the `-products` and `-profiles` parameters to determine the set of ports that it checks for conflicts. The tool generates a default set of ports that includes the ports used by the specified products and profiles. If you do not specify this parameter, the port validator tool checks for port conflicts in the products specified by the `servicetools -products` parameter.

If you specify this parameter and the `-products` parameter for `servicetools`, the port validator tool checks only the products that you specify for the `-portconflict -products` parameter. You must specify the `-product` parameter for either the `servicetools` script or the port validator tool, or both.

#### **-profiles**

This is an optional parameter. The value `profile_list` specifies the profile or profiles for which you want to check for port conflicts. If you specify multiple profiles, separate them with a colon (:).

The port validator tool uses the `-products` and `-profiles` parameters to determine the default set of ports that it checks for conflicts. The tool generates a default set of ports that includes the ports used by the specified products and profiles. If you do not specify this parameter, the port validator tool checks for port conflicts in the profiles specified by the `servicetools -profiles` parameter, profiles within the products specified by the `-products` parameter.

If you specify this parameter and the `-profiles` parameter for `servicetools`, the port validator tool checks only the profiles that you specify for the `-portconflict -profiles` parameter. If you do not specify the `-profiles` parameter for either the `service tools` script or the port validator tool, the tool checks for port conflicts in all profiles in the specified products.

#### **-ports**

This is an optional parameter. The value `port_list` is a list of ports that you want to check for conflicts. If you specify this parameter, the tool generates a set of ports based on the value `port_list`. The tool checks for conflicts between this set of ports and the default set that is generated based on the `-products` and `-profiles` parameters.

You can specify individual ports, or port blocks. Separate ports or port blocks with a colon (:). For example, to check for conflicts on ports 6680, 7600-7610, and 13320, include specify this parameter: `-ports 6680:7600-7610:13320` If you do not specify this parameter, the port validator tool uses the values specified by the `-products`, `-profiles`, `-comparetoproduct`, and `-comparetoprofile` parameters to check for conflicts. You cannot specify the `-ports` parameter with the `-comparetoproduct` parameter or with the `-comparetoprofile` parameter.

#### **-comparetoproduct**

This is an optional parameter. The port validator tool compares port usage between the product specified by `compare_prod` and the products and profiles specified by `-products` and `-profiles`. If you specify this parameter, the port validator tool generates a set of ports based on the specified product. The tool checks for conflicts between this set of ports and the default set that is generated based on the `-products` and `-profiles` parameters.

You cannot specify the `-comparetoproduct` parameter with the `-ports` parameter.

#### **-comparetoprofile**

This is an optional parameter. The port validator tool compares port usage between the profile specified by `compare_inst` and the products and profiles specified by `-products` and `-profiles`. If you specify this parameter, the port validator tool generates a set of ports based on the specified profile. The tool checks for conflicts between this set of ports and the default set that is generated based on the `-products` and `-profiles` parameters.

You cannot specify the `-comparetoprofile` parameter with the `-ports` parameter.

### **-xmloutput**

This is an optional parameter. The value `output_file` is the fully qualified path of an XML file. If you specify this parameter, the port validator tool writes the output in XML format to the specified file, in addition to writing the output to the display.

---

## **prerequisite validator tool**

The prerequisite validator tool verifies your WebSphere Application Server installation, ensures that you have the appropriate prerequisite software and PTFs installed, and verifies certain configuration settings required by the product.

The prerequisite validator tool can also be run from the `checkprereqs` script. See [The checkprereqs script](#) for more information.

For descriptions of the syntax and parameters that apply to the `servicetools` script, see [The servicetools script](#).

### **Syntax**

The syntax to run the prerequisite validator tool is:

```
servicetools [ parameters ] -checkprereqs [ -xmlinput xml_input_file ]  
[ -xmloutput xml_output_file ] [ -verbose ]
```

### **Parameters**

The parameters for the prerequisite validator tool are:

#### ***parameters***

This optional parameter list specifies parameters for the `servicetools` script. See [The servicetools script](#) for more information. The `servicetools` parameters must be specified before the `-checkprereqs` parameter.

#### **-checkprereqs**

This parameter invokes the prerequisite validator.

