## How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

---

## Chapter 1. Using the administrative console

This topic provides information on using the administrative console to perform administrative activities.

The administrative console is a Web-based tool that you use to manage the IBM WebSphere Application Server product as well as the Network Deployment product. The administrative console supports a full range of product administrative activities.

1. Optionally install the administrative console through the `wsadmin` command.
2. Start the server for the administrative console.

For the Network Deployment product, the administrative console belongs to the deployment manager (`dmgr`) process, which you start with the **startmanager** command.

For more information on the deployment manager process, see the *Administering applications and their environment* PDF.

3. Access the administrative console.
4. Specify console preferences.
5. Access help.

---

### Installing and uninstalling the administrative console

You can install the administrative console during profile creation or after you create a profile. You can uninstall any administrative console that you install. To install an administrative console after profile creation, or to uninstall the administrative console, use the **wsadmin** command. This topic discusses how to use the **wsadmin** command to install and uninstall the administrative console.

If you install the administrative console through the **wsadmin** command, a profile that does not have an administrative console installed must exist.

Run the `deployConsole` script on the **wsadmin** command whenever you want to uninstall the administrative console, or whenever you want to install the administrative console to a profile that does not have an administrative console installed.

You can run the script in either connected or disconnected mode.

The usual security restrictions for the **wsadmin** command apply to this script. In connected mode, the user must authenticate if security is enabled.

Whenever the administrative console is installed, it is installed onto the deployment manager server. The **wsadmin** command attempts to remotely connect to the deployment manager to install or uninstall the administrative console. However, various situations can keep the **wsadmin** command from connecting to the deployment manager, and an error message results. The command cannot connect if:

- The deployment manager is not running.
- The deployment manager is running, but the script was run somewhere other than on the deployment manager. You are most likely running the script on a federated node.

The `deployConsole.py` script is located in the `profile_root/bin` directory.

- To install the administrative console, issue the following command:  
`wsadmin -f deployConsole.py install`
- To uninstall the administrative console, issue the following command:  
`wsadmin -f deployConsole.py remove`

The administrative console is installed or uninstalled, depending on whether you specified the install or remove option.

---

## Starting and logging off the administrative console

This topic describes how to set up the administrative console environment, to access the administrative console, and to log out of the administrative console.

To access the administrative console, you must first install WebSphere Application Server and the administrative console.

To access the administrative console, you must start it and then log in. After you finish working in the administrative console, save your work and log out.

1. Start the administrative console.
  - a. Enable cookies in the Web browser that you use to access the administrative console.
  - b. Optionally enable JavaScript. Enablement of JavaScript is recommended so that all the features of the administrative console are available to you.
  - c. In the same Web browser, type `http://your_fully_qualified_server_name:port_number/ibm/console`, where *your\_fully\_qualified\_server\_name* is the fully qualified host name for the machine that contains the administrative server, and *port\_number* is the administrative console port number. When the administrative console is on the local machine, *your\_fully\_qualified\_server\_name* can be `localhost` unless security is enabled. On Windows platforms, use the actual host name if `localhost` is not recognized. If security is enabled, your request is redirected to `https://your_fully_qualified_server_name:port_number/ibm/console`, where *your\_fully\_qualified\_server\_name* is the fully qualified host name for the machine that contains the administrative server, and *port\_number* is the administrative console secure port number.

The default port number for an unsecure administrative console is port 9060, and for a secure administrative console is port 9043. Each new administrative console that you deploy during profile creation is assigned a new unsecure port number, and, if you enable security during profile creation, a new secure port number.

Check the `SystemOut.log` file of the server that runs the console application to verify that the console application starts successfully. If the console application starts successfully, you see the `CWWSR0221I: Application started: isclite` message.

If you cannot start the administrative console because the console port conflicts with an application that is already running on the machine, use the `chgwassvr` script command to change the port number. See [Changing the ports associated with an application server](#) for further information. Alternatively, shut down the other application that uses the conflicting port before starting the WebSphere Application Server product.

For a listing of supported Web browsers, see [WebSphere Application Server system requirements](#) at

[http://www.ibm.com/support/docview.wss?  
rs=180&uid=swg27006921](http://www.ibm.com/support/docview.wss?rs=180&uid=swg27006921)

The Web address displays on two lines for printing purposes. Enter the Web address on one line in your browser.

- d. Wait for the console to load into the browser.

A login page displays after the console starts.
2. Log into the console.
    - a. Enter your user name or user ID.

The user ID lasts only for the duration of the session for which it is used to log in. Changes made to server configurations are saved to the user ID. Server configurations also are saved to the user ID if a session timeout occurs.

See the *Administering applications and their environment* PDF for more information on server configurations.

If you enter an ID that is already in use and in session, you are prompted to do one of the following actions:

- Log out the other user with the same user ID. You can recover changes made during the other user's session.
  - Return to the login page and enter a different user ID.
- b. If the console is secure, you must also enter a password for the user name. The console is secure if someone has taken the following actions for the console:
- Specified security user IDs and passwords
  - Enabled global security

See the *Securing applications and their environment* PDF for more information.

- c. Click **OK**.
3. Log off the administrative console. Click **System administration > Save changes to Master Repository > Save** to save work. Then click **Logout** to exit the console.

If you close the browser before saving your work, you can recover any unsaved changes the next time that you log in under the same user ID.

You have set up the administrative console environment, accessed the administrative console, and logged out of the administrative console.

Use the administrative console to manage WebSphere Application Server.

## Logging in

To access the console, enter your **User ID** and **Password** and then click **Log in**. The password is required only if security is enabled.

After you are logged in, be sure to use the **Logout** link in the console toolbar when you are finished using the console and to prevent unauthorized access. If there is no activity during this login session for an extended period of time, the session expires and you must login again to access the console. The administrator can change the session timeout. See “Changing the console session expiration” on page 27 for more information. The default is set to 30 minutes.

If the user ID that you provide is already logged in at a different location, you are prompted to choose between logging out from the other location or returning to the login page. If you log out the user from the other location, you might be prompted to recover unsaved changes made by that user.

If you have one or more different standalone servers running on the same machine and wish to administer them concurrently from the same or a different machine then you must:

1. Ensure that each server uses a unique value for its admin console port.
2. Run a separate web browser process for each admin console that you wish to access concurrently.

## Save changes to the master configuration

Use this topic to update the master repository with your administrative console changes, to discard your administrative console changes and continue working with the master repository, or to continue working with your administrative console changes that are not saved to the master repository.

Until you save changes to the master repository, the administrative console uses a local workspace to track your changes.

## Total changed documents

Specifies the total number of documents that you changed for your session, but that are not saved to the master repository. By clicking the +/- toggle key, you can see additional information about the changed documents:

- **Changed items**

When you change your local configuration, each path and configuration file that you can apply the update to in the master repository is displayed in the list.

- **Status**

The status can contain the following options:

- **Added:** If you save your changes to the master repository, a new configuration file is created on the indicated path.
- **Updated:** If you save your changes to the master repository, an existing configuration file is updated on the indicated path.
- **Deleted:** If you save your changes to the master repository, an existing configuration file is deleted on the indicated path.

## Synchronize changes with nodes

Specifies whether you want to force node synchronization at the time that you save your changes to the master repository, rather than when node synchronization normally occurs.

## Save conflict

Specifies that another user changed some configuration information since you began making changes. You can either click **Save** to overwrite the other user information, or **Discard** to discard your changes and keep the changes that the other user made.

---

## Administrative console buttons

This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

- **Select all items.** Selects each resource that is listed on the administrative console panel, in preparation for performing an action against the selected resources.
- **Deselect all items.** Removes all the listed resources from each selection so that no action is performed against any of the resources.
- **Show filter function.** Produces a dialog box for specifying the resources to view in the table on this administrative console page.
- **Hide filter function.** Hides the dialog box for specifying the resources to view in the table on this administrative console page.

When you produce the dialog box, select the column to filter and enter the filter criteria.

### Column to filter

Select the column to filter from the drop-down list. When you apply the filter, only those items in the selected column that meet the filter criteria are displayed.

For example, select **Names** to enter criteria by which to filter application server names.

### Filter criteria

Enter a string that must be found in the name of a collection entry to qualify the entry to display in the collection table. The string can contain percent sign (%), asterisk (\*), or question mark (?) symbols as wildcard characters. For example, enter \*App\* to find any application server whose name contains the string App.

Prefix each of the following characters ( ) ^ \* % { } \ + \$ with a backslash (\) so that the regular expression engine performing the search correctly matches the search criteria. For example, to search for all Java DataBase Connectivity (JDBC) providers containing (XA) in the provider name, specify the following string:

```
*\ (XA\)
```

- **Clear filter value.** Clears your filter changes and restores the most recently saved values.
- **Abort.** Stops a transaction that is not yet in the prepared state. All operations that the transaction completed are undone.
- **Activate.** Activates a group member.
- **Add.** Adds the selected or typed item to a list, or produces a dialog for adding an item to a list.
- **Add Node.** Displays the Add Node page, in which you specify the host name and SOAP connector port for a node that you want added to a cell.
- **Apply.** Saves your changes to a page without exiting the page.
- **Back.** Displays the previous page or item in a sequence. The administrative console does not support using the Back and Forward options of a browser, which can cause intermittent problems. Use Back or Cancel on the administrative console panels instead.
- **Balance.** Balances active members in high availability groups across servers that host the high availability groups. The administrator must first determine which groups have active members and select those groups before selecting Balance.
- **Browse.** Opens a dialog that enables you to look for a file on your system.
- **Calculate groups.** Calculates the number of high availability groups that are returned based on the match set.
- **Cancel.** Exits the current page or dialog, discarding unsaved changes. The administrative console does not support using the Back and Forward options of a browser, which can cause intermittent problems. Use Cancel on the administrative console panels instead.
- **Change.** In the context of security, you can search the user registry for a user ID for an application to run under. In the context of container properties, you can change the data source that the container is using.
- **Clear.** Clears your changes and restores the most recently saved values.
- **Clear selections.** Clears any selected cells in the tables on this tabbed page.
- **Close.** Exits the dialog.
- **Collapse all.** Collapses all the expanded items.
- **Commit.** Releases all locks that are held by a prepared transaction and forces the transaction to commit.
- **Copy.** Creates copies of the selected application servers.
- **Create.** Saves your changes to all the tabbed pages in a dialog and exits the dialog.
- **Create tables.** Develops scheduler database tables.
- **Deactivate.** Deactivates a group member. The group member must be in the active state to be deactivated. The deactivate option causes the group member to move to the idle state. The group policy overrides which members are activated and deactivated for a group. The policy is enforced for every member state change. If the deactivate option conflicts with the group policy, the policy resets who is the active member of the group.
- **Delete.** Removes the selected instance.
- **Details.** Shows the details about a transaction.
- **Disable.** Disables a group or group member. When you disable a group or group member, the active group or group member is first deactivated. If the deactivate option is successful, the group or group member moves to the disable state. A disabled group or group member cannot be activated.
- **Disable Auto Start.** Requires you to start the application manually.
- **Discard.** Discards your local changes instead of saving them to the master configuration.
- **Done.** Saves your changes to all the tabbed pages in a dialog and exits the dialog.
- **Down.** Moves through a list.
- **Drop tables.** Removes scheduler database tables.
- **Dump.** Activates a dump of a traced application server.
- **Edit.** Lets you edit the selected item in a list, or produces a dialog box for editing the item.
- **Enable.** Enables a group or a group member.
- **Enable Auto Start.** Starts an application automatically when the server on which the application resides starts.
- **Expand all.** Expands all the collapsed items.
- **Export.** Accesses a page for exporting enterprise archive (EAR) files for an enterprise application.
- **Export DDL.** Accesses a page for exporting data definition language (DDL) files for an enterprise application.

- **Export Keys.** Exports Lightweight Third-Party Authentication (LTPA) keys to other domains.
- **Export route table.** Exports the route table information for a selected cluster to a binary file in the configuration.
- **Filter.** Produces a dialog box for specifying the resources to view in the tables on this tabbed page.
- **Finish.** Forces a transaction to finish, regardless of whether its outcome has been reported to all participating applications.
- **First.** Displays the first record in a series of records.
- **Force delete.** Forces the removal of a node that is not removed properly from the cell in the master repository. The **Remove node** action is preferred over the **Force delete** action to delete a node from the configuration. If you click **Force delete**, but the node still exists in the configuration, uninstall the node or run the **removeNode** command by using the **-force** parameter on that node. Force delete action is equivalent to running the **cleanupNode** command at the deployment manager.
- **Full resynchronize.** Synchronizes the user's configuration immediately. Click full resynchronize on the Nodes page if automatic configuration synchronization is disabled, or if the synchronization interval is set to a long time, and a configuration change is made to the cell repository that needs to be replicated to that node. Clicking this option clears all synchronization optimization settings and performs configuration synchronization again, so no mismatches occur between node and cell configuration after this operation is performed. This operation can take awhile to perform.
- **Generate keys.** Generates new LTPA keys. When security is turned on for the first time with LTPA as the authentication mechanism, LTPA keys are automatically generated with the password entered in the panel. To generate new keys, use this option after the server is up with security turned on. Clicking this option generates the keys and propagates them to all active servers (cell, node, and application servers). The new keys can be used to encrypt and decrypt the LTPA tokens. Click **Save** on the console taskbar to save the new keys and the password in the repository.
- **Immediate stop.** Stops the server, but bypasses the normal server quiesce process that supports in-flight requests to complete before shutting down the entire server process. This shutdown mode is faster than the normal server stop processing, but some application clients can receive exceptions.
- **Import keys.** Imports new LTPA keys from other domains. To support single sign-on (SSO) in WebSphere Application Server across multiple WebSphere domains (cells), share LTPA keys and a password among the domains. After exporting the keys from one of the cells into a file, click this option to import the keys into all the active servers (cell, node, and application servers). The new keys can be used to encrypt and decrypt the LTPA token. Click **Save** on the console taskbar to save the new keys and the password in the repository.
- **Install.** Displays the Preparing for application installation page, which you use to deploy an application, an enterprise bean, or a Web component onto an application server.
- **Install RAR.** Opens a dialog that is used to install a Java 2 Platform, Enterprise Edition Connector Architecture (JCA) connector and to create a resource adapter.
- **Manage state.** Displays a list of MBeans that corresponds to your previous selection of data source or connection factory configurations. You can apply JCA lifecycle management operations to these MBeans to control the run-time status of the corresponding resources.
- **Manage transactions.** Displays a list of active transactions running on a server. You can forcibly finish any transaction that has stopped processing because a transactional resource is not available.
- **Modify.** Opens a dialog that is used to change a specification.
- **Move.** Moves the selected application servers to a different location in the administrative cell. When prompted, specify the target location.
- **Move down.** Moves downward through a list.
- **Move up.** Moves upward through a list.
- **New.** Displays a page that you use to define a new instance. For example, clicking **New** on the Application Servers page displays a page on which you can configure a new application server.
- **Next.** Displays the next page, frame, or item in a sequence.
- **OK.** Saves your changes and exits the page.
- **Pause.** In the context of JCA lifecycle management, stops all outbound communication that is conducted through a resource on a specified server to a backend.
- **Ping.** Attempts to contact selected application servers.
- **Previous.** Displays the previous page, frame, or item in a sequence.
- **Quit.** Exits a dialog box and discards any unsaved changes.

- **Reference shared libraries.** Opens the collection of shared library references available for use by your application or module. If no references are available, a message is displayed stating that there are no references.
- **Refresh.** Refreshes the view of data for instances that are currently listed on this tabbed page.
- **Regenerate encryption key.** Regenerates a key for global data replication. If you are using the DES or TRIPLE\_DES encryption type, regenerate a key at regular intervals (for example, monthly) to enhance security.
- **Remove.** Deletes the selected item.
- **Remove file.** Removes the specified file from the selected application or module.
- **Remove node.** Deletes the selected node.
- **Reset.** Clears your changes on the tab or page and restores the most recently saved values.
- **Restart all servers on node.** Stops all application servers on the node and starts them again.
- **Resume.** In the context of JCA lifecycle management, restarts the activity of a data source or a connection factory that was paused by a previous JCA lifecycle management operation.
- **Retrieve new.** Retrieves a new record.
- **Rollout update.** Sequentially updates an application that is installed on multiple cluster members across a cluster. After you update application files or a configuration, click **Rollout update** to install the configuration or the updated files for an application on all the cluster members of a cluster on which the application is installed. The Rollout update option applies the following steps to each cluster member in sequence:
  1. Saves an updated configuration.
  2. Stops the cluster member.
  3. Updates the application on the node by synchronizing the configuration.
  4. Restarts the cluster member.

Use **Rollout Update** if the application is deployed on one or more clusters spread across multiple nodes. This action reduces the amount of time that any single cluster member is unavailable to serve requests to the smallest interval possible. For a single node environment, use **Update** and then save and synchronize the node instead.

- **Save.** Saves the changes in your local configuration to the master configuration.
- **Select.** For resource analysis, lets you select a scope in which to monitor resources.
- **Set.** Saves your changes to settings in a dialog.
- **Settings.** Displays a dialog for editing servlet-related resource settings.
- **Settings in use.** Displays a dialog showing the settings in use.
- **Show groups.** Displays a collection of high availability groups, based on the match set.
- **Show servers.** Displays a collection of servers that are contained in the high availability groups that match the match set.
- **Start.** In the context of application servers, starts selected application servers. In the context of data collection, starts collecting data for the tables on this tabbed page.
- **Stop.** In the context of server components such as application servers, stops the selected server components. In the context of a data collection, stops collecting data for the tables on a tabbed page. In the context of nodes, stops servers on the selected nodes. In the context of deployment managers, stops the deployment manager server.
- **Synchronize.** Synchronizes the user's configuration immediately. Click Synchronize on the Nodes page if automatic configuration synchronization is disabled, or if the synchronization interval is set to a long time, and a configuration change is made to the cell repository that needs replicating to that node. A node synchronization operation is performed using the normal synchronization optimization algorithm. This operation is fast, but might not fix problems from manual file edits that occur on the node. It is possible for the node and cell configuration to be out of synchronization after this operation is performed. If problems persist, use Full Resynchronize.
- **Terminate.** Deletes the Application Server process or another process that cannot be stopped by the **Stop** or **Immediate Stop** commands. Some application clients can receive exceptions. Always attempt an immediate stop before using this option.

- **Test connection.** After you define and save a data source, you can select this option to ensure that the parameters in the data source definition are correct. On the Collection panel, you can select multiple data sources and test them simultaneously.
- **Uninstall.** Deletes a deployed application from the WebSphere Application Server configuration repository. Also deletes application binary files from the file system.
- **Update.** For applications, replaces an application that is deployed on a server with an updated application. As part of the updating, you might need to complete steps on the Preparing for application installation and Update application pages.  
For clusters, changes the configured weight or runtime weight assigned to a cluster member.
- **Update resource list.** Updates the data on a table. Discovers and adds new instances to the table.
- **Use cell CSI.** Enables Object Management Group (OMG) Common Secure Interoperability (CSI) protocol.
- **V6.0.x Use cell SAS.** Enables IBM Secure Authentication Service (SAS).
- **Use cell Security.** Enables cell security.
- **Verify tables.** Validates the mapping between the table names, scheduler resource, and data sources.
- **View.** Opens a dialog on a file.

---

## Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs.

Administrative console pages are arranged in a few basic patterns. Understanding their layout and behavior can help you use them more easily.

### Collection pages

Use collection pages to manage a collection of existing administrative objects. A collection page typically contains one or more of the following elements:

**Scope** Scope is described in “Administrative console scope settings” on page 16.

#### Preferences

Preferences are described in “Administrative console preference settings” on page 15.

#### Table of existing objects

The table displays existing administrative objects of the type specified by the collection page. The table columns summarize the values of the key settings for these objects. If no objects exist yet, an empty table is displayed. Use the available options to create a new object.

#### Buttons for performing actions

The available actions are described on the Administrative console buttons help panel. In most cases, you need to select one or more of the objects in the table, then click an action. The action is applied to the selected objects.

#### Sort toggle buttons

The column headings in the table are followed by icons for sort ascending (^) and sort descending (v). By default, items such as names are sorted in descending order (alphabetically). To enable another sorting order, click the icons for the column that you want to sort.

### Detail pages

Use detail pages to configure specific administrative objects, such as an application server. A detail page typically contains one or more of the following elements:

#### Configuration tabbed page

This tabbed page is for modifying the configuration of an administrative object. Each configuration page has a set of general properties that is specific to the administrative object. Other sets of properties display on the page, but vary depending on the administrative object.

### **Runtime tabbed page**

This tabbed page displays the configuration that is currently in use for the administrative object. The object is read-only in most cases. Some detail pages do not have runtime tabs.

If you can edit runtime properties, these properties directly affect the current runtime environment, but are not preserved when that environment is stopped.

### **Local Topology tabbed page**

This tabbed page displays the topology that is currently in use for the administrative object. View the topology by expanding and collapsing the different levels of the topology. Some detail pages do not have local topology tabs.

### **Buttons for performing actions**

Buttons to perform specific actions display on the configuration tabbed page and the Runtime tabbed page. The displayed buttons vary based on the administrative object. The available buttons are described on the Administrative console buttons help panel.

### **Wizard pages**

Use wizard pages to complete a configuration process comprised of several steps. Be aware that wizards show or hide certain steps depending on the characteristics of the specific object that you are configuring.

---

## **Console layout**

This topic describes the layout of the user interface for Integrated Solutions Console.

See Navigating the console for instructions on how to use the console controls.

### **Banner**

Displays a common image across all Integrated Solutions Console installations. The banner includes a greeting to the user who is logged in and links to log out of the console and to open console help.

### **Navigation tree**

Lists the tasks available in the console. Tasks are grouped into organizational nodes that represent categories of tasks, for example, Servers, or Applications. The organizational nodes can be nested in multiple levels.

The tasks shown are only those for which the user has access. When you click a task in the navigation, a page is displayed in the work area containing one or more modules for completing the task. Use the View selection list at the top of the navigation area to modify the list of tasks according to your preferences. You can organize the tasks as follows:

#### **All tasks**

This shows all tasks in the console. Tasks are grouped into organizational nodes, for example, Guided activities, Servers, or Applications.

#### **My tasks**

This shows only the tasks that you have added to the view. This list is initially empty, but provides a link to the **My Tasks** module. Use **My Tasks** to add and remove from the My Tasks list in the navigation.

#### **Product selection**

Selecting a product name shows only the tasks for that particular product, for example, WebSphere Application Server.

### **Work area**

When you launch a page, the content of the page is displayed in the work area. If you have not launched any pages, the Welcome page is displayed in the work area. A page contains one or more console modules that are used to perform operations. Each console module has its own navigation controls. Some pages include a control to close the page and return to the Welcome page.

---

## Navigating the console

This topic describes how to navigate pages and tasks in the Integrated Solutions Console.

- Launching pages from the navigation tree
- Filtering tasks in the navigation
- Using the title bar controls
- Accessing help
- Using the console help controls

Be sure you understand the terms and information in the “Console layout” on page 9 before reading this section.

### Launching pages from the navigation tree

The console navigation provides a hierarchical view of all of the *tasks* available in the console. A task is a page in the work area consisting of one or more console modules. All of the modules on the page are provided to start and complete the task. To open a task, simply click the task name in the navigation. The task is opened in a new page in the work area.

The following table describes the controls for the console navigation tree and entries in the tree.

Icon	Function
	Represents an organizational node in the navigation tree that contains pages or other navigation nodes. Click the icon to expand the node.
	Closes an organizational node.

### Filtering tasks in the navigation

When you first access the console, all tasks to which you have access are displayed in the navigation. Use the view menu at the top of the navigation to filter the list of tasks by product. Or, you can create a customized list by selecting My tasks from the **View** menu. For instructions on creating and managing your custom list of tasks, see My tasks.

### Using the title bar controls

Each page contains one or more Web applications or *console modules*. A console module enables you to perform an operation, such as displaying a list or stopping a managed system. The title and the controls for the module are displayed on the title bar. Depending on the functions supported by the module, the following icons might be displayed on the title bar:

- The  icon is displayed if the module allows you to edit settings for the portlet. For example, a module that retrieves performance data could permit you to specify the server to be analyzed. When you click the icon, an edit screen is displayed. Click the  icon to return to the previous screen.
- The  icon allows you to return to the previous screen.
- The  icon is displayed if help is available for the module. When you click the icon, the help is displayed in a separate browser window.
- The  icon allows you to minimize the module view. When you click the icon, only the title bar is visible on the page. Click the  icon to return to the maximize state.

- The  icon allows you to maximize a module view. When you click the icon, the full portlet view is visible on the page. Click the  icon to return to the minimize state.

In addition to the controls on the title bar, a module can include controls for other actions, such as a button to submit input. Some modules have controls that launch other modules. If a module launches another module, the newly launched module is displayed on a new page.

## Accessing help

Help is available for the entire console or for a specific module in the console.

To access console help, perform the following steps:

1. Click **Help** on the console toolbar. The Help is displayed in a separate browser window.
2. In the help navigation tree, click the help set you want to view. For example, click **Console help** to view topics that provide helpful information for new console users. Use the console help controls as needed.

To access help for a module on a page, perform the following steps:

1. On the title bar for the module, click the  icon. That icon is displayed only if help is available for the module. The help is displayed in a separate browser window.
2. Close the help window when you are finished viewing it.

## Using the console help controls

Icon	Function
	Use these controls to navigate the list of pages you have viewed. Click  to return to the previous help topic that was displayed. Click  to move forward in the history list.
	Click either of these icons to synchronize the navigation tree with the current topic. The current topic will be highlighted in the navigation tree. This function is useful if you followed links from one help topic to other topics and you want to determine where the current topic is listed in the help navigation tree.
	Permits you to add the current page to your browser favorites list or bookmarks.
	Displays a window for printing the help topic that is displayed.
	Maximizes the target view. This control is available for the Table of Contents view, the Search Results view, and the topic display area.
	Restores a maximized view to its normal size.
	Changes the view to the Search Results view. To search all of the help topics, type a word or words in the <b>Search</b> field. Enclose a phrase within double quotes. You can use Boolean operators (such as OR) in the search string. To limit the scope of the search, click <b>Search scope</b> . Click <b>GO</b> to start the search. A list of topics that contain the target strings are displayed in the results frame.

Icon	Function
	Changes from the Search Results view to the Table of Contents view.

---

## Supported browsers

The following Web browsers are supported for use with Integrated Solutions Console:

- Microsoft Internet Explorer V6.0 SP1
- Mozilla V1.7.8
- Firefox V1.5

---

## Console accessibility

- Accessibility features
- Navigating the console by using the keyboard
- Navigating help by using the keyboard

### Accessibility features

The Integrated Solutions Console has the following accessibility features:

- The following features are for vision-impaired users:
  - Supports interfaces commonly used by screen readers (Windows systems only)
  - Can be operated by using only the keyboard
  - Communicates all information independent of color
  - Supports interfaces commonly used by screen magnifiers (Windows systems only)
  - Supports the attachment of alternate output devices
  - Provides help information in an accessible format
- The following features are for users who have mobility impairments or limited use of their hands:
  - Allows the user to request more time to complete timed responses
  - Can be operated by using only the keyboard
  - Supports the attachment of alternative input and output devices
- The following features are for the deaf and hard of hearing users:
  - Supports alternatives to audio information
  - Supports adjustable volume control
- The console does not flash the screen at rates that could induce epileptic seizures.

The help system for Integrated Solutions Console has the following accessibility features:

- Uses the accessibility support enabled by the browser that is used to display the help
- Enables navigation by using the keyboard

### Navigating the console by using the keyboard

To move through the controls on a particular page, use the Tab key.

To click a link or control on a page using the keyboard, navigate to the link or control and press Enter.

To change the navigation view using the keyboard, follow these steps.

1. Navigate to the **View** selection list using the Tab key.

2. Use the up and down arrows to change the value of the selection list.
3. Press Enter. The tasks displayed in the navigation are changed according to your selection.

## Navigating help by using the keyboard

Use the following key combinations to navigate the help system by keyboard:

- To bring the Topic pane (the right hand side) into focus, press Alt+K, and then press Tab.
- In the Topic pane, to go to the next link, press Tab. To go to the previous link, press Shift+Tab.
- To go directly to the Search Results view in the left hand side, press Alt+R, and then press Enter or Up arrow to enter the view.
- To go directly to the Navigation (Table of Contents) view in the left hand side, press Alt+C, and then press Enter or Up arrow to enter the view.
- To navigate your browser history, press Alt+Left arrow to go back. If you have navigated back to a previously view page, you can use Alt+Right arrow to navigate forward again.
- To expand and collapse a node in the navigation tree, tab to the + or - image next to it to bring the image into focus, and then press the Right or Left arrows.
- To go to the next frame in the help system, press F6. To go to the previous frame in the help system, press Shift+F6.
- In the navigation, to move to the next topic node, press the Down arrow or Tab. To move to the previous topic node, press the Up arrow or Shift+Tab.
- To go to the next link, button, or topic node from inside a view, press Tab.
- To scroll all the way up or down in a frame, press Home or End, respectively.
- To print the active pane, press Ctrl+P.
- To move to the search entry field, press Alt+S.

---

## Welcome

The Welcome page displays the products that are installed that use the Integrated Solutions Console for administrative tasks. The page lists the product name and version number. If provided by the product, you can click the product name to display a page that provides more information about the product.

---

## My tasks

Use My tasks to create and edit a list of tasks to view in the console navigation. A task includes a page that contains one or more Web applications, or *console modules*, that are used to complete that task. When you first access the console, all tasks to which you have access are displayed in the navigation. My tasks is especially useful to customize the navigation to show only the tasks you use most often. After you customize your tasks, My Tasks is initially displayed each time you log in to the console.

Follow these general steps to customize your task list in the navigation.

1. Select My tasks from the **View** selection list in the navigation. If you have never used My tasks before, you must click **Add tasks** to open it.
2. Use the checkboxes to select and deselect tasks from the My tasks navigation.
3. To save your changes, click **Apply**.
4. To cancel your changes, click **Reset**.

After applying your selections, your customized task list is displayed in the navigation.

Use the following buttons to customize your task selections.

**Apply** Saves the current selections.

**Reset** Backtracks all changes to the selections that were set since the last time My tasks was applied. This is useful if you need to cancel your changes.

**Select All**  
Checks every task.

**Deselect All**  
Unchecks every task.

**Expand All**  
Expands each node in the display and reveals all subtasks in the navigation.

**Collapse All**  
Collapses each node in the display so that only the top level nodes are displayed.

---

## Specifying console preferences

Use this topic to customize how much data displays on an administrative console panel.

Throughout the administrative console are pages that have Preferences fields, Scope fields, and Filter radio buttons. By selecting these fields and radio buttons you can customize how much data is shown.

For example, examine the Preferences field for the Enterprise Applications page:

1. Go to the navigation tree of the administrative console and click **Applications > Enterprise Applications**.
2. Expand **Preferences**.
3. For the **Maximum rows** field, specify the maximum number of rows to display when the collection is large. The default is 20. Rows that exceed the maximum number display on subsequent pages.
4. Select **Retain filter criteria** if you want to retain the last filter criteria that is entered in the filter function. When you return to the Applications page, the page initially uses the retained filter criteria to display the collection of applications in the table following the preferences. Otherwise, clear **Retain filter criteria** and the last filter criteria is not retained.
5. Click **Apply** to apply your selections or click **Reset** to return to the default values. The default is not to enable (not have a check mark beside) **Retain filter criteria**.

Other pages have similar fields and radio buttons that you can use to specify console preferences. While Preferences fields, Scope fields, and Filter buttons control how much data is shown in the console, the **Preferences** option controls general behavior of the console. Click **System administration > Console Preferences** to view the Preferences page.

## Console Preferences settings

Use the Console Preferences page to specify how you want features of the administrative console workspace to behave.

To view this administrative console page, click **System administration > Console Preferences**.

### Turn on workspace automatic refresh

Specifies whether you want the administrative console workspace to redraw automatically after the administrative configuration changes.

The default is for the workspace to redraw automatically. If you direct the console to create a new instance of, for example, an application server, the Application Servers page refreshes automatically and shows the new server name in the collection of servers.

Specifying that the workspace not redraw automatically means that you must access a page again by clicking the console navigation tree or links on collection pages to see the changes that are made to the

administrative configuration.

**Default** true (selected)

### **No confirmation on workspace discard**

Specifies whether the confirmation dialog is displayed after a request is received to discard the workspace. The default is to display confirmation dialogs.

**Default** false (cleared)

### **Use default scope**

Specifies whether the default scope is the administrative console node.

**Default** false (cleared)

### **Show the help portlet**

Specifies whether the help portlet on the right of the console displays.

**Default** true (selected)

### **Synchronize changes with nodes**

Specifies whether to synchronize changes that are saved to the deployment manager profile with all the nodes that are running.

**Default** false (cleared)

### **Enable command assistance notifications**

Specifies whether to send Java Management Extensions (JMX) notifications that contain command assistance data from the administrative console. Enablement of the notifications allows integration with product tools such as the WebSphere Application Server Toolkit (AST) Jython editor. Enablement of this option is recommended for non-production environments only.

**Default** false (cleared)

### **Log command assistance commands**

Specifies whether to log all the command assistance wsadmin data to a file. This file is saved to `${LOG_ROOT}/server/commandAssistanceJythonCommands_user name.log`, where:

- *server* is the server process where the console runs, such as dmgr or server1.
- *user name* is the administrative console user name.

Occasionally clean out the file to manage its growth.

**Default** false (cleared)

## **Administrative console preference settings**

Use the preference settings to specify how you want information to display on an administrative console page.

### **Maximum rows**

Indicates the maximum number of rows to display per page when the collection is large.

## Filter history

Indicates whether to use the same filter criteria to display this page the next time that you visit.

Select the **Retain filter criteria** check box to retain the last filter criteria entered. When you return to the page, retained filter criteria control the application collection that is displayed in the table.

## Show resources in the scope hierarchy

Select the check box if you want to display the resources in the hierarchy for a particular scope.

The hierarchy is:

- cell > node > server
- cell > cluster

For example, if you select a node scope, all node scope resources and all cell scope resources display for the node.

This preference is available for resource factory panels only.

## Show built-in resources

Select the check box if you want to display resources that are pre-defined to support certain internal components of the product. For example, the product includes built-in configurations of a Cloudscape JDBC provider and a data source to support the Universal Description, Discovery and Integration Protocol (UDDI) registry for Web services.

## Show confirmation for stop command

Select the check box if you want a confirmation that the **stop** command is successful.

## Show confirmation for immediate stop command

Select the check box if you want a confirmation that the **immediate stop** command is successful.

## Show confirmation for terminate command

Select the check box if you want a confirmation that the **terminate** command is successful.

## Administrative console scope settings

Use this page to specify the level at which a resource is visible on the administrative console panel. A resource can be visible in the administrative console collection table at the cell, node, cluster, or server scope. By changing the value for Scope, you see only the resources that are defined at that scope. The contents of the collection table might change.

If the list of scopes is less than fifty, the console displays a drop-down list of all the scopes available. To change the scope, select any item from the drop-down list.

If the list is fifty or greater, click **Browse** next to a field to see choices for changing the scope of the field. If a field is read-only, you cannot change the scope. For example, if only one server exists, you cannot switch the scope to a different server.

All scopes is the default. You cannot select All scopes to create a new resource. You must select one of the available scopes from the drop down list to create a new resource.

You always create resources at the current scope that is selected in the administrative console panel, even though the resources might be visible at more than one scope.

Resources such as Java Database Connectivity (JDBC) providers, namespace bindings, or shared libraries can be defined at multiple scopes. Resources that are defined at more specific scopes override duplicate resources that are defined at more general scopes:

- The application scope has precedence over all the scopes.
- The server scope has precedence over the node, cell, and cluster scopes.
- The cluster scope has precedence over the node and cell scopes.
- The node scope has precedence over the cell scope.

Despite the scope of a defined resource, the resource properties apply at an individual server level only. For example, if you define the scope of a data source at the cell level, all the users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define the maximum connections as 10, then each server in that cell can have 10 connections.

The cell scope is the most general scope and does not override any other scope. The recommendation is that you generally specify a more specific scope than the cell scope. When you define a resource at a more specific scope, you provide greater isolation for the resource. When you define a resource at a more general scope, you provide less isolation. Greater exposure to cross-application conflicts occur for a resource that you define at a more general scope.

**Cell** Limits the visibility to all servers on the named cell. The resource factories within the cell scope are:

- Defined for all servers within this cell
- Overridden by any resource factories that are defined within application, server, cluster, and node scopes that are in this cell and have the same Java Naming and Directory Interface (JNDI) name

The resource providers that are required by the resource factories must be installed on every node within the cell before applications can bind or use them.

#### **Cluster**

Limits the visibility to all the servers on the named cluster. All cluster members must at least be at Version 6 to use cluster scope for the cluster. The resource factories that are defined within the cluster scope:

- Are available for all the members of this cluster to use
- Override any resource factories that have the same JNDI name that is defined within the cell scope

The resource factories that are defined within the cell scope are available for this cluster to use, in addition to the resource factories, that are defined within this cluster scope.

**Node** Limits the visibility to all the servers on the named node. The node scope is the default scope for most resource types. The resource factories that are defined within the node scope:

- Are available for servers on this node to use
- Override any resource factories that have the same JNDI name defined within the cell scope

The resource factories that are defined within the cell scope are available for servers on this node to use, in addition to the resource factories that are defined within this node scope.

#### **Server**

Limits the visibility to the named server. The server scope is the most specific scope for defining resources. The resource factories that are defined within the server scope:

- Are available for applications that are deployed on this server
- Override any resource factories that have the same JNDI name defined within the node and cell scopes

The resource factories that are defined within the node and cell scopes are available for this server to use, in addition to the resource factories that are defined within this server scope.

#### **Application**

Limits the visibility to the named application. Application scope resources can be viewed and edited from the console, but not created. You can additionally use the WebSphere Application Server Toolkit (AST) or the wsadmin tool to view or edit the application scope resource configuration. The resource factories that are defined within the application scope are available for this application to use only. The application scope overrides all other scopes.

You can configure resources and the product variables under all five scopes. You can configure namespace bindings and shared libraries under cell, node, and server scopes only.

---

## Accessing help and product information from the administrative console

This topic describes how to use administrative console help and how to link to product documentation from the administrative console.

You must have a connection to the Internet to access information about WebSphere Application Server from the Welcome page of the administrative console.

All of the helps panels that you can access from the administrative console, you can access from the WebSphere Application Server Information Center. This topic describes how to access the help panels, the information center, and other product documentation from the administrative console.

- Click **Welcome** on the administrative console navigation tree. In the workspace to the right of the navigation tree, select the appropriate links to access the WebSphere Application Server Information Center, the WebSphere Application Server product information, and the WebSphere Application Server technical information on developerWorks.
- Access help in the following ways:
  - Click either of the following tabs of an online help page:
    - Click the **Help index** tab and select from the list of help panels to view administrative console help information.
    - Click the **Search** tab, provide search terms, and then click **Search**. Under Results, select a help panel that contains the search information.
  - In the help portal that is on the right side of the administrative console panel, do one or all of the following tasks:
    - Click a field label or a list marker in the administrative console panel for the help to display under Field help. Alternatively, place the cursor over the field label or the list marker for the corresponding help to display at the cursor.
    - Click the link under Page help to access the help panel for the administrative console panel. The help panel is the same help panel that displays when you click the **?** icon.
    - If Command assistance is listed, click the link under Command assistance to view wsadmin scripting commands for the last action run for this console panel.

You can continue to access help information from the administrative console. Alternatively, you can access the help information from the WebSphere Application Server Information Center.

You can continue to access the WebSphere Application Server Information Center, the WebSphere Application Server product information, and the WebSphere Application Server technical information on developerWorks from the administrative console. Alternatively you can access the information from the IBM Web site.

## Accessing command assistance from the administrative console

Using command assistance, you can view wsadmin scripting commands in the Jython language for the last action run in the administrative console. This topic discusses how to access command assistance from the administrative console.

You must have WebSphere Application Server and the administrative console running to access command assistance.

Use command assistance to see wsadmin scripting commands that correspond to actions in the administrative console. Seeing these commands might help you develop the commands necessary to administer WebSphere Application Server from the wsadmin utility.

If a command assistance link is listed in the help portlet, **wsadmin** commands exist for the last console action that you completed, and command assistance is available for that action.

**When command assistance is unavailable in the help portlet:** Some console actions do not have **wsadmin** commands directly associated with them. When the help portlet on the right side of the administrative console panel does not have a command assistance link in it, no command assistance data is available for the last console action.

1. Click the link under **Command assistance** to view wsadmin scripting commands for the last action run for this administrative console panel.

After the Command assistance window opens, it refreshes automatically when new command assistance data is available.

Examples of actions include a click on a button or a click on a link in the navigation bar, a collection panel, or a detail panel. The editing of forms is not a user action.

The wsadmin scripting commands display in the Jython language in a secondary window that you can view by clicking on the Command assistance link in the help portlet.

If you perform an administrative console action after you launch the Command assistance window, whether or not the scripting commands display in the window depends on whether your browser supports Java scripts. If your browser supports Java scripts, the Command assistance window automatically refreshes the command list to reflect the most recent console action. If the browser does not support Java scripts, click the link again under **Command assistance** in the help portal to refresh the command list.

2. To view the description of a specific **wsadmin** command, place your cursor over the command. Hover text is displayed.
3. Optionally, log the command assistance data to a file by selecting the **Log command assistance commands** setting on the Preferences page of the administrative console.

A timestamp and the breadcrumb trail of the panel that produced the command assistance data are provided with the wsadmin data.