#### **-xmlinput**

This is an optional parameter. The value `xml_input_file` specifies the fully qualified path of the XML file that lists the prerequisites that the script checks. If this parameter is not specified, the script uses the default XML input file that is included in the `ServiceTools.jar` file.

#### **-xmloutput**

This is an optional parameter. The value `xml_output_file` specifies the fully qualified path of the XML file to which the script writes the results. If neither this parameter nor the `-output` parameter is specified, output information is written to the display.

#### **-verbose**

This is an optional parameter. If you specify this parameter, the script displays all result information. If you do not specify this parameter, the script does not display successful result information.

---

## **configureOs400WebServerDefinition command**

The **`configureOs400WebServerDefinition`** command creates a web server definition in a WebSphere Application Server or deployment manager profile.

To run this command, your user profile must have `*ALLOBJ` authority. For more information about running this command, see the [Using command line tools](#) article.

Use an http profile when your web server resides on a different node than the Application Server or deployment manager. This script will generate another script when you run it against an HTTP profile. Use the generated script to create the web server definition in an Application Server or deployment manager profile by running the generated script from the appserver-profile-dir/bin directory, where appserver-profile-dir is the location of your application server or deployment manager. For additional information, see the [Selecting a Web server topology diagram and roadmap](#) article.

## Syntax

The command syntax is as follows:

```
configureOs400WebServerDefinition
  -webserver.instance.name webserverInstanceName |
  -webserver.name webserverName
  [ -webserver.admin.userID userId ]
  [ -webserver.admin.password password ]
  [ -profileName profile1 ]
  [ -webserver.type webserverType ]
  [ -webserver.host hostName | -webserver.node webserverNode ]
  [ -mapType mapType ]
  [ -webserver.port webserverPort ]
  [ -webserver.admin.port adminPort ]
  [ -was.admin.userId wasUserId ]
  [ -was.admin.password wasPassword ]
  [ -help | -? ]
```

## Parameters

The following options are available for the **configureOs400WebServerDefinition** command:

### **-webserver.instance.name**

This parameter is optional when **-webserver.name** is specified. The value *webserverInstanceName* specifies the name of the Web Server instance on the iSeries. The default value is *webserverName*.

### **-webserver.name**

This parameter is optional when **-webserver.instance.name** is specified. The value of *webserverName* specifies the name of the web server definition. The default value is *webserverType\_webserverInstanceName*.

### **-webserver.admin.userId**

This is an optional parameter. The value *userId* specifies the user id of the HTTP Administrator on the host name of the Web server.

### **-webserver.admin.password**

This is an optional parameter. The value *password* specifies the password of the HTTP Administrator on the host name of the Web server.

### **-profileName**

This is an optional parameter. The value *profile1* specifies the profile where the web server definition will be configured. The default value is *default*.

### **-webserver.type**

This is an optional parameter. It specifies the type of the Web Server. The value is either *IHS* or *DOMINO*. The default value is *IHS*.

### **-webserver.host**

This is an optional parameter. The *hostName* value specifies the host name of the Web server. The default value is *localhost*.

### **-webserver.node**

This is an optional parameter. The *webserverNode* value specifies the node name of the Web server definition. The default value is *hostName-node*.

**-mapType**

This is an optional parameter. The value specifies which applications are mapped to the web server definition. You must map applications to a Web server so that the Web server can serve requests to the application. The values allowed are: MAP\_NONE, MAP\_DEFAULT or MAP\_ALL. The default value is MAP\_ALL. MAP\_DEFAULT will only map the default application.

**-webserver.port**

This is an optional parameter. The value specifies the listening port of the Web server. The default is 80.

**-webserver.admin.port**

This is an optional parameter. The adminPort value specifies the admin port of the Web server. The default administrative port for the iseries HTTP Administrative GUI is 2001.

**-was.admin.userId**

This is an optional parameter. The wasUserId value specifies the user ID of the WebSphere Application Server administrator when the server is running in secure mode.

**-was.admin.password**

This is an optional parameter. The wasPassword value specifies the password of the WebSphere Application Server administrator when the server is running in secure mode.

**Usage scenario**

The following examples demonstrate correct syntax:

**Run on an http profile**

```
configureOs400WebServerDefinition -profileName profile1.remote -webserver.instance.name WEB1 -webserver.name WEB1
```

The profile1.remote profile is an http profile created using the http profile template.