4. Optionally, allow command assistance to emit Java Management Extensions (JMX) notifications by selecting the **Enable command assistance notifications** setting on the Preferences page of the administrative console.

Enablement of the notifications allows integration with product tools such as the WebSphere Application Server Toolkit (AST) Jython editor to assist you in writing scripts.

The notification type is `websphere.command.assistance.jython.user_name` where *user\_name* is the name of the administrative console user.

You have viewed wsadmin scripting commands from the administrative console, optionally logged the commands to a file, and optionally allowed command assistance to emit JMX notifications.

You can continue your administration of the administrative console.

## Administrative console actions with command assistance

Using command assistance, you can view wsadmin scripting commands in the Jython language for the last action run in the administrative console. This topic lists the administrative console actions that have **wsadmin** commands available in the command assistance option of the Help portlet.

The table lists the components and the actions in the administrative console that have command assistance for a particular component.

Component	Action
Applications	<ul style="list-style-type: none"> <li>• List the applications.</li> <li>• Set the application information.</li> <li>• Install the application.</li> </ul>
Web servers	<ul style="list-style-type: none"> <li>• Create a Web server.</li> <li>• Delete a Web server.</li> <li>• List the virtual hosts.</li> <li>• Create Secure Sockets Layer (SSL) virtual hosts.</li> <li>• Generate a plug-in configuration.</li> <li>• Propagate the plug-in configuration.</li> <li>• Propagate the key ring for the plug-in configuration.</li> <li>• Start the Web server.</li> <li>• Stop the Web server.</li> <li>• Ping the Web server.</li> <li>• Terminate the Web server.</li> </ul>
Channel framework	<ul style="list-style-type: none"> <li>• List the SSL repertoires.</li> <li>• List the Transmission Control Protocol (TCP) endpoints.</li> <li>• List the TCP thread pools.</li> <li>• Delete a chain.</li> <li>• List the chains.</li> <li>• Get the TCP endpoint.</li> <li>• Create a TCP endpoint.</li> <li>• Create a chain.</li> </ul>
Node groups	<ul style="list-style-type: none"> <li>• Create a node group.</li> <li>• Remove a node group.</li> <li>• Add a node group member.</li> <li>• Remove a node group member.</li> <li>• Modify a node group property.</li> </ul>
Core group	<ul style="list-style-type: none"> <li>• List eligible bridge interfaces.</li> <li>• Get a named TCP endpoint.</li> <li>• Create a core group.</li> <li>• List the core groups.</li> <li>• Delete a core group.</li> <li>• Move a core group server.</li> <li>• Move a core group cluster.</li> </ul>

Component	Action
Clusters	<ul style="list-style-type: none"> <li>• Create a cluster.</li> <li>• Delete a cluster.</li> <li>• Create a cluster member.</li> <li>• Delete a cluster member.</li> <li>• Start a cluster.</li> <li>• Stop a cluster.</li> <li>• Stop a cluster immediately.</li> <li>• Ripplestart a cluster.</li> <li>• Get a cluster weight table.</li> <li>• Set a cluster weight table.</li> <li>• Set a backup cluster.</li> <li>• Get a backup cluster.</li> </ul>

Component	Action
Service integration	<ul style="list-style-type: none"> <li>• Create a bus.</li> <li>• Delete a bus.</li> <li>• Add a bus member.</li> <li>• Delete a bus member.</li> <li>• List the bus members.</li> <li>• Delete the messaging engine.</li> <li>• Create a queue.</li> <li>• Create a topic space.</li> <li>• Create an alias destination.</li> <li>• Create a foreign destination.</li> <li>• Mediate a destination.</li> <li>• Unmediate a destination.</li> <li>• Delete a destination.</li> <li>• Create a mediation.</li> <li>• Delete a mediation.</li> <li>• Modify a mediation.</li> <li>• Delete a foreign bus.</li> <li>• Create a Java Message Service (JMS) activation specification.</li> <li>• Modify a JMS activation specification</li> <li>• Delete a JMS activation specification.</li> <li>• List the JMS activation specifications.</li> <li>• Show a JMS activation specification.</li> <li>• Create a JMS connection factory.</li> <li>• Modify a JMS connection factory.</li> <li>• Delete a JMS connection factory.</li> <li>• List the JMS connection factories.</li> <li>• Show a JMS connection factory.</li> <li>• Create a JMS queue connection factory.</li> <li>• Modify a JMS queue connection factory.</li> <li>• Delete a JMS queue connection factory.</li> <li>• List the JMS queue connection factories.</li> <li>• Show a JMS queue connection factory.</li> <li>• Create a JMS topic connection factory.</li> <li>• Modify a JMS topic connection factory.</li> <li>• Delete a JMS topic connection factory.</li> <li>• List the JMS topic connection factories.</li> <li>• Show a JMS topic connection factory.</li> </ul>

Component	Action
Service integration (continued)	<ul style="list-style-type: none"> <li>• Create a JMS queue.</li> <li>• Modify a JMS queue.</li> <li>• Delete a JMS queue.</li> <li>• List the JMS queues.</li> <li>• Show a JMS queue.</li> <li>• Create a JMS topic.</li> <li>• Modify a JMS topic.</li> <li>• Delete a JMS topic.</li> <li>• List the JMS topics.</li> <li>• Show a JMS topic.</li> <li>• Create a WebSphere MQ server.</li> <li>• Modify a WebSphere MQ server.</li> <li>• Modify a WebSphere MQ server bus member.</li> <li>• Add a permitted transport.</li> <li>• Add a user to a bus connector role.</li> <li>• Add a group to a bus connector role.</li> <li>• Add an inbound port to an inbound service.</li> <li>• Add an outbound port to an outbound service.</li> <li>• Connect an endpoint listener to a service integration bus.</li> <li>• Create an endpoint listener.</li> <li>• Create an inbound service.</li> <li>• Create an outbound service.</li> <li>• Delete an endpoint listener.</li> <li>• Delete an inbound service.</li> <li>• Delete an outbound service.</li> <li>• Disconnect an endpoint listener from a service integration bus.</li> <li>• Publish an inbound service to a Universal Description, Discovery, and Integration (UDDI) registry.</li> <li>• Refresh the Web Services Description Language (WSDL) definition for an inbound service.</li> <li>• Refresh the WSDL definition for an outbound service.</li> <li>• Remove an inbound port.</li> <li>• Remove an outbound port.</li> <li>• Set the default outbound port for an outbound service.</li> <li>• Remove an inbound service from a UDDI registry.</li> <li>• Add a target service for routing from a gateway service.</li> <li>• Create a gateway service.</li> <li>• Create a proxy service deployed to a gateway instance.</li> <li>• Delete a gateway service.</li> <li>• Delete a gateway instance.</li> <li>• Delete a proxy service.</li> <li>• Remove a target service.</li> </ul>

---

## Administrative console: Resources for learning

Use the following links to find relevant supplemental information about the IBM WebSphere Application Server administrative console. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

View links to additional information:

### Administration

- IBM WebSphere Application Server Redbooks

This site contains a listing of all WebSphere Application Server Redbooks.

- IBM WebSphere developerWorks

This site is the home of technical information for developers working with WebSphere products. You can download WebSphere software, take a fast path to developerWorks zones, such as VisualAge Java or WebSphere Application Server, learn about WebSphere products through a newcomers page, tutorials, technology previews, training, and Redbooks, get answers to questions about WebSphere products, and join the WebSphere community, where you can keep up with the latest developments and technical papers.

- WebSphere Application Server Support page

Take advantage of the Web-based Support and Service resources from IBM to quickly find answers to your technical questions. You can easily access this extensive Web-based support through the IBM Software Support portal at Web address <http://www-3.ibm.com/software/support/> and search by product category, or by product name. For example, if you are experiencing problems specific to WebSphere Application Server, click **WebSphere Application Server** in the product list. The WebSphere Application Server Support page appears.

---

## Changing the console session expiration

Run this JACL script to set how long Integrated Solutions Console can be used until the login session expires.

The following JACL script serves as an example of how to set the duration that an Integrated Solutions Console can be used until the login session expires. Other scripting types, such as JYTHON, could be used.

1. Copy the following script into a file.

```
set dep [$AdminConfig getid /Deployment:isclite/]
set appDep [$AdminConfig list ApplicationDeployment $dep]
set sesMgmt [$AdminConfig list SessionManager $appDep]

# check if existing sesMgmt there or not, if not then create a new one, if exist then modify it
if {$sesMgmt == ""} {
  # get applicationConfig to create new SessionManager
  set appConfig [$AdminConfig list ApplicationConfig $appDep]
  if {$appConfig == ""} {
    # create a new one
    set appConfig [$AdminConfig create ApplicationConfig $appDep {}]
    # then create a new SessionManager using new Application Config just created
    set sesMgmt [$AdminConfig create SessionManager $appConfig {}]
  } else {
    # create new SessionManager using the existing ApplicationConfig
    set sesMgmt [$AdminConfig create SessionManager $appConfig {}]
```

```

    }
}

# get tuningParams config id
set tuningParams [$AdminConfig showAttribute $sesMgmt tuningParams]
if {$tuningParams == ""} {
    # create a new tuningParams
    $AdminConfig create TuningParams $sesMgmt {{invalidationTimeout <timeout value>}}
} else {
    #modify the existing one
    $AdminConfig modify $tuningParams {{invalidationTimeout <timeout value>}}
}

# saving the configuration changes
$AdminConfig save

```

2. Change the *<timeout value>* on the two lines of this sample to the new session expiration value. This number specifies the number of minutes the console preserves the session during inactivity.
3. Save the file to any directory using, for example, the filename `timeout.jacl`.
4. Start the `wsadmin` scripting client from the `<WAS-install>/profiles/<profile_name>/bin` directory.
5. Issue the following command.

```
wsadmin -f <path to jacl file>/timeout.jacl
```

---

## Changing the class loader order of the console module deployed in Integrated Solutions Console

Run this JACL script to change the class loader order of the console module deployed in the Integrated Solutions Console.

The following JACL script serves as an example of how to change the class loader order of the console module deployed in the Integrated Solutions Console. Other scripting types, such as JYTHON, could be used.

1. Copy the following script into a file.

```

set app [$AdminConfig getid /Deployment:isclite/]
set webModules [$AdminConfig list WebModuleDeployment $app]

foreach webModule $webModules {
    set uri [$AdminConfig showAttribute $webModule uri]
    if {$uri == "<WAR_NAME>"} {
        #modify the classloader for <WAR_NAME>
        set cl [$AdminConfig list ClassLoader $webModule]
        # check if the classloader exist
        if {$cl == ""} {
            # create a new one with the appropriate mode
            $AdminConfig create ClassLoader $webModule {{mode <MODE>}}
        } else {
            # modify the existing one
            $AdminConfig modify $cl {{mode <MODE>}}
        }
    }
}

# save the configuration change
$AdminConfig save

```

2. Change the `<WAR_NAME>` on the two lines of this sample to the name of the console module file deployed in the Integrated Solutions Console which class loader order you want to change.
3. Change the `<MODE>` on the two lines of this sample to `PARENT_LAST` or `PARENT_FIRST` as required.

4. Save the file to any directory using, for example, the file name classloaderorder.jacl.
5. Start the wsadmin scripting client from the <WAS-install>/profiles/<profile\_name>/bin directory.
6. Issue the following command.

```
wsadmin -f <path to jacl file>/classloader.jacl
```

---

## Chapter 2. Developing console modules

Console modules are Web applications that are accessed from Integrated Solutions Console. Console modules provide the business logic and transaction processes that enable administration functions.

The following skills are essential for developing and testing console modules.

- Java 2 Platform , Enterprise Edition (J2EE)
- XML
- Portlet development using the Java Portlet Specification (JSR 168)

The console also supports existing modules that have been developed using Struts and Tiles APIs. This is only for legacy support. New console modules are supported only if they are developed using standard portlet APIs.

- Review the console module samples. The sample console modules provide examples of portal application archives and how to use the APIs and other features.
- Set up the development environment. IBM provides WebSphere Application Server Toolkit and Rational Application Developer to enable you to quickly develop, test, and deploy your portlet applications.
- Develop your first console module. This topic is for developers new to console module development. It is assumed that you already have a development environment, like Rational Application Developer, already prepared. The topics in this section take you through the process of creating a simple console module. The console module in this exercise consists of a single portlet which is deployed to a single page as a member of the sample console modules provided by IBM. Be sure you have successfully deployed the sample console modules before starting.
- Adding advanced API features. The class files for console modules are developed using the portlet API of the Java Portlet Specification (JSR 168). Integrated Solutions Console includes additional APIs for launching pages, passing properties to other console modules, and launching Eclipse-based help. This topic provides information about the APIs available to console modules.

---

### Overview of Integrated Solutions Console

Integrated Solutions Console offers several advantages for implementing administration functions, as described in this topic.

Integrated Solutions Console provides a single, common interface for system administration. It provides the main platform on which IBM and non-IBM products can build administrative user interfaces as individual plug-ins to a common console framework. Standardizing product administration functions to run on the Integrated Solutions Console platform gives them a more common look and feel and a more consistent behavior, thereby reducing the learning curve and adoption as new management components are introduced. Administrators can interact with multiple IBM and non-IBM products from a single browser-based console.

#### Consistency across administrative interfaces

Integrated Solutions Console provides a common appearance (for example, theme, layout and banner) and behavior (for example, navigation and authentication) to enable consistent user interaction for administering software products.

#### A standards-based architecture

Integrated Solutions Console provides a standards-based architecture for Web administration. Each Integrated Solutions Console module consists of one or more Web applications that have access to services within the Java 2 Enterprise Edition (J2EE) environment provided by WebSphere Application

Server. The help interface is implemented using the Eclipse open standard. Console modules are developed using the Java Portlet Specification.

## Easy deployment of product administration consoles

The Integrated Solutions Console framework provides an XML-based interface for deploying console modules to a console installation. XML descriptors provide the information needed to deploy the portlet, resources, and setup the page layout and navigation in the console. A console module can be easily removed without impact to the remaining console modules.

## Accelerated development of solutions

Using Integrated Solutions Console enables products to reduce the time required to develop solutions that require administration functions. The standards-based architecture, common framework, and support for existing investment help reduce the time required to implement solutions.

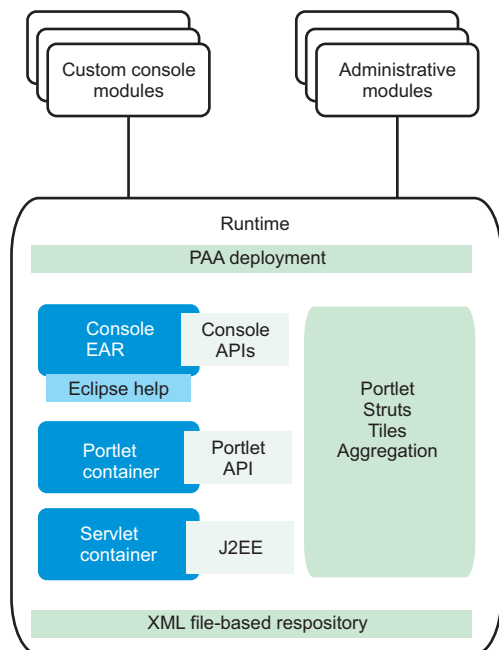

## Improved administration efficiency

Customers invest significant resources in training administrative personnel. Providing a common interface across IBM products enables customers to reduce training time and expense.

## Integrated Solutions Console components

This topic describes the components of the administrative console.

This figure illustrates the Integrated Solutions Console platform.

The following components and features support console modules running in Integrated Solutions Console.

- A common console
  - Provides a common appearance and navigation behavior for console modules. For example, each portlet is rendered using a common skin, rendering the same title bar icons for actions such as editing preferences, maximizing, or requesting help for the portlet.
- Built-in administration console modules

Provide security, log and trace, and other functions that apply to the entire the Integrated Solutions Console installation.

- A portlet container

Supports portlets developed using the Java Portlet Specification. The current specification as of this writing is JSR 168.

- PAA deployment

XML descriptors are provided for the developer to specify pages, navigation nodes, and access control for the console module, which are created at deployment. The descriptor can also register the following information about the console module.

- Custom roles for the application in addition to the roles provided by the application server
- An about page with links to useful information and resources for a product
- A pointer to another console module that is the lead application for the product
- Prerequisite applications and console modules that should be already deployed
- Portlets that are already deployed on the server that should be reused for the console module
- Multiple entities of a single portlet definition that can be used on different pages
- External URLs that can be launched from the console navigation
- Row and column layout of a page
- Windows that contain portlets on the page
- Empty windows on a page that are filled at runtime depending on the user's navigation selection
- The order and nesting of navigation nodes used by the console module
- Parent navigation nodes under which the navigation tree for the current console module are placed
- Navigation nodes from other products that should be included under the current console module's navigation

- An application server

Provides a complete J2EE runtime environment for console modules.

- APIs for console modules

Supports the following actions:

- Passing properties between portlets
- Launching a page from a portlet
- Invoking Eclipse-based help

- Eclipse Help

Eclipse Help is provided as a Web application running on the same server as Integrated Solutions Console. Eclipse Help serves help documents for a single module as well as for the entire console.

## What is new in Integrated Solutions Console

If you have developed console modules for previous, stand-alone releases of Integrated Solutions Console, there are some changes in this release.

- Integration with WebSphere Application Server

This is the first release in which Integrated Solutions Console is delivered as part of WebSphere Application Server, enabling other products to integrate their administrative interfaces into the application server console. The console was previously made available to business partners only through the Autonomic Computing Toolkit.

- Portal application archive

A new model for packaging and deploying console modules. The portal application archive (PAA) is a standard portlet application with the addition of two XML files that describe the topology and security characteristics of the module. The portal application archive replaces the former method of packaging and deploying console modules as portlet WAR files with an additional component.xml descriptor.

- Migration

There is no supported migration path for console modules written to previous versions of Integrated Solutions Console.

- Changes to APIs provided for Integrated Solutions Console.

#### **Page launching**

A subset of the Dynamic UI Manager APIs is provided for launching pages and passing properties to portlets on the same or other pages. Launching a module on an existing page is not supported for this release.

#### **Form persistence**

The FormUtils class is not provided for this release.

#### **Eclipse-based help**

The EclipseHelp class replaces the ISCHelp class to launch help from the Eclipse help server, which is package and deployed with Integrated Solutions Console. Help is available from the console and from each console module that supports help. Page and message help is not available in this release.

#### **Obtaining user and group information**

The PUMA SPI was provided in V6.0 to obtain information about the user and the user's group. This API is not available for this release.

#### **External launching**

Launching the console to a specific page or portlet is not supported in this release.

#### **Product filtering**

The console allows the user to display tasks for a specific product.

#### **External URLs**

Console modules can add links to external Web sites to the console navigation.

---

## **Console module samples**

The sample console modules provide examples of portal application archives and how to use the APIs and other features. These samples are available from the *Samples for WebSphere Application Server* page at the following location

<http://www.ibm.com/developerworks/websphere/library/samples/index.html>

These samples help understand the structure of a console module WAR package and the portal application descriptors that distinguish the application as a console module. After downloading the samples, follow the instructions in "Deploying a console module" on page 41. The following table lists the samples that are ready for deployment.

<b>Sample</b>	<b>Description</b>
Page layout (pagelayout.war)	Demonstrates how to specify the layout of console modules on a page using the elements of the portal topology descriptor. This sample shows how the lead application of a product provides an about page, which contains helpful information and resources about the product. The about page can be accessed from the console Welcome page. This module also demonstrates how to reuse a portlet from another module (Tree merge).

Sample	Description
Tree merge (TreeMerge.war)	Demonstrates how a subordinate application deploys into the lead application for a product. The <PAA-ref/> element indicates the page layout sample as the lead application. Also, the <requires/> element indicates the page layout sample as a prerequisite that must already be deployed. The <parent-tree/> element merges the navigation nodes for the tree merge sample into the page layout navigation tree.
Portlet context (PortletContext.war)	Demonstrates how to use the Dynamic UI Manager APIs to launch a page and how to pass properties to other console modules. The module receiving these properties can be on the same page or on another page.
Modes (Modes.war)	Demonstrates how to implement the Edit and Help modes in a module and how to invoke Eclipse-based help.
Basic module (Basicmodule.war)	Demonstrates how to implement basic module components.

---

## Setting up the development environment

This topic describes how to setup your development and testing tools to facilitate the development of console modules.

IBM provides the following tool that enables you to quickly develop, test, and deploy your portlet applications.

- WebSphere Application Server Toolkit, version 6.1

You can also add the Integrated Solutions Console in WAS Portal Application Archive (PAA) Visual Designer plugin, available for download at the Integrated Solutions Console in WAS PAA Visual Designer download site. For additional information, see [www.ibm.com/support](http://www.ibm.com/support).

Use the plugin to develop the topology and security descriptors necessary to convert portlet applications into console modules that you may deploy into an Integrated Solutions Console in WAS console. The PAA Visual Designer is supported for use with Application Server Toolkit, version 6.1. Follow these steps to add the PAA Visual Designer plugin to Application Server Toolkit.

1. Confirm that Application Server Toolkit is not running.
2. Download PAA Visual Designer.
3. Extract the download package to the /eclipse directory in the Application Server Toolkit.
4. Start Application Server Toolkit.

After installing the PAA Visual Designer plugin, you can add the portal topology and security descriptors to your JSR 168 portlet application projects. See online documentation for details.

As you test your console modules, you might discover that changes that you make to the JSPs are not rendered when you log in to the application server. If so, you probably need to check the **reloadingEnabled** attribute in the module's extended deployment descriptor (ibm-web-ext.xmi) Make sure this value is set to true to enable the JSP to reload each time you deploy a new change. See the "Hot deployment and dynamic reloading" topic in the *Developing and deploying applications* PDF for more information.

---

## Developing your first console module

This topic is for developers new to console module development.

It is assumed that you already have a development environment, like Application Server Toolkit, already prepared. The topics in this section take you through the process of creating a simple console module. The sample console module consists of a single portlet which is deployed to a single page as part of the set of sample console modules provided by IBM. Be sure you have successfully deployed the sample console modules before starting.

## Developing the portlet

This topic is intended for developers who are unfamiliar with portlet development. A simple Java class and JSP are provided.

### Developing the source Java class file

The following example shows the Java code for a portlet in its simplest form.

```
package com.ibm.isclite.samples.basicmodule;

import java.io.*;
import javax.portlet.*;

public class BasicModule extends GenericPortlet {

    public void doView(RenderRequest request, RenderResponse response)
        throws PortletException, IOException {
        // Set the MIME type for the render response
        response.setContentType("text/html");

        // Invoke the JSP to render
        PortletRequestDispatcher rd = getPortletContext().getRequestDispatcher("/jsp/basicView.jsp");
        rd.include(request, response);
    }
}
```

The portlet code must extend the `GenericPortlet` class and output for the response in the `doView()` method. Portlets are rendered in different modes. The initial mode when a portlet is called to render is the view mode. The response output is provided by a JSP, which provides markup that can be aggregated into a larger HTML page. The package name in this example is consistent with the console module samples.

### Developing the JSP

The following shows a portlet JSP for view mode in its simplest form.

```
<%@ page language="java" contentType="text/html; charset=ISO-8859-1"
    pageEncoding="ISO-8859-1" session="false" buffer="none"%>
<%@ page import="javax.portlet.*" %>
<%@ taglib uri="http://java.sun.com/portlet" prefix="portletAPI" %>

<portletAPI:defineObjects />

<%
    PortletPreferences prefs = renderRequest.getPreferences();
    String URL = prefs.getValue("website","");
%>

<p><a name="<portletAPI:namespace/>basicAnchor">Basic contents</a></p>

<p>
    <a href="<%=URL%>" target="_blank">
        <img src='<%=renderResponse.encodeURL(renderRequest.getContextPath() + "/images/logo.gif")%>'
            alt="logo" />
        </a>
    </p>
<p><em>Company logo with link.</em></p>
```

The taglib directive specifies the portlet tags from the Java Portlet Specification. The following tags are used in this example.

### **namespace**

Uniquely qualifies named HTML tags or JavaScript functions to prevent clashes with other portlets on the page using the same name.

### **defineObjects**

Makes the RenderRequest, RenderResponse, and PortletConfig objects available to the JSP. This tag is used in this example so that the image can be rendered using the encodeURL() method of the render response, and to allow the JSP to read preferences in the portlet descriptor.

## **Creating the descriptors for the console module**

The following descriptors are required for the console module.

- Web application descriptor (web.xml). This descriptor is required and described by the Java Servlet Specification.
- Portlet application descriptor (portlet.xml). This descriptor is required and described by the Java Portlet Specification. Refer to the console module samples for examples of how to create the portlet.xml.
- Portal topology descriptor (ibm-portal-topology.xml). This descriptor is unique to console modules and defines the portlets and resources in the module, how it is laid out on the page, and how it is accessed from the navigation.
- Portal security descriptor (ibm-portal-security.xml). This descriptor is unique to console modules and defines roles and access to navigation nodes and portlets.

The topology and security descriptors are the main component of PAA packages that distinguish them from other portal application WAR files. The console module samples include these descriptors and demonstrate their features. The sample descriptors provide inline comments that explain the elements and how they are used.

For your first console module, you should use the PAA Visual Designer plugin to the Application Server Toolkit to develop the descriptors. If you prefer to create them manually to become familiar with the structure of the XML, the steps in this topic show how to create simple descriptors that can be used to deploy an application into the samples provided by IBM. After following these steps, you should refer to the samples and the reference topics for the PAA schemas for more complete information.

### **Portal topology descriptor**

To follow these steps, open a file with the name `ibm-portal-topology.xml` in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into `ibm-portal-topology.xml`. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>

<ibm-portal-topology
  xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd"
  xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

  xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd">

  <application-definition appId="com.ibm.isclite.samples.basicModule" version="6.1">

    </application-definition>
    <PAA-ref>com.ibm.isclite.samples.PageLayout</PAA-ref>

</ibm-portal-topology>
```

- The elements in this step provide the top level content of the topology descriptor.
- Most of the content for this descriptor will be placed inside the <application-definition/> element.
- The value of the **appid** attribute is consistent with the naming convention used by the sample console modules. The **version** attribute matches the version used by the sample console modules.
- The <PAA-ref/> element specifies the **appid** of the page layout sample, which is the lead application to which this application will be deployed.
- The following convention is used for unique name for all of the elements in the descriptor.  
namespace + element\_type + identifier

2. Create a title for your application. The title is the first element in the application definition element.

```
<title>
  <base:nls-string lang="en">My basic module</base:nls-string>
</title>
```

3. Place the component tree after the <requires/> element as shown.

```
<component-tree uniqueName="com.ibm.isclite.samples.basicModule.appTree">
  <portlet-definition uniqueName="com.ibm.isclite.samples.basicModule.portletDefinition.A">
    <title>
      <base:nls-string lang="en">My basic module</base:nls-string>
    </title>
    <resource-link name="basicModule"
      portletApplication="com.ibm.isclite.samples.basicmodule.BasicModule.01a"
      type="static"/>
  </portlet-definition>
  <portlet-entity uniqueName="com.ibm.isclite.samples.basicModule.portletEntity.A"
    portletDefinitionRef="com.ibm.isclite.samples.basicModule.portletDefinition.A">
    <title>
      <base:nls-string lang="en">My basic module</base:nls-string>
    </title>
  </portlet-entity>
</component-tree>
```

- The **name** attribute of the <resource-link/> element must specify the <portlet-name/> from the portlet deployment descriptor.
- The **portletApplication** attribute of the <resource-link/> element must specify the **id** attribute of the <portlet-app/> element from the portlet deployment descriptor.
- The **portletDefinitionRef** attribute of the <portlet-entity/> element references the unique name of the <portlet-definition/>. Subsequent elements in this descriptor use the unique name of the <portlet-entity/> to invoke the portlet. Multiple portlet entities can point to the same portlet definition. For the purpose of this exercise, a single portlet definition is provided with a single portlet entity.
- The portlet title that is rendered in this example is derived from the title in the portlet entity. If that value is not provided, the portlet title is rendered by the title provided by the <window/> element in the layout tree. If that value is also not provided, the title is obtained from the <portlet-name/> element in the portlet.xml for the portlet indicated by the <resource-link/>.

4. Place the layout tree after the component tree as shown.

```
<layout-tree>
  <layout-element uniqueName="com.ibm.isclite.samples.basicModule.layoutElement.A">
    <title>
      <base:nls-string lang="en">My basic module</base:nls-string>
    </title>
    <simple-container orientation="row"
      uniqueName="com.ibm.isclite.samples.basicModule.container.A">
      <window uniqueName="com.ibm.isclite.samples.basicModule.window.A">
        <title>
          <base:nls-string lang="en">My basic module</base:nls-string>
        </title>
        <component-definition-ref>
          com.ibm.isclite.samples.basicModule.portletEntity.A
        </component-definition-ref>
      </window>
    </simple-container>
  </layout-element>
</layout-tree>
```

```

        </window>
    </simple-container>
</layout-element>
</layout-tree>

```

- Each layout element in the layout tree defines the layout of a page in the console.
- Each page can have nested containers, and each simple container can have multiple windows. Each simple container has either a row or column orientation. The nesting of these containers can create a complex table structure for the page layout.
- The `<component-definition-ref/>` element specifies the unique name of the portlet entity that provides the content of this window.

5. Create the navigation element after the layout tree as shown.

```

<navigation-element uniqueName="com.ibm.isclite.samples.navigationElement.basicModule"
    layoutElementRef="com.ibm.isclite.samples.basicModule.layoutElement.A">
    <title>
        <base:nls-string lang="en">Basic Module Sample</base:nls-string>
    </title>
    <preference name="ProductFilter">
        <base:value>
            <base:string>com.ibm.isclite.samples.PageLayout</base:string>
        </base:value>
    </preference>
    <parent-tree parentTreeRef="com.ibm.isclite.samples.navigationElement.Samples"/>
</navigation-element>

```

- Each navigation element defines a node in the console navigation. If you nest the navigation elements, it creates a hierarchical tree structure that is reflected in the console navigation. For the purpose of this exercise, only a single navigation element is provided. The **layoutElementRef** attribute indicates the unique name of the layout element that is rendered on the page that is displayed when this element is selected by the console user.
- The content of the `ProductFilter` preference indicates the **appid** of the lead application. This is used to render this navigation element when the lead product is selected by the console user for filtering the navigation.
- The content of the **parentTreeRef** element indicates the unique name of the parent navigation element for this element.

The following figure shows how this navigation element is rendered with the page layout sample. In this figure, the user has selected Integrated Solutions Console Sample from the **View** selection list to filter the navigation.

Figure 1. Sample console module navigation

When you have finished, save and close the file and store in the `/WEB-INF` directory of your console module project.

## Sample portal security descriptor

To follow these steps, open a file with the name `ibm-portal-security.xml` in a text or XML editor and save each change at the end of each step.

1. Copy the following elements into `ibm-portal-security.xml`. Some information is split on multiple lines for printing purposes.

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<ibm-portal-security
  xmlns="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd"
  xmlns:base="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

  xsi:schemaLocation="http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-topology.xsd
ibm-portal-topology.xsd
  http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-base.xsd ibm-portal-base.xsd
  http://www.ibm.com/websphere/appserver/schemas/6.0/ibm-portal-security.xsd ibm-portal-security.xsd">

  </ibm-portal-security>
```

2. Add the `<application-role/>` element as the content of the `<ibm-portal-security/>` element.

```
<application-role uniqueName="monitor">
```

```
</application-role>
```

This sample identifies the administrative role, `monitor`, for access rights. See “Portal security schema” on page 62 for a complete description of this element and the `uniqueName` attribute.

3. Add the following `<portal-role/>` elements as the content of the application role.

```
<portal-role object-ref="com.ibm.isclite.samples.navigationElement.basicModule"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.navigationElement.A"/>
<portal-role object-ref="com.ibm.isclite.samples.basicModule.portletEntity.A"
  role-type="Privileged User"/>
```

This sample assigns permission to a user with `monitor` access to view two navigation elements and to view, edit, and access help for one portlet. See “Portal security schema” on page 62 for a complete description of this element and its attributes.

When you have finished, save and close the file and store in the `/WEB-INF` directory of your console module project.

## Packaging a console module

Before you start this task, be sure your Java sources compile without errors and the XML descriptors have been validated against the corresponding schemas.

An Integrated Solutions Console module must be packaged as a WAR file for deployment. For best results, use a comprehensive development tool such as WebSphere Application Server Toolkit or Rational Application Developer. Otherwise, you can follow these steps to package your console module resources into the WAR file.

1. Create a working directory to collect all of the files that need to be packaged in the WAR file.
2. Organize your portlets and other resource files in the prescribed directory structure for portlet WAR files using the following steps:
  - a. Place the following deployment descriptors in the directory `/WEB-INF` directory:
    - `ibm-portal-topology.xml` (topology descriptor)
    - `ibm-portal-security.xml` (security descriptor)
    - `portlet.xml` (portlet descriptor)
    - `web.xml` (Web application descriptor)

- b. Place individual Java classes for your portlets in the directory `/WEB-INF/classes`. Use a directory structure that reflects the fully-qualified class name of your portlet, for example, `/com/ibm/isclite/samples/basicModule`.
  - c. Put JAR files in the directory `/WEB-INF/lib`.
  - d. If the console module supports multiple languages, place the properties file that contains the translated strings (the resource bundles) in the directory `/WEB-INF/classes/nls`.
  - e. Put any JavaServer Pages that must be served directly by the client in a directory that is not under the `/WEB-INF` directory (such `/jsp`). Resources in the `/WEB-INF` directory are protected and are not URL-addressable. JavaServer Pages that are accessed only by the portlets in the console module can be placed in the `/WEB-INF` path.
  - f. If the console module has help files, copy the Eclipse help plug-in files to the directory `/help/plugin_name`, where *plugin\_name* is the name of the Eclipse help plug-in, such as `com.ibm.myprod.help.doc`.
3. Use the Java JAR utility to create the WAR file. For instructions, see the Java Tutorial at <http://java.sun.com/docs/books/tutorial/jar/basics/index.html>. You can also use an assembly tool like Application Server Toolkit or Rational Application Developer to create the WAR file for the console module.

## Deploying a console module

After you create the WAR file for a console module, you can deploy the console module to a system where the runtime for Integrated Solutions Console is installed and then test that the console module works correctly. Only one instance of a console module can be deployed on an Integrated Solutions Console installation. This rule applies even if the versions of the console module are different.

If you need to update the version of a console module, you must perform these steps.

1. Remove the console module.
2. Update the module with the required changes.
3. Reissue the deploy command.

To deploy a console module on a system where the runtime for Integrated Solutions Console is installed, perform the following procedure:

1. Go to the machine where the Integrated Solutions Console runtime is installed. You can also use a machine that has remote access to the drive where the runtime is installed.
2. Copy the console module WAR file to the `app_server_root/systemApps/isclite.ear` directory. As an alternative, you can extract the WAR file into a subdirectory of this location using the WAR file name for the subdirectory. For example, you would extract `pagelayout.war` to the `app_server_root/systemApps/isclite.ear/pagelayout.war` directory.
3. Open a command prompt.
4. If you want to deploy the console module to an application server profile other than the default, change to the `app_server_root/profiles/profile_name/bin` directory and enter the `setupCmdLine.[bat|sh]` command. If you want to deploy to the default application server profile, change to the `app_server_root/bin` directory.
5. Start the `wsadmin` scripting client. If the server is not running, use the `-conntype NONE` option to run in local mode.
6. At the **wsadmin** command prompt, enter the command syntax. The following example presents the syntax:

```
$AdminApp update isclite modulefile {
-operation add
-contents path_to_war
```

```
-contenturi war_filename
-custom paavalidation=true -usedefaultbindings
-contextroot /context
-MapWebModToVH {{.* .* admin_host}}}
```

**Note:** The values of the `-contents` and `-contenturi` are case sensitive and should match the war file name that you are ready to deploy. The option `custom paavalidation=true` is optional.

As an example, if you were to deploy the page layout sample to a Windows machine, the command would be as follows.

```
$AdminApp update isclite modulefile {
-operation add
-contents C://WebSphere//AppServer//systemApps//isclite.ear//pagelayout.war
-contenturi pagelayout.war
-custom paavalidation=true -usedefaultbindings
-contextroot /pagelayout
-MapWebModToVH {{.* .* admin_host}}}
```

The following messages are displayed if the deployment is successful.

```
Update of isclite has started.
ADMA5009I: An application archive is extracted at D:\IBM\WebSphere_63\AppServer\
profiles\AppSrv01\wstemp\wstemp\app_10793d84b8e\ext/pagelayout.war
ADMA5064I: FileMergeTask completed successfully for isclite.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5110I: The application isclite is installed as a hidden application and will
not be exposed via administrative interfaces such as GUI client, wsadmin or MBe
an Java API. In order to perform management operations on this application, the
application name must be known.
CWLAA10001I: The Integrated Solutions Console module was deployed successfully.
ADMA5005I: The application isclite is configured in the WebSphere Application Se
rver repository.
ADMA5011I: The cleanup of the temp directory for application isclite is complete
.
Update of isclite has ended.
```

7. After the deployment has completed successfully, save your work by issuing the following command:

```
$AdminConfig save
```

If the deployment is successful, the WAR file contents are extracted to the `/systemApps/isclite.war` directory and the module metadata is copied to the `app_server_root/profiles/profilename/config/cells/cellname/applications/isclite.ear/deployments/isclite` directory.

To view your console module, you must log back in to the console. Make sure the navigation is updated correctly. If so, select the new navigation nodes verify that the new pages and console modules are rendered correctly.

## Testing a console module

Use the following checklist to test your console module after it has been deployed.

1. Log in to Integrated Solutions Console as an administrator.
2. If the module includes an `<about-page/>` element in the topology descriptor, verify that your suite and its version are listed in the table on the Welcome page. Also confirm that the product is listed in the **View** selection list for the navigation,
3. Verify that the console navigation tree contains all of the organizational nodes and pages that were defined. Verify that each node is at the correct level in the tree.
4. For each page, verify that the portlets on the page work correctly. If a portlet on the page launches a new page in work area, verify that the launching works correctly.

5. To test the access permissions specified in the console module descriptor, logout and then log in as a different user to verify that the correct pages are accessible.
6. If the console module included a help plug-in, make sure you can launch the help.
7. If the console module contains errors, refer to the SystemOut.log and SystemErr.log for any errors or messages. These logs are located in the *app\_server\_root/profiles/profilename/logs/server1* directory.

## Removing a console module

Follow these steps to delete a console module.

1. Ensure that the server is started. You do not need to log in to the console.
2. Open a command prompt.
3. If the console module is deployed to an application server profile other than the default, change to the *app\_server\_root/profiles/profile\_name/bin* directory and enter the `setupCmdLine.[bat|sh]` command. Otherwise, change to the *app\_server\_root/bin* directory.
4. Start the wsadmin scripting client.
5. Enter the following command from the wsadmin command prompt.  

```
$AdminApp update isclite modulefile {-operation delete -contenturi module_file_name.war}
```
6. Save your configuration changes.  

```
$AdminConfig save
```
7. Exit the wsadmin command environment.  

```
quit
```

---

## Adding advanced API features

The class files for console modules are developed using the Java Portlet Specification. Integrated Solutions Console includes additional APIs for launching pages, passing properties to other portlets, and launching Eclipse-based help. This section provides information about the APIs available to console modules.

## Developing portlets

Integrated Solutions Console supports console modules written to the Java Portlet Specification. A packaged console module WAR file contains one or more portlets or reuses portlets from other modules. According to the JSR 168 specification, a *portlet* is a Java technology based Web component, managed by a portlet container, that processes requests and generates content that contributes to the overall portal page. Portlets share many of the same characteristics as servlets. However, portlets also exhibit differences. For example, portlets cannot set HTTP headers and can contribute only markup fragments to the portal page. The portlet specification leverages the functionality of the servlet specification as much as possible, and many parts of the Java Portlet Specification have been modeled after the servlet specification.

The application server includes a JSR 168-compliant portlet container to support deploying and running console modules in Integrated Solutions Console. The JSR 168 portlet container relies on the J2EE architecture implemented by the application server. Consequently, an Integrated Solutions Console module and its portlets are packaged and deployed similar to J2EE Web applications. In addition to the Web application descriptor and the portlet descriptor, the WAR file for an Integrated Solutions Console module includes descriptors for a portal application archive (PAA), which provides additional information needed to deploy the application to a console installation.

The following Web resources can be useful for learning more about portlet development.

## Launching pages

Typically, users of the console launch pages using the links in the console navigation. However, portlets in a console module also launch pages directly using the Dynamic UI Manager API.

The DynamicUI Manager APIs are provided by 3 services: PropertyFactory, DynamicUIManagerFactoryService, and URLGeneratorFactoryService. To use these services the portlet must first perform a JNDI lookup to get the PortletServiceHome object which you then can use to get the actual service interface object. This is demonstrated in the GetApps portlet of the PortletContext sample.. The following code is placed in a try block of the portlet's init() method.