Example output:

```
Web server configuration file: profile_root
/config/WEB1/configureWEB1 was created for remote profile
profile1.remote.
```

You need to copy the "*profile\_root*  
/config/WEB1/configureWEB1" script to the bin directory of the "Application Server" or "dmgr" profile and run it to create the web server definition "WEB1". Make sure you start the "Application Server" or "dmgr" before you run the script.

The above call created the following script in the profile1.remote profile:

```
profile_root/config/WEB1/configureWEB1
```

and indicated the steps needed to complete the web server definition creation.

**Run on a non http profile**

IHS Example

```
configureOs400WebServerDefinition -profileName profile1 -webserver.instance.name INSTANCE1 -webserver.name SERV1
```

Domino Example

```
configureOs400WebServerDefinition -profileName profile1 -webserver.type DOMINO -webserver.instance.name DOMIN01
```

---

## removeOs400WebServerDefinition command

The **removeOs400WebServerDefinition** command deletes a web server definition from the configuration repository of a Standalone or Deployment Manager profile.

To run this command, your user profile must have \*ALLOBJ authority. For more information about running this command, see the Using command line tools article.

### Syntax

The command syntax is as follows:

```
removeOs400WebServerDefinition
  -webserver.name webserverName
  -webserver.node webserverNode
  [-profileName profile1]
  [-removeNode]
  [-help | -?]
```

### Parameters

The following options are available for the **removeOs400WebServerDefinition** command:

#### **-webserver.name**

This is a required parameter. The value `webserverName` specifies the web server definition name you want to delete.

#### **-profileName**

This is an optional parameter. The value `profile1` specifies the profile whose web server definition is to be deleted. The default value is `default`.

#### **-webserver.node**

This is a required parameter. The value `webserverNode` specifies the node under which the web server is defined.

#### **-removeNode**

This is an optional parameter. Indicates to remove the Web server node. If you do not specify the `-removeNode` parameter, the Web server node is not removed.

### Usage scenario

The following example deletes the web server definition, `WEBSERVER1`, under the unmanaged node, `MYHOST-node`, and removes the node. It also updates the deployment data for any application that was mapped to the above Web server definition.

```
removeOs400WebServerDefinition -profileName profile1 -webserver.name WEBSERVER1
  -webserver.node MYHOST-node -removeNode
```

---

## dspwasinst command

The **dspwasinst** command displays information about a profile and the application servers it contains.

The script displays the following information:

- Application servers. For each application server, the script displays this information:
  - Port numbers
  - Installed applications
  - Status (running or stopped)
  - Job ID (if the application server is running)
- Profile type, location and template used to create.

- Cell name
- Node name
- Network Deployment managing host and port (for a base application server, if you are using Network Deployment)
- Nodes that are managed by the profile (for a Network Deployment profile)

For usage instructions and examples, see the Display profile properties article. To run this script, your user profile must have \*ALLOBJ authority.

## Syntax

The command syntax is as follows:

```
dspwasinst [-profileName profile] [-server servername] [-help]
```

## Parameters

The following options are available for the **dspwasinst** command:

### **-profileName**

This is an optional parameter. The value *profile* specifies the name of the profile that you want to display the properties for. The default value is *default*.

### **-server**

This is an optional parameter. The value *servername* specifies the name of the application server to display. If this value is not specified, all of the application servers in the profile are displayed. To display properties for multiple servers, specify multiple **-server** parameters.

### **-help**

This optional parameter displays the help message. If you specify this parameter, the script ignores all other parameters.

---

## chgwassvr command

The **chgwassvr** command allows you to change the ports for an application server within a profile.

For usage instructions and examples, see the Change application server properties article. To run this script, your user profile must have \*ALLOBJ authority.

In a Network Deployment environment, use the **chgwassvr** command from the Network Deployment profile to modify port values for the servers managed by the deployment manager for the cell. When you modify a port of a managed server, you must use the **-node** parameter to specify the node name of the managed node that contains the server that you want to modify. The configuration documents for the servers are updated when the next synchronization between the deployment manager and the nodes occurs. You can also synchronize the configuration with the **syncNode** command. For more information, see “syncNode command” on page 948 article. You run the **syncNode** command from the WebSphere Application Server base application server for the node.