Some information is split on multiple lines for printing purposes.

```
Context ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
// get propertyfactory service

propertyFactoryServiceHome = (PortletServiceHome)ctx.lookup("portletservice/com.ibm.portal.
propertybroker.service.PropertyBrokerService");
if (propertyFactoryServiceHome == null)
    logger.log(Level.FINE, "no PropertyBrokerService propertyFactoryServiceHome");
else
    propertyFactoryService =

        (PropertyFactory)propertyFactoryServiceHome.getPortletService(com.ibm.portal.
propertybroker.service.PropertyBrokerService.class);
logger.log(Level.FINE, "propertyBrokerService="+propertyFactoryService);
// get dynamicUIManagerFactory service
dynamicUIManagerFactoryServiceHome =
(PortletServiceHome)ctx.lookup("portletservice/com.ibm.portal.portlet.service.DynamicUIManagerFactoryService");
if (dynamicUIManagerFactoryServiceHome == null)
    logger.log(Level.FINE, "no dynamicUIManagerFactoryService propertyFactoryServiceHome");
else
    dynamicUIManagerFactoryService =

        (DynamicUIManagerFactoryService)dynamicUIManagerFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.DynamicUIManagerFactoryService.class);
logger.log(Level.FINE, "dynamicUIManagerFactoryService="+dynamicUIManagerFactoryService);
// get urlGeneratorFactory service
urlGeneratorFactoryServiceHome =
(PortletServiceHome)ctx.lookup("portletservice/com.ibm.portal.portlet.service.URLGeneratorFactoryService");
if (urlGeneratorFactoryServiceHome == null)
    logger.log(Level.FINE, "no urlGeneratorFactoryService propertyFactoryServiceHome");
else
    urlGeneratorFactoryService =
```

```
(URLGeneratorFactoryService) urlGeneratorFactoryServiceHome.getPortletService
(com.ibm.portal.portlet.service.URLGeneratorFactoryService.class);
logger.log(Level.FINE, "urlGeneratorFactoryService="+urlGeneratorFactoryService);
```

A portlet can launch a new page using the `dynamicUICtrl` interface, passing the object ID of the page definition for the new page. The object ID is determined by performing a JNDI lookup on the unique name of the navigation element that launches the page. If you are planning to launch a navigation element, the navigation node must point to a layout element. In other words the navigation element must contain the **layoutElementRef** attribute. The `addPage()` method returns the object ID of the page instance, which should be saved by the portlet to create a URL and launch the page. The following excerpt from the `PortletContext` sample demonstrates how this works. The portlet `GetApps.java` includes a `launchPage()` method with this code.

```
Context ctx;
ObjectID pageDefinitionID = null;
String pagename="com.ibm.isclite.portletcontext.navigationElement.B";
logger.log(Level.FINE, "launch page=" + pagename);

PortletSession ps = request.getPortletSession(false);
try {
    ctx = new InitialContext();
    pageDefinitionID =(ObjectID)ctx.lookup("portal:uniquename/"+pagename);
} catch (NamingException ne) {
    return;
}
try {
    PropertyController cproperty = propertyFactoryService.createProperty(myconfig);
    PropertyController cproperty2 = propertyFactoryService.createProperty(myconfig);

    cproperty.setType("String");
    cproperty.setName("servername");
    cproperty2.setType("String");
    cproperty2.setName("appDeployed");
    PropertyValue[] propertyValues = new PropertyValue[2];
    propertyValues[0] =
        propertyFactoryService.createPropertyValue(request, cproperty, serverName);
    propertyValues[1] =
        propertyFactoryService.createPropertyValue(request, cproperty2, appDeployed);

    DynamicUICtrl dmanagerCtrl =
        dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

    ObjectID newPageID =
        dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);

    RedirectURLGenerator urlGenerator =
        urlGeneratorFactoryService.getURLGenerator(request, response);

    EngineURL redirectURL = urlGenerator.createPageURL(newPageID);

    response.sendRedirect(redirectURL.toString());
} catch ...
```

- The `pagename` String is created with the unique name of the navigation element (from the topology descriptor) that launches the page.
- The object ID is found by performing a JNDI lookup on this Context instance using this String:  
"portal:uniquename/"+pagename

The String `portal:uniquename/` is required to obtain the object ID for the navigation element.

- Properties are created to be passed to the portlets on the page. The property names are `servername` and `appDeployed`.
- In addition to the request and response, you must include the String `isc.tasklaunch` as the configuration name on the `getDynamicUICtrl()` method.

- Use the `addPage()` method of the new `DynamicUICtrl` instance to create and instance of the page. Any properties that need to be passed to portlets on the new page must be provided in this method. The `addPage()` method does not launch the page, but it returns the object ID of the page instance. The next two methods, `getURLGenerator()` and `createPageURL()`, are used to construct the URL that opens the page. The URL contains property names and values if they have been provided.
- The URL to open the page is provided on the `sendRedirect()` method of the response.

## Passing properties to other portlets

This topic describes how portlets can exchange properties. You should be familiar with the concepts for launching console pages before reading this topic.

Information can be provided to portlets on the same page using the `addSharedPortlet()` method. Property values are of the type `com.ibm.portal.propertybroker.property.PropertyValue`. The example in “Launching pages” on page 44 shows these properties passed to the page using an instance of the `PropertyValue` interface (`propertyValues`) and shows how that object was created using the `PropertyFactory` interface.

The `SetServer.java` source from the `PortletContext` sample shows how to pass properties to a portlet on the same page. It is assumed that the portlet has already performed a JNDI lookup to determine that the `PropertyFactory`, `DynamicUIManagerFactoryService`, and `URLGeneratorFactoryService` services are available. This is described in “Launching pages” on page 44

- In this example, the portlet that is the source of the properties needs the object ID of the target portlet. The object ID is determined by performing a JNDI lookup using the values from the portlet’s `<resource-link/>` element in the topology descriptor.
- The property, `cproperty`, is created using the `PropertyController` interface and the `createProperty()` method of the `PropertyFactory` interface. The data type for the property must be a `String`.
- Prior to sending the property, the source portlet creates an instance of the `DynamicUICtrl` interface, passing the string “isc.tasklaunch” as the configuration name.
- The `addSharedPortlet()` method sends the properties to the target portlet on the request. After the action phase, the target portlet updates the output for the response.

```
Context ctx = null;
ObjectID portletDefinitionID1 = null;
ObjectID portletDefinitionID2 = null;

String portletname1="com.ibm.isclite.samples.PortletContext/PortletGetPerformance";
String portletname2="com.ibm.isclite.samples.PortletContext/PortletGetApps";

PortletSession ps = request.getPortletSession(false);

try
{
    ctx = new InitialContext(com.ibm.portal.jndi.Constants.ENV);
    portletDefinitionID1 =
        (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname1);
    portletDefinitionID2 =
        (ObjectID)ctx.lookup("portal:config/portletdefinition/"+portletname2);
} catch (NamingException ne)
{
    logger.log(Level.FINE, "portletdefinitionID not found - Naming exception:"+ne.getMessage());
    return;
}
logger.log(Level.FINE, "portletdefinitionID="+portletDefinitionID1.toString());

try
{
    PropertyController cproperty =
        propertyFactoryService.createProperty(myconfig);
    cproperty.setType("String");

    PropertyValue[] propertyValues = new PropertyValue[1];
```

```

propertyValues[0] =
    propertyFactoryService.createPropertyValue(request, cproperty, serverName);

DynamicUICtrl dmanagerCtrl =
    dynamicUIManagerFactoryService.getDynamicUICtrl(request, response, "isc.tasklaunch");

ObjectID newPortletID1 =
    dmanagerCtrl.addSharedPortlet(portletDefinitionID1, null, propertyValues);
ObjectID newPortletID2 =
    dmanagerCtrl.addSharedPortlet(portletDefinitionID2, null, propertyValues);

    logger.log(Level.FINE, "portlet ID created:"+newPortletID1.getOID());
} catch ...

```

In some cases, the target portlet might be on a separate page. In this case, the properties are passed using the `addPage()` method. The target portlet receives the properties only when the page is launched that contains the portlet. If a property value is set multiple times before the page is launched, the value that was set last for the property is passed to the portlets on the page. You can use the `URLGeneratorFactoryService` interface to redirect the console to the page for the target portlet. This is demonstrated in the `GetApps` portlet of the `PortletContext` sample.

```

ObjectID newPageID = dmanagerCtrl.addPage(pageDefinitionID, null, propertyValues);
RedirectURLGenerator urlGenerator = urlGeneratorFactoryService.getURLGenerator(request, response);
EngineURL redirectURL = urlGenerator.createPageURL(newPageID);
response.sendRedirect(redirectURL.toString());

```

To use the `URLGeneratorFactoryService`, the portlet must first perform a JNDI lookup for this portlet service. Refer to the `GetApps.java` source to see how to obtain a reference to the portlet service.

## Receiving properties

To receive properties, the target portlet must provide the `com.ibm.portal.pagecontext.enable` preference parameter in the `portlet.xml` with a value of `true`. If the portlet should receive any subsequent updates, the `com.ibm.portal.context.enable` read-only preference should also be set to `true`. Only String property types are supported and the context is passed as parameters of the action request. The following example shows how the `GetApps` portlet receives properties passed by the `SetServer` portlet.

```

public void processAction(ActionRequest request, ActionResponse response)
    throws PortletException, IOException {

    PortletSession ps = request.getPortletSession(true);
    appDeployed = request.getParameter("appDeployed");
    serverName=request.getParameter("servername");

    ps.setAttribute("servername",serverName);
    ps.setAttribute("appDeployed",appDeployed);
    launchPage(request, response);

}

```

A target portlet can check `com.ibm.portal.action` parameter of the request during action processing to determine if any properties have been passed. If properties are being passed to the portlet, the value of this parameter is `com.ibm.portal.pagecontext.receive`. For example:

```

String action = req.getParameter(com.ibm.portal.action.name);
if (action!=null && action.equalsIgnoreCase("com.ibm.portal.pagecontext.receive")) {

    // code to get the properties as a parameter on the request

}

```

## Launching Eclipse-based help

If your Integrated Solutions Console module contains a portlet that requires a help page, follow the instructions in this topic to implement help for the portlet.

### Sample

The Modes sample (modes.war) demonstrates how a console module can provide user assistance or help. This sample is described in “Console module samples” on page 34.

### Enabling portlet help

To implement portlet help, you use the portlet’s doHelp() method, the EclipseHelp class, and the help setting in the portlet.xml file. Inside the doHelp() method, link to the target help topic in your Eclipse help plug-in by using the portletHelp() method of the EclipseHelp class. By including a doHelp() method in your portlet and adding the help setting to the portlet.xml file, you enable the portlet help mode. When portlet help mode is enabled, the  icon is displayed on the portlet title bar. When a user clicks the icon, a separate browser window opens and displays only that help topic.

### Adding the doHelp method

To add the doHelp() method to your portlet, perform the following procedure:

1. In the portlet Java file, include the following import statement:

```
import com.ibm.portal.help.EclipseHelp;
```

2. Implement the doHelp() method in the portlet.

```
public void doHelp(RenderRequest request, RenderResponse response)
    throws PortletException, IOException {

}
```

3. Inside the method, create a String to contain the help topic. The syntax for specifying a help topic is *pluginID/file\_path/file\_name*, where *pluginID* is the Eclipse help plug-in ID as specified in its plugin.xml file, *file\_path* is the sub-directory path (if any), and *file\_name* is the filename and extension of the help content file.

```
public void doHelp(RenderRequest request, RenderResponse response)
    throws PortletException, IOException {

    String topic = "com.ibm.isc.help.modes/help_mode.html";
}
```

4. Call the method EclipseHelp.portletHelp() passing in the request, response, and topic as shown in the code snippet below.

```
public void doHelp(RenderRequest request, RenderResponse response)
    throws PortletException, IOException{

    String topic = "com.ibm.isc.help.modes/help_mode.html";
    EclipseHelp.portletHelp(request, response, topic);

}
```

### Setting help mode in the portlet.xml file

In addition to implementing the doHelp() method, you must set the help mode for that portlet in the portlet.xml file. To set help mode in the portlet.xml file, perform the following steps:

1. Use a text editor to open the portlet deployment descriptor (the portlet.xml file). See topics under Developing portlets for more information about creating a portlet.xml file.
2. Inside the <portlet-app> element, locate the <portlet> element for the portlet that implements the doHelp() method.

3. Inside the `<supports>` sub-element, add a `<portlet-mode>` element like the one shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
  version="1.0" id="com.ibm.isclite.samples.Modes"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
    http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
  <portlet id="Modes_Portlet" >
    <portlet-name>ModesPortlet</portlet-name>
    <display-name>Modes portlet1 (JSR 168)</display-name>
    <display-name xml:lang="en">Modes portlet1 (JSR 168)</display-name>
    <portlet-class>com.ibm.isclite.samples.Modes</portlet-class>
    <expiration-cache>0</expiration-cache>
    <supports>
      <mime-type>text/html</mime-type>
      <portlet-mode>VIEW</portlet-mode>
      <portlet-mode>EDIT</portlet-mode>
      <portlet-mode>HELP</portlet-mode>
    </supports>
    <supported-locale>en</supported-locale>
    <resource-bundle>nls.HTML</resource-bundle>
  </portlet>
</portlet-app>
```

## Creating Eclipse help

Refer to <http://help.eclipse.org> for information about providing HTML help as an Eclipse plugin.

## Support for bidirectional characters

Integrated Solutions Console supports bidirectional text. If your console module provides support for Hebrew, it must provide two identical resource bundles for the translated Strings. The file name for one resource bundle must be appended with the `_iw` suffix and the other resource bundle must be appended with the `_he` suffix. For example:

```
portlet_iw.properties
portlet_he.properties
```

---

## Console module schemas

### Descriptors for a console module

Console modules are packaged as *portal application archives* (PAA). A portal application archive is similar to a standard JSR 168 portlet WAR file - it includes one or more portlets plus the servlet and portlet descriptors (`web.xml` and `portlet.xml`) However, the portal application archive includes two additional descriptors:

#### **ibm-portal-topology.xml**

Defines the console module and its components, page layout, and location in the navigation. Based on the schema definitions in `ibm-portal-topology.xsd`.

#### **ibm-portal-security.xml**

Describes portal application security, such as application roles and access control. Based on the schema definitions in `ibm-portal-security.xsd`.

When a console module is deployed, Integrated Solutions Console reads these descriptors and uses that information to add the console module to the installation. The XML descriptor files must be well-formed and validate with the associated schemas. If the file is not valid, deployment ends and an error message is generated.

A copy of the schema files (with descriptive comments embedded) is in the *app\_server\_root/properties/schemas* directory. Not all elements and attributes in the schemas are supported, however. Only elements and attributes that are documented in the following sections are supported:

- “Base schema”
- “Portal topology schema”
- “Application definition elements” on page 52
- “Portal security schema” on page 62

## Base schema

The topology and security schemas reference the base schema for portal application archives, *ibm-portal-base.xsd*. The following complex type element definitions from the base schema are used most often in the topology and security descriptors. These elements can be used within any other element in the descriptor that requires a localized string to be displayed, for example, in the title or description elements.

### NlsString

specifies localized strings to be displayed. This tag is intended to be used during development before the application has been updated to support multiple languages through resource bundles. The `xml:lang` attribute enables a programmer to get started with the code without having to define a resource bundle right at the start. The value of the `xml:lang` attribute should adhere to RFC 1766 (<http://www.ietf.org/rfc/rfc1766.txt>). The default value of the `xml:lang` attribute is English(en).

```
<base:nls-string lang="locale">string</base:nls-string>
```

### NlsRef

specifies localized strings that are maintained in a Java resource bundle. You must include the location of the resource bundle and the name of the key for lookup.

```
<base:nls-ref key="key_name" locationName="path_to_resource_bundle"/>
```

where *path\_to\_resource\_bundle* specifies a path relative to the `/WEB-INF` directory of the module's WAR file. For example, if the resource bundle is located in `/WEB-INF/classes/nls/myresources.properties`, specify `/classes/nls/myresources`.

If the resource bundle cannot be located, the key name is returned. That is, if the property string that could not be found is intended to be displayed in the console, the key name would be displayed instead.

### Preference

Used to describe name/value pairs used by the application. The preference name is specified as an attribute and the preference value is specified as a subelement.

```
<preference name="preference_name">
  <base:value>
    <base:string>preference_value</base:string>
  </base:value>
</preference>
```

The preference value can be specified as a string, `NlsString`, or `NlsRef`.

## Portal topology schema

The portal topology descriptor distinguishes the console module from other portlet applications by providing additional information about the portlets in the application. Whereas the `portlet.xml` provides a unique identifier for each portlet, its fully-qualified class name, and supported modes, the portal topology descriptor describes a console module in a generic sense, including a list of component portlets, the page layout, and navigation information. Portlets in the application can be packaged in the WAR file or already deployed from another archive. The only mapping between the descriptors is a reference from the portal

application's <resource-link/> element, using the portlet application ID and portlet name from the portlet descriptor.

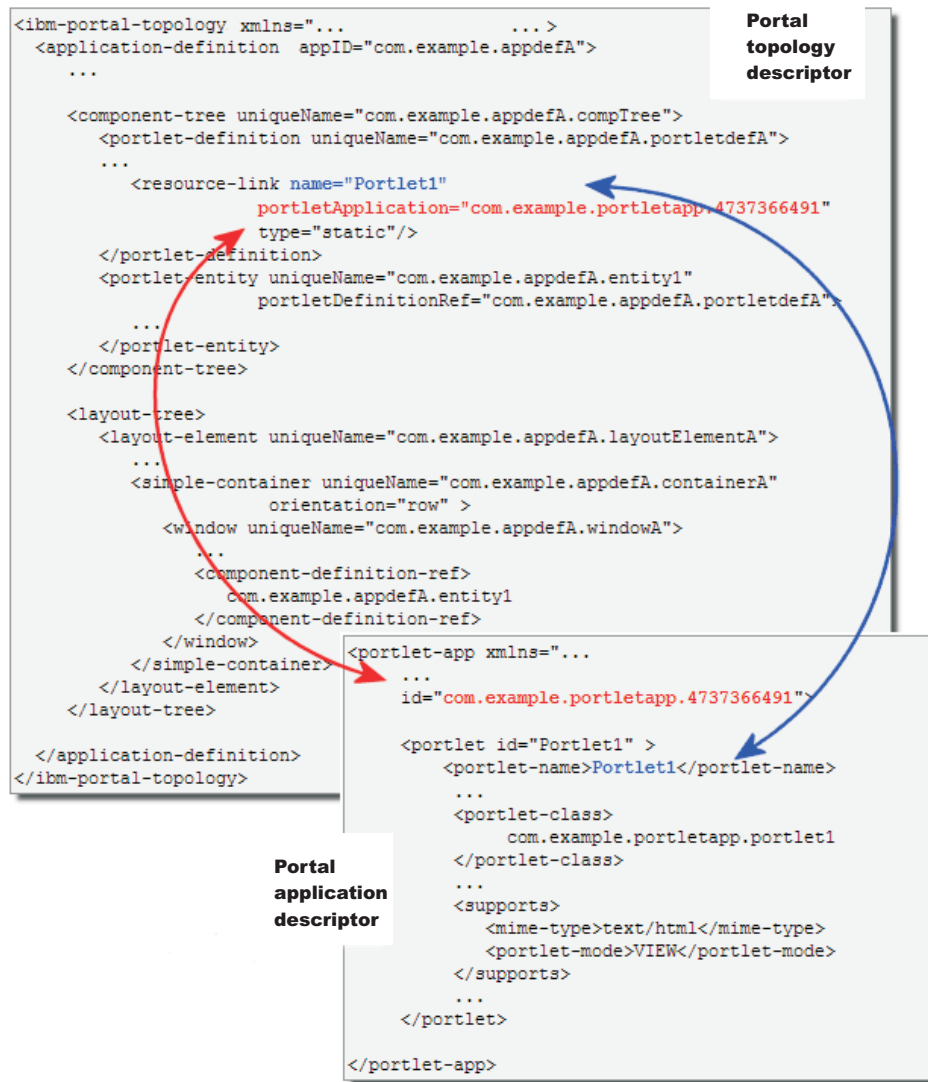

Figure 2. References from the portal topology descriptor to the portlet descriptor

## Description of the top level topology elements

Only the following elements, along with those described in “Application definition elements” on page 52, are supported for this release.

### <ibm-portal-topology/>

Required. the root element of the portal topology descriptor. The content of this tag is one or more <application-definition/> tags and, optionally, either an <about-page/> or a <PAA-ref/> element.

### <application-definition/>

At least one is required. This element describes an application with its component portlets, page layout, and portal navigation structure. See Application definition elements.

After the application definition, only one of the following elements can be defined.

### **<about-page/>**

Optional. The about page is provided by the lead application for a product and provides a description of the product and other resources for support. This content is specified using the unique name of the layout element in the application definition that contains the about page content. At runtime, the about page is accessed from the main welcome page of the console. Providing the <about-page/> element also causes the console module to appear in the View selection list of the navigation.

In the following example from the page layout sample, about page refers to a layout element with the unique name `com.ibm.isclite.pagelayout.layoutElement.F`.

```
<about-page>com.ibm.isclite.pagelayout.layoutElement.F</about-page>
```

The layout element provided in this sample includes a portlet with the about page content.

### **<PAA-ref/>**

Optional. This element references the **appid** of the lead application for the product. The **appid** name should be unique in the install. This element is intended for subcomponents of an application that spans multiple archives.

## **Application definition elements**

The <application-definition/> element describes the portal application, its components, page layout, and navigation. It is contained by the <ibm-portal-topology/> element in the portal topology descriptor.

### **Basic structure of the application definition**

The following figure illustrates the elements of the application definition that are supported for this release.

---

```

<application-definition appID="" version="">

  <title/>

  <requires uniqueName="" version=""/>

  <component-tree uniqueName="">
    <portlet-definition uniqueName="">
      <title/>
      <resource-link name="" type="" portletApplication=""/>
    </portlet-definition>
    <portlet-entity uniqueName="" portletDefinitionRef="">
      <title/>
    </portlet-entity>
    <url-link uniqueName="" url="" absolute="" />
  </component-tree>

  <layout-tree>
    <layout-element uniqueName="">
      <title/>
      <simple-container uniqueName="" orientation="">
        <window uniqueName="">
          <title/>
          <component-definition-ref/>
        </window>
      </simple-container>
    </layout-element>
  </layout-tree>

  <navigation-element uniqueName="" layoutElementRef="">
    <title/>
    <preference>
      <value/>
    </preference>
    <url-mapping/>
    <parent-tree parentTreeRef="" ordinal=""/>
    <navigation-content uniqueName="" componentDefinitionRef="" windowRef=""/>
  </navigation-element>

</application-definition>

```

---

Figure 3. Elements in the portal application definition

Other elements of the application definition that can be found in the `ibm-portal-topology.xsd` schema are not supported for this release. At a minimum, the application definition requires a title, a component tree, and a layout tree. The following sections describe the `<application-definition/>` element, its attributes, and its subelements.

## Application definition

The `<application-definition/>` element defines one or more applications that are part of the package. Exactly one is required.

The following attributes are used with this element.

**appID** Required. Specifies a unique identifier for this portal application. The appID has no relationship with IDs in the `portlet.xml`. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

### version

Required. Specifies the numerical version of the application. The format of the version is defined in the `ibm-portal-base.xsd` schema under the simple type for `VersionString`.

## Title

Exactly one is required. The `<title/>` element provides a title for the application. If this is the lead application for a product, this title is displayed on the Welcome page when the user logs into the console. A lead application is the one that includes the `<about-page/>` element in the topology definition. Subcomponents of the product use the `<PAA-ref/>` element to specify the lead application to which they belong.

The content of the `<title/>` element can be specified as a simple string element from the base schema. To provide a localized string, use the `<base:nls-string/>` or `<base:nls-ref/>` elements for the title content. For example:

```
<title>
  <base:nls-string lang="en">Integrated Solutions Console Sample</base:nls-string>
</title>
```

## Requires

Optional, multiple allowed. The `<requires/>` element indicates the unique ID of a portal application that is a prerequisite for this application. Any prerequisites for the application must be already deployed. The application can have multiple prerequisites.

The following attributes are used with this element.

### uniqueName

Required. Specifies the unique identifier of another application that must already be deployed on the server. This value must match the `appID` attribute from the `<application-definition/>` element of the required application's topology descriptor. Otherwise, deployment fails.

### version

Required. Specifies the numerical version from the required application's `<application-definition/>` element. If the version is not identical to the required application's version string, deployment fails. Required.

The following example shows how the tree merge sample indicates the page layout sample as a prerequisite application.

```
<requires uniqueName="com.ibm.isclite.samples.PageLayout" version="6.1"/>
```

The following example shows the attributes for the `<application-definition/>` element of the page layout sample. These attributes are used as the values for attributes on the `<requires/>` element for the tree merge sample.

```
<application-definition appID="com.ibm.isclite.samples.PageLayout" version="6.1">
  ...
```

## Component tree

Exactly one is required. The `<component-tree/>` element describes all portlets in the console module. The tree structure of the component definitions can be used for organizing the components in the portal application. There are no semantics associated with this organization and the portal may not respect this structure for organizing the actual portal resources corresponding to it.

The following attribute is used with this element.

### uniqueName

Required. Specifies a unique identifier for the component tree. To guarantee uniqueness, see "Guidelines for unique identifiers" on page 62.

The following elements make up the content of the `<component-tree/>` element.

## <portlet-definition/>

Optional, multiple allowed. This element describes one portlet. The portlet can be included in the same archive or already deployed on the server.. A portlet definition refers to a portlet defined in a portlet.xml deployment descriptor in a portlet WAR file. A portlet can be associated with a window in a layout. In most cases, the application artifact is actually defined by its own deployment descriptor within the archive and the <resource-link/> element is used for referencing it so that it can be integrated into the portal application page layout and navigation.

The following attribute is used with this element.

### uniqueName

Required. Specifies a unique identifier for the portlet definition. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

The following element makes up the content of the <portlet-definition/>.

### <title/>

Required, exactly one allowed. This element provides a title for the portlet definition. This title is not displayed in the console for this release. To provide a localized string, use the <base:nls-string/> or <base:nls-ref/> elements for the title content.

### <resource-link/>

Required, exactly one allowed. This element provides a link to a portlet definition that is included in the PAA package or is already deployed separately in the portal.

The following attributes are used with this element.

**name** Specifies the name of the portlet as defined by the <portlet-name/> element in the portlet.xml. If the name of the portlet is not unique within the PAA, an additional portlet-application attribute must be specified.

**type** The value `static` specifies that the resource must be available at the time the PAA package is deployed. This is the default and the only value that is supported for this release.

### portletApplication

Specifies the ID attribute of the <portlet-app/> element in the portlet.xml. Since different PAA packages could have portlets with the same name, it is necessary to name space them.

The following example shows the <resource-link/> element for the page layout sample.

```
<resource-link name="PageLayoutPortlet1"
  portletApplication="com.ibm.isclite.samples.PageLayout" type="static"/>
```

The following example is taken from the portlet.xml for the page layout sample to show the values needed for the previous <resource-link/> example.

```
...
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd"
  version="1.0" id="com.ibm.isclite.samples.PageLayout"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd
    http://java.sun.com/xml/ns/portlet/portlet-app_1_0.xsd">
  <portlet id="PageLayout_Portlet1" >
    <portlet-name>PageLayoutPortlet1</portlet-name>
  ...
```

The next example is also from the page layout sample. In this example, the <resource-link/> uses values from a portlet that is already deployed to the portal. These values come from the portlet.xml of the portlet (TempPortlet) from the tree merge sample.

```

<portlet-definition uniqueName="com.ibm.isclite.TreeMerge.appElementDefinition.A">
  <title>
    <base:nls-string lang="en">TreeMergePortlet</base:nls-string>
  </title>
  <resource-link name="TempPortlet"
    portletApplication="com.ibm.isclite.samples.TreeMerge" type="static"/>
</portlet-definition>
<portlet-entity uniqueName="com.ibm.isclite.TreeMerge.appElement.B"
  portletDefinitionRef="com.ibm.isclite.TreeMerge.appElementDefinition.A">
  <title>
    <base:nls-string lang="en">TempPortlet</base:nls-string>
  </title>
</portlet-entity>

```

### <portlet-entity/>

Optional, multiple allowed. This element specifies an instance of a portlet definition with additional configuration values. The portlet entity's uniqueName is used by the <window/> element to place the portlet on the page. The portlet definition that is specified can reside in the current archive or already be deployed on the server.

The following attributes are used with this element.

#### uniqueName

Required. Specifies a unique identifier for the portlet entity. To guarantee uniqueness, see "Guidelines for unique identifiers" on page 62.

#### portletDefinitionRef

Required. References the unique name of the portlet definition within the same topology descriptor file.

The following element makes up the content of the portlet definition.

#### <title/>

Optional, no more than one allowed. This element provides a title for the portlet entity. To provide a localized string, use the <base:nls-string/> or <base:nls-ref/> elements for the title content. This title is rendered in the portlet window.

### <url-link/>

Optional and multiple elements are allowed. This element is used to include links to external URLs that are added to the console navigation . The following attributes are used with this element.

#### uniqueName

Required. Specifies a unique identifier for the url link. To guarantee uniqueness, see "Guidelines for unique identifiers" on page 62.

#### absolute

Optional. Indicates whether the URL is an absolute value (true) or relative value (false). Only absolute values are supported for this release and the default value is true.

**url** Required. Specifies an external address or URL that will be added to the console navigation.

In the following example, the URL for a company support page is provided.

```
<url-link uniqueName="my.example.com.support.page" url="http://my.example.com/support" absolute="true"/>
```

The following example shows part of the <component-tree/> element for the page layout sample with the first portlet definition and corresponding portlet entity.

```

<component-tree uniqueName="com.ibm.isclite.pagelayout.appTree">
  <!-- PageLayoutPortlet 1-->
  <portlet-definition uniqueName="com.ibm.isclite.pagelayout.appElementDefinition.A">
    <title>
      <base:nls-string lang="en">RowPortlet</base:nls-string>
    </title>

```

```

    <resource-link name="PageLayoutPortlet1"
        portletApplication="com.ibm.isclite.samples.PageLayout" type="static"/>
</portlet-definition>
<portlet-entity uniqueName="com.ibm.isclite.pagelayout.appElement.A"
    portletDefinitionRef="com.ibm.isclite.pagelayout.appElementDefinition.A">
    <title>
        <base:nls-string lang="en">RowPortlet</base:nls-string>
    </title>
</portlet-entity>

```

...

## Layout tree

Exactly one is required. Each layout element describes the layout for a page that is opened by a navigation element. There is a one to one correspondence between a page and a layout element. The page layout is determined by row and column containers. Each row or column can contain any number of windows, which in turn contain one portlet each. The layout elements, containers, and windows can be fully defined, including their content, or they can be empty templates to be filled when content is added subsequently.

The following element makes up the content of the layout tree.

### <layout-element/>

Optional and multiple allowed. The layout element describes the layout of a portal page. Provide one layout element for each page that you want to define in the application.

The following attribute is used with this element.

#### **uniqueName**

Required. Specifies a unique identifier for the layout element. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

The following elements make up the content of the layout element.

### <title/>

Exactly one is required. This element provides a title for the layout element. To provide a localized string, use the <base:nls-string/> or <base:nls-ref/> elements for the title content. This title is displayed as the title for the corresponding page.

### <simple-container/>

At least one is required. This element defines a row or column in the page layout. This element can be nested.

The following attributes are used with this element.

#### **uniqueName**

Required. Specifies a unique identifier for the layout element. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

#### **orientation**

Required. Specifies how the contents of the container are arranged. The value `row` arranges content from left to right. The value `column` arranges content from top to bottom.

The following element makes up the content of this element.

### <window/>

Optional and multiple are allowed. A window describes a place in the page layout where portlet content can be inserted. The window can either contain an application artifact or a nested layout.

The following attribute is used for the window.

**uniqueName**

Required. Specifies a unique identifier for the window. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

The following elements make up the content of this element.

**<title/>**

Optional, no more than one allowed. To provide a localized string, use the <base:nls-string/> or <base:nls-ref/> elements for the title content. This string is rendered in the portlet title bar if the title for the <portlet-entity/> is not provided. If neither the portlet entity or the window provide a title, the title is obtained from the portlet.xml (<portlet-name/> element) of the portlet.

**<component-definition-ref/>**

Optional, but no more than one allowed. This element specifies a reference to the unique name of the component definition for the portlet to be included in this window.

The page layout sample contains six layout elements in its layout tree. This provides six pages showing different ways to arrange the content on the page. The following example shows the first layout element with its simple containers and windows. The inline comments are also shown.

```
<layout-tree>
```

```

<!--PageLayout A contains Two Seperate Containers:
  The first Container has row orientation with one window inside the container
  The second Container has column orientation with one window inside the container

  This layout uses is-spot to specify the application for the window.
  Therefore you must specify the navigation-content in the navigation element
  below that uses this layout element.
-->
<layout-element uniqueName="com.ibm.isclite.pagelayout.layoutElement.A">
  <title>
    <base:nls-string lang="en">Two independent Containers</base:nls-string>
  </title>
  <simple-container orientation="row"
    uniqueName="com.ibm.isclite.pagelayout.container.A1A">
    <simple-container orientation="row"
      uniqueName="com.ibm.isclite.pagelayout.container.A1">
      <window uniqueName="com.ibm.isclite.pagelayout.window.A1">
        <title>
          <base:nls-string lang="en">Row Portlet</base:nls-string>
        </title>
        <component-definition-ref>
          com.ibm.isclite.pagelayout.appElement.A
        </component-definition-ref>
      </window>
    </simple-container>

    <simple-container orientation="column"
      uniqueName="com.ibm.isclite.pagelayout.container.A2">
      <window uniqueName="com.ibm.isclite.pagelayout.window.A2">
        <title>
          <base:nls-string lang="en">Column Portlet</base:nls-string>
        </title>
      </window>
    </simple-container>
  </simple-container>
</layout-element>

```

## Navigation element

Optional, and multiple are allowed. The `<navigation-element/>` element describes an element or *node* in the navigation tree. This element can be nested. Navigation elements also require unique names in the installation.

Navigation elements are arranged in a tree that reflects the structure of the navigation hierarchy that is created in the portal when the application is deployed. For example, a navigation tree with two primary nodes and two branch nodes each would exhibit the following structure:

```
<navigation-element>
  <navigation-element/>
  <navigation-element/>
</navigation-element>
<navigation-element>
  <navigation-element/>
  <navigation-element/>
</navigation-element>
```

In most cases, a navigation element references the layout element of the page that is displayed when the node is selected.

The following are the attributes of the `<navigation-element/>` element.

### hidden

Optional. The default is `false`. When `true`, this attribute hides the navigation element from the console navigation tree. When this attribute hides a parent navigation element, it also hides any children. It is recommended that you associate a **parentTreeRef** attribute containing an empty string with each hidden navigation element. If you are planning to launch a navigation node, the navigation node must point to a layout element. In other words the navigation element must contain the **layoutElementRef** attribute.

### uniqueName

Required. Specifies a unique identifier for the navigation element. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

You can also use this attribute to associate a navigation element from another product with this product. In this case, you must omit the title element from the navigation element. For example, if Product A has a navigation element titled “Setting the background color” that also works with Product B, then Product B would include a navigation element without a title that specifies the same unique name as this node from Product A. In addition, you can specify a wild card pattern to include multiple navigation elements from another products. The wild card is specified using two dashes (`--`). For example, the following pattern would include all of the navigation elements from a product that is already deployed and that have a unique name starting with `com.ibm.`

```
<navigation-element uniqueName="com.ibm.--">
</navigation-element>
```

### layoutElementRef

Optional. Specifies the page to be displayed when the node is selected.

The following elements make up the content of the navigation element.

### <title/>

Optional, no more than one allowed. This element provides a title for the node to be displayed in the navigation. This title is also displayed in the task tree for My Tasks, and in the View selection menu over the navigation . Because of the limited viewable width of the View selection menu, try to keep the character length of the title to a minimum. To provide a localized string, use the `<base:nls-string/>` or `<base:nls-ref/>` elements for the title content.

### <parent-tree/>

Optional, no more than one allowed. Specifies the parent node and position under the parent node

where the current navigation element is to be located. The parent node need not be part of the current application definition. If a requested parent node does not exist, the node is appended to the bottom of the navigation tree and is merged into the parent when the parent application is deployed.

The following attributes are used with this element.

**parentTreeRef**

Required. Indicates the unique name of the navigation element under which this node should be placed.

**ordinal**

Optional. Provides a non negative integer to determine the relative order of nodes under a particular parent tree. If no ordinal is specified, or if two navigation elements specify the same ordinal for a navigation level, the node is located in the order in which it is deployed.

The following example from the tree merge sample shows how the <parent-tree/> element is used to merge the navigation elements into the navigation for the page layout sample. The parentTreeRef attribute specifies the unique name of the top level navigation element for the page layout sample. Child navigation elements are placed under the corresponding top level node for tree merge. Ordinal is not specified, so this navigation tree is appended to the page layout navigation tree.

```
<navigation-element uniqueName="com.ibm.isclite.samples.navigationElement.TreeMerge">
    ...
    <parent-tree parentTreeRef="com.ibm.isclite.samples.navigationElement.Topology"/>
    <navigation-element uniqueName="com.ibm.isclite.treemerge.navigationElement.A"
        layoutElementRef="com.ibm.isclite.TreeMerge.layoutElement.A">
        ...
    </navigation-element>
    <navigation-element uniqueName="com.ibm.isclite.treemerge.navigationElement.B"
        layoutElementRef="com.ibm.isclite.TreeMerge.layoutElement.B">
        ...
    </navigation-element>
</navigation-element>
```

**<navigation-content/>**

Optional, multiple allowed. This element defines the content of a window in a page layout. This can be used to supply the content for a window at runtime or to map different portlets to the same window, depending on which navigation element is selected.

The following attributes are used with this element.

**uniqueName**

Required. Specifies a unique identifier for the navigation content. To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

**componentDefinitionRef**

Required. Indicates the unique name of the component definition that should be rendered in the window. The component definition can be a portlet entity or a url link. If the component definition specifies a url-link, omit the windowRef attribute. Windows cannot render external URLs.

**windowRef**

Optional. Indicates the unique name of the window where the component definition should be rendered. If this attribute is not specified, the component definition applies to the entire layout element. Multiple <navigation-content/> elements can specify the same window.  
Optional.

The following example from the page layout sample illustrates how the <navigation-content/> element can be used.

1. A portlet is defined in a component definition with the unique name `com.ibm.isclite.pagelayout.appElement.B`.

```
<portlet-entity uniqueName="com.ibm.isclite.pagelayout.appElement.B"
                portletDefinitionRef="com.ibm.isclite.pagelayout.appElementDefinition.B">
  <title>
    <base:nls-string lang="en">ColumnPortlet</base:nls-string>
  </title>
</portlet-entity>
```

2. A window is defined without a component definition reference, which means it has empty content.

```
<simple-container orientation="column"
                 uniqueName="com.ibm.isclite.pagelayout.container.A2">
  <window uniqueName="com.ibm.isclite.pagelayout.window.A2">
    <title>
      <base:nls-string lang="en">Column Portlet</base:nls-string>
    </title>
  </window>
</simple-container>
```

3. The navigation content specifies the unique name of the portlet and window for the `componentDefinitionRef` and `windowRef` attributes respectively.

```
<!--This Navigation Element is for Layout A -->
<navigation-element uniqueName="com.ibm.isclite.pagelayout.navigationElement.pagelayoutA"
                   layoutElementRef="com.ibm.isclite.pagelayout.layoutElement.A">
  <title>
    <base:nls-string lang="en">2 Separate Containers</base:nls-string>
  </title>
  <navigation-content uniqueName="com.ibm.isclite.pagelayout.navigationContent.A2"
                    componentDefinitionRef="com.ibm.isclite.pagelayout.appElement.B"
                    windowRef="com.ibm.isclite.pagelayout.window.A2"/>
</navigation-element>
```

### <preference/>

Optional. Indicates the unique name of the application definition for a product. This is used to include the node in the navigation tree of the product when console users select the product title to filter the navigation. For example:

1. The page layout sample is deployed with the title `Integrated Solutions Console Sample` (as defined by the title tag for the application definition). This title is added to the product filter of the navigation **View** selection list.
2. The tree merge sample is subsequently deployed specifying page layout as a prerequisite application. To ensure that navigation nodes for tree merge are also displayed when the console user selects `Integrated Solutions Console Sample` for product filtering, the navigation elements includes this preference definition.