You can also use the administrative console to create and manage application servers. See the Administering application servers article for more information.

## Syntax

The command syntax is as follows:

```
chgwassvr -server servername
  [instance instancename] [-profileName instancename]
  [-node nodename] [-portblock portnumber]
  [-transport -oldport oldvalue -newport newvalue]
```

```
[-endpoint endpointname -port newvalue]
[-inhttp inhttpport]
[-inhttps inhttpsport] [-admin adminport]
[-adminssl adminsslport] [-soap soapport]
[-nameservice nameserviceport]
[-celldiscovery celldiscoveryport]
[-sas sasserverport] [-csiv2server csiv2serverauthport]
[-csiv2client csiv2clientauthport] [-nodediscovery nodediscoveryport]
[-nodemulti nodemultdiscoveryport] [-verbose] [-help | -?]
```

## Parameters

The following options are available for the **chgwassvr** command:

### -server

This is a required parameter. The value *servername* specifies the name of the server to change. For the default WebSphere Application Server profile, the default server name is *server1*. For the default Network Deployment profile, the default server name is *dmgr*. The value for this parameter is case-sensitive and must match the server name exactly. You can use the **dspwasinst** command to view the servers associated with a profile. For more information, see the “*dspwasinst* command” on page 975 article.

### -profileName

This is an optional parameter. The value *profile* specifies the name of the profile that contains the application server you want to change. The default value is *default*.

### -node

This is an optional parameter. The value *nodename* specifies the node that hosts the application server that you want to change. The default value is the Network Deployment managing profile.

### -portblock

This is an optional parameter. The value *portblock* specifies the first number of a block of port numbers that your profile uses. If you specify this parameter, the script changes all of the port numbers for your application server. If you do not specify this parameter, the port numbers for your application server are not changed, unless you specify a port parameter to change (see port parameters below). You can use the Work with TCP/IP Network Status (NETSTAT \*CNN) command to display a list of port numbers that are currently being used.

- A WebSphere Application Server profile uses several ports for various functions. When you change an application server’s properties, ports are assigned based on the following ordered conditions:
  - **Specific port parameters** If you specify values for specific port parameters, the script uses those values. Specific port parameters are *-inhttp* (Base application server), *-admin*, *-jmsqueued* (Base application server), *-jmsdirect* (Base application server), *-jmssecure* (Base application server), *-soap*, *-orblister* (Network Deployment), *-nameservice*, *-drclient*, and *-celldiscovery* (Network Deployment).
  - **The -portblock parameter** Services for which you have not specified a port number are assigned ports sequentially starting with the value of the *-portblock* parameter. If a script encounters a port that is in use, it skips that port number and continues with the next unused port.
  - **Current values** If *-portblock* is not specified, any services for which you have not specified a port parameter retain their current value.
- For the *-portblock* parameter, the script checks only a master index of all profiles of WebSphere Application Server Version 5.1 and WebSphere Application Server Network Deployment Version 5.1. The script is not able to detect port usage by other applications, including previous versions of WebSphere Application Server.

### -transport

This is an optional parameter set. The value *oldvalue* specifies the port number of the Web container transport that you want to change. The value *newvalue* specifies the new port number that you want to

assign to the Web container transport. If the Web Container transport is also specified in the host alias for a virtual host, the port for the host alias is also updated.

Use the `-transport` parameter set instead of the `-admin`, `-adminssl`, `-inhttp` or `-inhttps` parameters. These parameters are deprecated.

**-endpoint**

This is an optional parameter. The value *endpointname* specifies the name of the endpoint port to modify. The value *newvalue* specifies port number to which to set the endpoint's port.