```
<preference name="ProductFilter">
  <base:value>
    <base:string>com.ibm.isclite.samples.PageLayout</base:string>
  </base:value>
</preference>
```

**Note:** The name attribute must be set to `ProductFilter`. The `<base:string/>` element must indicate the unique name of the application definition for the prerequisite product.

## Organizing the navigation tree

The console navigation tree provides access to the pages for which the user has permission. The hierarchy of nodes and pages on the navigation tree is defined by the <navigation-element/> element in the portal topology descriptor. All pages accessible from the navigation tree must be defined within the content hierarchy.

Before you start authoring the <navigation-element/> section of the ibm-portal-topology.xml file, take time to plan the entries that you want to be displayed on the console navigation tree. Identify the pages that will be accessible from the console navigation tree. If possible, reuse existing primary organizational nodes and any appropriate sub-nodes in your console navigation tree.

## Guidelines for unique identifiers

A console module consists of XML descriptors that must provide element identifiers that are unique throughout the application. This topic provides guidelines for setting these identifiers to help ensure uniqueness. Some development tools, like WebSphere Application Server Toolkit, assign randomly-generated unique names for you. If you need to manage unique names yourself, follow these guidelines.

It is recommended that product or product suite teams define a naming convention for their console modules. For maximum effectiveness, the conventions should be defined before console modules are developed to allow time for refinement and avoid rework. The following convention provides one guideline that can help manage the unique names for an application.

namespace + module\_name + element name + identifier

The identifier is necessary to distinguish different elements in the same descriptor. For example, the following unique names are used in the portal topology descriptor of the TreeMerge sample:

```
<component-tree           uniqueName="com.ibm.isclite.TreeMerge.appTree"           ...
<portlet-definition       uniqueName="com.ibm.isclite.TreeMerge.appElementDefinition.A"   ...
<portlet-entity          uniqueName="com.ibm.isclite.TreeMerge.appElement.A"     ...
<portlet-definition      uniqueName="com.ibm.isclite.TreeMerge.appElementDefinition.B" ...
<portlet-entity          uniqueName="com.ibm.isclite.TreeMerge.appElement.B"     ...
<layout-element          uniqueName="com.ibm.isclite.TreeMerge.layoutElement.A"   ...
<simple-container         uniqueName="com.ibm.isclite.TreeMerge.container.A"     ...
<window                  uniqueName="com.ibm.isclite.TreeMerge.window.A">       ...
<layout-element          uniqueName="com.ibm.isclite.TreeMerge.layoutElement.B"   ...
<simple-container         uniqueName="com.ibm.isclite.TreeMerge.container.B"     ...
<window                  uniqueName="com.ibm.isclite.TreeMerge.window.B"       ...
<navigation-element      uniqueName="com.ibm.isclite.treemerge.navigationElement.A" ...
<navigation-element      uniqueName="com.ibm.isclite.treemerge.navigationElement.B" ...
<navigation-content      uniqueName="com.ibm.isclite.treemerge.navigationContent.B" ...
```

## Portal security schema

The portal security descriptor describes application roles for a portal application and maps those roles to actual users and groups of the console. The following example shows the ibm-portal-security.xml for the page layout sample.

### Description of the portal security elements

#### <ibm-portal-security/>

Root element of the portal security descriptor. This element contains the following element.

#### <application-role/>

Optional and multiple allowed. Specifies an application role for the portal application. An application role maps a set of permissions, or role type, to a specific resource defined in the application's topology descriptor. The following attribute is used with this element.

#### uniqueName

Required. Specifies the administrative role for this application. The role can be one of the existing roles that are provided by the application server or you can specify a new role for the application that is created during deployment.

- When you specify one of the application server roles, make sure you use all lower case (for example, *administrator*, *operator*, *monitor*, or *configurator*) rather than the initial capitalization that appears in the console interface (*Administrator*, *Operator*, *Monitor*, or *Configurator*). If there is a mismatch in upper or lower casing (*MOonitor* instead of *monitor*), then the role cannot be created.

- When you specify a new role for an application, use lowercase characters as a guideline.
- The administrative console also provides the *all authenticated portal users* virtual role. Resources with *all authenticated portal users* permission are available to all authenticated users.
- When you specify a new role, it inherits the access rights of the *monitor* role when it is created. A user with the new administrative role has access to the same resources as a user with the *monitor* role.
- When you specify a resource in the topology descriptor without protecting it with an administrative role or virtual role, it becomes unavailable to any role.

To guarantee uniqueness, see “Guidelines for unique identifiers” on page 62.

The following element makes up the content of the application role.

#### **<portal-role/>**

Optional and multiple allowed. Associates a resource with a role type. The role type determines what actions a user can perform on that resource. The following attributes can be used with this element.

##### **object-ref**

Specifies the unique name of a resource in the topology descriptor. For this release, only portlet entities and navigation elements are supported.

##### **role-type**

Specifies the set of actions the user with this role type can perform on the resource. For this release, role-type has meaning only for portlet entities. The following values are allowed for this release (case-sensitive):

- **User**

A user with this role type is allowed to view the resource and access help.

- **Privileged User**

A user with this role type is allowed to view the resource, edit preferences, and access help.

These role mappings cannot be changed through the console. Instead, you can update the descriptor in its extracted location on the server. You must delete and redeploy the application to cause the changes to take effect.

The console module samples provide examples of how to develop the elements of the portal security descriptor.

---

## Chapter 3. Using scripting (wsadmin)

The WebSphere administrative (wsadmin) scripting program is a powerful, non-graphical command interpreter environment enabling you to run administrative operations in a scripting language.

The wsadmin tool is intended for production environments and unattended operations. You can use the wsadmin tool to perform the same tasks that you can perform using the administrative console.

The following list highlights the topics and tasks available with scripting:

- **Getting started with scripting** Provides an introduction to WebSphere Application Server scripting and information about using the wsadmin tool. Topics include information about the scripting languages and the scripting objects, and instructions for starting the wsadmin tool.
- **Deploying applications** Provides instructions for deploying and uninstalling applications. For example, stand-alone Java archive files and Web archive files, the administrative console, remote Enterprise Archive (EAR) files, file transfer applications, and so on.
- **Managing deployed applications** Includes tasks that you perform after the application is deployed. For example, starting and stopping applications, checking status, modifying listener address ports, querying application state, configuring a shared library, and so on.
- **Configuring servers** Provides instructions for configuring servers, such as creating a server, modifying and restarting the server, configuring the Java virtual machine, disabling a component, disabling a service, and so on.
- **Configuring connections to Web servers** Includes topics such as regenerating the plug-in, creating new virtual host templates, modifying virtual hosts, and so on.
- **Managing servers** Includes tasks that you use to manage servers. For example, stopping nodes, starting and stopping servers, querying a server state, starting a listener port, and so on.
- **Clustering servers** Includes topics about clusters, such as creating clusters, creating cluster members, querying a cluster state, removing clusters, and so on.
- **Configuring security** Includes security tasks, for example, enabling and disabling administrative security, enabling and disabling Java 2 security, and so on.
- **Configuring data access** Includes topics such as configuring a Java DataBase Connectivity (JDBC) provider, defining a data source, configuring connection pools, and so on.
- **Configuring messaging** Includes topics about messaging, such as Java Message Service (JMS) connection, JMS provider, WebSphere queue connection factory, MQ topics, and so on.
- **Configuring mail, URLs, and resource environment entries** Includes topics such as mail providers, mail sessions, protocols, resource environment providers, referenceables, URL providers, URLs, and so on.
- **Troubleshooting** Provides information about how to troubleshoot using scripting. For example, tracing, thread dumps, profiles, and so on.
- **Scripting reference material** Includes all of the reference material related to scripting. Topics include the syntax for the wsadmin tool and for the administrative command framework, explanations and examples for all of the scripting object commands, the scripting properties, and so on.

---

### Getting started with scripting

*Scripting* is a non-graphical alternative that you can use to configure and manage WebSphere Application Server.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. The wsadmin tool supports a full range of product administrative activities.

The following figure illustrates the major components involved in a wsadmin scripting solution:

Figure 1: A WebSphere Application Server scripting solution

The wsadmin tool supports two scripting languages: Jacl and Jython. Five objects are available when you use scripts:

- **AdminControl:** Use to run operational commands.
- **AdminConfig:** Use to run configurational commands to create or modify WebSphere Application Server configurational elements.
- **AdminApp:** Use to administer applications.
- **AdminTask:** Use to run administrative commands.
- **Help:** Use to obtain general help.

The scripts use these objects to communicate with MBeans that run in WebSphere Application Server processes. MBeans are Java objects that represent Java Management Extensions (JMX) resources. JMX is an optional package addition to Java 2 Platform Standard Edition (J2SE). JMX is a technology that provides a simple and standard way to manage Java objects.

To perform a task using scripting, you must first perform the following steps:

1. Choose a scripting language. The wsadmin tool only supports Jacl and Jython scripting languages. Jacl is the language specified by default. If you want to use the Jython scripting language, use the `-lang` option or specify it in the `wsadmin.properties` file.
2. Start the wsadmin scripting client interactively, as an individual command, in a script, or in a profile.

Before you perform any task using scripting, make sure that you are familiar with the following concepts:

- Java Management Extensions (JMX)
- WebSphere Application Server configuration model
- wsadmin tool
- Jacl syntax or Jython syntax
- Scripting objects

Optionally, you can customize your scripting environment. For more information, see [Scripting environment properties](#).

After you become familiar with the scripting concepts, choose a scripting language, and start the scripting client, you are ready to perform tasks using scripting.

## Java Management Extensions (JMX)

Java Management Extensions (JMX) is a framework that provides a standard way of exposing Java resources, for example, application servers, to a system management infrastructure. Using the JMX framework, a provider can implement functions, such as listing the configuration settings, and editing the settings. This framework also includes a notification layer that management applications can use to monitor events such as the startup of an application server.

### JMX key features

The key features of the WebSphere Application Server Version 6 implementation of JMX include:

- All processes that run the JMX agent.
- All run-time administration that is performed through JMX operations.
- Connectors that are used to connect a JMX agent to a remote JMX-enabled management application. The following connectors are supported:
  - SOAP JMX Connector
  - Remote Method Invocation over the Internet Inter-ORB Protocol (RMI-IIOP) JMX Connector
- Protocol adapters that provide a management view of the JMX agent through a given protocol. Management applications that connect to a protocol adapter are usually specific to a given protocol.
- The ability to query and update the configuration settings of a run-time object.
- The ability to load, initialize, change, and monitor application components and resources during run-time.

### JMX architecture

The JMX architecture is structured into three layers:

- Instrumentation layer - Dictates how resources can be wrapped within special Java beans, called managed beans (MBeans).
- Agent layer - Consists of the MBean server and agents, which provide a management infrastructure. The services that are implemented include:
  - Monitoring
  - Event notification
  - Timers
- Management layer - Defines how external management applications can interact with the underlying layers in terms of protocols, APIs, and so on. This layer uses an implementation of the distributed services specification (JSR-077), which is not yet part of the Java 2 platform, Enterprise Edition (J2EE) specification.

The layered architecture of JMX is summarized in the following figure:

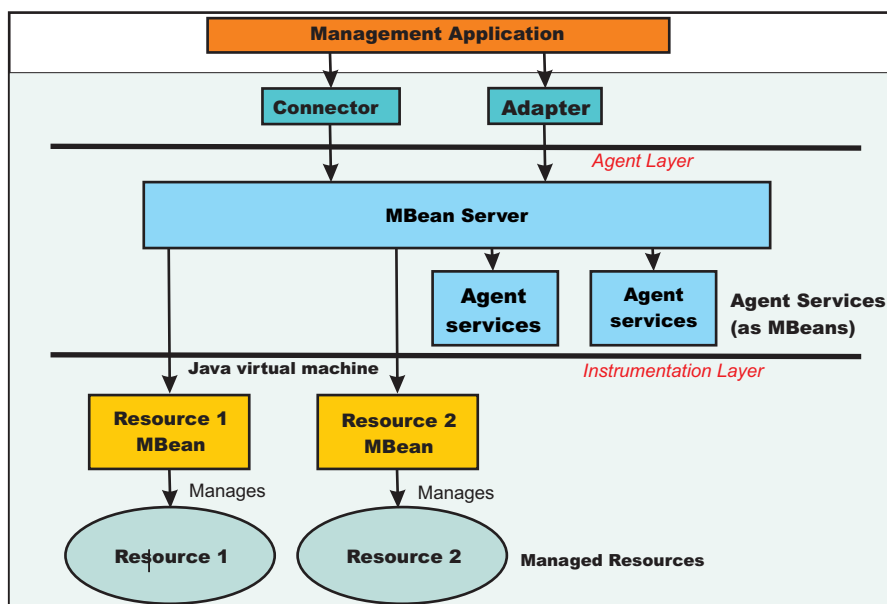

Figure 1: JMX architecture

### JMX distributed administration

The following figure shows how the JMX architecture fits into the overall distributed administration topology of a Network Deployment environment:

Figure 2: WebSphere Application Server distributed administration of JMX

The key points of this distributed administration architecture include:

- Internal MBeans that are local to the Java virtual machine (JVM) register with the local MBean server.
- External MBeans have a local proxy to their MBean server. The proxy registers with the local MBean server. Using the MBean proxy the local MBean server can pass the message to an external MBean server that is located on:
  - A node agent that has an MBean proxy for all the servers within its node. The MBean proxies for other nodes are not used.
  - The deployment manager has MBean proxies for all the node agents in the cell.

## JMX Mbeans

WebSphere Application Server provides a number of MBeans, each of which has different functions and operations available. For example, an application server MBean can expose operations such as start and stop. An application MBean can expose operations such as install and uninstall. Some JMX usage scenarios that you can encounter include:

- External programs that are written to control the Network Deployment run time and its WebSphere resources by programmatically accessing the JMX API.
- Third-party applications that include custom JMX MBeans as part of the deployed code, supporting the JMX API management of application components and resources.

The following example illustrates how to obtain an MBean:

Using Jacl:

```
set am [$AdminControl queryNames type=ApplicationManager,process=server1,*]
```

Using Jython:

```
am = AdminControl.queryNames('type=ApplicationManager,process=server1,*')
```

Each WebSphere Application Server runtime MBean can have attributes, operations, and notifications. The complete documentation for each MBean that is supplied with WebSphere Application Server is available in an HTML table that is installed in each copy of the WebSphere Application Server product. Under the main installation directory for the product, there is the web directory. Under the web directory there is another directory called mbeanDocs. In the mbeanDocs directory there are several HTML files; one HTML file for each MBean supplied with WebSphere Application Server. There is also an index.html file that ties all the individual MBean files together in a top-level navigation tree. Each MBean provides a summary of its attributes, operations, and notifications.

## JMX benefits

The use of JMX for management functions in WebSphere Application Server provides the following benefits:

- Enables the management of Java applications without significant investment.
- Relies on a core-managed object server that acts as a management agent.
- Java applications can embed a managed object server and make some of its functionality available as one or several MBeans that are registered with the object server.
- Provides a scalable management architecture.
- Every JMX agent service is an independent module that can be plugged into the management agent.
- The API is extensible, allowing new WebSphere Application Server and custom application features to be easily added and exposed through this management interface.
- Integrates existing management solutions.
- Each process is self-sufficient when it comes to the management of its resources. No central point of control exists. In principle, a JMX-enabled management client can be connected to any managed process and interact with the MBeans that are hosted by that process.
- JMX provides a single, flat, domain-wide approach to system management. Separate processes interact through MBean proxies that support a single management client to seamlessly navigate through a network of managed processes.
- Defines the interfaces that are necessary for management only.
- Provides a standard API for exposing application and administrative resources to management tools.

## WebSphere Application Server configuration model

Understanding the relationship between the different configuration objects is essential when creating wsadmin scripts that perform configuration function.

Configuration data is stored in several different XML files which the server run time reads when it starts and responds to the component settings stored there. The configuration data includes the settings for the run time, such as, Java virtual machine (JVM) options, thread pool sizes, container settings, and port numbers the server will use. Other configuration files define Java 2 Platform, Enterprise Edition (J2EE) resources to which the server connects in order to obtain data that is needed by the application logic. Security settings are stored in a separate document from the server and resource configuration. Application-specific configuration, such as, deployment target lists, session configuration, and cache settings, are stored in files under the root directory of each application. When viewing the XML data in the configuration files, you can discern relationship between the configuration objects.

For more information on the WebSphere Application Server configuration objects view the HTML tables in the *installroot/web/configDocs* directory. There are several subdirectories, one for each configuration package in the model. The index.html file ties all of the individual configuration packages together in a top-level navigation tree. Each configuration package lists the supported configuration classes and the configuration class lists all of the supported properties. The properties with names that end with the at (@)

character imply that property is a reference to a different configuration object within the configuration data. The properties with names that end with an asterisk (\*) character imply that the property is a list of other configuration objects.

## Jacl

Jacl is an alternate implementation of TCL, and is written entirely in Java code.

The wsadmin tool uses Jacl V1.3.2.

### Deprecation of the Jacl syntax in the wsadmin tool

Deprecation of a product feature does not mean that the feature is removed from the product immediately. Deprecation is a process of announcing the intent to remove the feature at some future time. The WebSphere Application Server deprecation procedure calls for a feature to remain in the product for two full release cycles before the feature can be removed. For more information about deprecation of features, see the *Deprecated and removed features* article in the *Migrating, coexisting, and interoperating* PDF.

The wsadmin administrative scripting program supports two scripting languages, Jacl and Jython. The Version 6.1 release of WebSphere Application Server represents the start of the deprecation process for the Jacl syntax that is associated with the wsadmin tool. The Jacl syntax for the wsadmin tool continues to remain in the product and is supported for at least two major product releases. After that time, the Jacl language support might be removed from the wsadmin tool.

The Jython syntax for the wsadmin tool is the strategic direction for WebSphere Application Server administrative automation. In the V6.1 release, WebSphere Application Server contains significantly enhanced administrative functions and tooling that support product automation and the use of the Jython syntax. The following new Jython scripting-related enhancements are provided in WebSphere Application Server V6.1:

- The Eclipse-based WebSphere Application Server Tool (AST) now includes substantial support for automation scripting, providing a full function development environment for wsadmin scripts, including a Jython editor, color-coded keyword highlighting, statement completion assistance, and script debugging support.
- Administrative console command assist - A new feature of the WebSphere Application Server administrative console that displays the wsadmin command that is equivalent to the action taken by the user that interacts with the console. The output from the console command assist feature can be transferred directly to the WebSphere Application Server Tool, which simplifies the development of Jython scripts that are based on administrative console actions. You can also save the output after using the console command assist feature in a plain text file for later use.
- Jacl-to-Jython conversion utility - a program that converts Jacl syntax wsadmin scripts into equivalent Jython syntax wsadmin scripts. Dozens of new wsadmin high-level commands that decouple the script from the underlying administrative model through use of simple parameters and smart default logic.

All future enhancements in the area of WebSphere Application Server scripting will focus on use of the Jython syntax. While Jacl will remain as a component that is shipped with WebSphere Application Server for at least two full releases, no new tooling or explicit enhancements will be created for the Jacl syntax.

### Basic syntax:

The basic syntax for a Jacl command is the following:

```
Command arg1 arg2 arg3 ...
```

The command is either the name of a built-in command or a Jacl procedure. For example:

```
puts stdout {Hello, world!}  
=> Hello, world!
```

In this example, the command is **puts** which takes two arguments, an I/O stream identifier and a string. The **puts** command writes the string to the I/O stream along with a trailing new line character. The arguments are interpreted by the command. In the example, `stdout` is used to identify the standard output stream. The use of `stdout` as a name is a convention employed by the **puts** command and the other I/O commands. `stderr` identifies the standard error output, and `stdin` identifies the standard input.

## Variables

The **set** command assigns a value to a variable. This command takes two arguments: the name of the variable and the value. Variable names can be any length and are case sensitive. You do not have to declare Jacl variables before you use them. The interpreter will create the variable when it is first assigned a value. For example:

```
set a 5
=> 5

set b $a
=> 5
```

The second example assigns the value of variable `a` to variable `b`. The use of dollar sign (\$) indicates variable substitution. You can delete a variable with the **unset** command, for example:

```
unset varName1 varName2 ...
```

You can pass any number of variables to the **unset** command. The **unset** command will give error if a variable is not already defined. You can delete an entire array or just a single array element with the **unset** command. Using the **unset** command on an array is a easy way to clear out a big data structure. The existence of a variable can be tested with the **info exists** command. You may have to test for the existence of the variable because the `incr` parameter requires that a variable exist first, for example:

```
if ![info exists foobar] {set foobar 0} else {incr foobar}
```

## Command substitution:

The second form of substitution is command substitution. A nested command is delimited by square brackets, `[ ]`. The Jacl interpreter evaluates everything between the brackets and evaluates it as a command. For example:

```
set len [string length foobar]
=> 6
```

In this example, the nested command is the following: `string length foobar`. The **string** command performs various operations on strings. In this case, the command asks for the length of the string `foobar`. If there are several cases of command substitution within a single command, the interpreter processes them from left bracket to right bracket. For example:

```
set number "1 2 3 4"
=> 1 2 3 4

set one [lindex $number 0]
=> 1

set end [lindex $number end]
=> 4

set another {123 456 789}
=> 123 456 789

set stringLen [string length [lindex $another 1]]
=> 3

set listLen [llength [lindex $another 1]]
=> 1
```

## Math expressions:

The Jacl interpreter does not evaluate math expressions. Use the **expr** command to evaluate math expressions. The implementation of the **expr** command takes all arguments, concatenates them into a single string, and parses the string as a math expression. After the **expr** command computes the answer, it is formatted into a string and returned. For example:

```
expr 7.2 / 3
=> 2.4
```

### Backslash substitution:

The final type of substitution done by the Jacl interpreter is backslash substitution. Use this to quote characters that have special meaning to the interpreter. For example, you can specify a literal dollar sign, brace, or bracket by quoting it with a backslash. If you are using lots of backslashes, instead you can group things with curly braces to turn off all interpretation of special characters. There are cases where backslashes are required. For example:

```
set dollar "This is a string \$contain dollar char"
=> This is a string $contain dollar char
```

```
set x $dollar
=> This is a string $contain dollar char
```

```
set group {$ {} [] { [ ] }}
=> $ {} [] { [ ] }
```

You can also use backslashes to continue long commands on multiple lines. A new line without the backslash terminates a command. A backslashes that are the last character on a line convert into a space. For example:

```
set totalLength [expr [string length "first string"] + \
[string length "second string"]]
=> 25
```

### Grouping with braces and double quotes:

Use double quotes and curly braces to group words together. Quotes allow substitutions to occur in the group and curly braces prevent substitution. This rule applies to command, variable, and backslash substitutions. For example:

```
set s Hello
=> Hello
```

```
puts stdout "The length of $s is [string length $s]."
=> The length of Hello is 5.
```

```
puts stdout {The length of $s is [string length $s].}
=> The length of $s is [string length $s].
```

In the second example, the Jacl interpreter performs variable and command substitution on the second argument from the **puts** command. In the third command, substitutions are prevented so the string is printed as it is.

### Procedures and scope:

Jacl uses the **proc** command to define procedures. The basic syntax to define a procedure is the following:

```
proc name arglist body
```

The first argument is the name of the procedure being defined. The name is case sensitive, and in fact it can contain any characters. Procedure names and variable names do not conflict with each other. The

second argument is a list of parameters to the procedures. The third argument is a command, or more typically a group of commands that form the procedure body. Once defined, a Jacl procedure is used just like any of the built-in commands. For example:

```
proc divide {x y} {
  set result [expr $x/$y]
  puts $result
}
```

Inside the script, this is how to call divide procedure:

```
divide 20 5
```

And it will give the result like below:

```
4
```

It is not really necessary to use the variable `c` in this example. The procedure body could also be written as:

```
return [expr sqrt($a * $a + $b * $b)]
```

The `return` command is optional in this example because the Jacl interpreter returns the value of the last command in the body as the value of the procedure. So, the procedure body could be reduced to:

```
expr sqrt($a * $a + $b * $b)
```

The result of the procedure is the result returned by the last command in the body. The `return` command can be used to return a specific value.

There is a single, global scope for procedure names. You can define a procedure inside another procedure, but it is visible everywhere. There is a different name space for variables and procedures therefore you may have a procedure and a variable with the same name without a conflict. Each procedure has a local scope for variables. Variables introduced in the procedures only exist for the duration of the procedure call. After the procedure returns, those variables are undefined. If the same variable name exists in an outer scope, it is unaffected by the use of that variable name inside a procedure. Variables defined outside the procedure are not visible to a procedure, unless the global scope commands are used.

- **global** command - Global scope is the top level scope. This scope is outside of any procedure. You must make variables defined at the global scope accessible to the commands inside procedure by using the **global** command. The syntax for the **global** command is the following:

```
global varName1 varName2 ...
```

## Comments

Use the pound character (`#`) to make comments.

## Command line arguments

The Jacl shells pass the command line arguments to the script as the value of the `argv` variable. The number of command line arguments is given by `argc` variable. The name of the program, or script, is not part of `argv` nor is it counted by `argc`. Instead, it is put into the `argv0` variable. The `argv` variable is a list. Use the **lindex** command to extract items from the argument list, for example:

```
set first [lindex $argv 0]
set second [lindex $argv 1]
```

## Strings and pattern matching

Strings are the basic data item in the Jacl language. There are multiple commands that you can use to manipulate strings. The general syntax of the **string** command is the following:

```
string operation stringvalue otherargs
```

The operation argument determines the action of the string. The second argument is a string value. There may be additional arguments depending on the operation.

The following table includes a summary of the **string** command:

Command	Description
string compare str1 str2	Compares strings lexicographically. Returns 0 if equal, -1 if str1 sorts before str2, else 1.
string first str1 str2	Returns the index in str2 of the first occurrence of str1, or -1 if str1 is not found.
string index string index	Returns the character at the specified index.
string last str1 str2	Returns the index in str2 of the last occurrence of str1, or -1 if str1 is not found.
string length string	Returns the number of character in string.
string match pattern str	Returns 1 if str matches the pattern, else 0.
string range str i j	Returns the range of characters in str from i to j
string tolower string	Returns string in lower case.
string toupper string	Returns string in upper case.
string trim string ?chars?	Trims the characters in chars from both ends of string. chars defaults to white space.
string trimleft string ?chars?	Trims the characters in chars from the beginning of string. chars defaults to white space.
string trimright string ?chars?	Trims the characters in chars from the end of string. chars defaults to white space.
string wordend str ix	Returns the index in str of the character after the word containing the character at index ix.
string wordstart str ix	Returns the index in str of the first character in the word containing the character at index ix.

### The append command

The first argument of the **append** command is a variable name. It concatenates the remaining arguments onto the current value of the named variable. For example:

```
set foo z
=> z
```

```
append foo a b c
=> zabc
```

### The regexp command

The **regexp** command provides direct access to the regular expression matcher. The syntax is the following:

```
regexp ?flags? pattern string ?match sub1 sub2 ...?
```

The return value is 1 if some part of the string matches the pattern. Otherwise, the return value will be 0. The pattern does not have to match the whole string. If you need more control than this, you can anchor the pattern to the beginning of the string by starting the pattern with `^`, or to the end of the string by ending the pattern with dollar sign, `$`. You can force the pattern to match the whole string by using both characters. For example:

```
set text1 "This is the first string"
=> This is the first string
```

```
regexp "first string" $text1
=> 1
```

```
regexp "second string" $text1
=> 0
```

## Jacl data structures

The basic data structure in the Jacl language is a string. There are two higher level data structures: lists and arrays. Lists are implemented as strings and the structure is defined by the syntax of the string. The syntax rules are the same as for commands. Commands are a particular instance of lists. Arrays are variables that have an index. The index is a string value so you can think of arrays as maps from one string (the index) to another string (the value of the array element).

### Jacl lists

The lists of the Jacl language are strings with a special interpretation. In the Jacl language, a list has the same structure as a command. A list is a string with list elements separated by white space. You can use braces or quotes to group together words with white space into a single list element.

The following table includes commands that are related to lists:

Command	Description
list arg1 arg2	Creates a list out of all its arguments.
lindex list i	Returns the i'th element from list.
llength list	Returns the number of elements in list.
lrange list i j	Returns the i'th through j'th elements from list.
lappend listVar arg arg ...	Appends elements to the value of listVar
linsert list index arg arg ...	Inserts elements into list before the element at position index. Returns a new list.
lreplace list i j arg arg ...	Replaces elements i through j of list with the args. Return a new list.
lsearch mode list value	Returns the index of the element in list that matches the value according to the mode, which is -exact, -glob, or -regexp, -glob is the default. Return -1 if not found.
lsort switches list	Sorts elements of the list according to the switches: -ascii, -integer, -real, -increasing, -decreasing, -command command. Return a new list.
concat arg arg arg ...	Joins multiple lists together into one list.
join list joinString	Merges the elements of a list together by separating them with joinString.
split string splitChars	Splits a string up into list elements, using the characters in splitChars as boundaries between list elements.

## Arrays

Arrays are the other primary data structure in the Jacl language. An array is a variable with a string-valued index, so you can think of an array as a mapping from strings to strings. Internally an array is implemented with a hash table. The cost of accessing each element is about the same. The index of an array is

delimited by parentheses. The index can have any string value, and it can be the result of variable or command substitution. Array elements are defined with the **set** command, for example:

```
set arr(index) value
```

Substitute the dollar sign (\$) to obtain the value of an array element, for example:

```
set foo $arr(index)
```

For example:

```
set fruit(best) kiwi
=> kiwi
```

```
set fruit(worst) peach
=> peach
```

```
set fruit(ok) banana
=> banana
```

```
array get fruit
=> ok banana worst peach best kiwi
```

```
array exists fruit
=> 1
```

The following table includes array commands:

Command	Description
array exists arr	Returns 1 if arr is an array variable.
array get arr	Returns a list that alternates between an index and the corresponding array value.
array names arr ?pattern?	Return the list of all indices defined for arr, or those that match the string match pattern.
array set arr list	Initializes the array arr from list, which should have the same form as the list returned by get.
array size arr	Returns the number of indices defined for arr.
array startsearch arr	Returns a search token for a search through arr.
array nextelement arr id	Returns the value of the next element in array in the search identified by the token id. Returns an empty string if no more elements remain in the search.
array anymore arr id	Returns 1 if more elements remain in the search.
array donesearch arr id	Ends the search identified by id.

## Control flow commands

The following looping commands exist:

- while
- foreach
- for

The following are conditional commands:

- if
- switch

The following is an error handling command:

- catch

The following commands fine-tune control flow:

- break
- continue
- return
- error

## If Then Else

The **if** command is the basic conditional command. It says that if an expression is true, then run the second line of code, otherwise run a different line of code. The second command body (the else clause) is optional. The syntax of the command is the following:

```
if boolean then body1 else body2
```

The then and else keywords are optional. For example:

```
if {$x == 0} {  
  puts stderr "Divide by zero!"  
} else {  
  set slope [expr $y/$x]  
}
```

## Switch

Use the **switch** command to branch to one of many commands depending on the value of an expression. You can choose based on pattern matching as well as simple comparisons. Any number of pattern-body pairs can be specified. If multiple patterns match, only the code body of the first matching pattern is evaluated. The general form of the command is the following:

```
switch flags value pat1 body1 pat2 body2 ...
```

You can also group all the pattern-body pairs into one argument:

```
switch flags value {pat1 body1 pat2 body2 ...}
```

There are four possible flags that determines how value is matched.

- -exact Matches the value exactly to one of the patterns.
- -glob Uses glob-style pattern matching.
- -regexp Uses regular expression pattern matching.
- -- No flag (or end of flags). Useful when value can begin with a dash (-).

For example:

```
switch -exact -- $value {  
  foo {doFoo; incr count(foo)}  
  bar {doBar; return $count(foo)}  
  default {incr count(other)}  
}
```

If the pattern that is associated with the last body is default, then the command body is started if no other patterns match. The default keyword only works on the last pattern-body pair. If you use the default pattern on an earlier body, it will be treated as a pattern to match the literal string default.

## Foreach

The **foreach** command loops over a command body and assigns a loop variable to each of the values in a list. The syntax is the following:

```
foreach loopVar valueList commandBody
```

The first argument is the name of a variable. The command body runs one time for each element in the loop with the loop variable having successive values in the list. For example:

```
set numbers {1 3 5 7 11 13}
foreach num $numbers {
  puts $num
}
```

The result from the previous example will be the following output, assuming that only one server exists in the environment. If there is more than one server, the information for all servers returns:

```
1
3
5
7
11
13
```

## While

The **while** command takes two arguments; a test and a command body, for example:

```
while booleanExpr body
```

The **while** command repeatedly tests the boolean expression and runs the body if the expression is true (non-zero). For example:

```
set i 0
while {$i < 5} {
  puts "i is $i"
  incr i}
}
```

The result from the previous example will be like the following output, assuming that there is only one server. If there is more than one servers, it will print all of the servers:

```
i is 0
i is 1
i is 2
i is 3
i is 4
```

## For

The **for** command is similar to the C language for statement. It takes four arguments, for example:

```
for initial test final body
```

The first argument is a command to initialize the loop. The second argument is a boolean expression which determines if the loop body will run. The third argument is a command that runs after the loop body: For example:

```
set numbers {1 3 5 7 11 13}
for {set i 0} {$i < [llength $numbers]} {incr i 1} {
  puts "i is $i"
}
```

The result from previous example will be like the following output, assuming that there is only one server in the environment. If there is more than one server, it will print all of the server names:

```
i is 1
i is 3
i is 5
i is 7
i is 11
i is 13
```

## Break and continue

You can control loop execution with the **break** and **continue** commands. The **break** command causes an immediate exit from a loop. The **continue** command causes the loop to continue with the next iteration.

## Catch

An error will occur if you call a command with the wrong number of arguments or if the command detects some error condition particular to its implementation. An uncaught error prevents a script from running. Use the **catch** command trap such errors. The catch command takes two arguments, for example:

```
catch command ?resultVar?
```

The first argument is a command body. The second argument is the name of a variable that will contain the result of the command or an error message if the command raises an error. The **catch** command returns a value of zero if no error was caught or a value of one if the command catches an error. For example:

```
catch {expr 20 / 5} result
==> 0
puts $result
==> 4
catch {expr text / 5} result
==> 1
puts $result
==> syntax error in expression "text / 5"
```

## Return

Use the **return** command to return a value before the end of the procedure body or if a contrast value needs to be returned.

## Namespaces

Jacl keeps track of named entities such as variables, in namespaces. The wsadmin tool also adds entries to the global namespace for the scripting objects, such as, the AdminApp object

When you run a proc command, a local namespace is created and initialized with the names and the values of the parameters in the proc command. Variables are held in the local namespace while you run the proc command. When you stop the proc command, the local namespace is erased. The local namespace of the proc command implements the semantics of the automatic variables in languages such as C and Java.

While variables in the global namespace are visible to the top level code, they are not visible by default from within a proc command. To make them visible, declare the variables globally using the **global** command. For the variable names that you provide, the global command creates entries in the local namespace that point to the global namespace entries that actually define the variables.

If you use a scripting object provided by the wsadmin tool in a proc, you must declare it globally before you can use it, for example:

```
proc { ... } {
  global AdminConfig
  ... [$AdminConfig ...]
}
```

## Calling scripts using another script

Use the **source** command to call a Jacl script from another Jacl script. For example:

Create a script called *test1.jacl*.

Create a script called *testProcedure.jacl*.

```
proc printName {first last} {  
  puts "My name is $first $last"  
}
```

Pass the following path as a script argument.

You must use forward slashes (/) as your path separator. Backward slashes (\) will not work.

For more information about Jacl, see the [Scripting: Resources for Learning](#) article.

## Jython

Jython is an alternate implementation of Python, and is written entirely in Java.

The wsadmin tool uses Jython V2.1. The following information is a basic summary of the Jython syntax:

### Basic function

The function is either the name of a built-in function or a Jython function. For example:

```
print "Hello, World!"  
=> Hello, World!
```

```
import sys  
sys.stdout.write("Hello World!\n")  
=> Hello World!
```

In the example, `print` identifies the standard output stream. You can use the built-in module by running `import` statements such as the previous example. The statement `import` runs the code in a module as part of the importing and returns the module object. `sys` is a built-in module of the Python language. In the Python language, modules are name spaces which are places where names are created. Names that reside in modules are called attributes. Modules correspond to files and the Python language creates a module object to contain all the names defined in the file. In other words, modules are name spaces.

### Variable

To assign objects to names, the target of an assignment should be on the left side of an equal sign (=) and the object that you are assigning on the right side. The target on the left side can be a name or object component, and the object on the right side can be an arbitrary expression that computes an object. The following rules exist for assigning objects to names:

- Assignments create object references.
- Names are created when you assign them.
- You must assign a name before referencing it.

Variable name rules are similar to the rules for the C language, for example:

- An underscore character (`_`) or a letter plus any number of letters, digits or underscores

The following reserved words can not be used for variable names:

```
and    assert  break   class  continue  
def    del     elif    else   except  
exec   inally   for     from   global  
if     importin is     lambda  
not    or      pass   print  raise  
return try    while
```

For example:

```

a = 5
print a
=> 5

b = a
print b
=> 5

text1, text2, text3, text4 = 'good', 'bad', 'pretty', 'ugly'
print text3
=> pretty

```

The second example assigns the value of variable a to variable b.

## Types and operators

The following list contains a few of the built-in object types:

- Numbers. For example:

```
8, 3.133, 999L, 3+4j
```

```
num1 = int(10)
print num1
=> 10

```

- Strings. For example:

```
'name', "name's", ''
```

```
print str(12345)
=> '12345'

```

- Lists. For example:

```
x = [1, [2, 'free'], 5]
y = [0, 1, 2, 3]
y.append(5)
print y
=> [0, 1, 2, 3, 5]

```

```
y.reverse()
print y
=> [5, 3, 2, 1, 0]

```

```
y.sort()
print y
=> [0, 1, 2, 3, 5]

```

```
print list("apple")
=> ['a', 'p', 'p', 'l', 'e']

```

```
print list((1,2,3,4,5))
=> [1, 2, 3, 4, 5]

```

```
test = "This is a test"
test.index("test")
=> 10

```

```
test.index('s')
=> 3

```

The following list contains a few of the operators:

- x or y

y is evaluated only if x is false. For example:

```
print 0 or 1
=> 1

```

- x and y

y is evaluated only if x is true. For example:

```
print 0 and 1
=> 0
```

- x + y , x - y

Addition and concatenation, subtraction. For example:

```
print 6 + 7
=> 13
```

```
text1 = 'Something'
text2 = ' else'
print text1 + text2
=> Something else
```

```
list1 = [0, 1, 2, 3]
list2 = [4, 5, 6, 7]
print list1 + list2
=> [0, 1, 2, 3, 4, 5, 6, 7]
```

```
print 10 - 5
=> 5
```

- x \* y, x / y, x % y

Multiplication and repetition, division, remainder and format. For example:

```
print 5 * 6
=> 30
```

```
print 'test' * 3
=> test test test
```

```
print 30 / 6
=> 5
```

```
print 32 % 6
=> 2
```

- x[i], x[i:j], x(...)

Indexing, slicing, function calls. For example:

```
test = "This is a test"
print test[3]
=> s
```

```
print test[3:10]
=> s is a
```

```
print test[5:]
=> is a test
```

```
print x[:-4]
=> This is a print len(test)
=> 14
```

- <, <=, >, >=, ==, <>, !=, is is not

Comparison operators, identity tests. For example:

```
l1 = [1, ('a', 3)]
l2 = [1, ('a', 2)]
l1 < l2, l1 == l2, l1 > l2, l1 <> l2, l1 != l2, l1 is l2, l1 is not l2
=> (0, 0, 1, 1, 1, 0, 1)
```

## Backslash substitution

If a statement needs to span multiple lines, you can also add a back slash (\) at the end of the previous line to indicate you are continuing on the next line. For example:

```
text = "This is a tests of a long lines" \  
" continuing lines here."  
print text  
=> This is a tests of a long lines continuing lines here.
```

## Functions and scope

Jython uses the `def` statement to define functions. Functions related statements include:

- `def`, `return`  
The `def` statement creates a function object and assigns it to a name. The `return` statement sends a result object back to the caller. This is optional, and if it is not present, a function exits so that control flow falls off the end of the function body.
- `global`  
The `global` statement declares module-level variables that are to be assigned. By default, all names assigned in a function are local to that function and exist only while the function runs. To assign a name in the enclosing module, list functions in a global statement.

The basic syntax to define a function is the following:

```
def name (arg1, arg2, ... ArgN):  
statements  
return value
```

where *name* is the name of the function being defined. It is followed by an open parenthesis, a close parenthesis and a colon. The arguments inside parenthesis include a list of parameters to the procedures. The next line after the colon is the body of the function. A group of commands that form the body of the function. After you define a Jython function, it is used just like any of the built-in functions. For example:

```
def intersect(seq1, seq2):  
    try:  
        res = []  
        for x in seq1:  
            if x in seq2:  
                res.append(x)  
        return res  
    except:
```

To call the function above, use the following command:

```
s1 = "SPAM"  
s2 = "SCAM"  
intersect(s1, s2)  
=> [S, A, M]
```

```
intersect([1,2,3], (1.4))  
=> [1]
```

## Comments

Make comments in the Jython language with the pound character (`#`).

## Command line arguments

The Jython shells pass the command line arguments to the script as the value of the `sys.argv`. The name of the program, or script, is not part of `sys.argv`. `sys.argv` is an array, so you use the index command to extract items from the argument list, for example:

```
import sys  
first = sys.argv[0]  
second = sys.argv[1]  
arglen = len(sys.argv)
```

## Basic statements

There are two looping statements: `while` and `for`. The conditional statement is `if`. The error handling statement is `try`. Finally, there are some statements to fine-tune control flow: `break`, `continue` and `pass`. The following is a list of syntax rules in Python:

- Statements run one after another until you say otherwise. Statements normally end at the end of the line they appear on. When statements are too long to fit on a single line you can also add a back sash (`\`) at the end of the prior line to indicate you are continuing on the next line.
- Block and statement boundaries are detected automatically. There are no braces, or `begin` or `end` delimiter, around blocks of code. Instead, the Python language uses the indentation of statements under a header in order to group the statements in a nested block. Block boundaries are detected by line indentation. All statements indented the same distance to the right belong to the same block of code until that block is ended by a line less indented.
- Compound statements = header; `:`, indented statements. All compound statements in the Python language follow the same pattern: a header line terminated with a colon, followed by one or more nested statements indented under the header. The indented statements are called a block.
- Spaces and comments are usually ignored. Spaces inside statements and expressions are almost always ignored (except in string constants and indentation), so are comments.

### If

The `if` statement selects actions to perform. The `if` statement may contain other statements, including other `if` statements. The `if` statement can be followed by one or more optional `elif` statements and ends with an optional `else` block.

The general format of an `if` looks like the following:

```
if test1
    statements1
elif test2
    statements2
else test3
    statements3
```

For example:

```
weather = 'sunny'
if weather == 'sunny':
    print "Nice weather"
elif weather == 'raining':
    print "Bad weather"
else:
    print "Uncertain, don't plan anything"
```

### While

The `while` statement consists of a header line with a test expression, a body of one or more indented statements, and an optional `else` statement that runs if control exits the loop without running into a `break` statement. The `while` statement repeatedly executes a block of indented statements as long as a test at the top keeps evaluating a true value. The general format of an `while` looks like the following:

```
while test1
    statements1
else
    statements2
```

For example:

```
a = 0; b = 10
while a < b:
    print a
    a = a + 1
```

## For

The for statement begins with a header line that specifies an assignment target or targets, along with an object you want to step through. The header is followed by a block of indented statements which you want to repeat.

The general format of a for statement looks like the following:

```
for target in object:
    statements
else:
    statements
```

It assigns items in the sequence object to the target, one by one, and runs the loop body for each. The loop body typically uses the assignment target to refer to the current item in the sequence as if it were a cursor stepping through the sequence. For example:

```
sum = 0
for x in [1, 2, 3, 4]:
    sum = sum + x
```

## Break, continue, and pass

You can control loops with the break, continue and pass statements. The break statement jumps out of the closest enclosing loop (past the entire loop statement). The continue statements jumps to the top of the closest enclosing loop (to the header line of the loop), and the pass statement is an empty statement placeholder.

## Try

A statement will raise an error if it is called with the wrong number of arguments, or if it detects some error condition particular to its implementation. An uncaught error aborts execution of a script. The try statement is used to trap such errors. Python try statements come in two flavors, one that handles exceptions and one that executes finalization code whether exceptions occur or not. The try, except, else statement starts with a try header line followed by a block of indented statements, then one or more optional except clauses that name exceptions to be caught, and an optional else clause at the end. The try, finally statements starts with a try header line followed by a block of indented statements, then finally clause that always runs on the way out whether an exception occurred while the try block was running or not.

The general format of the try, except, else function looks like the following:

```
try:
    statements
except name:
    statements
except name, data:
    statements
else
    statements
```

For example:

```
try:
    myfunction()
except:
    import sys
    print 'uncaught exception', sys.exc_type, sys.exc_value
```

```

try:
    myfilereader()
except EOFError:
    break
else:
    process next line here

```

The general format of a try and finally looks like the following:

```

try:
    statements
finally:
    statements

```

For example:

```

def divide(x, y):
    return x / y

def tester(y):
    try:
        print divide(8, y)
    finally:
        print 'on the way out...'

```

## Calling scripts using another script

Use the **execfile** command to call a Jython script from another Jython script. For example:

Create a script called *test1.py* that contains the following: Create a script called *testFunctions.py* that contains the following:

```

def printName(first, last):
    name = first + ' ' + last
    return name

```

Then pass the following path as a script argument:

You must use forward slashes (/) as your path separator. Backward slashes (\) will not work.

For more information about the Jython language, see the [Scripting: Resources for Learning](#) article.

## Scripting objects

The wsadmin tool operates on configurations and running objects through the following set of management objects: AdminConfig, AdminControl, AdminApp, AdminTask, and Help.

Each of these objects has commands that you can use to perform administrative tasks. To use the scripting objects, specify the scripting object, a command, and command parameters. For example:

Using Jacl:

```
$AdminConfig attributes ApplicationServer
```

Using Jython:

```
print AdminConfig.attributes('ApplicationServer')
```

where AdminConfig is the scripting object, attributes is the command, and ApplicationServer is the command parameter.

To find out more specific information about each of the scripting objects, including command and command parameter information, see AdminConfig, AdminApp, AdminControl, AdminTask, or Help.

WebSphere Application Server system management separates administrative functions into two categories: functions that work with the configuration of WebSphere Application Server installations, and functions that work with the currently running objects in WebSphere Application Server installations.

Scripts work with both categories of objects. For example, an application server is divided into two distinct entities. One entity represents the configuration of the server that resides persistently in a repository on permanent storage. You can create, query, change, or remove this configuration without starting an application server process. The **AdminConfig object**, the **AdminTask object**, and the **AdminApp object** handle configuration functionality. You can invoke configuration functions with or without being connected to a server.

The second entity represents the running instance of an application server by a *Java Management Extensions (JMX) MBean*. This instance can have attributes that you can interrogate and change, and operations that you can invoke. These operational actions taken against a running application server do not have an effect on the persistent configuration of the server. The attributes that support manipulation from an MBean differ from the attributes that the corresponding configuration supports. The configuration can include many attributes that you cannot query or set from the running object. The WebSphere Application Server scripting support provides functions to locate configuration objects, and running objects. Objects in the configuration do not always represent objects that are currently running. The **AdminControl object** manages running objects.

You can use the **Help object** to obtain information about the AdminConfig, AdminApp, AdminControl, and AdminTask objects, to obtain interface information about running MBeans, and to obtain help for warnings and error messages.

### Help object for scripted administration

The Help object provides general help, online information about running MBeans, and help on messages.

Use the Help object to obtain general help for the other objects supplied by the wsadmin tool for scripting: the AdminApp, AdminConfig, AdminTask, and AdminControl objects. For example, using Jacl, `$Help AdminApp` or using Jython, `Help.Adminapp()`, provides information about the AdminApp object and the available commands.

The Help object also provides interface information about MBeans running in the system. The commands that you use to get online information about the running MBeans include: **all**, **attributes**, **classname**, **constructors**, **description**, **notification**, **operations**.

You can also use the Help object to obtain information about messages using the **message** command. The **message** command provides aid to understand the cause of a warning or error message and find a solution for the problem. For example, you receive a WASX7115E error when running the AdminApp **install** command to install an application, use the following example:

Using Jacl:

```
$Help message WASX7115E
```

Using Jython:

```
print Help.message('WASX7115E')
```

Example output:

```
Explanation: wsadmin failed to read an ear file when
preparing to copy it to a temporary location for AdminApp
processing. User action: Examine the wsadmin.traceout
log file to determine the problem; there may be file permission problems.
```

The user action specifies the recommended action to correct the problem. It is important to understand that in some cases the user action may not be able to provide corrective actions to cover all the possible causes of an error. It is an aid to provide you with information to troubleshoot a problem.

To see a list of all available commands for the Help object, see the [Commands for the Help object](#) article or you can also use the **Help** command, for example:

Using Jacl:

```
$Help help
```

Using Jython:

```
print Help.help()
```

## Using the AdminApp object for scripted administration

Use the AdminApp object to manage applications.

This object communicates with the run time application management object in WebSphere Application Server to make application inquiries and changes, for example:

- Installing and uninstalling applications
- Listing applications
- Editing applications or modules

Because applications are part of configuration data, any changes that you make to an application are kept in the configuration session, similar to other configuration data. Be sure to save your application changes so that the data transfers from the configuration session to the master repository.

With the application already installed, the AdminApp object can update application metadata, map virtual hosts to Web modules, and map servers to modules. You must perform any other changes, such as specifying a library for the application to use or setting session management configuration properties, using the AdminConfig object.

You can run the commands for the AdminApp object in local mode. If a server is running, it is not recommended that you run the scripting client in local mode because any configuration changes that are made in local mode will not be reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration.

In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

To see a list of all available commands for the AdminApp object:

- See the [Commands for the AdminApp object](#) article.
- You can also use the **Help** command, for example:

Using Jacl:

```
$AdminApp help
```

Using Jython:

```
print AdminApp.help()
```

### ***Listing applications with the wsadmin tool:***

You can list installed applications using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

- Query the configuration and create a list of installed applications, for example:

- Using Jacl:

```
$AdminApp list
```

- Using Jython:

```
print AdminApp.list()
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application object management
list	is an AdminApp command

Example output:

```
DefaultApplication  
SampleApp  
app1serv2
```

- Query the configuration and create a list of installed applications on a given target scope, for example:

- Using Jacl:

```
$AdminApp list WebSphere:cell=myCell,node=myNode,server=myServer
```

- Using Jython:

```
print AdminApp.list("WebSphere:cell=myCell,node=myNode,server=myServer")
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application object management
list	is an AdminApp command
<i>WebSphere:cell=myCell,node=myNode,server=myServer</i>	is an optional target scope

Example output:

```
DefaultApplication  
PlantsByWebSphere  
SamplesGallery  
ivtApp  
query
```

### **Editing application configurations with the wsadmin tool:**

Use the wsadmin tool to configure an application’s settings.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

1. Edit the entire application or a single application module. Use one of the following commands:

- The following command uses the installed application and the command option information to edit the application:

- Using Jacl:

```
$AdminApp edit appname {options}
```

- Using Jython list:  
AdminApp.edit('appname', ['options'])
  - Using Jython string:  
AdminApp.edit('appname', '[options]')
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application object management
edit	is an AdminApp command
appname	is the name of application or application module to edit. For the application module name, use the module name returned from <b>listModules</b> command as the value.
{options}	is a list of edit options and tasks similar to the ones for the install command

- The following command changes the application information by prompting you through a series of editing tasks:
    - Using Jacl:  
\$AdminApp editInteractive appname
    - Using Jython:  
AdminApp.editInteractive('appname')
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application object management
editInteractive	is an AdminApp command
appname	is the name of application or application module to edit. For the application module name, use the module name returned from <b>listModules</b> command as the value.

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Using the AdminControl object for scripted administration

The AdminControl scripting object is used for operational control. It communicates with MBeans that represent live objects running a WebSphere server process.

It includes commands to query existing running objects and their attributes and invoke operation on the running objects. In addition to the operational commands, the AdminControl object supports commands to query information on the connected server, convenient commands for client tracing, reconnecting to a server, and start and stop server for network deployment environment.

Many of the operational commands have two sets of signatures so that they can either invoke using string based parameters or using Java Management Extension (JMX) objects as parameters. Depending on the server process to which a scripting client is connected, the number and type of MBeans available varies. If a scripting client is connected to a deployment manager, then all MBeans in all server processes are

visible. If a scripting client is connected to a node agent, all MBeans in all server processes on that node are accessible. When connected to an application server, only MBeans running in that application server are visible.

The following steps provide a general method to manage the cycle of an application:

- Install the application.
- Edit the application.
- Update the application.
- Uninstall the application.

To see a list of all available commands for the AdminControl object:

- See the Commands for the AdminControl object article.
- You can also use the **Help** command, for example:

Using Jacl:

```
$AdminControl help
```

Using Jython:

```
print AdminControl.help()
```

### ***ObjectName, Attribute, and AttributeList classes:***

WebSphere Application Server scripting commands use the underlying Java Management Extensions (JMX) classes, ObjectName, Attribute, and AttributeList, to manipulate object names, attributes and attribute lists respectively.

The WebSphere Application Server ObjectName class uniquely identifies running objects. The ObjectName class consists of the following elements:

- The domain name WebSphere.
- Several key properties, for example:
  - **type** - Indicates the type of object that is accessible through the MBean, for example, ApplicationServer, and EJBContainer.
  - **name** - Represents the display name of the particular object, for example, MyServer.
  - **node** - Represents the name of the node on which the object runs.
  - **process** - Represents the name of the server process in which the object runs.
  - **mbeanIdentifier** - Correlates the MBean instance with corresponding configuration data.

When ObjectName classes are represented by strings, they have the following pattern:

```
[domainName]:property=value[,property=value]*
```

For example, you can specify `WebSphere:name="My Server",type=ApplicationServer,node=n1,*` to specify an application server named My Server on node n1. (The asterisk (\*) is a wildcard character, used so that you do not have to specify the entire set of key properties.) The AdminControl commands that take strings as parameters expect strings that look like this example when specifying running objects (MBeans). You can obtain the object name for a running object with the **getObjectName** command.

Attributes of these objects consist of a name and a value. You can extract the name and value with the **getName** and the **getValue** methods that are available in the `javax.management.Attribute` class. You can also extract a list of attributes.

### ***Example: Collecting arguments for the AdminControl object:***

This example shows how to use multiple arguments with the AdminControl object.

Verify that the arguments parameter is a single string. Each individual argument in the string can contain spaces. Collect each argument that contains spaces in some way.

- An example of how to obtain an MBean follows:

Using Jacl:

```
set am [$AdminControl queryNames type=ApplicationManager,process=server1,*]
```

Using Jython:

```
am = AdminControl.queryNames('type=ApplicationManager,process=server1,*')
```

- Multiple ways exist to collect arguments that contain spaces. Choose one of the following alternatives:

Using Jacl:

```
- $AdminControl invoke $am startApplication {"JavaMail Sample"}
- $AdminControl invoke $am startApplication {{JavaMail Sample}}
- $AdminControl invoke $am startApplication "\"JavaMail Sample\""
```

Using Jython:

```
- AdminControl.invoke(am, 'startApplication', '[JavaMail Sample]')
- AdminControl.invoke(am, 'startApplication', '\"JavaMail Sample\"')
```

### **Example: Identifying running objects:**

Use the AdminControl object to interact with running MBeans.

In the WebSphere Application Server, MBeans represent running objects. You can interrogate the MBean server to see the objects it contains.

- Use the **queryNames** command to see running MBean objects. For example:

Using Jacl:

```
$AdminControl queryNames *
```

Using Jython:

```
print AdminControl.queryNames('*')
```

This command returns a list of all MBean types. Depending on the server to which your scripting client attaches, this list can contain MBeans that run on different servers:

- If the client attaches to a stand-alone WebSphere Application Server, the list contains MBeans that run on that server.
- If the client attaches to a node agent, the list contains MBeans that run in the node agent and MBeans that run on all application servers on that node.
- If the client attaches to a deployment manager, the list contains MBeans that run in the deployment manager, all of the node agents communicating with that deployment manager, and all application servers on the nodes served by those node agents.
- The list that the queryNames command returns is a string representation of JMX ObjectName objects. For example:

```
WebSphere:cell=MyCell,name=TraceService,mbeanIdentifier=TraceService,
type=TraceService,node=MyNode,process=server1
```

This example represents a TraceServer object that runs in *server1* on *MyNode*.

- The single queryNames argument represents the ObjectName object for which you are searching. The asterisk ("\*") in the example means return all objects, but it is possible to be more specific. As shown in the example, ObjectName has two parts: a domain, and a list of key properties. For MBeans created by the WebSphere Application Server, the domain is WebSphere. If you do not specify a domain when you invoke queryNames, the scripting client assumes the domain is WebSphere. This means that the first example query above is equivalent to:

Using Jacl:

```
$AdminControl queryNames WebSphere:*
```

Using Jython:

```
AdminControl.queryNames('WebSphere:*')
```

- WebSphere Application Server includes the following key properties for the ObjectName object:
  - name

- type
- cell
- node
- process
- mbeanIdentifier

These key properties are common. There are other key properties that exist. You can use any of these key properties to narrow the scope of the **queryNames** command. For example:

Using Jacl:

```
$AdminControl queryNames WebSphere:type=Server,node=myNode,*
```

Using Jython:

```
AdminControl.queryNames('WebSphere:type=Server,node=myNode,*')
```

This example returns a list of all MBeans that represent server objects running the node *myNode*. The, \* at the end of the ObjectName object is a JMX wildcard designation. For example, if you enter the following:

Using Jacl:

```
$AdminControl queryNames WebSphere:type=Server,node=myNode
```

Using Jython:

```
print AdminControl.queryNames('WebSphere:type=Server,node=myNode')
```

you get an empty list back because the argument to queryNames is not a wildcard. There is no Server MBean running that has exactly these key properties and no others.

- If you want to see all the MBeans representing applications running on a particular node, invoke the following example:

Using Jacl:

```
$AdminControl queryNames WebSphere:type=Application,node=myNode,*
```

Using Jython:

```
print AdminControl.queryNames('WebSphere:type=Application,node=myNode,*')
```

### ***Specifying running objects using the wsadmin tool:***

Use scripting and the wsadmin tool to specify running objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to specify running objects:

1. Obtain the configuration ID with one of the following ways:
  - Obtain the object name with the **completeObjectName** command, for example:
    - Using Jacl:
 

```
set var [$AdminControl completeObjectName template]
```
    - Using Jython:
 

```
var = AdminControl.completeObjectName(template)
```

where:

set	is a Jacl command
var	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process

completeObjectName	is an AdminControl command
template	is a string containing a segment of the object name to be matched. The template has the same format as an object name with the following pattern: [domainName]:property=value[,property=value]*. See Object name, Attribute, Attribute list for more information.

If there are several MBeans that match the template, the **completeObjectName** command only returns the first match. The matching MBean object name is then assigned to a variable.

To look for *server1* MBean in *mynode*, use the following example:

– Using Jacl:

```
set server1 [$AdminControl completeObjectName node=mynode,type=Server,name=server1,*]
```

– Using Jython:

```
server1 = AdminControl.completeObjectName('node=mynode,type=Server,name=server1,*')
```

- Obtain the object name with the **queryNames** command, for example:

– Using Jacl:

```
set var [$AdminControl queryNames template]
```

– Using Jython:

```
var = AdminControl.queryNames(template)
```

where:

set	is a Jacl command
var	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application server process.
queryNames	is an AdminControl command
template	is a string containing a segment of the object name to be matched. The template has the same format as an object name with the following pattern: [domainName]:property=value[,property=value]*

2. If there are more than one running objects returned from the **queryNames** command, the objects are returned in a list syntax. One simple way to retrieve a single element from the list is to use the **index** command in Jacl and **split** command in Jython. The following example retrieves the first running object from the server list:

• Using Jacl:

```
set allServers [$AdminControl queryNames type=Server,*]
set aServer [index $allServers 0]
```

• Using Jython:

```
allServers = AdminControl.queryNames('type=Server,*')
```

```
# get line separator
```

```
import java
```

```
lineSeparator = java.lang.System.getProperty('line.separator')
```

```
aServer = allServers.split(lineSeparator)[0]
```

For other ways to manipulate the list and then perform pattern matching to look for a specified configuration object, refer to the Jacl syntax.

You can now use the running object in with other AdminControl commands that require an object name as a parameter.

### Identifying attributes and operations for running objects with the wsadmin tool:

You can use scripting to identify attributes and operations for running objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the **attributes** or **operations** commands of the Help object to find information on a running MBean in the server.

1. Specify a running object.
2. Use the **attributes** command to display the attributes of the running object:

- Using Jacl:  
\$Help attributes MBeanObjectName
- Using Jython:  
Help.attributes(MBeanObjectName)

where:

\$	is a Jacl operator for substituting a variable name with its value
Help	is the object that provides general help and information for running MBeans in the connected server process
attributes	is a Help command
MBeanObjectName	is the string representation of the MBean object name that is obtained in step 2

3. Use the **operations** command to find out the operations that are supported by the MBean:

- Using Jacl:  
\$Help operations MBeanObjectname  
  
or  
\$Help operations MBeanObjectname operationName
- Using Jython:  
Help.operations(MBeanObjectname)  
  
or  
Help.operations(MBeanObjectname, operationName)

where:

\$	is a Jacl operator for substituting a variable name with its value
Help	is the object that provides general help and information for running MBeans in the connected server process
operations	is a Help command
MBeanObjectname	is the string representation of the MBean object name that is obtained in step number 2
operationName	(optional) is the specified operation from which you want to obtain detailed information

If you do not provide the operationName value, all the operations that are supported by the MBean return with the signature for each operation. If you specify the operationName value, only the operation

that you specify returns and it contains details which include the input parameters and the return value. To display the operations for the server MBean, use the following example:

- Using Jacl:

```
set server [$AdminControl completeObjectName type=Server,name=server1,*]
$Help operations $server
```

- Using Jython:

```
server = AdminControl.completeObjectName('type=Server,name=server1,*')
print Help.operations(server)
```

To display detailed information about the stop operation, use the following example:

- Using Jacl:

```
$Help operations $server stop
```

- Using Jython:

```
print Help.operations(server, 'stop')
```

### **Performing operations on running objects using the wsadmin tool:**

You can use scripting to invoke operations on running objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to perform operations on running objects:

1. Obtain the object name of the running object. For example:

- Using Jacl:

```
$AdminControl completeObjectName name
```

- Using Jython:

```
AdminControl.completeObjectName(name)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
completeObjectName	is an AdminControl command
<i>name</i>	is a fragment of the object name. It is used to find the matching object name. For example: type=Server,name=server1,*. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc.

2. Set the s1 variable to the running object, for example:

- Using Jacl:

```
set s1 [$AdminControl completeObjectName type=Server,name=server1,*]
```

- Using Jython:

```
s1 = AdminControl.completeObjectName('type=Server,name=server1,*')
```

where:

set	is a Jacl command
s1	is a variable name

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
completeObjectName	is an AdminControl command
type	is the object name property key
Server	is the name of the object
name	is the object name property key
server1	is the name of the server where the operation is invoked

### 3. Invoke the operation. For example:

- Using Jacl:  

```
$AdminControl invoke $s1 stop
```
- Using Jython:  

```
AdminControl.invoke(s1, 'stop')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
invoke	is an AdminControl command
s1	is the ID of the server that is specified in step number 3
stop	is an operation to invoke on the server

The following example is for operations that require parameters:

- Using Jacl:  

```
set traceServ [$AdminControl completeObjectName type=TraceService,process=server1,*]
$AdminControl invoke $traceServ appendTraceString "com.ibm.ws.management.*=all=enabled"
```
- Using Jython:  

```
traceServ = AdminControl.completeObjectName('type=TraceService,process=server1,*')
AdminControl.invoke(traceServ, 'appendTraceString', "com.ibm.ws.management.*=all=enabled")
```

### **Modifying attributes on running objects with the wsadmin tool:**

Use scripting and the wsadmin tool to modify attributes on running objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to modify attributes on running objects:

#### 1. Obtain the name of the running object, for example:

- Using Jacl:  

```
$AdminControl completeObjectName name
```
- Using Jython:  

```
AdminControl.completeObjectName(name)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans that run in a WebSphere Application Server process
completeObjectName	is an AdminControl command
name	is a fragment of the object name that is used to find the matching object name. For example: type=TraceService,node=mynode,*. This value can be any valid combination of domain and key properties, for example, type, name, cell, node, process, and so on.

2. Set the ts1 variable to the running object, for example:

- Using Jacl:  
set ts1 [AdminControl completeObjectName name]
- Using Jython:  
ts1 = AdminControl.completeObjectName(name)

where:

set	is a Jacl command
ts1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
completeObjectName	is an AdminControl command
name	is a fragment of the object name. It is used to find the matching object name. For example: type=TraceService,node=mynode,*. It can be any valid combination of domain and key properties, for example, type, name, cell, node, process, and so on.

3. Modify the running object, for example:

- Using Jacl:  
AdminControl setAttribute \$ts1 ringBufferSize 10
- Using Jython:  
AdminControl.setAttribute(ts1, 'ringBufferSize', 10)

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
setAttribute	is an AdminControl command
ts1	evaluates to the ID of the server specified in step number 3
ringBufferSize	is an attribute of modify objects
10	is the value of the ringBufferSize attribute

You can also modify multiple attribute name and value pairs, for example:

- Using Jacl:

```
set ts1 [$AdminControl completeObjectName type=TraceService,process=server1,*]
$AdminControl setAttributes $ts1 {{ringBufferSize 10} {traceSpecification com.ibm.*=all=disabled}}
```

- Using Jython list:

```
ts1 = AdminControl.completeObjectName('type=TraceService,process=server1,*')
AdminControl.setAttributes(ts1, [['ringBufferSize', 10], ['traceSpecification', 'com.ibm.*=all=disabled']])
```

- Using Jython string:

```
ts1 = AdminControl.completeObjectName('type=TraceService,process=server1,*')
AdminControl.setAttributes(ts1, '['ringBufferSize 10] [traceSpecification com.ibm.*=all=disabled]')
```

The new attribute values are returned to the command line.

### **Synchronizing nodes with the wsadmin tool:**

You can propagate node changes using scripting and the wsadmin tool. This article applies to network deployment installations only.

A node synchronization is necessary in order to propagate configuration changes to the affected node or nodes. By default, this situation occurs periodically, as long as the node can communicate with the deployment manager. You can propagate changes explicitly by performing the following steps:

1. Set the variable for node synchronization.

- Using Jacl:

```
set Sync1 [$AdminControl completeObjectName type=NodeSync,node=myNodeName,*]
```

- Using Jython:

```
Sync1 = AdminControl.completeObjectName('type=NodeSync,node=myNodeName,*')
```

where:

set	is a Jacl command
Sync1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
completeObjectName	is an AdminControl command
type=NodeSync,node= <i>myNodeName</i>	is a fragment of the object name. The complete name is returned by this command. This fragment is used to find the matching object name which is the SyncNode object for the <i>myNodeName</i> node, where <i>myNodeName</i> is the name of the node that you use to synchronize configuration changes. For example: type=Server, name=serv1. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, and so on.

Example output:

```
WebSphere:platform=common,cell=myNetwork,version=5.0,name=node
Sync,mbeanIdentifier=nodeSync,type=NodeSync,node=myBaseNode,
process=nodeagent
```

2. Synchronize the node by issuing the following command:

- Using Jacl:

```
$AdminControl invoke $Sync1 sync
```

- Using Jython:

```
AdminControl.invoke(Sync1, 'sync')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans that run in a WebSphere Application Server process
invoke	is an AdminControl command
Sync1	evaluates the ID of the server that is specified in step number 1
sync	is an attribute of modify command

Example output:

```
true
```

You receive an output value of `true`, if the synchronization completes.

## Using the AdminConfig object for scripted administration

Use the AdminConfig object to manage the configuration information that is stored in the repository.

This object communicates with the WebSphere Application Server configuration service component to make configuration inquiries and changes. You can use it to query existing configuration objects, create configuration objects, modify existing objects, remove configuration objects, and obtain help.

Updates to the configuration through a scripting client are kept in a private temporary area called a workspace and are not copied to the master configuration repository until you run a **save** command. The workspace is a temporary repository of configuration information that administrative clients including the administrative console use. The workspace is kept in the `wstemp` subdirectory of your WebSphere Application Server installation. The use of the workspace allows multiple clients to access the master configuration. If the same update is made by more than one client, it is possible that updates made by a scripting client will not save because there is a conflict. If this occurs, the updates will not be saved in the configuration unless you change the default save policy with the **setSaveMode** command.

The AdminConfig commands are available in both connected and local modes. If a server is currently running, it is not recommended that you run the scripting client in local mode because the configuration changes made in the local mode is not reflected in the running server configuration and vice versa. In connected mode, the availability of the AdminConfig commands depend on the type of server to which a scripting client is connected in a Network Deployment installation.

The AdminConfig commands are available only if a scripting client is connected to a deployment manager. When connected to a node agent or an application server, the AdminConfig commands will not be available because the configuration for these server processes are copies of the master configuration that resides in the deployment manager. The copies are created in a node machine when configuration synchronization occurs between the deployment manager and the node agent. You should make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

- The following steps provide a general method to update a configuration object:
  1. Identify the configuration type and the corresponding attributes.
  2. Query an existing configuration object to obtain a configuration ID to use.
  3. Modify the existing configuration object or create a one.
  4. Save the configuration.
- See the Commands for the AdminConfig object article. You can also use the **Help** command, for example:

Using Jacl:

```
$AdminConfig help
```

Using Jython:

```
print AdminConfig.help()
```

### **Creating configuration objects using the wsadmin tool:**

You can use scripting and the wsadmin tool to create configuration objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform this task if you want to create an object. To create new objects from the default template, use the **create** command. Alternatively, you can create objects using an existing object as a template with the **createUsingTemplate** command.

1. Use the AdminConfig object **listTemplates** command to list available templates:

- Using Jacl:

```
$AdminConfig listTemplates JDBCProvider
```

- Using Jython:

```
AdminConfig.listTemplates('JDBCProvider')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
listTemplates	is an AdminConfig command
JDBCProvider	is an object type

2. Assign the ID string that identifies the existing object to which the new object is added. You can add the new object under any valid object type. The following example uses a node as the valid object type:

- Using Jacl:

```
set n1 [$AdminConfig getid /Node:mynode/]
```

- Using Jython:

```
n1 = AdminConfig.getid('/Node:mynode/')
```

where:

set	is a Jacl command
\$	is a Jacl operator for substituting a variable name with its value
n1	is a variable name
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Node	is an object type
mynode	is the host name of the node where the new object is added

3. Specify the template that you want to use:

- Using Jacl:
- Using Jython:

where:

set	is a Jacl command
\$	is a Jacl operator for substituting a variable name with its value
t1	is a variable name
AdminConfig	is an object that represents the WebSphere Application Server configuration
listTemplates	is an AdminConfig command
JDBCProvider	is an object type
<i>DB2 JDBC Provider (XA)</i>	is the name of the template to use for the new object

If you supply a string after the name of a type, you get back a list of templates with display names that contain the string you supplied. In this example, the AdminConfig **listTemplates** command returns the JDBCProvider template whose name matches *DB2 JDBC Provider (XA)*. This example assumes that the variable that you specify here only holds one template configuration ID. If the environment contains multiple templates with the same string, for example, *DB2 JDBC Provider (XA)*, the variable will hold the configuration IDs of all of the templates. Be sure to identify the specific template that you want to use before you perform the next step, creating an object using a template.

4. Create the object with the following command:

- Using Jacl:

```
$AdminConfig createUsingTemplate JDBCProvider $n1 {{name newdriver}} $t1
```

- Using Jython:

```
AdminConfig.createUsingTemplate('JDBCProvider', n1, [['name', 'newdriver']], t1)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
createUsingTemplate	is an AdminConfig command
JDBCProvider	is an object type
n1	evaluates the ID of the host node that is specified in step number 3
name	is an attribute of JDBCProvider objects
<i>newdriver</i>	is the value of the name attribute
t1	evaluates the ID of the template that is specified in step number 4

All **create** commands use a template unless there are no templates to use. If a default template exists, the command creates the object.

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

**Interpreting the output of the AdminConfig attributes command using scripting:**

Use scripting to interpret the output of the AdminConfig attributes command.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The **attributes** command is a wsadmin tool on-line help feature. When you issue the **attributes** command, the information that displays does not represent a particular configuration object. It represents information about configuration object types, or object metadata. This article discusses how to interpret the attribute type display.

- Simple attributes

Using Jacl:

```
$AdminConfig attributes ExampleType1  
"attr1 String"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType1')  
attr1 String
```

Types do not display as fully qualified names. For example, String is used for java.lang.String. There are no ambiguous type names in the model. For example, x.y.ztype and a.b.ztype. Using only the final portion of the name is possible, and it makes the output easier to read.

- Multiple attributes

Using Jacl:

```
$AdminConfig attributes ExampleType2  
"attr1 String" "attr2 Boolean" "attr3 Integer"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType2')  
attr1 String attr2 Boolean attr3 Integer
```

All input and output for the scripting client takes place with strings, but attr2 Boolean indicates that true or false are appropriate values. The attr3 Integer indicates that string representations of integers (“42”) are needed. Some attributes have string values that can take only one of a small number of predefined values. The wsadmin tool distinguishes these values in the output by the special type name ENUM, for example:

Using Jacl:

```
$AdminConfig attributes ExampleType3  
"attr4 ENUM(ALL, SOME, NONE)"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType3')  
attr4 ENUM(ALL, SOME, NONE)
```

where: attr4 is an ENUM type. When you query or set the attribute, one of the values is ALL, SOME, or NONE. The value A\_FEW results in an error.

- Nested attributes

Using Jacl:

```
$AdminConfig attributes ExampleType4  
"attr5 String" "ex5 ExampleType5"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType4')  
attr5 String ex5 ExampleType5
```

The ExampleType4 object has two attributes: a string, and an ExampleType5 object. If you do not know what is contained in the ExampleType5 object, you can use another **attributes** command to find out. The **attributes** command displays only the attributes that the type contains directly. It does not recursively display the attributes of nested types.

- Attributes that represent lists

The values of these attributes are object lists of different types. The \* character distinguishes these attributes, for example:

Using Jacl:

```
$AdminConfig attributes ExampleType5
"ex6 ExampleType6*"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType5')
ex6 ExampleType6*
```

In this example, objects of the ExampleType5 type contain a single attribute, ex6. The value of this attribute is a list of ExampleType6 type objects.

- Reference attributes

An attribute value that references another object. You cannot change these references using modify commands, but these references display because they are part of the complete representation of the type. Distinguish reference attributes using the @ sign, for example:

Using Jacl:

```
$AdminConfig attributes ExampleType6
"attr7 Boolean" "ex7 ExampleType7@"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType6')
attr7 Boolean ex7 ExampleType7@
```

ExampleType6 objects contain references to ExampleType7 type objects.

- Generic attributes

These attributes have generic types. The values of these attributes are not necessarily this generic type. These attributes can take values of several different specific types. When you use the AdminConfig attributes command to display the attributes of this object, the various possibilities for specific types are shown in parentheses, for example:

Using Jacl:

```
$AdminConfig attributes ExampleType8
"name String" "beast AnimalType(HorseType, FishType, ButterflyType)"
```

Using Jython:

```
print AdminConfig.attributes('ExampleType8')
name String beast AnimalType(HorseType, FishType, ButterflyType)
```

In this example, the beast attribute represents an object of the generic AnimalType. This generic type is associated with three specific subtypes. The wsadmin tool gives these subtypes in parentheses after the name of the base type. In any particular instance of ExampleType8, the beast attribute can have a value of HorseType, FishType, or ButterflyType. When you specify an attribute in this way, using a modify or create command, specify the type of AnimalType. If you do not specify the AnimalType, a generic AnimalType object is assumed (specifying the generic type is possible and legitimate). This is done by specifying beast:HorseType instead of beast.

### **Specifying configuration objects using the wsadmin tool:**

Specify configuration objects with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

To manage an existing configuration object, identify the configuration object and obtain a configuration ID of the object to use for subsequent manipulation.

1. Obtain the configuration ID in one of the following ways:

- Obtain the ID of the configuration object with the **getid** command, for example:
  - Using Jacl:

```

set var [$AdminConfig getid /type:name/]
- Using Jython:
var = AdminConfig.getid('/type:name/')

```

where:

set	is a Jacl command
var	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
/type:name/	is the hierarchical containment path of the configuration object
type	is the object type. The name of the object type that you input here is the one that is based on the XML configuration files and does not have to be the same name that is displayed in the administrative console.
name	is the optional name of the object

You can specify multiple /type:name/ value pairs in the string, for example, /type:name/type:name/type:name/. If you specify the type in the containment path without the name, include the colon, for example, /type:/. The containment path must be a path that contains the correct hierarchical order. For example, if you specify /Server:server1/Node:node/ as the containment path, you do not receive a valid configuration ID because Node is a parent of Server and comes before Server in the hierarchy.

This command returns all the configuration IDs that match the representation of the containment and assigns them to a variable.

To look for all the server configuration IDs that reside in the mynode node, use the code in the following example:

```

- Using Jacl:
set nodeServers [$AdminConfig getid /Node:mynode/Server:/]
- Using Jython:
nodeServers = AdminConfig.getid('/Node:mynode/Server:/')

```

To look for the server1 configuration ID that resides in mynode, use the code in the following example:

```

- Using Jacl:
set server1 [$AdminConfig getid /Node:mynode/Server:server1/]
- Using Jython:
server1 = AdminConfig.getid('/Node:mynode/Server:server1/')

```

To look for all the server configuration IDs, use the code in the following example:

```

- Using Jacl:
set servers [$AdminConfig getid /Server:/]
- Using Jython:
servers = AdminConfig.getid('/Server:/')

```

- Obtain the ID of the configuration object with the **list** command, for example:

```

- Using Jacl:
set var [$AdminConfig list type]

```

or

```

set var [$AdminConfig list type scopeId]

```

- Using Jython:

```
var = AdminConfig.list('type')
```

or

```
var = AdminConfig.list('type', 'scopeId')
```

where:

set	is a Jacl command
var	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
list	is an AdminConfig command
type	is the object type. The name of the object type that you input here is the one that is based on the XML configuration files and does not have to be the same name that is displayed in the administrative console.
scopeId	is the configuration ID of a cell, a node, or a server object

This command returns a list of configuration object IDs of a given type. If you specify the *scopeId* value, the list of objects is returned within the specified scope. The returned list is assigned to a variable.

To look for all the server configuration IDs, use the following example:

- Using Jacl:

```
set servers [AdminConfig list Server]
```

- Using Jython:

```
servers = AdminConfig.list('Server')
```

To look for all the server configuration IDs in the *mynode* node, use the code in the following example:

- Using Jacl:

```
set scopeid [AdminConfig getid /Node:mynode/]
set nodeServers [AdminConfig list Server $scopeid]
```

- Using Jython:

```
scopeid = AdminConfig.getid('/Node:mynode/')
nodeServers = AdminConfig.list('Server', scopeid)
```

2. If more than one configuration ID is returned from the **getid** or the **list** command, the IDs are returned in a list syntax. One way to retrieve a single element from the list is to use the **index** command. The following example retrieves the first configuration ID from the server object list:

- Using Jacl:

```
set allServers [AdminConfig getid /Server:/]
set aServer [index $allServers 0]
```

- Using Jython:

```
allServers = AdminConfig.getid('/Server:/')

# get line separator
import java
lineSeparator = java.lang.System.getProperty('line.separator')

arrayAllServers = allServers.split(lineSeparator)
aServer = arrayAllServers[0]
```

For other ways to manipulate the list and perform pattern matching to look for a specified configuration object, refer to the Jacl syntax.

You can now use the configuration ID in any subsequent AdminConfig commands that require a configuration ID as a parameter.

### ***Listing attributes of configuration objects using the wsadmin tool:***

You can use scripting to generate a list of attributes of configuration objects.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to create a list of attributes of configuration objects:

1. List the attributes of a given configuration object type, using the **attributes** command, for example:

- Using Jacl:  
`$AdminConfig attributes type`
- Using Jython:  
`AdminConfig.attributes('type')`

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
attributes	is an AdminConfig command
type	is an object type

This command returns a list of attributes and its data type.

To get a list of attributes for the JDBCProvider type, use the following example command:

- Using Jacl:  
`$AdminConfig attributes JDBCProvider`
- Using Jython:  
`AdminConfig.attributes('JDBCProvider')`

2. List the required attributes of a given configuration object type, using the **required** command, for example:

- Using Jacl:  
`$AdminConfig required type`
- Using Jython:  
`AdminConfig.required('type')`

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
required	is an AdminConfig command
type	is an object type

This command returns a list of required attributes.

To get a list of required attributes for the JDBCProvider type, use the following example command:

- Using Jacl:  
`$AdminConfig required JDBCProvider`

- Using Jython:  
AdminConfig.required('JDBCProvider')

3. List attributes with defaults of a given configuration object type, using the **defaults** command, for example:

- Using Jacl:  
\$AdminConfig defaults type
- Using Jython:  
AdminConfig.defaults('type')

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
defaults	is an AdminConfig command
type	is an object type

This command returns a list of all the attributes, types, and defaults.

To get a list of attributes with the defaults displayed for the JDBCProvider type, use the following example command:

- Using Jacl:  
\$AdminConfig defaults JDBCProvider
- Using Jython:  
AdminConfig.defaults('JDBCProvider')

**Modifying configuration objects with the wsadmin tool:**

You can modify configuration objects using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to modify a configuration object:

1. Retrieve the configuration ID of the objects that you want to modify, for example:

- Using Jacl:  
set jdbcProvider1 [\$AdminConfig getid /JDBCProvider:myJdbcProvider/]
- Using Jython:  
jdbcProvider1 = AdminConfig.getid('/JDBCProvider:myJdbcProvider/')

where:

set	is a Jacl command
jdbcProvider1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
/JDBCProvider:myJdbcProvider/	is the hierarchical containment path of the configuration object

JDBCProvider	is the object type
<i>myJdbcProvider</i>	is the optional name of the object

2. Show the current attribute values of the configuration object with the **show** command, for example:

- Using Jacl:  
\$AdminConfig show \$jdbcProvider1
- Using Jython:  
AdminConfig.show(jdbcProvider1)

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
show	is an AdminConfig command
jdbcProvider1	evaluates to the ID of the host node that is specified in step number 1

3. Modify the attributes of the configuration object, for example:

- Using Jacl:  
\$AdminConfig modify \$jdbcProvider1 {{description "This is my new description"}}
- Using Jython list:  
AdminConfig.modify(jdbcProvider1, [['description', "This is my new description"]])
- Using Jython string:  
AdminConfig.modify(jdbcProvider1, '[[description "This is my new description"]]' )

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
modify	is an AdminConfig command
jdbcProvider1	evaluates to the ID of the host node that is specified in step number 1
description	is an attribute of server objects
<i>This is my new description</i>	is the value of the description attribute

You can also modify several attributes at the same time. For example:

- Using Jacl:  
{{name1 val1} {name2 val2} {name3 val3}}
- Using Jython list:  
[['name1', 'val1'], ['name2', 'val2'], ['name3', 'val3']]
- Using Jython string:  
'[[name1 val1] [name2 val2] [name3 val3]]'

4. List all of the attributes that can be modified:

- Using Jacl:  
\$AdminConfig attributes JDBCProvider
- Using Jython:

```
print AdminConfig.attributes('JDBCProvider')
```

Example output:

```
$AdminConfig attributes JDBCProvider
"classpath String*"
"description String"
"implementationClassName String"
"name String"
"nativepath String*"
"propertySet J2EEResourcePropertySet"
"providerType String"
"xa boolean"
```

5. Modify an attribute that has a type of list and collection. By default, if you try to modify an attribute that has a type of list and collection, and the attribute has an existing value in the list, it will append the new value to the existing values. An attribute that has a type of list and collection will have a star (\*). In the following example, the attribute classpath has an type of list and collection and the value is String. If you want to replace the existing value, you must change the classpath to be an empty list before you modify the new value. For example:

- Using Jacl:

```
$AdminConfig modify $jdbcProvider1 {{classpath {}}}
```

```
$AdminConfig modify $jdbcProvider1 [list [list classpath /temp/db2j.jar]]
```

- Using Jython list:

```
AdminConfig.modify(jdbcProvider1, [['description', []]])
```

```
AdminConfig.modify(jdbcProvider1, [['description', '/temp/db2j.jar']])
```

- Using Jython string:

```
AdminConfig.modify(jdbcProvider1, '[]')
```

```
AdminConfig.modify(jdbcProvider1, '[[description /temp/db2j.jar]]')
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

### **Removing configuration objects with the wsadmin tool:**

Use this task to delete a configuration object from the configuration repository. This action only affects the configuration.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

If a running instance of a configuration object exists when you remove the configuration, the change has no effect on the running instance.