**-inhttp**

This is an optional parameter. The value *inhttpport* specifies the port number on which the Web container listens for requests from the Web server. If neither the `-portblock` parameter nor the `-inhttp` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-inhttps**

This is an optional parameter. The value *inhttpsport* specifies the port number that your application server uses for secure communications with internal HTTP server. If neither the `-portblock` parameter nor the `-inhttps` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-admin**

This is an optional parameter. The value *adminport* specifies the port number to use for the administrative console. If neither the `-portblock` parameter nor the `-admin` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-adminssl**

This is an optional parameter. The value *adminportssl* specifies the port number to use for the secure communications with administrative console. If neither the `-portblock` parameter nor the `-adminssl` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-soap**

This is an optional parameter. The value *soapport* specifies the port number to use for SOAP. If neither the `-portblock` parameter nor the `-soap` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-nameservice**

This is an optional parameter. The value *nameserviceport* specifies the port number to use for name service (or RMI connector) port. If neither the `-portblock` parameter nor the `-nameservice` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-celldiscovery**

This is an optional parameter. The value *celldiscoveryport* specifies the port on which the Network Deployment profile listens for a node attempting to find the cell to which the node belongs. If neither the `-portblock` parameter nor the `-celldiscovery` parameter is specified, this port is not changed. See the `-portblock` parameter for more information.

**-sas**

This is an optional parameter. The value *sasserverport* specifies the port on which the Secure Association Services (SAS) listen for inbound authentication requests. If the `-sas` parameter is not specified, this port is not changed. This port is specified by the `SAS_SSL_SERVERAUTH_LISTENER_ADDRESS` property in `serverindex.xml`.

**-csiv2server**

This is an optional parameter. The value *csiv2serverauthport* specifies the port on which the Common Secure Interoperability Version 2 (CSIV2) Service listens for inbound server authentication requests. If the `-csiv2server` parameter is not specified, this port is not changed. This port is specified by the `CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS` property in `serverindex.xml`.

**-csiv2client**

This is an optional parameter. The value *csiv2clientauthport* specifies the port on which the Common Secure Interoperability Version 2 (CSIV2) Service listens for inbound client authentication requests. If

the `-csiv2client` parameter is not specified, this port is not changed. This port is specified by the `CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS` property in `serverindex.xml`.

**-nodediscovery**

This is an optional parameter. The value *nodedisport* specifies the port on which the node of the node agent discovery service listens.

**-nodemulti**

This is an optional parameter. The value *nodemultidiscport* specifies the port on which the node agent's multicast discovery service listens.

**-verbose**

This optional parameter turns on verbose messages, which can be helpful if you need to debug the script.

**-help**

This optional parameter displays the help message. If you specify this parameter, the script ignores all other parameters.

---

## grtwasaut command

The **grtwasaut** command grants a user authority to a profile and the objects associated with it.

For usage instructions and examples, see the Grant authority to a profile article. To run this script, your user profile must have \*ALLOBJ authority.

### Syntax

The command syntax is as follows:

```
grtwasaut [-profileName profile] {-user usrprf | -authlist authlist}
          {-dtaut dataAuth | -objaut objectAuth} [-object path]
          [-recursive] [-verbose] [-help]
```

When you run the **grtwasaut** command, you must specify the following parameters:

- `-user`, `-authlist`, or both
- `-dtaut`, `objaut`, or both

### Parameters

The following options are available for the **grtwasaut** command:

**-profileName**

This is an optional parameter. The value *profile* specifies the name of the profile to which you are granting authority. The default value is *default*.

**-user**

The value *usrprf* specifies the OS/400 user profile to which you are granting authority. To grant authority to multiple user profiles, specify all of the user profiles with a single `-user` parameter. Enclose the list of profiles in double quotation marks ("). For example, to grant authority to `usrprf1` and `usrprf2`, specify `-user "usrprf1 usrprf2"`. You must specify `-user`, `-authlist`, or both.

**-authlist**

The value *authlist* specifies the OS/400 authorization list to which you are granting authority. You must specify `-user`, `-authlist`, or both.

**-dtaut**

The value *dataAuth* specifies the data authorities that you are granting to the user specified by the `-user` parameter. Valid values are `none`, `rxw`, `rx`, `rw`, `wx`, `r`, `w`, `x`, `exclude`, `autl`, and `same`. The value that

you specify replaces the user's current data authorities to the object. You must specify `-dtaut`, `-objaut`, or both. For more information on the values for this parameter, see the CHGAUT (Change Authority) command description.