1. Assign the ID string that identifies the server that you want to remove:

Using Jacl:

```
set s1 [$AdminConfig getid /Node:mynode/Server:myserver/]
```

Using Jython:

```
s1 = AdminConfig.getid('/Node:mynode/Server:myserver/')
```

where:

set	is a Jacl command
s1	is a variable name

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Node	is an object type
<i>mynode</i>	is the host name of the node from which the server is removed
Server	is an object type
<i>myserver</i>	is the name of the server to remove

2. Remove the configuration object. For example:

- Using Jacl:  
`$AdminConfig remove $s1`
- Using Jython:  
`AdminConfig.remove(s1)`

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
remove	is an AdminConfig command
s1	evaluates the ID of the server that is specified in step number 2

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

The WebSphere Application Server configuration no longer contains a specific server object. Running servers are not affected.

### ***Removing the trust association interceptor class using scripting:***

Use the wsadmin tool to remove the trust association interceptor class.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the following example as a Jacl script file and run it with the “-f” option:

Using Jacl:

```
set variableName "com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus"
set cellName $env(local.cell)

foreach taiEntry [$AdminConfig list TAInterceptor] {
  set interceptorClass [lindex [$AdminConfig showAttribute $taiEntry interceptorClassName] 0]
  if { [string compare $interceptorClass $variableName] == 0 } {
    puts "found $interceptorClass"
    puts "Removing the TAInterceptor class '$interceptorClass'"
    set tai taiEntry
  }
}
```

```

        #set t [$AdminConfig getid /Cell:$cellName/TAInterceptor:/]
        #AdminConfig remove $t
        AdminConfig remove $taiEntry
        puts "'$interceptorClass' is removed."
        break
    }
}

if { ![info exists tai] } {
    puts "The class '$variableName' does not exist."
}

AdminConfig save

```

**Example output:**

```

[root@svtaix23] /tmp
==>/usr/6*/A*/profiles/D*/bin/wsadmin.sh -f tai.jacl

```

```

WASX7209I: Connected to process "dmgr" on node svtaix23CellManager01 using SOAP connector;
The type of process is: DeploymentManager
found com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus
Removing the TAInterceptor class 'com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus'
'com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus' is removed.

```

**Changing the WebSphere Application Server configuration using the wsadmin tool:**

You can use the wsadmin AdminConfig and AdminApp objects to make changes to the WebSphere Application Server configuration.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information. For this task, the wsadmin scripting client must be connected to the deployment manager server in a network deployment environment.

The purpose of this article is to illustrate the relationship between the commands that are used to change the configuration and the files that are used to hold configuration data. This discussion assumes that you have a network deployment installation, but the concepts are very similar for a WebSphere Application Server installation.

1. Set a variable for creating a server:

- Using Jacl:
 

```
set n1 [$AdminConfig getid /Node:mynode/]
```
- Using Jython:
 

```
n1 = AdminConfig.getid('/Node:mynode/')
```

where:

set	is a Jacl command
n1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Node	is the object type
mynode	is the name of the object to modify

2. Create a server with the following command:

- Using Jacl:

```
set serv1 [$AdminConfig create Server $n1 {{name myserv}}]
```

- Using Jython list:

```
serv1 = AdminConfig.create('Server', n1, [['name', 'myserv']])
```

- Using Jython string:

```
serv1 = AdminConfig.create('Server', n1, '[[name myserv]]')
```

where:

set	is a Jacl command
serv1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
create	is an AdminConfig command
Server	is an AdminConfig object
n1	evaluates to the ID of the host node that is specified in step number 1
name	is an attribute
myserv	is the value of the name attribute

After this command completes, some new files can be seen in a workspace used by the deployment manager server on behalf of this scripting client. A workspace is a temporary repository of configuration information that administrative clients use. Any changes made to the configuration by an administrative client are first made to this temporary workspace. For scripting, when a **save** command is invoked on the AdminConfig object, these changes are transferred to the real configuration repository. Workspaces are kept in the wstemp subdirectory of a WebSphere Application Server installation.

### 3. Make a configuration change to the server with the following command:

- Using Jacl:

```
$AdminConfig modify $serv1 {{stateManagement {{initialState STOP}}}}
```

- Using Jython list:

```
AdminConfig.modify(serv1, [['stateManagement', [['initialState', 'STOP']]])
```

- Using Jython string:

```
AdminConfig.modify(serv1, '[[stateManagement [[initialState STOP]]]')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
modify	is an AdminConfig command
serv1	evaluates to the ID of the host node that is specified in step number 2
stateManagement	is an attribute
initialState	is a nested attribute within the stateManagement attribute
STOP	is the value of the initialState attribute

This command changes the initial state of the new server. After this command completes, one of the files in the workspace is changed.

### 4. Install an application on the server.

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

### **Modifying nested attributes with the wsadmin tool:**

You can modify nested attributes for a configuration object using scripting and the wsadmin tool.

The attributes for a WebSphere Application Server configuration object are often deeply nested. For example, a JDBCProvider object has an attribute factory, which is a list of the J2EEResourceFactory type objects. These objects can be DataSource objects that contain a connectionPool attribute with a ConnectionPool type that contains a variety of primitive attributes.

1. Invoke the AdminConfig object commands interactively, in a script, or use the **wsadmin -c** commands from an operating system command prompt.
2. Obtain the configuration ID of the object, for example:

Using Jacl:

```
set t1 [$AdminConfig getid /DataSource:TechSamp/]
```

Using Jython:

```
t1=AdminConfig.getid('/DataSource:TechSamp/')
```

where:

set	is a Jacl command
t1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
DataSource	is the object type
TechSamp	is the name of the object that will be modified

3. Modify one of the object parents and specify the location of the nested attribute within the parent, for example:

Using Jacl:

```
$AdminConfig modify $t1 {{connectionPool {{reapTime 2003}}}}
```

Using Jython list:

```
AdminConfig.modify(t1, [["connectionPool", ["reapTime", 2003]]])
```

Using Jython string:

```
AdminConfig.modify(t1, '[[connectionPool [[reapTime 2003]]]]')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
modify	is an AdminConfig command
t1	evaluates to the configuration ID of the datasource in step number 2

connectionPool	is an attribute
reapTime	is a nested attribute within the connectionPool attribute
2003	is the value of the reapTime attribute

4. Save the configuration by issuing an AdminConfig **save** command. For example:

Using Jacl:

```
$AdminConfig save
```

Using Jython:

```
AdminConfig.save()
```

Use the **reset** command of the AdminConfig object to undo changes that you made to your workspace since your last save.

An alternative way to modify nested attributes is to modify the nested attribute directly, for example:

Using Jacl:

```
set techsamp [$AdminConfig getid /DataSource:TechSamp/]
set pool [$AdminConfig showAttribute $techsamp connectionPool]
$AdminConfig modify $pool {{reapTime 2003}}
```

Using Jython list:

```
techsamp=AdminConfig.getid('/DataSource:TechSamp/')
pool=AdminConfig.showAttribute(techsamp,'connectionPool')
AdminConfig.modify(pool,['reapTime',2003])
```

Using Jython string:

```
techsamp=AdminConfig.getid('/DataSource:TechSamp/')
pool=AdminConfig.showAttribute(techsamp,'connectionPool')
AdminConfig.modify(pool,['[reapTime 2003]'])
```

In this example, the first command gets the configuration id of the DataSource, and the second command gets the connectionPool attribute. The third command sets the reapTime attribute on the ConnectionPool object directly.

### ***Saving configuration changes with the wsadmin tool:***

Use the wsadmin tool and scripting to save configuration changes to the master configuration repository.

The wsadmin tool uses the workspace to hold configuration changes. You must save your changes to transfer the updates to the master configuration repository. If a scripting process ends and you have not saved your changes, the changes are discarded.

Use the following commands to save the configuration changes:

1. Using Jacl:

```
$AdminConfig save
```

2. Using Jython:

```
AdminConfig.save()
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration

If you are using interactive mode with the wsadmin tool, you will be prompted to save your changes before they are discarded. If you are using the `-c` option with the wsadmin tool, changes are automatically saved.

You can use the **reset** command of the AdminConfig object to undo changes that you made to your configuration since your last save.

## Using the AdminTask object for scripted administration

Use the AdminTask object to access a set of administrative commands that provide an alternative way to access the configuration commands and the running object management commands.

The administrative commands run simple and complex commands. They provide more user friendly and task-oriented commands. The administrative commands are discovered dynamically when you start a scripting client. The set of available administrative commands depends on the edition of WebSphere Application Server that you installed. You can use the AdminTask object commands to access these commands.

Administrative commands are grouped based on their function. You can use administrative command groups to find related commands. For example, the administrative commands that are related to server management are grouped into a server management command group. The administrative commands that are related to the security management are grouped into a security management command group. An administrative command can be associated with multiple command groups because it can be useful for multiple areas of system management. Both administrative commands and administrative command groups are uniquely identified by their name.

Two run modes are always available for each administrative command, namely the *batch* and *interactive mode*. When you use an administrative command in interactive mode, you go through a series of steps to collect your input interactively. This process provides users a text-based wizard and a similar user experience to the wizard in the administrative console. You can also use the **help** command to obtain help for any administrative command and the AdminTask object.

The administrative commands do not replace any existing configuration commands or running object management commands but provide a way to access these commands and organize the inputs. The administrative commands can be available in connected or local mode. The set of available administrative commands is determined when you start a scripting client in connected or local mode. If a server is running, it is not recommended that you run the scripting client in local mode because any configuration changes made in local mode are not reflected in the running server configuration and vice versa. If you save a conflicting configuration, you could corrupt the configuration.

In a deployment manager environment, configuration updates are available only if a scripting client is connected to a deployment manager. When connected to a node agent or a managed application server, you will not be able to update the configuration because the configuration for these server processes are copies of the master configuration which resides in the deployment manager. The copies are created on a node machine when a configuration synchronization occurs between the deployment manager and the node agent. Make configuration changes to the server processes by connecting a scripting client to a deployment manager. For this reason, to change a configuration, do not run a scripting client in local mode on a node machine. It is not a supported configuration.

In V6.1, you can use parameter name and parameter value pairs instead of using parameter value one-to-one mapping as in V6.x. This way, you can specify the parameters of a step in any order and you do not have to specify option parameters. This applies to all commands for the AdminTask object. For example:

Syntax for V6.x:

```
$AdminTask commandName {-stepName {{param1Value param2Value param3Value ...}}}
```

Syntax for V6.1:

```
$AdminTask commandName {-stepName {-param1Name param1Value -param3Name param3Value -param2Name param2Value ...}}
```

Example using Jacl in V6.x:

```
$AdminTask createCluster {-clusterConfig {{cluster1 true}}}
```

Example using Jython in V6.x:

```
AdminTask.createCluster ('[-clusterConfig [[cluster1 true]]]')
```

Example using Jacl in V6.1:

```
$AdminTask createCluster {-clusterConfig {-clusterName cluster1 -preferLocal true}}
```

Example using Jython in V6.1:

```
AdminTask.createCluster('[-clusterConfig [-clusterName cluster1 -preferLocal true]]')
```

To find out the names of the step parameters, use the following command: `$AdminTask help command_name step_name`. For example using Jacl:

```
$AdminTask help createCluster clusterConfig
```

For example using Jython:

```
AdminTask.help('createCluster', 'clusterConfig')
```

- Read “Invoking an administrative command in batch mode” on page 121 to use administrative commands in batch mode.
- Read “Invoking an administrative command in interactive mode” on page 126 to use administrative commands in interactive mode.
- Read “Obtaining online help using scripting” to learn how to use scripting for online help.

### ***Obtaining online help using scripting:***

You can select from three levels of online help for administrative commands.

The top-level help provides general information for the AdminTask object and associated commands. The second-level help provides information about all of the available administrative commands and command groups. The third-level help provides specific help on a command group, a command, or a step. Command group-specific help provides descriptions for the command group that you specify and the commands that belong to the associated group. Command-specific help provides description for the specified command, and associated parameters and steps. Step-specific help provides a description for the specified step and the associated parameters. For command and step-specific help, required parameters are marked with an asterisk (\*) in the help output.

- To obtain general help, use the following examples:

Using Jacl:

```
$AdminTask help
```

Using Jython:

```
print AdminTask.help()
```

Example output:

```
WASX8001I: The AdminTask object enables the execution of available
admin commands. AdminTask commands operate in two modes:
the default mode is one which AdminTask communicates with the
WebSphere server to accomplish its task. A local mode is also
available in which no server communication takes place. The local
mode of operation is invoked by bringing up the scripting client
using the command line "-conntype NONE" option or setting the
```

"com.ibm.ws.scripting.connectiontype=NONE" property in wsadmin.properties file.

The number of admin commands varies and depends on your WebSphere install. Use the following help commands to obtain a list of supported commands and their parameters:

```
help -commands
    list all the admin commands
help -commandGroups
    list all the admin command groups
help commandName
    display detailed information for
    the specified command
help commandName stepName
    display detailed information for
    the specified step belonging to
    the specified command
help commandGroupName
    display detailed information for
    the specified command group
```

There are various flavors to invoke an admin command:

`commandName`  
invokes an admin command that does not require any argument.

`commandName targetObject`  
invokes an admin command with the specified target object string, for example, the configuration object name of a resource adapter. The expected target object varies with the admin command invoked. Use help command to get information on the target object of an admin command.

`commandName options`  
invokes an admin command with the specified option strings. This invocation syntax is used to invoke an admin command that does not require a target object. It is also used to enter interactive mode if "-interactive" mode is included in the options string.

`commandName targetObject options`  
invokes an admin command with the specified target object and options strings. If "-interactive" is included in the options string, then interactive mode is entered. The target object and options strings vary depending on the admin command invoked. Use help command to get information on the target object and options.

- To list the available command groups, use the following examples:

Using Jacl:

```
$AdminTask help -commandGroups
```

Using Jython:

```
print AdminTask.help('-commandGroups')
```

Example output:

```
WASX8005I: Available admin command groups:
```

```
ClusterConfigCommands - Commands for configuring application
server clusters and cluster members.
```

```
JCAManagement - A group of admin commands that helps to configure
Java2 Connector Architecture(J2C) related resources.
```

- To list the available commands, use the code in the following examples:

Using Jacl:

`$AdminTask help -commands`

Using Jython:

```
print AdminTask.help('-commands')
```

Example output:

WASX8004I: Available administrative commands:

`copyResourceAdapter` - copy the specified J2C resource adapter to the specified scope  
`createCluster` - Creates a new application server cluster.  
`createClusterMember` - Creates a new member of an application server cluster.  
`createJ2CConnectionFactory` - Create a J2C connection factory  
`deleteCluster` - Delete the configuration of an application server cluster.  
`deleteClusterMember` - Deletes a member from an application server cluster.  
`listConnectionFactoryInterfaces` - list all of the defined connection factory interfaces on the specified J2C resource adapter.  
`listJ2CConnectionFactories` - List J2C connection factories that have a specified connection factory interface defined in the specified J2C resource adapter  
`createJ2CAdminObject` - Create a J2C administrative object.  
`listAdminObjectInterfaces` - List all the defined administrative object interfaces on the specified J2C resource adapter.  
`interface` on the specified J2C resource adapter.  
`listJ2CAdminObjects` - List the J2C administrative objects that have a specified administrative object interface defined in the specified J2C resource adapter.  
`createJ2CActivationSpec` - Create a J2C activation specification.  
`listMessageListenerTypes` - list all of the defined messageListener type on the specified J2C resource adapter.  
`listJ2CActivationSpecs` - List the J2C activation specifications that have a specified message listener type defined in the specified J2C resource adapter.

- To obtain help about a command group, use the following examples:

Using Jacl:

```
$AdminTask help JCAManagement
```

Using Jython:

```
print AdminTask.help('JCAManagement')
```

Example output:

WASX8007I: Detailed help for command group: JCAManagement

Description: A group of administrative commands that help to configure Java 2 Connector Architecture (J2C)-related resources.

Commands:

`createJ2CConnectionFactory` - Create a J2C connection factory  
`listConnectionFactoryInterfaces` - list all of the defined connection factory interfaces on the specified J2C resource adapter.  
`listJ2CConnectionFactories` - List J2C connection factories that have a specified connection factory interface defined in the specified J2C resource adapter.  
`createJ2CAdminObject` - Create a J2C administrative object.  
`listAdminObjectInterfaces` - List all the defined administrative object interfaces on the specified J2C resource adapter.  
`listJ2CAdminObjects` - List the J2C administrative objects that have a specified administrative object interface defined in the specified J2C resource adapter.  
`createJ2CActivationSpec` - Create a J2C activation specification.  
`listMessageListenerTypes` - list all of the defined message listener types on the specified J2C resource adapter.  
`listJ2CActivationSpecs` - List the J2C activation specifications that have a specified message listener type defined in the specified J2C resource adapter.  
`copyResourceAdapter` - copy the specified J2C resource adapter to the specified scope.

- To obtain help about an administrative command, use the following examples:

Using Jacl:

```
$AdminTask help createJ2CConnectionFactory
```

Using Jython:

```
print AdminTask.help('createJ2CConnectionFactory')
```

Example output:

```
WASX8006I: Detailed help for command: createJ2CConnectionFactory
```

```
Description: Create a J2C connection factory
```

```
*Target object: The parent J2C resource adapter of the created J2C connection factory.
```

Arguments:

```
*connectionFactoryInterface - A connection factory interface that is defined in the deployment description of the parent J2C resource adapter.
```

```
*name - The name of the J2C connection factory.
```

```
*jndiName - The JNDI name of the created J2C connection factory.
```

```
description - The description for the created J2C connection factory.
```

```
authDataAlias - the authentication data alias of the created J2C connection factory.
```

Steps:

```
None
```

In the command-specific help output that is previously listed, an administrative command is divided into three input areas: target object, arguments, and steps. Each area can require input depending on the administrative command. If an area requires input, each input is described by its name and a description; except for the target object area, which contains the description of the target object only. When you use an administrative command in batch mode, you can use any input name that resides in the argument area as the argument name.

If an input is required, an asterisk (\*) is located before the name. If an area does not require an input, it is marked None. The following example uses the help output for the **createJ2CConnectionFactory** command:

- The target object area requires the configuration object name of a J2CResourceAdapter.
- In the arguments area, there are five inputs with three being required inputs. The argument names are connectionFactoryInterface, name, jndiName, description, and authDataAlias. These names are used as the parameter names in the option string to run an administrative command in batch mode, for example:

```
-connectionFactoryInterface javax.resource.cci.ConnectionFactory -name newConnectionFactory  
-jndiName CF/newConnectionFactory
```

See “Administrative command invocation syntax” on page 843 for more information about specifying argument options.

- No step is associated with this administrative command.
- To obtain help on a command step, use the step-specific help.

Step-specific help provides the following data:

- A description for the command step.
- Information indicating if this step supports collection. A collection includes objects of the same type. In a command step, a collection contains objects that have the same set of parameters.
- Information regarding each step parameter with its name and description. If a step parameter is required, an asterisk (\*) is located in front of the name.

The following example obtains help on a command step:

Using Jacl:

```
$AdminTask help createCluster clusterConfig
```

Using Jython:

```
print AdminTask.help('createCluster', 'clusterConfig')
```

### Example output:

WASX8013I: Detailed help for step: clusterConfig

Description: Specifies the configuration of the new server cluster.

Collection: No

#### Arguments:

- \*clusterName - Name of server cluster.
- preferLocal - Enables node-scoped routing optimization for the cluster.

This example indicates the following information about the clusterConfig step:

- This step does not support collection. Only one set of parameter values for the clusterName and preferLocal parameters is supported.
- This step contains two input arguments with one argument that is indicated as required. The required arguments is clusterName and the non-required parameter is preferLocal. The syntax to provide step parameter values is different from the command argument values. You have to provide all argument values of a step and provide them in the exact order as displayed in the step specific help. For any optional argument that you do not want to specify a value, put double quotes ("" ) in place of a value. If a command step is a collection type, for example, it can contain multiple objects where each object has the same set of arguments, you can specify multiple objects with each object enclosed by its own pair of braces. To run an administrative command in batch mode and to include this step in the option string, use the following syntax:

Using Jacl:

```
-clusterConfig {{newCluster false}}
```

Using Jython:

```
-clusterConfig [[newCluster false]]
```

See “Administrative command invocation syntax” on page 843 for more information about specifying parameter options.

### **Invoking an administrative command in batch mode:**

Use this commands to invoke an administrative command in batch mode.

To invoke an administrative command in interactive mode, see “Invoking an administrative command in interactive mode” on page 126.

1. Invoke the AdminTask object commands interactively, in a script, or use the **wsadmin -c** command from an operating system command prompt.
2. Issue one of the following commands:

- If an administrative command does not have a target object and an argument, use the following command:

Using Jacl:

```
$AdminTask commandName
```

Using Jython:

```
AdminTask.commandName()
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object allowing administrative command management
<i>commandName</i>	is the name of the administrative command to invoke

- If an administrative command includes a target object but does not include any arguments or steps, use the following command:

Using Jacl:

```
$AdminTask commandName targetObject
```

Using Jython:

```
AdminTask.commandName(targetObject)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke
<i>targetObject</i>	is the target object string for the invoked administrative command. The expect target object varies with each administrative command. View the online help for the invoked administrative command to learn more about what you should specify as the target object.

- If an administrative command includes an argument or a step but does not include a target object, use the following command:

Using Jacl:

```
$AdminTask commandName options
```

Using Jython:

```
AdminTask.commandName(options)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke

*options*

is the option string for the invoked administrative command. Depending on which administrative command you are invoking, the administrative command can have required or optional option values. The options string is different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps listed on the online administrative command help are specified as options in the option string.

Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. If the invoked administrative command includes target objects, arguments, or steps, then the `-interactive` option is available to enter interactive mode. For example, using the output of the following online help for the `listDataSource` command:

WASX8006I: Detailed help for command: `exportServer`

Description: export the configuration of a server to a config archive.

Target object: None

Arguments:

\*serverName - the name of a server  
\*nodeName - the name of a node. This parameter becomes optional if the specified server name is unique across the cell.  
\*archive - the fully qualified file path of a config archive.

Steps:

None

Option names are specified with a dash before the names. Three options are required for this administrative command. The required options are `-serverName`, `-nodename`, and `-archive`. In addition, the `-interactive` option is available. Options are specified in the option string, which is enclosed by a pair of braces ({} in Jacl and a pair of brackets ([]) in Jython.

- If an administrative command includes a target object, and arguments or steps:

Using Jacl:

```
$AdminTask commandName targetObject options
```

Using Jython:

```
AdminTask.commandName(targetObject, options)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke

*targetObject*

is the target object string for the invoked administrative command. The expected target object varies with each administrative command. View the online help for the invoked administrative command to obtain information about what to specify as a target object. For example, using the output of the following online help for `createJ2CConnectionFactory`:

WASX8006I: Detailed help for command:  
`createJ2CConnectionFactory`

Description: Create a J2C connection factory

\*Target object: The parent J2C resource adapter of the created J2C connection factory.

Arguments:

\*`connectionFactoryInterface` - A connection factory interface that is defined in the deployment description of the parent J2C resource adapter.

\*`name` - The name of the J2C connection factory.

\*`jndiName` - The JNDI name of the created J2C connection factory.

`description` - The description for the created J2C connection factory.

`authDataAlias` - the authentication data alias of the created J2C connection factory.

Steps:

None

The target object is a configuration object name of a J2C resource adapter.

*options*

is the option string for the invoked administrative command. Depending on which administrative command you are invoking, the administrative command can have required or optional option values. The options string is different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps that are listed on the online administrative command help are specified as options in the option string. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. If the invoked administrative command includes target objects, arguments, or steps, then the `-interactive` option is available to enter interactive mode. For example, using the output of the following online help for `listDataSource`:

WASX8006I: Detailed help for command:  
`createdJ2CConnectionFactory`

Description: Create a J2C connection factory

\*Target object: The parent J2C resource adapter of the created J2C connection factory.

Arguments:

\*`connectionFactoryInterface` - A connection factory interface that is defined in the deployment description of the parent J2C resource adapter.

\*`name` - The name of the J2C connection factory.

\*`jndiName` - The JNDI name of the created J2C connection factory.

`description` - The description for the created J2C connection factory.

`authDataAlias` - the authentication data alias of the created J2C connection factory.

Steps:

None

Option names are specified with a dash before the names. The required options for this administrative command include: `-connectionFactoryInterface`, `-name`, and `-jndiName`. The optional options include: `-description` and `-authDataAlias`. In addition, you can also use the `-interactive` option. Options are specified in the option string, which is enclosed by a pair of braces (`{}`) in Jacl and a pair of brackets (`[]`) in Jython.

- The following example invokes an administrative command with no target object, argument, or step:

Using Jacl:

```
$AdminTask listNodes
```

Using Jython:

```
print AdminTask.listNodes()
```

Example output:

```
myNode
```

- The following example invokes an administrative command with a target object string:

Using Jacl:

```
set s1 [$AdminConfig getid /Server:server1/]  
$AdminTask showServerInfo $s1
```

Using Jython:

```
s1 = AdminConfig.getid('/Server:server1/')
print AdminTask.showServerInfo(s1)
```

Example output:

```
{cell myCell}
{serverType APPLICATION_SERVER}
{com.ibm.websphere.baseProductVersion 6.0.0.0}
{node myNode}
{server server1}
```

- The following example invokes an administrative command with an option string:

Using Jacl:

```
$AdminTask getNodeMajorVersion {-nodeName myNode}
```

Using Jython:

```
print AdminTask.getNodeMajorVersion('[-nodeName myNode]')
```

Example output:

```
6
```

- The following example invokes an administrative command with a target object and non-step option strings:

Using Jacl:

```
set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
$AdminTask createJ2CConnectionFactory $ra {-name myJ2CCF -jndiName j2c/cf -connectionFactoryInterface
javax.resource.cci.ConnectionFactory}
```

Using Jython:

```
ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
AdminTask.createJ2CConnectionFactory(ra, '[-name myJ2CCF -jndiName j2c/cf -connectionFactoryInterface
javax.resource.cci.ConnectionFactory]')
```

Example output:

```
myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
```

- The following example invokes an administrative command with a target object and a step option:

Using Jacl:

```
set serverCluster [$AdminConfig getid /ServerCluster:myCluster/]
$AdminTask createClusterMember $serverCluster {-memberConfig {{myNode myClusterMember "" "" false false}}}
```

Using Jython:

```
serverCluster = AdminConfig.getid('/ServerCluster:myCluster/')
AdminTask.createClusterMember(serverCluster, '[-memberConfig [[myNode myClusterMember "" "" false false]]]')
```

Example output:

```
myClusterMember(cells/myCell/nodes/myNode|cluster.xml#ClusterMember_3673839301876)
```

### **Invoking an administrative command in interactive mode:**

These steps demonstrate how to invoke an administrative command in interactive mode.

To invoke an administrative command in batch mode, see “Invoking an administrative command in batch mode” on page 121.

1. Invoke the AdminTask object commands interactively, in a script, or use the **wsadmin -c** command from an operating system command prompt.
2. Invoke an administrative command in interactive mode by issuing one of the following commands:
  - Use the following command invocation to enter interactive mode without providing another input in the command invocation:

Using Jacl:

```
$AdminTask commandName {-interactive}
```

### Using Jython:

```
AdminTask.commandName('[-interactive]')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke
-interactive	is the interactive option

- Use the following command invocation to enter interactive mode using an administrative command that takes a target object. You do not have to provide a target object to enter interactive mode. Target objects provided in the command invocation will be applied to the command and displayed as the current target object value during interactive prompting.

Using Jacl:

```
$AdminTask commandName targetObject {-interactive}
```

Using Jython:

```
AdminTask.commandName(targetObject, '[-interactive]')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke
<i>targetObject</i>	is the target object string for the invoked administrative command. The target object is different for each administrative command. View the online help for the invoked administrative command to learn more about what to specify as a target object.
-interactive	is the interactive option

- Use the following command invocation to enter interactive mode for an administrative command that takes options. You do not have to provide other options to enter interactive mode. Options provided in the command invocation are applied to the command and the option values will be displayed as the current values during interactive prompting.

Using Jacl:

```
$AdminTask commandName {-interactive commandOptions}
```

Using Jython:

```
AdminTask.commandName('[-interactive commandOptions]')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke
-interactive	is the interactive option

*commandOptions*

is the command option that is available for the associated administrative command. Available command options are different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps that are listed on the online administrative command help are specified as command options. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. For example, using the output of the following online help for the createJ2CConnectionFactory command:

```
WASX8006I: Detailed help for command:
createJ2CConnectionFactory
```

Description: Create a J2C connection factory

\*Target object: The parent J2C resource adapter of the created J2C connection factory.

Arguments:

\*connectionFactoryInterface - A connection factory interface that is defined in the deployment description of the parent J2C resource adapter.  
\*name - The name of the J2C connection factory.  
\*jndiName - The JNDI name of the created J2C connection factory.  
description - The description for the created J2C connection factory.  
authDataAlias - the authentication data alias of the created J2C connection factory.

Steps:  
None

In this example, five options are available:

- -connectionFactoryInterface
- -name
- -jndiName
- -description
- -authDataAlias

Each option requires a value. Three of the options are required and are denoted with a star (\*).

- Use the following command invocation to enter interactive mode for an administrative command that has a target object and options. You do not have to specify a target object to enter interactive mode. The values specified are applied to the command before the command data is displayed. As a result, the values specified will be displayed as the current values during interactive prompting.

Using Jacl:

```
$AdminTask commandName targetObject {-interactive commandOptions}
```

Using Jython:

```
AdminTask.commandName(targetObject, '[-interactive commandOptions']')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminTask	is an object that supports administrative command management
<i>commandName</i>	is the name of the administrative command to invoke
<i>targetObject</i>	is the target object string for the invoked administrative command. The expect target object varies with each admin command. Consult the online help on the invoked administrative command to learn more about what to specify as target object.
-interactive	is the interactive option
<i>commandOptions</i>	<p>is the command option that is available for the associated administrative command. Available command options are different for each administrative command. View the online help for the invoked administrative command to obtain more information about which options are available. Arguments and steps that are listed on the online administrative command help are specified as command options. Each option consists of a dash followed immediately by an option name, and then followed by an option value if the option requires a value. For example, using the output of the following online help for the createJ2CConnectionFactory command:</p> <pre> WASX8006I: Detailed help for command: createdJ2CConnectionFactory  Description: Create a J2C connection factory  *Target object: The parent J2C resource adapter of the created J2C connection factory.  Arguments: *connectionFactoryInterface - A connection factory interface that is defined in the deployment description of the parent J2C resource adapter. *name - The name of the J2C connection factory. *jndiName - The JNDI name of the created J2C connection factory. description - The description for the created J2C connection factory. authDataAlias - the authentication data alias of the created J2C connection factory.  Steps: None  In this example, five options are available: <ul style="list-style-type: none"> <li>• -connectionFactoryInterface</li> <li>• -name</li> <li>• -jndiName</li> <li>• -description</li> <li>• -authDataAlias</li> </ul> Each option requires a value. Three of the options are required and are denoted with a star (*).</pre>

- The following example invokes an administrative command in interactive mode by specifying the `-interactive` option:

Using Jacl:

```
$AdminTask createJ2CConnectionFactory {-interactive}
```

Using Jython:

```
AdminTask.createJ2CConnectionFactory('[-interactive]')
```

Example output:

```
Create a J2C connection factory
```

```
*The J2C resource adapter: "WebSphere Relational ResourceAdapter
(cells/myCell/nodes/myNode|resources.xml#builtin_rra)"
```

```
A connection factory
interface (connectionFactoryInterface):javax.resource.cci.ConnectionFactory
*Name (name): myJ2CCF
*The JNDI name (jndiName): j2c/cf
Description (description):
authentication data alias (authDataAlias):
```

```
create J2C connection factory
```

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
```

- The following example invokes an administrative command using the `-interactive` option with a target object that is specified in the command invocation:

Using Jacl:

```
set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
$AdminTask createJ2CConnectionFactory $ra {-interactive}
```

Using Jython:

```
ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
AdminTask.createJ2CConnectionFactory(ra, '[-interactive]')
```

Example output:

```
Create a J2C connection factory
```

```
*The J2C resource adapter: ["WebSphere Relational ResourceAdapter
(cells/myCell/nodes/myNode|resources.xml#builtin_rra)"]
```

```
A connection factory interface (connectionFactoryInterface):
javax.resource.cci.ConnectionFactory
*Name (name): myJ2CCF
*The JNDI name (jndiName): j2c/cf
Description (description):
authentication data alias (authDataAlias):
```

```
create J2C Connection Factory
```

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
myJ2CCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_1069690568269)
```

- The following example invokes an administrative command using the `-interactive` option where both the target object and the additional command options are specified in the command invocation:

Using Jacl:

```
set ra [$AdminConfig getid /J2CResourceAdapter:myResourceAdapter/]
$AdminTask createJ2CConnectionFactory $ra {-name myNewCF -interactive}
```

Using Jython:

```
ra = AdminConfig.getid('/J2CResourceAdapter:myResourceAdapter/')
AdminTask.createJ2CConnectionFactory(ra, '[-name myNewCF -interactive]')
```

Example output:

Create a J2C connection factory

```
*The J2C resource adapter: ["WebSphere Relational ResourceAdapter
(cells/myCell/nodes/myNode|resources.xml#builtin_rra)"]
```

A connection factory interface (connectionFactoryInterface):javax.resource.cci.ConnectionFactory

```
*Name (name): [myNewCF]
```

```
*The JNDI name (jndiName): j2c/cf
```

```
Description (description):
```

```
authentication data alias (authDataAlias):
```

create J2C Connection Factory

F (Finish)

C (Cancel)

Select [F, C]: [F]

```
myNewCF(cells/myCell/nodes/myNode|resources.xml#J2CConnectionFactory_3839439380269)
```

#### *Administrative command interactive mode environment:*

An administrative command can be run in interactive mode by providing the `-interactive` option in the options string when invoking the command.

You can still provide other options, even when using the interactive option. The options values that are specified are applied to the command before the command data is displayed. Whether or not other options are specified, the `wsadmin` tool steps the user through the command to collect command information.

The general interactive flow sequence is:

1. Collect user inputs for target object and parameters
2. If the command does not include a step, the command execution menu displays to run or cancel the command.
3. If the command includes a step, the menu to select the step displays. When all the required inputs are entered, the menu includes command execution.
4. When a step is selected, if the step supports collection, then the menu to select an object in the collection displays and you can exit the step. If you exit the step, repeat steps 1-3.
5. Collect user inputs for the selected step or for an object in the collection
6. Repeat steps 4 and 5 if from the collection step menu
7. Repeat steps 3-5 if from step selection menu

Depending on what input area is enabled by an administrative command, you can go through part or all of the interactive flow sequence. If an administrative command is run in interactive mode, the syntax to run the command except for the deletion of collection object in batch mode is generated and logged as a `WASX7278I` message in both the interactive session and in the `wsadmin` trace file.

#### **Collect user inputs for target object and parameters**

The following interactive prompt is used to collect inputs for the Target object and Arguments input areas that are displayed in the command-specific help:

Command title

Command Description

```
*target object title [current or default value]:  
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]  
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]  
...
```

This screen is usually the first interactive screen that is displayed when an administrative command is invoked interactively unless the invoked command does not contain any target object and non-step command parameters. If a command does not have a target object, then the prompt for the target object is skipped. The number of parameters depends on the number of arguments in the Argument area of the command-specific help. If an input is required, then an asterisk (\*) is placed in front of the title. The parameter name is displayed for information and is the name that is used to set this parameter in batch mode. If a parameter value is restricted to a set of values, then the valid choices are displayed. If current or default value is available, it is displayed. You can accept the existing value by pressing the Enter key. To add or change an existing value, enter a new value and click Enter.

### Display command execution menu

If an administrative command does not contain a step, you are presented with the following menu after collecting values for target object and parameters:

Command title

```
F (Finish)  
C (Cancel)
```

Select [F, C]: F

The Finish option runs the command and the Cancel option cancels the command. The default selection is F (Finish). This menu is the last menu that is displayed for a non-step command to exit interactive mode by either canceling or running the command.

### Display command step selection and execution menu

If an administrative command contains a step, the following menu is displayed after collecting values for target object and parameters:

```
Command title  
Command description  
-> *1. step1 title (step1 name)  
   2. step2 title (step2 name)  
   *3. step3 title (step3 name)  
   (4. step4 title (step4 name))  
   ...  
   n. stepn title (stepn name)
```

```
S (Select)  
N (Next)  
P (Previous)  
F (Finish)  
C (Cancel)  
H (Help)
```

Select [S, N, P, F, C, H]: S

The number of steps that is displayed in the menu depends on the administrative command. The step name is displayed for information and is the name that is used to set data in this step in batch mode. The following notations are used to describe a step:

- A “->” before the step indicates the current step position.

- A “\*\*” before the step indicates a required step.
- A ( ) enclosing the entire step indicates a disabled step. You cannot navigate to this step by using the Next or Previous options.

Using the menu, you can navigate through steps sequentially by selecting Previous or Next. Select selects the current step, Finish runs the command, Cancel cancels the command, and Help provides online help for the command. Not all menu choices are available. Previous is not available if the current step is the first step. Next is not available if the current step is the last step. Finish is not available if still steps are still missing required inputs. The default selection is S (Select) if the current step is a valid step and steps are missing required inputs. Default selection is F (Finish) if all the required input is provided for the steps.

For commands with steps, you can exit interactive mode on this menu by either canceling or running the command.

### Display collection step menu

A step might or might not support collection. A collection refers to objects of the same type. In an administrative command, a collection contains objects that have the same set of parameters. If a step that supports collection is selected, the wsadmin tool displays the following menu to add and select an object in the collection:

```
Step title (step name)
  | key param1 title (key param1 name), key param2 title (key param2 name), ...
-----
-> | object1 key param1 value, key param2 value, ...
   *| object2 key param1 value, key param2 value, ...
   ...
key param1 title, key param2 title, ... must be provided to specify a row in batch row.

S (Select Row)
N (Next)
P (Previous)
A (Add Row or Add Row Before)
D (Delete Row)
F (Finish)
H (Help)

Select [S, N, P, A, D, F, H]: F
```

The number of objects that display in the menu depends on the command step. Key parameters are identified by the step to use to uniquely identify an object in a collection. Key parameter values are displayed to identify an object to select. As with the command step selection menu, an arrow (->) is used to indicate the current object position, and an asterisk (\*) is used to indicate that required input is missing in the object.

Use the menu to navigate through objects sequentially by selecting Previous or Next. Select Row selects the current object, Add Row adds a new object, Add Row Before adds a new object before the current object, Delete Row deletes the current object, Finish returns control back to the step selection and execution menu, and Help provides on-line help for the step. Not all menu choices are available. Previous is not available if there is no object in the collection or the first object is the current object. Next is not available if there is no object in the collection or the last object is the current object. Select Row is available only if there is a current object. Add Row is provided only if there is no object in the collection and the step supports new object to be added. Add Row Before is provided if the step supports new object to be added and there are existing objects in the collection. Delete Row is provided only if there is a current object and the step supports an object to be deleted. Finish is not available if there are still objects missing required inputs. Default selection is A (Add Row) when there is no object in the collection and the step supports objects to be added. Default selection is S (Select Row) if there is a current object and there are still objects missing required inputs. Default selection is F (Finish) if there is no required input missing in any object.

## Collect user inputs for parameters of a collection object

After a collection object is selected, the parameter value for each parameter is prompted sequentially as shown in the following example:

```
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...
```

The number of parameters depends on the number of arguments in the Argument area of the command step-specific help. The same asterisk (\*) notation is used to denote a required parameter. If a parameter value is restricted to a set of values, then the valid choices are displayed. If the current or default value is available, it is displayed. For each writable parameter, you can accept the existing value by pressing Enter. To add or change an existing value, enter a new value and press Enter. For a read-only parameter, the parameter and its value are displayed. You will not be given the prompt to modify its value. After you go through all of the parameters, the wsadmin tool returns to the collection step menu.

## Collect user inputs for non-collection step

This step has two parts. The first part displays the current or default parameter values for the selected step, as shown in the following example:

```
Step title (step name)

*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...

Select [C (Cancel), E (Edit)]: [E]
```

No prompting is included in this part. Instead, this part is more like a help function providing parameter information on the selected step. The number of parameters depends on the number of arguments in the argument area of the command step specific help. The asterisk (\*) notation denotes a required parameter. If a parameter value is restricted to a set of values, then the valid choices will be displayed. If the current or default value is available, it is displayed. You can choose to cancel the step or continue to the next part to provide parameter inputs. The default selection is Edit. Because it is possible that you are seeing default values assigned to a new piece of data that is not yet set in the step, you can accept the default selection to continue to the next part. Otherwise, if no data exists in the selected step, selecting Cancel does not result in creating the data.

If you accept the default Edit selection, collect user inputs for parameters sequentially just like Collect user inputs for parameters of a collection object.

```
*param1 title (param1 name) [choice1, choice2, ...]: [current/default value]
param2 title (param2 name) [choice1, choice2, ...]: [current/default value]
...
```

For each writable parameter, you can accept the existing value by pressing Enter. To add or change an existing value, enter a new value and then press Enter. For a read-only parameter, the parameter and its value are displayed. You will not be given the prompt to modify the value of the parameter. As soon as you step through all the parameters, the wsadmin tool will lead you back to the command step selection and execution menu.

## Starting the wsadmin scripting client

You can use the wsadmin tool to manage a WebSphere Application Server Network Deployment V6.x installation, as well as configuration, application deployment, and server run-time operations.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. The WebSphere Application Server wsadmin tool only supports the Jacl and Jython scripting languages.

You must start the wsadmin scripting client before you perform any other task using scripting.

1. Locate the command that starts the wsadmin scripting client.

Choose one of the following:

- Invoke the scripting process using a specific profile. The command for invoking a scripting process is located in the *profile\_root/bin* directory. Use the *wsadmin.bat* file for a Windows system, and the *wsadmin.sh* file for an operating systems such as AIX or Linux. Using this option, you do not need to specify the *-profileName profilename* parameter.
- Invoke the scripting process using the default profile. The *wsadmin Qshell* command is located in the *app\_server\_root/bin* directory. If you do not want to connect to the default profile, you must specify the *-profileName profilename* parameter to indicate the profile that you want to use.

2. Start the wsadmin scripting client. You can start the wsadmin scripting client in several different ways. To specify the method for running scripts, perform one of the following wsadmin tool options:

Option for starting the wsadmin scripting client:	Explanation:	Examples:
Run scripting commands interactively	<p>Run wsadmin with an option other than <i>-f</i> or <i>-c</i> or without an option.</p> <p>An interactive shell is displayed with a wsadmin prompt. From the wsadmin prompt, enter any Jacl or Jython command. You can also invoke commands using the AdminControl, AdminApp, AdminConfig, AdminTask, or Help wsadmin objects.</p> <p>To leave an interactive scripting session, use the <b>quit</b> or <b>exit</b> commands. These commands do not take any arguments.</p>	<p>Using Jacl: wsadmin</p> <p>If security is enabled: wsadmin -user wsadmin -password wsadmin</p> <p>Using Jython: wsadmin -lang jython</p> <p>By default security is enabled: wsadmin -lang jython -user wsadmin -password wsadmin</p> <p>Example output: WASX7209I: Connected to process server1 on node myhost using SOAP connector; The type of process is: UnManagedProcess WASX7029I: For help, enter: "\$Help help" wsadmin&gt;\$AdminApp list adminconsole DefaultApplication ivtApp wsadmin&gt;exit</p>
Run scripting commands as individual commands	Run the wsadmin tool with the <i>-c</i> option.	<p>Using Jacl: wsadmin -c "\$AdminApp list"</p> <p>Using Jython: wsadmin -lang jython -c "AdminApp.list()"</p> <p>Example output: WASX7209I: Connected to process "server1" on node myhost using SOAP connector; The type of process is: UnManagedProcess adminconsole DefaultApplication ivtApp</p>

<p>Run scripting commands in a script</p>	<p>Run the wsadmin tool with the <code>-f</code> option, and place the commands that you want to run into the file.</p>	<p>Using Jacl:</p> <pre>wsadmin -f al.jacl</pre> <p>where the <code>al.jacl</code> file contains the following commands:</p> <pre>set apps [\$AdminApp list] puts \$apps</pre> <p>Using Jython:</p> <pre>wsadmin -lang jython -f al.py</pre> <p>where the <code>al.py</code> file contains the following commands:</p> <pre>apps = AdminApp.list() print apps</pre> <p>Example output:</p> <pre>WASX7209I: Connected to process "server1" on node myhost using SOAP connector; The type of process is:   UnManagedProcess   adminconsole   DefaultApplication   ivtApp</pre>
---	---	--

<p>Run scripting commands in a profile script</p>	<p>A <i>profile script</i> is a script that runs before the main script, or before entering interactive mode. You can use profile scripts to set up a scripting environment that is customized for the user or the installation.</p> <p>By default, the following profile script files might be configured for the <code>com.ibm.ws.scripting.profiles</code> property in the <code>app_server_root/properties/wsadmin.properties</code> file:</p> <pre>app_server_root/bin/securityProcs.jacl app_server_root/bin/LTPA_LDAPSecurityProcs.jacl</pre> <p>By default, these files are in ASCII. If you use the <code>profile.encoding</code> option to run EBCDIC encoded profile script files, change the encoding of the files to EBCDIC.</p> <p>To run scripting commands in a profile script, run the <code>wsadmin</code> tool with the <code>-profile</code> option, and include the commands that you want to run into the profile script.</p> <p>To customize the script environment, specify one or more profile scripts to run.</p>	<p>Using Jacl:</p> <pre>wsadmin -profile alprof.jacl</pre> <p>where the <code>alprof.jacl</code> file contains the following commands:</p> <pre>set apps [\$AdminApp list] puts "Applications currently installed:\n\$apps"</pre> <p>Example output:</p> <pre>WASX7209I: Connected to process "server1" on node myhost using SOAP connector; The type of process is: UnManagedProcess Applications currently installed: adminconsole DefaultApplication ivtApp WASX7029I: For help, enter: "\$Help help" wsadmin&gt;</pre> <p>Using Jython:</p> <pre>wsadmin -lang jython -profile alprof.py</pre> <p>where the <code>alprof.py</code> file contains the following commands:</p> <pre>apps = AdminApp.list() print "Applications currently installed:\n " + apps</pre> <p>Example output:</p> <pre>WASX7209I: Connected to process "server1" on node myhost using SOAP connector; The type of process is: UnManagedProcess Applications currently installed: adminconsole DefaultApplication ivtApp WASX7029I: For help, enter: "Help.help()" wsadmin&gt;</pre>
---	---	---

## Scripting: Resources for learning

Use the following links to find relevant supplemental information about the Jacl and Jython scripting languages, and about using scripting with WebSphere Application Server.

The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Programming instructions and examples

- Java command language
- Jacl: A Tcl implementation in Java
- Charming Jython
- Jython
- Sample scripts for WebSphere Application Server

---

## Deploying applications using scripting

Use these topics to learn more about deploying applications with scripting and the wsadmin tool.

This topic contains the following tasks:

- “Installing applications with the wsadmin tool”
- “Uninstalling applications with the wsadmin tool” on page 140
- “Managing Integrated Solutions Console applications using scripting” on page 140

### Installing applications with the wsadmin tool

You can use the wsadmin tool and scripting to install an application into the run time.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

On a single server installation, the server must be running before you install an application. See the “Starting servers using scripting” on page 224 article for more information.

On a network deployment installation, the deployment manager must be running before you install an application. See the “startManager command” on page 935 article for more information.

You can install the application in batch mode, using the **install** command, or you can install the application in interactive mode using the **installinteractive** command. Interactive mode prompts you through a series of tasks to provide information. Both the **install** command and the **installinteractive** command support a set of options. See the “Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands” on page 768 article for a list of valid options for the **install** and **installinteractive** commands. You can also obtain a list of supported options for an Enterprise Archive (EAR) file using the **options** command, for example:

Using Jacl:

```
$AdminApp options
```

Using Jython:

```
AdminApp.options()
```

For more information for the **options**, **install**, or **installinteractive** commands, see the “Commands for the AdminApp object” on page 741 article.

The application that you install must be an enterprise archive file (EAR), a Web archive (WAR) file, a servlet archive (SAR), or a Java archive (JAR) file. The archive file must end in .ear, .jar, .sar or .war for the wsadmin tool to be able to install it. The wsadmin tool uses these extensions to figure out the archive type. If the file is a WAR or JAR file, it will be automatically wrapped as an EAR file.

If you are installing an application that has the AdminApp useMetaDataFromBinary option specified, then you can only install this application on a WebSphere Application Server V6.x deployment target. This also applies to editing the application, using the AdminApp **edit** command, after you install it. If you use the V5.x wsadmin tool to install or edit an application on a WebSphere Application Server V6.x cell, only the steps available for the V5.x wsadmin tool will be shown.

Perform the following steps to install an application into the run time:

1. Install the application.
  - Using batch mode:
    - For a single server installation only, the following example uses the EAR file and the command option information to install the application:

- Using Jacl:
 

```
$AdminApp install /home/myProfile/MyStuff/application1.ear {-server serv2}
```
  - Using Jython list:
 

```
AdminApp.install('/home/myProfile/MyStuff/application1.ear', ['-server', 'serv2'])
```
  - Using Jython string:
 

```
AdminApp.install('home/myProfile/MyStuff/application1.ear', '[-server serv2]')
```
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application object management
install	is an AdminApp command
<i>MyStuff/application1.ear</i>	is the name of the application to install
server	is an installation option
<i>serv2</i>	is the value of the server option

- For a network deployment installation only, the following command uses the EAR file and the command option information to install the application on a cluster:

- Using Jacl:
 

```
$AdminApp install /home/myProfile/MyStuff/application1.ear {-cluster cluster1}
```
  - Using Jython list:
 

```
AdminApp.install('/home/myProfile/MyStuff/application1.ear', ['-cluster', 'cluster1'])
```
  - Using Jython string:
 

```
AdminApp.install('/home/myProfile/MyStuff/application1.ear', '[-cluster cluster1]')
```
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects to be managed
install	is an AdminApp command
<i>MyStuff/application1.ear</i>	is the name of the application to install
cluster	is an installation option
<i>cluster1</i>	the value of the cluster option which will be cluster name

- Using interactive mode, the following command changes the application information by prompting you through a series of installation tasks:

- Using Jacl:
 

```
$AdminApp installInteractive /home/myProfile/MyStuff/application1.ear
```
  - Using Jython:
 

```
AdminApp.installInteractive('/home/myProfile/MyStuff/application1.ear')
```
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects to be managed
installInteractive	is an AdminApp command
<i>MyStuff/application1.ear</i>	is the name of the application to install

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Uninstalling applications with the wsadmin tool

You can uninstall applications with the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See “Starting the wsadmin scripting client” on page 134 for more information.

Steps to uninstall an application follow:

1. Uninstall the application:

Specify the name of the application you want to uninstall, not the name of the Enterprise ARchive (EAR) file.

- Using Jacl:

```
$AdminApp uninstall application1
```

- Using Jython:

```
AdminApp.uninstall('application1')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object supporting application objects management
uninstall	is an AdminApp command
<i>application1</i>	is the name of the application to uninstall

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

Uninstalling an application removes it from the WebSphere Application Server configuration and from all the servers that the application was installed on. The application binaries (EAR file contents) are deleted from the installation directory. This occurs when the configuration is saved for single server WebSphere Application Server editions or when the configuration changes are synchronized from deployment manager to the individual nodes for network deployment configurations.

## Managing Integrated Solutions Console applications using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The Integrated Solutions Console EAR file must be unarchived before you install it.

- To deploy a portlet based Integrated Solutions Console application into the Integrated Solutions Console EAR file, use the following examples:

- Using Jacl:

```
$AdminApp update isclite modulefile {-operation add -contents
/WebSphere/AppServer/systemApps/isclite.ear/upzippedWarName
-contenturi upzippedWARName -usedefaultbindings -contextroot contextroot
```

```
$AdminConfig save
```

- To remove a portlet based Integrated Solutions Console WAR file, use the following examples:
  - Using Jacl:
 

```
$AdminApp update isclite modulefile "-operation delete -contenturi WarName"

$AdminConfig save
```

---

## Managing deployed applications using scripting

Use these topics to learn more about managing deployed applications with scripting and the wsadmin tool.

This topic contains the following tasks:

- “Starting applications with scripting”
- “Updating installed applications with the wsadmin tool” on page 142
- “Stopping applications with scripting” on page 145
- “Listing the modules in an installed application with scripting” on page 147
- “Querying the application state using scripting” on page 151
- “Configuring applications for session management using scripting” on page 153
- “Configuring applications for session management in Web modules using scripting” on page 156
- “Exporting applications using scripting” on page 160
- “Configuring a shared library using scripting” on page 161
- “Configuring a shared library for an application using scripting” on page 164
- “Setting background applications using scripting” on page 167

## Starting applications with scripting

Use scripting and the wsadmin tool to start applications.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

You must install the application before starting it. See the “Installing applications with the wsadmin tool” on page 138 article for more information.

Perform the following steps to start an application:

1. Identify the application manager MBean for the server where the application resides and assign it the `appManager` variable. The following example returns the name of the application manager MBean.

- Using Jacl:

```
set appManager [$AdminControl queryNames cell=mycell,node=mynode,type=ApplicationManager,process=server1,*]
```

- Using Jython:

```
appManager = AdminControl.queryNames('cell=mycell,node=mynode,type=ApplicationManager,process=server1,*')
print appManager
```

where:

<code>set</code>	is a Jacl command
<code>appManager</code>	is a variable name
<code>\$</code>	is a Jacl operator for substituting a variable name with its value
<code>AdminControl</code>	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
<code>queryNames</code>	is an AdminControl command

cell= <i>mycell</i> ,node= <i>mynode</i> ,type= <i>ApplicationManager</i> ,process= <i>server1</i>	is the hierarchical containment path of the configuration object
print	is a Jython command

Example output:

```
WebSphere:cell=mycell,name=ApplicationManager,mbeanIdentifier=ApplicationManager,
type=ApplicationManager,node=mynode,process=server1
```

2. Start the application. The following example invokes the startApplication operation on the MBean, providing the application name that you want to start.

- Using Jacl:

```
$AdminControl invoke $appManager startApplication myApplication
```

- Using Jython:

```
AdminControl.invoke(appManager, 'startApplication', 'myApplication')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
invoke	is an AdminControl command
appManager	evaluates to the ID of the server that is specified in step number 1
startApplication	is an attribute of the modify command
<i>myApplication</i>	is the value of the startApplication attribute

## Updating installed applications with the wsadmin tool

Use the wsadmin tool and scripting to update installed applications on an application server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Before starting an application, it must be installed. See the “Installing applications with the wsadmin tool” on page 138 article for more information.

Both the **update** command and the **updateinteractive** command support a set of options. See the “Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands” on page 768 article for a list of valid options for the **update** and **updateinteractive** commands. You can also obtain a list of supported options for an Enterprise Archive (EAR) file using the **options** command, for example:

Using Jacl:

```
$AdminApp options
```

Using Jython:

```
print AdminApp.options()
```

For more information for the **options**, **update**, or **updateinteractive** commands, see the “Commands for the AdminApp object” on page 741 article. Perform the following steps to update an application:

- Update the installed application using one of the following options:

- The following command updates a single file in a deployed application:

– Using Jacl:

```
$AdminApp update app1 file {-operation update -contents /home/myProfile/apps/app1/my.xml
-contenturi app1.jar/my.xml}
```

– Using Jython string:

```
AdminApp.update('app1', 'file', '[-operation update -contents /home/myProfile/
apps/app1/my.xml -contenturi app1.jar/my.xml]')
```

– Using Jython list:

```
AdminApp.update('app1', 'file', ['-operation', 'update', '-contents', '/home/myProfile/apps/
app1/my.xml', '-contenturi', 'app1.jar/my.xml'])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application objects management
update	is an AdminApp command
app1	is the name of the application to update
file	is the content type value
operation	is an option of the <b>update</b> command
update	is the value of the operation option
contents	is an option of the <b>update</b> command
/apps/app1/my.xml	is the value of the contents option
contenturi	is an option of the <b>update</b> command
app1.jar/my.xml	is the value of the contenturi option

- The following command adds a module to the deployed application, if the module does not exist. Otherwise, the existing module is updated.

– Using Jacl:

```
$AdminApp update app1 modulefile {-operation addupdate -contents
/home/myProfile/apps/app1/Increment.jar -contenturi Increment.jar -nodeployejb
-BindJndiForEJBNonMessageBinding {"Increment Enterprise Java Bean"
Increment Increment.jar,META-INF/ejb-jar.xml Inc}}
```

– Using Jython string:

```
AdminApp.update('app1', 'modulefile', '[-operation addupdate -contents
/home/myProfile/apps/app1/Increment.jar -contenturi Increment.jar -nodeployejb
-BindJndiForEJBNonMessageBinding [{"Increment Enterprise Java Bean
" Increment Increment.jar,META-INF/ejb-jar.xml Inc}]]')
```

– Using Jython list:

```
bindJndiForEJBValue = [{"Increment Enterprise Java Bean",
"Increment", " Increment.jar,META-INF/ejb-jar.xml", "Inc"}]

AdminApp.update('app1', 'modulefile', ['-operation', 'addupdate', '-contents',
'/home/myProfile/apps/app1/Increment.jar', '-contenturi', 'Increment.jar' '-nodeployejb',
~-BindJndiForEJBNonMessageBinding', bindJndiForEJBValue])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application objects management
update	is an AdminApp command

app1	is the name of the application to update
modulefile	is the content type value
operation	is an option of the <b>update</b> command
addupdate	is the value of the operation option
contents	is an option of the <b>update</b> command
<i>/apps/app1/Increment.jar</i>	is the value of the contents option
contenturi	is an option of the <b>update</b> command
<i>Increment.jar</i>	is the value of the contenturi option
nodeployejb	is an option of the <b>update</b> command
BindJndiForEJBNonMessageBinding	is an option of the <b>update</b> command
"Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc	is the value of the BindJndiForEJBNonMessageBinding option
bindJndiForEJBValue	is a Jython variable that contains the value of the BindJndiForEJBNonMessageBinding option

- The following command uses a partial application to update a deployed application:

- Using Jacl:

```
$AdminApp update app1 partialapp {-contents /home/myProfile/apps/app1/app1Partial.zip}
```

- Using Jython string:

```
AdminApp.update('app1', 'partialapp', '[-contents /home/myProfile/apps/app1/app1Partial.zip]')
```

- Using Jython list:

```
AdminApp.update('app1', 'partialapp', ['-contents', '/home/myProfile/apps/app1/app1Partial.zip'])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application objects management
update	is an AdminApp command
app1	is the name of the application to update
partialapp	is the content type value
contents	is an option of the <b>update</b> command
<i>/apps/app1/app1Partial.zip</i>	is the value of the contents option

- The following command updates the entire deployed application:

- Using Jacl:

```
$AdminApp update app1 app {-operation update -contents /home/myProfile/apps/app1/newApp1.jar
-usedefaultbindings -nodeployejb -BindJndiForEJBNonMessageBinding
{"Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc}}
```

- Using Jython string:

```
AdminApp.update('app1', 'app', '[-operation update -contents /home/myProfile/apps/app1/newApp1.ear
-usedefaultbindings -nodeployejb -BindJndiForEJBNonMessageBinding
[["Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc]]')
```

- Using Jython list:

```
bindJndiForEJBValue = [["Increment Enterprise Java Bean", "Increment", " Increment.jar,META-INF/
ejb-jar.xml", "Inc"]]
```

```
AdminApp.update('app1', 'app', ['-operation', 'update', '-contents',
'c:/apps/app1/NewApp1.ear', '-usedefaultbindings', '-nodeployejb',
~-BindJndiForEJBNonMessageBinding', bindJndiForEJBValue])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object that supports application objects management
update	is an AdminApp command
app1	is the name of the application to update
app	is the content type value
operation	is an option of the <b>update</b> command
update	is the value of the operation option
contents	is an option of the <b>update</b> command
/apps/app1/newApp1.ear	is the value of the contents option
usedefaultbindings	is an option of the <b>update</b> command
nodeployejb	is an option of the <b>update</b> command
BindJndiForEJBNonMessageBinding	is an option of the <b>update</b> command
"Increment Enterprise Java Bean" Increment Increment.jar,META-INF/ejb-jar.xml Inc	is the value of the BindJndiForEJBNonMessageBinding option
bindJndiForEJBValue	is a Jython variable containing the value of the BindJndiForEJBNonMessageBinding option

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a Network Deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Stopping applications with scripting

You can stop applications using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The following example stops all running applications on a server:

1. Identify the application manager MBean for the server where the application resides, and assign it to the appManager variable.

- Using Jacl:

```
set appManager [$AdminControl queryNames cell=mycell,node=mynode,type=
ApplicationManager,process=server1,*]
```

- Using Jython:

```
appManager = AdminControl.queryNames('cell=mycell,node=mynode,type=
ApplicationManager,process=server1,*')
print appManager
```

where:

set	is a Jacl command
appManager	is a variable name

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
queryNames	is an AdminControl command
cell= <i>mycell</i> ,node= <i>mynode</i> ,type= <i>ApplicationManager</i> ,process= <i>server1</i>	is the hierarchical containment path of the configuration object
print	is a Jython command

This command returns the application manager MBean.

Example output:

```
WebSphere:cell=mycell,name=ApplicationManager,mbeanIdentifier=ApplicationManager,
type=ApplicationManager,node=mynode,process=server1
```

## 2. Query the running applications belonging to this server and assign the result to the apps variable.

- Using Jacl:

```
set apps [AdminControl queryNames cell=mycell,node=mynode,type=Application,
process=server1,*]
```

- Using Jython:

```
# get line separator
import java.lang.System as sys
lineSeparator = sys.getProperty('line.separator')

apps = AdminControl.queryNames('cell=mycell,node=mynode,type=Application,
process=server1,*').split(lineSeparator)
print apps
```

where:

set	is a Jacl command
apps	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere server process
queryNames	is an AdminControl command
cell= <i>mycell</i> ,node= <i>mynode</i> ,type= <i>ApplicationManager</i> ,process= <i>server1</i>	is the hierarchical containment path of the configuration object
print	is a Jython command

This command returns a list of application MBeans.

Example output:

```
WebSphere:cell=mycell,name=adminconsole,mbeanIdentifier=deployment.xml
#ApplicationDeployment_1,type=Application,node=mynode,Server=server1,
process=server1,J2EENAME=adminconsole
WebSphere:cell=mycell,name=filetransfer,mbeanIdentifier=deployment.xml
#ApplicationDeployment_1,type=Application,node=mynode,Server=server1,
process=server1,J2EENAME=filetransfer
```

## 3. Stop all the running applications.

- Using Jacl:

```
foreach app $apps {
    set appName [AdminControl getAttribute $app name]
    AdminControl invoke $appManager stopApplication $appName}
}
```

- Using Jython:

```

for app in apps:
    appName = AdminControl.getAttribute(app, 'name')
    AdminControl.invoke(appManager, 'stopApplication', appName)

```

This command stops all the running applications by invoking the stopApplication operation on the MBean, passing in the application name to stop.

Once you complete the steps for this task, all running applications on the server are stopped.

## Listing the modules in an installed application with scripting

Use the AdminApp object **listModules** command to list the modules in an installed application.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use this example:

- Using Jacl:
 

```
$AdminApp listModules DefaultApplication -server
```
  - Using Jython:
 

```
print AdminApp.listModules('DefaultApplication', '-server')
```
- where:

\$	is a Jacl operator for substituting a variable name with its value
print	is a Jython command
AdminApp	is an object that supports application object management
listmodules	is an AdminApp command
<i>DefaultApplication</i>	is the name of the application
-server	is an optional option specified

Example output:

```

DefaultApplication#IncCMP11.jar+META-INF/ejb-jar.xml#WebSphere:cell=mycell,node=mynode,server=myserver
DefaultApplication#DefaultWebApplication.war+WEB-INF/web.xml#WebSphere:cell=mycell,node=mynode,server=myserver

```

### Example: Listing the modules in an application server

This example lists all of the modules on all of the enterprise applications that are installed on the server1 server in a node named node1.

An asterisk (\*) means that the module is installed on server1 and node1 and another server or node. A plus sign (+) means that the module is installed on server1 and node1 only.

147 }
148 }
149

```

```

150
151 proc filterAndPrint {lists flag} {
152     global webList
153     global ejbList
154     set webExists "false"
155     set ejbExists "false"
156
157     #-----
158     # If list already exists, flag it so as not to print the title more then once
159     # and reset the list
160     #-----
161     if {$webList != {}} {
162         set webExists "true"
163         set webList {}
164     }
165     if {$ejbList != {}} {
166         set ejbExists "true"
167         set ejbList {}
168     }
169
170     #-----
171     # do some filtering for web modules and ejb modules
172     #-----
173     foreach list $lists {
174         set temp [lindex [split $list .] 1]
175         if {$temp == "war"} {
176             set webList [linsert $webList end $list]
177         } elseif {$temp == "jar"} {
178             set ejbList [linsert $ejbList end $list]
179         }
180     }
181
182     #-----
183     # sort the list before printing
184     #-----
185     set webList [lsort -dictionary $webList]
186     set ejbList [lsort -dictionary $ejbList]
187
188     #-----
189     # print out all the web modules installed in server1
190     #-----
191     if {$webList != {}} {
192         if {$webExists == "false"} {
193             puts stdout "\t\tWeb Modules:"
194         }
195         foreach web $webList {
196             puts stdout "\t\t\t$web $flag"
197         }
198     }
199
200     #-----
201     # print out all the ejb modules installed in server1
202     #-----
203     if {$ejbList != {}} {
204         if {$ejbExists == "false"} {
205             puts stdout "\t\tEJB Modules:"
206         }
207         foreach ejb $ejbList {
208             puts stdout "\t\t\t$ejb $flag"
209         }
210     }
211 }

```

Example output for server1 on node node1:

```

Application name: TEST1
EJB Modules:
    deplmtest.jar +

```

```

Web Modules:
    mtcomps.war *
Application name: TEST2
Web Modules:
    mtcomps.war +
EJB Modules:
    deplmtest.jar +
Application name: TEST3
Web Modules:
    mtcomps.war *
EJB Modules:
    deplmtest.jar *
Application name: TEST4
EJB Modules:
    deplmtest.jar *
Web Modules:
    mtcomps.war

```

## Querying the application state using scripting

Use the wsadmin tool and scripting to determine if an application is running.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The following example queries the presence of the Application MBean to find out whether the application is running.

- Using Jacl:

```
$AdminControl completeObjectName type=Application,name=myApplication,*
```

- Using Jython:

```
print AdminControl.completeObjectName('type=Application,name=myApplication,*')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminControl	is an object that enables the manipulation of MBeans running in a WebSphere Application Server process
completeObjectName	is an AdminControl command
type=Application,name= <i>myApplication</i>	is the hierarchical containment path of the configuration object
print	is a Jython command

If *myApplication* is running, then an MBean is created. Otherwise, the command returns nothing. If *myApplication* is running, the output would resemble the following:

```
WebSphere:cell=mycell,name=myApplication,mbeanIdentifier=cells/mycell/applications/myApplication.ear/
deployments/myApplication/deployment.xml#ApplicationDeployment_1,type=Application,node=mynode,Server=
dmgr,process=dmgr,J2EEName=myApplication
```

## Disabling application loading in deployed targets using scripting

You can use the AdminConfig object and scripting to disable application loading in deployed targets.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The following example uses the AdminConfig object to disable application loading in deployed targets:

1. Obtain the Deployment object for the application and assign it to the deployments variable, for example:

- Using Jacl:
 

```
set deployments [$AdminConfig getid /Deployment:myApp/]
```
- Using Jython:
 

```
deployments = AdminConfig.getid("/Deployment:myApp/")
```

where:

set	is a Jacl command
deployments	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is an attribute
myApp	is the value of the attribute

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

2. Obtain the target mappings in the application and assign them to the targetMappings variable, for example:

- Using Jacl:
 

```
set deploymentObj1 [$AdminConfig showAttribute $deployments deployedObject]
set targetMap1 [lindex [$AdminConfig showAttribute $deploymentObj1 targetMappings] 0]
```

Example output:

```
(cells/mycell/applications/ivtApp.ear/deployments/ivtApp|deployment.xml#DeploymentTargetMapping_1)
```

- Using Jython:
 

```
deploymentObj1 = AdminConfig.showAttribute(deployments, 'deployedObject')
targetMap1 = AdminConfig.showAttribute(deploymentObj1, 'targetMappings')
targetMap1 = targetMap1[1:len(targetMap1)-1].split(" ")
print targetMap1
```

Example output:

```
['(cells/mycell/applications/ivtApp.ear/deployments/ivtApp|deployment.xml#DeploymentTargetMapping_1)']
```

where:

set	is a Jacl command
deploymentObj1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates the ID of the Deployment object that is specified in step number 1
deployedObject	is an attribute
targetMap1	is a variable name
targetMappings	is an attribute
lindex	is a Jacl command

print	is a Jython command
-------	---------------------

3. Disable the loading of the application on each deployed target, for example:

- Using Jacl:

```
foreach tm $targetMap1 {
    $AdminConfig modify $tm {{enable false}}
}
```

- Using Jython:

```
for targetMapping in targetMap1:
    AdminConfig.modify(targetMapping, [["enable", "false"]])
```

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

5. In a Network Deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring applications for session management using scripting

This task provides an example that uses the AdminConfig object to configure a session manager for the application.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

You can use the AdminApp object to set configurations in an application. Some configuration settings are not available through the AdminApp object.

1. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:

- Using Jacl:

```
set deployments [$AdminConfig getid /Deployment:myApp/]
```

- Using Jython:

```
deployments = AdminConfig.getid('/Deployment:myApp/')
print deployments
```

where:

set	is a Jacl command
deployments	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is an attribute
myApp	is the value of the attribute

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

2. Retrieve the application deployment object and assign it to the appDeploy variable. For example:

- Using Jacl:

```
set appDeploy [$AdminConfig showAttribute $deployments deployedObject]
```

- Using Jython:

```

appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
print appDeploy
where:

```

set	is a Jacl command
appDeploy	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates the ID of the deployment object that is specified in step number 1
deployedObject	is an attribute

**Example output:**

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ApplicationDeployment_1)
```

3. To obtain a list of attributes that you can set for a session manager, use the **attributes** command. For example:

- Using Jacl:

```
$AdminConfig attributes SessionManager
```
- Using Jython:

```
print AdminConfig.attributes('SessionManager')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
attributes	is an AdminConfig command
SessionManager	is an attribute

**Example output:**

```

"accessSessionOnTimeout Boolean"
"allowSerializedSessionAccess Boolean"
"context ServiceContext@"
"defaultCookieSettings Cookie"
"enable Boolean"
"enableCookies Boolean"
"enableProtocolSwitchRewriting Boolean"
"enableSSLTracking Boolean"
"enableSecurityIntegration Boolean"
"enableUrlRewriting Boolean"
"maxWaitTime Integer"
"properties Property(TypedProperty)*"
"sessionDRSPersistence DRSSettings"
"sessionDatabasePersistence SessionDatabasePersistence"
"sessionPersistenceMode ENUM(DATABASE, DATA_REPLICATION, NONE)"
"tuningParams TuningParams"

```

When you configure and application for session management, it is recommended that you specify each attribute.

4. Set up the attributes for the session manager. The following example sets four top-level attributes in the session manager. You can modify the example to set other attributes of the session manager,

including the nested attributes in `DRSSettings`, `SessionDataPersistence`, and `TuningParms` object types. To list the attributes for those object types, use the **attributes** command of the `AdminConfig` object.

- Using Jacl:

```
set attr1 [list enableSecurityIntegration true]
set attr2 [list maxWaitTime 30]
set attr3 [list sessionPersistenceMode NONE]
set kuki [list maximumAge -1]
set cookie [list $kuki]
Set cookieSettings [list defaultCookieSettings $cookie]
set attrs [list $attr1 $attr2 $attr3 $cookieSettings]
set sessionMgr [list sessionManagement $attrs]
```

Example output using Jacl:

```
sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30} {sessionPersistenceMode NONE}
{defaultCookieSettings {{maximumAge -1}}}}
```

- Using Jython:

```
attr1 = ['enableSecurityIntegration', 'true']
attr2 = ['maxWaitTime', 30]
attr3 = ['sessionPersistenceMode', 'NONE']
kuki = ['maximumAge', -1]
cookie = [kuki]
cookieSettings = ['defaultCookieSettings', cookie]
attrs = [attr1, attr2, attr3, cookieSettings]
sessionMgr = [['sessionManagement', attrs]]
```

Example output using Jython:

```
[[sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30], [sessionPersistenceMode, NONE],
[defaultCookieSettings [[maximumAge, -1]]]]]
```

where:

set	is a Jacl command
attr1, attr2, attr3, attrs, sessionMgr	are variable names
\$	is a Jacl operator for substituting a variable name with its value
enableSecurityIntegration	is an attribute
true	is a value of the enableSecurityIntegration attribute
maxWaitTime	is an attribute
30	is a value of the maxWaitTime attribute
sessionPersistenceMode	is an attribute
NONE	is a value of the sessionPersistenceMode attribute

5. Perform one of the following:

- Create the session manager for the application. For example:

- Using Jacl:

```
$AdminConfig create ApplicationConfig $appDeploy [list $sessionMgr]
```

- Using Jython:

```
print AdminConfig.create('ApplicationConfig', appDeploy, sessionMgr)
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration

create	is an AdminConfig command
ApplicationConfig	is an attribute
appDeploy	evaluates the ID of the deployed application that is specified in step number 2
list	is a Jacl command
sessionMgr	evaluates the ID of the session manager that is specified in step number 4

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ApplicationConfig_1)
```

- If a session manager already exists, use the **modify** command of the AdminConfig object to update the configuration of the session manager. For example:

- Using Jacl:

```
set configs [lindex [$AdminConfig showAttribute $appDeploy configs] 0]
set appConfig [lindex $configs 0]
set SM [$AdminConfig showAttribute $appConfig sessionManagement]
$AdminConfig modify $SM $attrs
```

- Using Jython:

```
configs = AdminConfig.showAttribute (appDeploy, 'configs').split(java.lang.System.getProperty('line.separator'))
appConfig = configs[1:len(configs)-1]
SM = AdminConfig.showAttribute (appConfig, 'sessionManagement')
AdminConfig.modify (SM, attrs)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a Network Deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring applications for session management in Web modules using scripting

Use scripting and the wsadmin tool to configure applications for session management in Web modules.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

You can use the AdminApp object to set configurations in an application. Some configuration settings are not available through the AdminApp object. The following task uses the AdminConfig object to configure a session manager for a Web module in the application.

1. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:

- Using Jacl:

```
set deployments [$AdminConfig getid /Deployment:myApp/]
```

- Using Jython:

```
deployments = AdminConfig.getid('/Deployment:myApp/')
print deployments
```

where:

set	is a Jacl command
deployments	is a variable name
\$	is a Jacl operator for substituting a variable name with its value

AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is an attribute
<i>myApp</i>	is the value of the attribute

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

2. Get all the modules in the application and assign them to the modules variable. For example:

- Using Jacl:

```
set appDeploy [$AdminConfig showAttribute $deployments deployedObject]
set mod1 [$AdminConfig showAttribute $appDeploy modules]
```

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#WebModuleDeployment_1)
(cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#EJBModuleDeployment_1)
(cells/mycell/applications/myApp.ear/deployments/myApp:deployment.xml#WebModuleDeployment_2)
```

- Using Jython:

```
appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
mod1 = AdminConfig.showAttribute(appDeploy, 'modules')
print mod1
```

Example output:

```
[(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#WebModuleDeployment_1)
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#EJBModuleDeployment_1)
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#EJBModuleDeployment_2)]
```

where:

set	is a Jacl command
appDeploy	is a variable name
mod1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployments	evaluates the ID of the deployment object that is specified in step number 1
deployedObject	is an attribute

3. To obtain a list of attributes that you can set for a session manager, use the **attributes** command. For example:

- Using Jacl:

```
$AdminConfig attributes SessionManager
```

- Using Jython:

```
print AdminConfig.attributes('SessionManager')
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration

attributes	is an AdminConfig command
SessionManager	is an attribute

**Example output:**

```
"accessSessionOnTimeout Boolean"
"allowSerializedSessionAccess Boolean"
"context ServiceContext@"
"defaultCookieSettings Cookie"
"enable Boolean"
"enableCookies Boolean"
"enableProtocolSwitchRewriting Boolean"
"enableSSLTracking Boolean"
"enableSecurityIntegration Boolean"
"enableUrlRewriting Boolean"
"maxWaitTime Integer"
"properties Property(TypedProperty)*"
"sessionDRSPersistence DRSSettings"
"sessionDatabasePersistence SessionDatabasePersistence"
"sessionPersistenceMode ENUM(DATABASE, DATA_REPLICATION, NONE)"
"tuningParams TuningParams"
```

4. Set up the attributes for session manager. The following example sets four top-level attributes in the session manager. You can modify the example to set other attributes in the session manager, including the nested attributes in Cookie, DRSSettings, SessionDataPersistence, and TuningParams object types. To list the attributes for those object types, use the **attributes** command of AdminConfig object.

- Using Jacl:

```
set attr0 [list enable true]
set attr1 [list enableSecurityIntegration true]
set attr2 [list maxWaitTime 30]
set attr3 [list sessionPersistenceMode NONE]
set attr4 [list enableCookies true]
set attr5 [list invalidationTimeout 45]
set tuningParamsDetailList [list $attr5]
set tuningParamsList [list tuningParams $tuningParamsDetailList]
set pwdList [list password 95ee608]
set userList [list userId Administrator]
set dsNameList [list datasourceJNDIName jdbc/session]
set dbPersistenceList [list $dsNameList $userList $pwdList]
set sessionDBPersistenceList [list $dbPersistenceList]
set sessionDBPersistenceList [list sessionDatabasePersistence $dbPersistenceList]
set kuki [list maximumAge 1000]
set cookie [list $kuki]
set cookieSettings [list defaultCookieSettings $cookie]
set sessionManagerDetailList [list $attr0 $attr1 $attr2 $attr3 $attr4 $cookieSettings
$tuningParamsList $sessionDBPersistenceList]
set sessionMgr [list sessionManagement $sessionManagerDetailList]
set id [$AdminConfig create ApplicationConfig $appDeploy [list $sessionMgr] configs]
set targetMappings [lindex [$AdminConfig showAttribute $appDeploy targetMappings] 0]
set attrs [list config $id]
$AdminConfig modify $targetMappings [list $attrs]
```

**Example output using Jacl:**

```
sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30}
{sessionPersistenceMode NONE} {enabled true}}
```

- Using Jython:

```
attr0 = ['enable', 'true']
attr1 = ['enableSecurityIntegration', 'true']
attr2 = ['maxWaitTime', 30]
attr3 = ['sessionPersistenceMode', 'NONE']
attr4 = ['enableCookies', 'true']
attr5 = ['invalidationTimeout', 45]
tuningParamsDetailList = [attr5]
tuningParamsList = ['tuningParams', tuningParamsDetailList]
```

```

pwdList = ['password', '95ee608']
userList = ['userId', 'Administrator']
dsNameList = ['datasourceJNDIName', 'jdbc/session']
dbPersistenceList = [dsNameList, userList, pwdList]
sessionDBPersistenceList = [dbPersistenceList]
sessionDBPersistenceList = ['sessionDatabasePersistence', dbPersistenceList]
kuki = ['maximumAge', 1000]
cookie = [kuki]
cookieSettings = ['defaultCookieSettings', cookie]
sessionManagerDetailList = [attr0, attr1, attr2, attr3, attr4, cookieSettings,
tuningParamsList, sessionDBPersistenceList]
sessionMgr = ['sessionManagement', sessionManagerDetailList]
id = AdminConfig.create('ApplicationConfig', appDeploy,[sessionMgr], 'configs')
targetMappings = AdminConfig.showAttribute(appDeploy, 'targetMappings')
targetMappings = targetMappings[1:len(targetMappings)-1]
print targetMappings
attrs = ['config', id]
AdminConfig.modify(targetMappings,[attrs])

```

Example output using Jython:

```
[sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30], [sessionPersistenceMode, NONE]]]
```

##### 5. Set up the attributes for the Web module. For example:

- Using Jacl:

```

set nameAttr [list name myWebModuleConfig]
set descAttr [list description "Web Module config post create"]
set webAttrs [list $nameAttr $descAttr $sessionMgr]

```

Example output:

```
{name myWebModuleConfig} {description {Web Module config post create}}
{sessionManagement {{enableSecurityIntegration true} {maxWaitTime 30}
{sessionPersistenceMode NONE} {enabled true}}}
```

- Using Jython:

```

nameAttr = ['name', 'myWebModuleConfig']
descAttr = ['description', "Web Module config post create"]
webAttrs = [nameAttr, descAttr, sessionMgr]

```

Example output:

```
[[name, myWebModuleConfig], [description, "Web Module config post create"],
[sessionManagement, [[enableSecurityIntegration, true], [maxWaitTime, 30],
[sessionPersistenceMode, NONE], [enabled, true]]]]
```

where:

set	is a Jacl command
nameAttr, descAttr, webAttrs	are variable names
\$	is a Jacl operator for substituting a variable name with its value
name	is an attribute
<i>myWebModuleConfig</i>	is a value of the name attribute
description	is an attribute
<i>Web Module config post create</i>	is a value of the description attribute

##### 6. Create the session manager for each Web module in the application. You can modify the following example to set other attributes of the session manager in a Web module configuration.

- Using Jacl:

```

foreach module $mod1 {
    if {[regexp WebModuleDeployment $module] == 1} {
        $AdminConfig create WebModuleConfig $module $webAttrs
        $AdminConfig save
    }
}

```

- Using Jython:

```

arrayModules = mod1[1:len(mod1)-1].split(" ")
for module in arrayModules:
    if module.find('WebModuleDeployment') != -1:
        AdminConfig.create('WebModuleConfig', module, webAttrs)
        Adminconfig.save()

```

Example output:

```
myWebModuleConfig(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#WebModuleConfiguration_1)
```

7. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
8. In a Network Deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Exporting applications using scripting

You can export your applications before you update installed applications or before you migrate to a different version of the WebSphere Application Server product.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Exporting applications enables you to back them up and preserve their binding information.