#### **-objaut**

The value *objAuth* specifies the object authorities that you are granting to the user specified in the `-user` parameter. Valid values are `none`, `all`, `objexist`, `objmgt`, `objalter`, `objref`, and `same`. The value that you specify replaces the user's current object authorities to the object. You must specify `-dtaut`, `-objaut`, or both. For more information on the values for this parameter, see the CHGAUT (Change Authority) command description.

#### **-object**

This is an optional parameter. The value *path* specifies the subdirectory or partially qualified object name to which you are granting authority. The profile root is prepended to the value to get the fully-qualified path. If you do not specify this parameter, the default value is the profile root. To grant authority to multiple objects, you must run the script for each object.

#### **-recursive**

This optional parameter specifies whether to grant authority to all subdirectories. If you do not specify this parameter, authority is granted only to the object specified with the `-object` parameter, or the profile root directory if the `-object` parameter is not specified. This parameter applies to all objects specified with `-object` parameters.

#### **-verbose**

This optional parameter turns on verbose messages, which can be helpful if you need to debug the script.

#### **-help**

This optional parameter displays the help message. If you specify this parameter, the script ignores all other parameters.

---

## **heapMonitor command**

The **heapMonitor** command manages the iSeries WebSphere Custom Service Heap Monitor, which sends messages to QSYSOPR when the WebSphere Java heap is close to exceeding or exceeds the storage pool size.

### **Product**

This script is available in WebSphere Application Server, WebSphere Application Server - Express, and WebSphere Application Server, Network Deployment.

### **Authority**

To run this script, your user profile must have `*ALLOBJ` authority.

### **Syntax**

```
heapMonitor [-profileName profile] [wsadmin_options]
[-server.name server_name] [-enable | -disable | -status | -viewlog] [-help]
```

- **-profileName**

The name of the profile to manage. The default profile is used if no profile is specified.

- **-server.name**

The name of the application server to manage. The default value is the name of the profile, or "server1" if the profile is named "default."

- **-enable**

Enables heap monitoring on a server. If heap monitoring is already enabled, it does nothing.

- **-disable**

Disables heap monitoring on a server. If heap monitoring is already disabled, it does nothing.

- **-status**

Displays whether heap monitoring is enabled on a server.

- **-viewlog**

Displays heap monitor messages since the last startup of the application server.

- **-help**

Displays this help message.

---

## Chapter 6. Using Ant to automate tasks

To support using Apache Ant with Java 2 Platform, Enterprise Edition (J2EE) applications running on the application server, the product provides a copy of the Ant tool and a set of Ant tasks that extend the capabilities of Ant to include product-specific functions. Ant has become a very popular tool among Java programmers.

Apache Ant is a Java-based build tool. In theory, it is similar to Make, but Ant is different. Instead of a model in which it is extended with shell-based commands, Ant is extended using Java classes. Instead of writing shell commands, XML-based configuration files are used. These files reference a target tree in which various tasks are run. Each task is run by an object that implements a particular Task interface.

By combining the following tasks with those provided by Ant, you can create build scripts that compile, package, install, and test your application on the application server:

- Install and uninstall applications
- Start and stop servers in a base configuration
- Run administrative scripts or commands
- Run the Enterprise JavaBeans (EJB) deployment tool
- Run the JavaServer Pages (JSP) file precompilation tool

For more detailed information about Ant, refer to the Apache organization Web site.

- To run Ant and have it automatically see the WebSphere classes, use the “ws\_ant command.”
- Use “Ant tasks for deployment and server operation.”

This topic describes where to find the API documentation for the Apache Ant tasks for deploying applications and operating application servers.

- Use “Ant tasks for building application code” on page 984.

This topic describes where to find the API documentation for the Apache Ant tasks for building applications.

---

### ws\_ant command

This topic describes where to find information about the ws\_ant command, which is provided for using with Apache Ant, a Java-based build tool that is popular among Java programmers.

In theory, Ant is similar to Make, but Ant is different. Instead of a model in which it is extended with shell-based commands, Ant is extended using Java classes. Instead of writing shell commands, XML-based configuration files are used. These files reference a target tree in which various tasks are run. Each task is run by an object that implements a particular Task interface.

For the Apache Ant tool that is provided by this product, see the file *app\_server\_root/bin/ws\_ant.bat* or *ws\_ant.sh*.

---

### Ant tasks for deployment and server operation

This topic describes where to find the API documentation for the Apache Ant tasks for deploying applications and operating application servers.

The Apache Ant tasks for the product reside in the Java package: `com.ibm.websphere.ant.tasks`. The API documentation for this package contains detailed information about all of the Ant tasks that are provided and how to use them. The API documentation is available in the **Reference** section of the information center.

---

## Ant tasks for building application code

This topic describes where to find the documentation for the Ant tasks provided for building application code using the Application Server Toolkit (which is a CD included with WebSphere Application Server as a separately installable toolkit).

Note that this toolkit includes an Automated Deployment example "Example: Automated Deploy" for JACL scripted deployment of multiple application updates to multiple servers and clusters in a WebSphere Network Deployment cell.

Within the Application Server Toolkit product documentation, open the section **Working with Ant**. You can locate the topic by searching for **Working with Ant**, or from the navigation view, select **Help > Help Contents > Application Server Toolkit > J2EE applications > Working with Ant**.

---

## Appendix. Directory conventions

References in product information to *app\_server\_root*, *profile\_root*, and other directories infer specific default directory locations. This topic describes the conventions in use for WebSphere Application Server Network Deployment.

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server Network Deployment products or components, of course, require multiple locations.

### **app\_server\_root - the install\_root for WebSphere Application Server**

The default installation root directory for WebSphere Application Server Network Deployment is the /QIBM/ProdData/WebSphere/AppServer/V61/ND directory.

### **profile\_root**

The default directory for a profile named *profile\_name* for WebSphere Application Server Network Deployment is the /QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/*profile\_name* directory.

### **app\_server\_user\_data\_root - the user\_data\_root for WebSphere Application Server**

The default user data directory for WebSphere Application Server Network Deployment is the /QIBM/UserData/WebSphere/AppServer/V61/ND directory.

### **plugins\_root**

The default installation root directory for Web server plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V61/webserver directory.

### **plugins\_user\_data\_root**

The default Web server plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V61/webserver directory.

### **plugins\_profile\_root**

The default Web server plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V61/webserver/profiles/*profile\_name* directory.

### **app\_client\_root**

The default installation root directory for the J2EE WebSphere Application Client is the /QIBM/ProdData/WebSphere/AppClient/V61/client directory.

### **app\_client\_user\_data\_root**

The default J2EE WebSphere Application Client user data root is the /QIBM/UserData/WebSphere/AppClient/V61/client directory.

### **app\_client\_profile\_root**

The default J2EE WebSphere Application Client profile root is the /QIBM/UserData/WebSphere/AppClient/V61/client/profiles/*profile\_name* directory.

### **web\_server\_root**

The default web server path is /www/*web\_server\_name*.

### **shared\_product\_library**

The shared product library, which contains all of the objects shared by all Version 6.1 installations on the system, is QWAS61. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

### **product\_library**

The product library, which contains program and service program objects (similar to .exe, .dll, .so objects for Windows, Linux, and UNIX operating system platforms), is: QWAS61x where x is A, B, C, ... For the default installation, the value is QWAS61A.

**product\_lib**

The product library that contains the service program objects for the web server plugins. For the default Web Server Plugins install, this is QWAS61A. If you install the Web Server Plugins multiple times, the product\_lib is QWAS61c, where *c* is B, C, D, ... The plugins\_install\_root/properties/product.properties contains the value for the product library..

**cip\_app\_server\_root**

The default installation root directory is the /QIBM/ProdData/WebSphere/AppServer/V61/ND/cip/cip\_uid directory for a customized installation package (CIP) produced by the Installation Factory.

A CIP is a WebSphere Application Server Network Deployment product bundled with optional maintenance packages, an optional configuration archive, one or more optional enterprise archive files, and other optional files and scripts.

**cip\_user\_data\_root**

The default user data root directory is the /QIBM/UserData/WebSphere/AppServer/V61/ND/cip/cip\_uid directory for a customized installation package (CIP) produced by the Installation Factory.

**cip\_profile\_root**

The default profile root directory is the /QIBM/UserData/WebSphere/AppServer/V61/ND/cip/cip\_uid/profiles/profile\_name directory for a customized installation package (CIP) produced by the Installation Factory.