- Export an enterprise application to a location of your choice, for example:
    - Using Jacl:
    - Using Jython:
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects management
export	is an AdminApp command
<i>app1</i>	is the name of the application that will be exported
/mystuff/exported.ear	is the name of the file where the exported application will be stored

- Export Data Definition Language (DDL) files in the enterprise bean module of an application to a destination directory, for example:
    - Using Jacl:
    - Using Jython:
- where:

\$	is a Jacl operator for substituting a variable name with its value
AdminApp	is an object allowing application objects management
exportDDL	is an AdminApp command
<i>app1</i>	is the name of the application whose DDL files will be exported

*/mystuff*

is the name of the directory where the DDL files export from the application

## Configuring a shared library using scripting

You can use scripting to configure a shared library for application servers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure an application server to use a shared library.

1. Identify the server and assign it to the server variable. For example:

- Using Jacl:

```
set serv [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
serv = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')  
print serv
```

where:

set	is a Jacl command
serv	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Cell	is an attribute
<i>mycell</i>	is the value of the attribute
Node	is an attribute
<i>mynode</i>	is the value of the attribute
Server	is an attribute
<i>server1</i>	is the value of the attribute

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Create the shared library in the server. For example:

- Using Jacl:

```
$AdminConfig create Library $serv {{name mySharedLibrary} {classPath  
/home/myProfile/mySharedLibraryClasspath}}
```

- Using Jython:

```
print AdminConfig.create('Library', serv, [['name', 'mySharedLibrary'], ['classPath',  
'home/myProfile/mySharedLibraryClasspath']])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
create	is an AdminConfig command

Library	is an attribute
serv	evaluates the ID of the server that is specified in step number 1
name	is an attribute
<i>mySharedLibrary</i>	is a value of the name attribute
classPath	is an attribute
<i>/mySharedLibraryClasspath</i>	is the value of the classpath attribute
print	is a Jython command

Example output:

```
MysharedLibrary(cells/mycell/nodes/mynode/servers/server1|libraries.xml#Library_1)
```

3. Identify the application server from the server and assign it to the appServer variable. For example:

- Using Jacl:

```
set appServer [$AdminConfig list ApplicationServer $serv]
```

- Using Jython:

```
appServer = AdminConfig.list('ApplicationServer', serv)
print appServer
```

where:

set	is a Jacl command
appServer	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
list	is an AdminConfig command
ApplicationServer	is an attribute
serv	evaluates the ID of the server that is specified in step number 1
print	is a Jython command

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)
```

4. Identify the class loader in the application server and assign it to the classLoader variable. For example:

- To use the existing class loader that is associated with the server, the following commands use the first class loader:

- Using Jacl:

```
set classLoad [$AdminConfig showAttribute $appServer classloaders]
set classLoader1 [lindex $classLoad 0]
```

- Using Jython:

```
classLoad = AdminConfig.showAttribute(appServer, 'classloaders')
cleanClassLoaders = classLoad[1:len(classLoad)-1]
classLoader1 = cleanClassLoaders.split(' ')[0]
```

where:

set	is a Jacl command
classLoad, classLoader1	is a variable name

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
appServer	evaluates the ID of the application server that is specified in step number 3
classloaders	is an attribute
print	is a Jython command

- To create a new class loader, issue the following command:
    - Using Jacl:
 

```
set classLoader1 [$AdminConfig create Classloader $appServer {{mode PARENT_FIRST}}]
```
    - Using Jython:
 

```
classLoader1 = AdminConfig.create('Classloader', appServer, [['mode', 'PARENT_FIRST']])
```
- where:

set	is a Jacl command
classLoader1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
create	is an AdminConfig command
Classloader	is an attribute
appServer	evaluates the ID of the application server that is specified in step number 3
mode	is an attribute
PARENT_FIRST	is the value of the attribute
print	is a Jython command

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#Classloader_1)
```

5. Associate the shared library that you created with the application server through the class loader. For example:
  - Using Jacl:
 

```
$AdminConfig create LibraryRef $classLoader1 {{libraryName MyshareLibrary} {sharedClassloader true}}
```
  - Using Jython:
 

```
print AdminConfig.create('LibraryRef', classLoader1, [['libraryName', 'MyshareLibrary'], ['sharedClassloader', 'true']])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
create	is an AdminConfig command
LibraryRef	is an attribute

<code>classLoader1</code>	evaluates the ID of the class loader that is specified in step number 4
<code>libraryName</code>	is an attribute
<code>MyshareLibrary</code>	is the value of the attribute
<code>sharedClassLoader</code>	is an attribute
<code>true</code>	is the value of the attribute
<code>print</code>	is a Jython command

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#LibraryRef_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring a shared library for an application using scripting

This task uses the AdminConfig object to configure a shared library for an application.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

You can use the AdminApp object to set certain configurations in the application.

1. Identify the shared library and assign it to the library variable. You can either use an existing shared library or create a new one, for example:
  - To create a new shared library, perform the following steps:
    - a. Identify the node and assign it to a variable, for example:

- Using Jacl:

```
set n1 [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
n1 = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print n1
```

where:

<code>set</code>	is a Jacl command
<code>n1</code>	is a variable name
<code>\$</code>	is a Jacl operator for substituting a variable name with its value
<code>AdminConfig</code>	is an object representing the WebSphere Application Server configuration
<code>getid</code>	is an AdminConfig command
<code>Cell</code>	is the object type
<code>mycell</code>	is the name of the object that will be modified
<code>Node</code>	is the object type
<code>mynode</code>	is the name of the object that will be modified

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

- b. Create the shared library in the node. The following example creates a new shared library in the node scope. You can modify it to use the cell or server scope.
        - Using Jacl:

- Using Jython:  
where:

set	is a Jacl command
library	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
create	is an AdminConfig command
Library	is an AdminConfig object
n1	evaluates to the ID of host node specified in step number 1
name	is an attribute
<i>mySharedLibrary</i>	is the value of the name attribute
classPath	is an attribute
<i>/mySharedLibraryClasspath</i>	is the value of the classPath attribute

Example output:

```
MySharedLibrary(cells/mycell/nodes/mynode|libraries.xml#Library_1)
```

- To use an existing shared library, issue the following command:

- Using Jacl:

```
set library [$AdminConfig getid /Library:mySharedLibrary/]
```

- Using Jython:

```
library = AdminConfig.getid('/Library:mySharedLibrary/')
print library
```

where:

set	is a Jacl command
library	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getid	is an AdminConfig command
Library	is an attribute
<i>mySharedLibrary</i>	is the value of the Library attribute

Example output:

```
MySharedLibrary(cells/mycell/nodes/mynode|libraries.xml#Library_1)
```

2. Identify the deployment configuration object for the application and assign it to the deployment variable. For example:

- Using Jacl:

```
set deployment [$AdminConfig getid /Deployment:myApp/]
```

- Using Jython:

```
deployment = AdminConfig.getid('/Deployment:myApp/')
print deployment
```

where:

set	is a Jacl command
-----	-------------------

deployment	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
getId	is an AdminConfig command
Deployment	is an attribute
<i>myApp</i>	is the value of the Deployment attribute
print	is a Jython command

Example output:

```
myApp(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#Deployment_1)
```

3. Retrieve the application deployment and assign it to the appDeploy variable. For example:

- Using Jacl:

```
set appDeploy [$AdminConfig showAttribute $deployment deployedObject]
```

- Using Jython:

```
appDeploy = AdminConfig.showAttribute(deployment, 'deployedObject')
print appDeploy
```

where:

set	is a Jacl command
appDeploy	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
deployment	evaluates the ID of the deployment configuration object specified in step number 2
deployedObject	is an attribute of modify objects
print	is a Jython command

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/
myApp|deployment.xml#ApplicationDeployment_1)
```

4. Identify the class loader in the application deployment and assign it to the classLoader variable. For example:

- Using Jacl:

```
set classLoad1 [$AdminConfig showAttribute $appDeploy classloader]
```

- Using Jython:

```
classLoad1 = AdminConfig.showAttribute(appDeploy, 'classloader')
print classLoad1
```

where:

set	is a Jacl command
classLoad1	is a variable name
\$	is a Jacl operator for substituting a variable name with its value

AdminConfig	is an object representing the WebSphere Application Server configuration
showAttribute	is an AdminConfig command
appDeploy	evaluates the ID of the application deployment specified in step number 3
classLoader	is an attribute of modify objects
print	is a Jython command

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#ClassLoader_1)
```

5. Associate the shared library in the application through the class loader. For example:

- Using Jacl:

```
$AdminConfig create LibraryRef $classLoad1 {{libraryName  
MyshareLibrary} {sharedClassLoader true}}
```

- Using Jython:

```
print AdminConfig.create('LibraryRef', classLoad1, [['libraryName',  
'MyshareLibrary'], ['sharedClassLoader', 'true']])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object representing the WebSphere Application Server configuration
create	is an AdminConfig command
LibraryRef	is an AdminConfig object
classLoad1	evaluates to the ID of class loader specified in step number 4
libraryName	is an attribute
MyshareLibrary	is the value of the libraryName attribute
sharedClassLoader	is an attribute
true	is the value of the sharedClassLoader attribute

Example output:

```
(cells/mycell/applications/myApp.ear/deployments/myApp|deployment.xml#LibraryRef_1)
```

6. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
7. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Setting background applications using scripting

You can enable or disable a background application using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Background applications specify whether the application must initialize fully before the server starts. The default setting is `false` and this indicates that server startup will not complete until the application starts. If you set the value to `true`, the application starts on a background thread and server startup continues without waiting for the application to start. The application may not be ready for use when the application server starts.

1. Locate the application deployment object for the application. For example:

- Using Jacl:

```
set applicationDeployment [$AdminConfig getid /Deployment:adminconsole/ApplicationDeployment:/]
```

- Using Jython:

```
applicationDeployment = AdminConfig.getid('/Deployment:adminconsole/ApplicationDeployment:/')
```

where:

set	is a Jacl command
applicationDeployment	is a variable name
\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
getid	is an AdminConfig command
Deployment	is a type
ApplicationDeployment	is a type
adminconsole	is the name of the application

2. Enable the background application. For example:

- Using Jacl:

```
$AdminConfig modify $applicationDeployment "{backgroundApplication true}"
```

- Using Jython:

```
AdminConfig.modify(applicationDeployment, ['backgroundApplication', 'true'])
```

where:

\$	is a Jacl operator for substituting a variable name with its value
AdminConfig	is an object that represents the WebSphere Application Server configuration
modify	is an AdminConfig command
applicationDeployment	is a variable name that was set in step 1
backgroundApplication	is an attribute
true	is the value of the backgroundApplication attribute

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

4. In a Network Deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Modifying WAR class loader policies for applications using scripting

You can use scripting and the wsadmin tool to modify WAR class loader policies for applications.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

To modify WAR class loader policies for an application, perform the following steps:

1. Retrieve the configuration ID of the object that you want to modify and set it to the dep variable. For example:

- Using Jacl:

- ```
set dep [AdminConfig getid /Deployment:MyApp/]
```
- Using Jython:

```
dep = AdminConfig.getid("/Deployment:MyApp/")
```
2. Identify the deployed object and set it to the `deployedObject` variable. For example:
    - Using Jacl:

```
set deployedObject [AdminConfig showAttribute $dep deployedObject]
```
    - Using Jython:

```
deployedObject = AdminConfig.showAttribute(dep, "deployedObject")
```
  3. Show the current attribute values of the configuration object with the **show** command, for example:
    - Using Jacl:

```
AdminConfig show $deployedObject warClassLoaderPolicy
```

Example output:

```
{warClassLoaderPolicy MULTIPLE}
```
    - Using Jython:

```
AdminConfig.show(deployedObject, 'warClassLoaderPolicy')
```

Example output:

```
'[warClassLoaderPolicy MULTIPLE]'
```
  4. Modify the attributes of the configuration object with the **modify** command, for example:
    - Using Jacl:

```
AdminConfig modify $deployedObject {{warClassLoaderPolicy SINGLE}}
```
    - Using Jython:

```
AdminConfig.modify(deployedObject, [['warClassLoaderPolicy', 'SINGLE']])
```
  5. Verify the changes that you made to the attribute value with the **show** command, for example:
    - Using Jacl:

```
AdminConfig show $deployedObject warClassLoaderPolicy
```

Example output:

```
{warClassLoaderPolicy SINGLE}
```
    - Using Jython:

```
AdminConfig.show(deployedObject, 'warClassLoaderPolicy')
```

Example output:

```
'[warClassLoaderPolicy SINGLE]'
```

## Modifying class loader modes for applications using scripting

You can modify class loader modes for an application with scripting and the `wsadmin` tool.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

To modify class loader modes for an application, perform the following steps:

1. Retrieve the configuration ID of the object that you want to modify and set it to the `dep` variable. For example:
  - Using Jacl:

```
set dep [AdminConfig getid /Deployment:ivtApp/]
```
  - Using Jython:

```
dep = AdminConfig.getid('/Deployment:ivtApp/')
```
2. Identify the deployed object and set it to the `depObject` variable. For example:
  - Using Jacl:

- ```
set depObject [$AdminConfig showAttribute $dep deployedObject]
```
- Using Jython:

```
depObject = AdminConfig.showAttribute(dep, 'deployedObject')
```
3. Identify the class loader and set it to the classldr variable. For example:
    - Using Jacl:

```
set classldr [$AdminConfig showAttribute $depObject classloader]
```
    - Using Jython:

```
classldr = AdminConfig.showAttribute(depObject, 'classloader')
```
  4. Show the current attribute values of the configuration object with the **showall** command, for example:
    - Using Jacl:

```
$AdminConfig showall $classldr
```

Example output:

```
{libraries {}} {mode PARENT_FIRST}
```
    - Using Jython:

```
print AdminConfig.showall(classldr)
```

Example output:

```
[libraries []] [mode PARENT_FIRST]
```
  5. Modify the attributes of the configuration object with the **modify** command, for example:
    - Using Jacl:

```
$AdminConfig modify $classldr {{mode PARENT_LAST}}
```
    - Using Jython:

```
AdminConfig.modify(classldr, [['mode', 'PARENT_LAST']])
```
  6. Verify the changes that you made to the attribute value with the **showall** command, for example:
    - Using Jacl:

```
$AdminConfig showall $classldr
```

Example output:

```
{libraries {}} {mode PARENT_LAST}
```
    - Using Jython:

```
AdminConfig.showall(classldr)
```

Example output:

```
[libraries []] [mode PARENT_LAST]
```

## Modifying the starting weight of applications using scripting

You can use the wsadmin tool and scripting to modify the starting weight of an application.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

To modify the starting weight of an application, perform the following steps:

1. Retrieve the configuration ID of the object that you want to modify and set it to the dep variable. For example:
  - Using Jacl:

```
set dep [$AdminConfig getid /Deployment:MyApp/]
```
  - Using Jython:

```
dep = AdminConfig.getid("/Deployment:MyApp/")
```
2. Identify the deployed object and set it to the depObject variable. For example:
  - Using Jacl:

- ```
set depObject [$AdminConfig showAttribute $dep deployedObject]
```
- Using Jython:
 

```
depObject = AdminConfig.showAttribute(dep, "deployedObject")
```
3. Show the current attribute values of the configuration object with the **show** command, for example:
    - Using Jacl:
 

```
$AdminConfig show $depObject startingWeight
```

 Example output:
 

```
{startingWeight 1}
```
    - Using Jython:
 

```
AdminConfig.show(depObject, 'startingWeight')
```

 Example output:
 

```
[startingWeight 1]
```
  4. Modify the attributes of the configuration object with the **modify** command, for example:
    - Using Jacl:
 

```
$AdminConfig modify $depObject {{startingWeight 2}}
```
    - Using Jython:
 

```
AdminConfig.modify(depObject, [['startingWeight', '2']])
```
  5. Verify the changes that you made to the attribute value with the **show** command, for example:
    - Using Jacl:
 

```
$AdminConfig show $depObject startingWeight
```

 Example output:
 

```
{startingWeight 2}
```
    - Using Jython:
 

```
AdminConfig.show(depObject, 'startingWeight')
```

 Example output:
 

```
[startingWeight 2]
```

## Commands for the WSScheduleCommands group of the AdminTask object

Use the commands in the WSScheduleCommands group to create or delete a schedule. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSScheduleCommands group of the AdminTask object:

Table 1.

| Command name:    | Description:                                                                                    | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createWSSchedule | <p>The <b>createWSSchedule</b> command creates the scheduler settings in the configuration.</p> | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name that uniquely identifies the scheduler. (String, required)</li> <li>- <b>frequency</b><br/>The period of time in days to wait before checking for expired certificates. (Integer, required)</li> <li>- <b>dayOfWeek</b><br/>The day of the week to check for expired certificates. (Integer, required)</li> <li>- <b>hour</b><br/>The hour of the day to check for expired certificates. (Integer, required)</li> <li>- <b>minute</b><br/>The minute to check for expired certificates. Use this parameter with the hour parameter. (Integer, required)</li> <li>- <b>nextStartDate</b><br/>The next time, in seconds, to check for expired certificate. (Long, optional)</li> </ul> </li> <li>• Returns: The configuration object name of the scheduler object that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:               <pre>\$AdminTask createWSSchedule { -name testSchedule -frequency 30 -hour 1 -minute 30 }</pre> </li> <li>• Using Jython string:               <pre>AdminTask.createWSSchedule (['-name testSchedule -frequency 30 -hour 1 -minute 30']')</pre> </li> <li>• Using Jython list:               <pre>AdminTask.createWSSchedule (['-name', 'testSchedule', '-frequency', '30', '-hour', '1', '-minute', '30'])</pre> </li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:               <pre>\$AdminTask createWSSchedule {-interactive}</pre> </li> <li>• Using Jython string:               <pre>AdminTask.createWSSchedule (['-interactive']')</pre> </li> <li>• Using Jython list:               <pre>AdminTask.createWSSchedule (['-interactive'])</pre> </li> </ul> |

Table 1. (continued)

| Command name:    | Description:                                                                                           | Parameters and return values:                                                                                                                                                                                                                                                  | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

(Integer, optional)</li> <li>- <b>hour</b><br/>The hour of the day to check for expired certificates. (Integer, optional)</li> <li>- <b>minute</b><br/>The minute to check for expired certificates. Use this parameter with the hour parameter. (Integer, optional)</li> <li>- <b>nextStartDate</b><br/>The next time, in seconds, to check for expired certificate. (Long, optional)</li> </ul> <ul style="list-style-type: none"> <li>• Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask modifyWSSchedule {-name testSchedule -frequency 7}</code></li> <li>• Using Jython string:<br/><code>AdminTask.modifyWSSchedule ('[-name testSchedule -frequency 7]')</code></li> <li>• Using Jython list:<br/><code>AdminTask.modifyWSSchedule (['-name', 'testSchedule', '-frequency', '7'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask modifyWSSchedule {-interactive}</code></li> <li>• Using Jython string:<br/><code>AdminTask.modifyWSSchedule (['-interactive'])</code></li> <li>• Using Jython list:<br/><code>AdminTask.modifyWSSchedule (['-interactive'])</code></li> </ul> |

## Commands for the WSNotifierCommands group of the AdminTask object

Use the commands in the WSNotifierCommands group to create or delete a notification. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSNotifierCommands group of the AdminTask object:

Table 2.

| Command name:    | Description:                                                                                                                                                       | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createWSNotifier | <p>The <b>createWSNotifier</b> command creates the notification settings in the configuration. Use this command to notify users when certificates are expired.</p> | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name that uniquely identifies the notification configuration. (String, required)</li> <li>- <b>logToSystemOut</b><br/>Set the value of this parameter to true if you want the certificate expiration information to log to system out. If not, set the value of this parameter to false. (Boolean, required)</li> <li>- <b>sendEmail</b><br/>Set the value of this parameter to true if you want to e-mail the certificate expiration information. If not, set the value of this parameter to false. (Boolean, required)</li> <li>- <b>emailList</b><br/>The list of e-mail addresses where you want to send certificate expiration information. Separate the values in the list with colons (:). (String, optional)</li> </ul> </li> <li>• Returns: The configuration object name of the notification object that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:           <pre>\$AdminTask createWSNotifier { -name testNotifier -logToSystemOut true -sendEmail false}</pre> </li> <li>• Using Jython string:           <pre>AdminTask.createWSNotifier ('[-name testNotifier -logToSystemOut true -sendEmail false]')</pre> </li> <li>• Using Jython list:           <pre>AdminTask.createWSNotifier (['-name', 'testNotifier', '-logToSystemOut', 'true', '-sendEmail', 'false'])</pre> </li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:           <pre>\$AdminTask createWSNotifier {-interactive}</pre> </li> <li>• Using Jython string:           <pre>AdminTask.createWSNotifier ('[-interactive]')</pre> </li> <li>• Using Jython list:           <pre>AdminTask.createWSNotifier (['-interactive'])</pre> </li> </ul> |

Table 2. (continued)

| Command name:    | Description:                                                                                       | Parameters and return values:                                                                                                                                                                                                                                                                                                  | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Commands for the WSGateway group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSGateway group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|               |              |                |                               |           |

|                                       |                                                                                                                                                                                                 |                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>addWSGW<br/>Target<br/>Service</p> | <p>The <b>addWSGW Target Service</b> command adds a target to a gateway service. You must specify the <code>targetService</code> parameter or the <code>targetDestination</code> parameter.</p> | <p>Object name of the GatewayService object</p> | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li><b>name</b><br/>The administrative name of the target service. (Required)</li> <li><b>targetDestination</b><br/>The name of the target destination. This can be within the same bus as the gateway destination or in a different bus. If the target destination is not within the same bus as the gateway destination, you must also specify the <code>targetBus</code> parameter. You must either specify the <code>targetDestination</code> parameter or the <code>targetService</code> parameter. (Conditional)</li> <li><b>targetService</b><br/>The name of the target outbound service. You must either specify the <code>targetDestination</code> parameter or the <code>targetService</code> parameter. (Conditional)</li> <li><b>targetBus</b><br/>The name of the WPM bus that contains the target. ## Commands for the CoreGroupManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the CoreGroupManagement group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                  |                                                                                                                                                                              |      |                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createCore Group | The <b>createCore Group</b> command creates a new core group. The core group that you create contains no members.                                                            | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>coreGroupName</b><br/>The name of the core group that you are creating. (String required)</li> </ul> </li> <li>Returns: None</li> </ul>         | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask createCoreGroup {-coreGroupName <i>MyCoreGroup</i>}</li> <li>Using Jython string:<br/>AdminTask.createCoreGroup ('[-coreGroupName <i>MyCoreGroup</i>']')</li> <li>Using Jython list:<br/>AdminTask.createCoreGroup (['-coreGroupName', '<i>MyCoreGroup</i>'])</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask createCoreGroup {-interactive}</li> <li>Using Jython string:<br/>AdminTask.createCoreGroup ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.createCoreGroup (['-interactive'])</li> </ul> |
| deleteCore Group | The <b>delete Core Group</b> command deletes an existing core group. The core group that you specify must not contain any members. You cannot delete the default core group. | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>coreGroupName</b><br/>The name of the existing core group that will be deleted. (String required)</li> </ul> </li> <li>Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask deleteCoreGroup {-coreGroupName <i>MyCoreGroup</i>}</li> <li>Using Jython string:<br/>AdminTask.deleteCoreGroup ('[-coreGroupName <i>MyCoreGroup</i>']')</li> <li>Using Jython list:<br/>AdminTask.deleteCoreGroup (['-coreGroupName', '<i>MyCoreGroup</i>'])</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask deleteCoreGroup {-interactive}</li> <li>Using Jython string:<br/>AdminTask.deleteCoreGroup ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.deleteCoreGroup (['-interactive'])</li> </ul> |

|                               |                                                                                                                                  |             |                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Commands for the CoreGroupBridgeManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the CoreGroupBridgeManagement group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                                   |                                                                                                                                                                                                                                                                                       |                                                                                |                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Configuring servers with scripting

You can configure servers using the wsadmin tool and scripting.

This topic contains the following tasks:

- “Creating a server using scripting”
- “Configuring the Java virtual machine using scripting” on page 194
- “Configuring enterprise bean containers using scripting” on page 195
- “Configuring a Performance Manager Infrastructure service using scripting” on page 199
- “Configuring an ORB service using scripting” on page 202
- “Configuring processes using scripting” on page 204
- “Configuring transaction properties for a server using scripting” on page 205
- “Setting port numbers kept in the serverindex.xml file using scripting” on page 207
- “Disabling components using scripting” on page 213
- “Disabling services using scripting” on page 214
- “Dynamic caching with scripting” on page 215
- “Modifying variables using scripting” on page 215
- “Increasing the Java virtual machine heap size using scripting” on page 216

## Creating a server using scripting

You can use scripting to create an application server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Creating an application server involves a configuration command. Perform the following steps to create a server:

1. Obtain the configuration ID of the object and assign it to the *mynode* variable, for example:

Using Jacl:

```
set node [$AdminConfig getid /Node:mynode/]
```

Using Jython:

```
node = AdminConfig.getid('/Node:mynode/')
```

2. There are two ways to create the server using the node that you specified in the first step. Perform one of the following:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask createApplicationServer mynode  
{-name test1 -templateName default}
```

- Using Jython:

```
AdminTask.createApplicationServer(mynode,  
[-name, 'test1', -templateName, 'default'])
```

- Using the AdminConfig object:

- Using Jacl:

```
$AdminConfig create Server $node {{name myserv}  
{outputStreamRedirect {{fileName myfile.out}}}}
```

- Using Jython:

```
AdminConfig.create('Server', node, [['name', 'myserv'],  
['outputStreamRedirect', [['fileName', 'myfile.out']]])
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring the Java virtual machine using scripting

Use scripting to configure settings for a Java virtual machine.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

To modify the Java virtual machine (JVM) of a server to turn on debug, perform the following steps:

1. There are two ways to perform this task. Choose one of the following:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask setJVMDebugMode {-serverName server1 -nodeName node1 -debugMode true}
```

- Using Jython:

```
AdminTask.setJVMDebugMode ([-serverName, 'server1', -nodeName, 'node1', -debugMode, 'true'])
```

- Using the AdminConfig object:

- a. Identify the server and assign it to the server1 variable.

- Using Jacl:

```
set server1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
server1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print server1
```

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

b. Identify the JVM belonging to this server and assign it to the `jvm` variable.

– Using Jacl:

```
set jvm [$AdminConfig list JavaVirtualMachine $server1]
```

– Using Jython:

```
jvm = AdminConfig.list('JavaVirtualMachine', server1)
print jvm
```

c. Modify the JVM to turn on debugging.

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring enterprise bean containers using scripting

You can configure enterprise bean containers using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See “Starting the wsadmin scripting client” on page 134 for more information.

Perform the following steps to configure an enterprise bean container:

1. Identify the application server and assign it to the `serv1` variable. For example:

• Using Jacl:

```
set serv1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

• Using Jython:

```
serv1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print serv1
```

where:

|                                                       |                                                                          |

| <code>Cell</code>                                     | is the object type                                                       |
| <code>mycell</code>                                   | is the optional name of the object                                       |
| <code>Node</code>                                     | is the object type                                                       |
| <code>mynode</code>                                   | is the optional name of the object                                       |
| <code>Server</code>                                   | is the object type                                                       |
| <code>server1</code>                                  | is the optional name of the object                                       |

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the EJB container belonging to the server and assign it to the ejbc1 variable. For example:

- Using Jacl:
 

```
set ejbc1 [$AdminConfig list EJBContainer $serv1]
```
- Using Jython:
 

```
ejbc1 = AdminConfig.list('EJBContainer', serv1)
print ejbc1
```

where:

|              |                                                                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| set          | is a Jacl command                                                                                                                                                                                                  |
| ejbc1        | is a variable name                                                                                                                                                                                                 |
| \$           | is a Jacl operator for substituting a variable name with its value                                                                                                                                                 |
| AdminConfig  | is an object representing the WebSphere Application Server configuration                                                                                                                                           |
| list         | is an AdminConfig command                                                                                                                                                                                          |
| EJBContainer | is the object type<br><b>Note:</b> The name of the object type that you input here is the one based on the XML configuration files and does not have to be the same name that the administrative console displays. |
| serv1        | evaluates to the ID of the server specified in step number 1                                                                                                                                                       |

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)
```

3. View all the attributes of the enterprise bean container.

- The following example command does not show nested attributes:
  - Using Jacl:
 

```
$AdminConfig show $ejbc1
```

Example output:

```
{cacheSettings (cells/mycell/nodes/mynode/servers/
server1|server.xml#EJBCache_1)}
{components {}}
{inactivePoolCleanupInterval 30000}
{parentComponent (cells/mycell/nodes/mynode/servers/
server1|server.xml#ApplicationServer_1)
{passivationDirectory ${USER_INSTALL_ROOT}/temp}
{properties {}}
{services {(cells/mycell/nodes/mynode/servers/
server1|server.xml#MessageListenerService_1)}
{stateManagement (cells/mycell/nodes/mynode/servers/
server1|server.xml#StateManageable_10)}
```

– Using Jython:

```
print AdminConfig.show(ejbc1)
```

Example output:

```
[cacheSettings (cells/mycell/nodes/myode/servers/
server1|server.xml#EJBCache_1)]
[components []]
[inactivePoolCleanupInterval 30000]
[parentComponent (cells/mycell/nodes/myode/servers/
server1|server.xml#ApplicationServer_1)
[passivationDirectory ${USER_INSTALL_ROOT}/temp]
[properties []]
```

```
[services [(cells/mycell/nodes/myode/servers/
server1|server.xml#MessageListenerService_1)]
[stateManagement (cells/mycell/nodes/mynode/servers/
server1|server.xml#StateManageable_10)]
```

where:

|             |                                                                                 |
|-------------|---------------------------------------------------------------------------------|
| \$          | is a Jacl operator for substituting a variable name with its value              |
| print       | is a Jython command                                                             |
| AdminConfig | is an object representing the WebSphere Application Server configuration        |
| showall     | is an AdminConfig command                                                       |
| ejbc1       | evaluates to the ID of the enterprise bean container specified in step number 2 |

- The following command example includes nested attributes:

– Using Jacl:

```
$AdminConfig showall $ejbc1
```

Example output:

```
{cacheSettings {{cacheSize 2053}
{cleanupInterval 3000}}}
{components {}}
{inactivePoolCleanupInterval 30000}
{parentComponent (cells/mycell/nodes/mynode/servers/
server1|server.xml#ApplicationServer_1)}
{passivationDirectory ${USER_INSTALL_ROOT}/temp}
{properties {}}
{services {{{context (cells/mycell/nodes/mynode/servers/
server1|server.xml#EJBContainer_1)}
{listenerPorts {}}
{properties {}}
{threadPool {{inactivityTimeout 3500}
{isGrowable false}
{maximumSize 50}
{minimumSize 10}}}}}
{stateManagement {{initialState START}
{managedObject (cells/mycell/nodes/mynode/servers/
server1|server.xml#EJBContainer_1)}}}
```

– Using Jython:

```
print AdminConfig.showall(ejbc1)
```

Example output:

```
[cacheSettings [[cacheSize 2053]
[cleanupInterval 3000]]]
[components []]
[inactivePoolCleanupInterval 30000]
[parentComponent (cells/mycell/nodes/mynode/servers/
server1|server.xml#ApplicationServer_1)]
[passivationDirectory ${USER_INSTALL_ROOT}/temp]
[properties []]
[services [[[context (cells/mycell/nodes/mynode/servers/
server1|server.xml#EJBContainer_1)]
[listenerPorts []]
[properties []]
[threadPool [[inactivityTimeout 3500]
[isGrowable false]
[maximumSize 50]
```

```

    [minimumSize 10]]]]]]
[stateManagement {{initialState START]
  [managedObject (cells/mycell/nodes/mynode/servers/
server1|server.xml#EJBContainer_1)]]]

```

where:

|             |                                                                                 |
|-------------|---------------------------------------------------------------------------------|
| \$          | is a Jacl operator for substituting a variable name with its value              |
| print       | is a Jython command                                                             |
| AdminConfig | is an object representing the WebSphere Application Server configuration        |
| showall     | is an AdminConfig command                                                       |
| ejbc1       | evaluates to the ID of the enterprise bean container specified in step number 2 |

#### 4. Modify the attributes.

- The following example modifies the enterprise bean cache settings and it includes nested attributes:

- Using Jacl:

```

$AdminConfig modify $ejbc1 {{cacheSettings
  {{cacheSize 2500} {cleanupInterval 3500}}}

```

- Using Jython:

```

AdminConfig.modify(ejbc1, [['cacheSettings',
  [['cacheSize', 2500], ['cleanupInterval', 3500]]])

```

where:

|                 |                                                                                 |
|-----------------|---------------------------------------------------------------------------------|
| \$              | is a Jacl operator for substituting a variable name with its value              |
| AdminConfig     | is an object representing the WebSphere Application Server configuration        |
| modify          | is an AdminConfig command                                                       |
| ejbc1           | evaluates to the ID of the enterprise bean container specified in step number 2 |
| cacheSettings   | is an attribute of modify objects                                               |
| cacheSize       | is an attribute of modify objects                                               |
| 2500            | is the value of the cacheSize attribute                                         |
| cleanupInterval | is an attribute of modify objects                                               |
| 3500            | is the value of the cleanupInterval attribute                                   |

- The following example modifies the cleanup interval attribute:

- Using Jacl:

```

$AdminConfig modify $ejbc1 {{inactivePoolCleanupInterval 15000}}

```

- Using Jython:

```

AdminConfig.modify(ejbc1, [['inactivePoolCleanupInterval', 15000]])

```

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |

|                             |                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------|
| modify                      | is an AdminConfig command                                                       |
| ejbc1                       | evaluates to the ID of the enterprise bean container specified in step number 2 |
| inactivePoolCleanupInterval | is an attribute of modify objects                                               |
| 15000                       | is the value of the inactivePoolCleanupInterval attribute                       |

5. Save the changes. For example:

- Using Jacl:  
\$AdminConfig save
- Using Jython:  
AdminConfig.save()

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |
| save        | is an AdminConfig command                                                |

## Configuring a Performance Manager Infrastructure service using scripting

You can use scripting to configure a Performance Manager Infrastructure service.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the following steps to configure the Performance Manager Infrastructure (PMI) service for an application server:

1. Identify the application server and assign it to the s1 variable, for example:

- Using Jacl:  
set s1 [\$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
- Using Jython:  
s1 = AdminConfig.getid('Cell:mycell/Node:mynode/Server:server1/')

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| set         | is a Jacl command                                                        |
| s1          | is a variable name                                                       |
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |
| getid       | is an AdminConfig command                                                |
| Cell        | is an attribute                                                          |
| mycell      | is the value of the Cell attribute                                       |
| Node        | is an attribute                                                          |
| mynode      | is the value of the Node attribute                                       |
| Server      | is an attribute                                                          |

|                      |                                      |
|----------------------|--------------------------------------|
| <code>server1</code> | is the value of the Server attribute |
|----------------------|--------------------------------------|

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the PMI service that belongs to the server and assign it to the `pmi` variable, for example:

- Using Jacl:

```
set pmi [$AdminConfig list PMIService $s1]
```

- Using Jython:

```
pmi = AdminConfig.list('PMIService', s1)
print pmi
```

where:

|                          |                                                                          |
|--------------------------|--------------------------------------------------------------------------|
| <code>set</code>         | is a Jacl command                                                        |
| <code>pmi</code>         | is a variable name                                                       |
| <code>\$</code>          | is a Jacl operator for substituting a variable name with its value       |
| <code>AdminConfig</code> | is an object representing the WebSphere Application Server configuration |
| <code>list</code>        | is an AdminConfig command                                                |
| <code>PMIService</code>  | is an AdminConfig object                                                 |
| <code>s1</code>          | evaluates to the ID of the application server specified in step number 1 |

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#PMIService_1)
```

3. Modify the attributes, for example:

- Using Jacl:

```
$AdminConfig modify $pmi {{enable true}
{initialSpecLevel beanModule=H:cacheModule=H:connectionPoolModule=
H:j2cModule=H:jvmRuntimeModule=H:orbPerfModule=H:servletSessionsModule=
H:systemModule=H:threadPoolModule=H:transactionModule=H:
webAppModule=H:webServicesModule=H:wlmModule=H:wsgwModule=H}}
```

- Using Jython:

```
AdminConfig.modify(pmi, [['enable', 'true'],
['initialSpecLevel', 'beanModule=H:cacheModule=H:connectionPoolModule=
H:j2cModule=H:jvmRuntimeModule=H:orbPerfModule=H:servletSessionsModule=
H:systemModule=H:threadPoolModule=H:transactionModule=H:webAppModule=H:
webServicesModule=H:wlmModule=H:wsgwModule=H']])
```

This example enables PMI service and sets the specification levels for all of components in the server. The following are the valid specification levels for the components:

|          |                           |
|----------|---------------------------|
| <b>N</b> | represents <b>none</b>    |
| <b>L</b> | represents <b>low</b>     |
| <b>M</b> | represents <b>medium</b>  |
| <b>H</b> | represents <b>high</b>    |
| <b>X</b> | represents <b>maximum</b> |

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Limiting the growth of Java virtual machine log files using scripting

You can use scripting to configure the size of Java virtual machine log files.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the following example to configure the rotation policy settings for Java virtual machine (JVM) logs:

1. Identify the application server and assign it to the server1 variable, for example:

- Using Jacl:

```
set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')  
print s1
```

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| set         | is a Jacl command                                                        |
| s1          | is a variable name                                                       |
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |
| getid       | is an AdminConfig command                                                |
| Cell        | is the object type                                                       |
| mycell      | is the name of the object that will be modified                          |
| Node        | is the object type                                                       |
| mynode      | is the name of the object that will be modified                          |
| Server      | is the object type                                                       |
| server1     | is the name of the object that will be modified                          |
| print       | a Jython command                                                         |

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the stream log and assign it to the log variable, for example:

- The following example identifies the output stream log:

- Using Jacl:

```
set log [$AdminConfig showAttribute $s1 outputStreamRedirect]
```

- Using Jython:

```
log = AdminConfig.showAttribute(s1, 'outputStreamRedirect')
```

- The following example identifies the error stream log:

- Using Jacl:

```
set log [$AdminConfig showAttribute $s1 errorStreamRedirect]
```

- Using Jython:

```
log = AdminConfig.showAttribute(s1, 'errorStreamRedirect')
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#StreamRedirect_2)
```

3. List the current values of the stream log, for example:

- Using Jacl:

```
$AdminConfig show $log
```

- Using Jython:

```
AdminConfig.show(log)
```

Example output:

```
{baseHour 24}
{fileName ${SERVER_LOG_ROOT}/SystemOut.log}
{formatWrites true}
{maxNumberOfBackupFiles 1}
{messageFormatKind BASIC}
{rolloverPeriod 24}
{rolloverSize 1}
{rolloverType SIZE}
{suppressStackTrace false}
{suppressWrites false}
```

#### 4. Modify the rotation policy for the stream log.

- The following example sets the rotation log file size to two megabytes:

- Using Jacl:

```
$AdminConfig modify $log {{rolloverSize 2}}
```

- Using Jython:

```
AdminConfig.modify(log, ['rolloverSize', 2])
```

- The following example sets the rotation policy to manage itself. It is based on the age of the file with the rollover algorithm loaded at midnight, and the log file rolling over every 12 hours:

- Using Jacl:

```
$AdminConfig modify $log {{rolloverType TIME}
{rolloverPeriod 12} {baseHour 24}}
```

- Using Jython:

```
AdminConfig.modify(log, [['rolloverType', 'TIME']
['rolloverPeriod', 12] ['baseHour', 24]])
```

- The following example sets the log file to roll over based on both time and size:

- Using Jacl:

```
$AdminConfig modify $log {{rolloverType BOTH} {rolloverSize 2}
{rolloverPeriod 12} {baseHour 24}}
```

- Using Jython:

```
AdminConfig.modify(log, [['rolloverType', 'BOTH'] ['rolloverSize', 2]
['rolloverPeriod', 12] ['baseHour', 24]])
```

#### 5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

#### 6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring an ORB service using scripting

You can use scripting to configure an ORB service.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to modify the Object Request Broker (ORB) service for an application server:

#### 1. Identify the application server and assign it to the server variable:

- Using Jacl:

```
set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print s1
```

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| set         | is a Jacl command                                                        |
| s1          | is a variable name                                                       |
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |
| getid       | is an AdminConfig command                                                |
| Cell        | is the object type                                                       |
| mycell      | is the name of the object that will be modified                          |
| Node        | is the object type                                                       |
| mynode      | is the name of the object that will be modified                          |
| Server      | is the object type                                                       |
| server1     | is the name of the object that will be modified                          |
| print       | a Jython command                                                         |

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the ORB belonging to the server and assign it to the orb variable:

- Using Jacl:

```
set orb [$AdminConfig list ObjectRequestBroker $s1]
```

- Using Jython:

```
orb = AdminConfig.list('ObjectRequestBroker', s1)
print orb
```

where:

|                     |                                                                          |
|---------------------|--------------------------------------------------------------------------|
| set                 | is a Jacl command                                                        |
| orb                 | is a variable name                                                       |
| \$                  | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig         | is an object representing the WebSphere Application Server configuration |
| list                | is an AdminConfig command                                                |
| ObjectRequestBroker | is an AdminConfig object                                                 |
| s1                  | evaluates to the ID of server specified in step number 1                 |
| print               | a Jython command                                                         |

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#ObjectRequestBroker_1)
```

3. Modify the attributes. The following example modifies the connection cache maximum and pass by value attributes. You can modify the example to change the value of other attributes.

- Using Jacl:

```
$AdminConfig modify $orb {{connectionCacheMaximum 252} {noLocalCopies true}}
```

- Using Jython:

```
AdminConfig.modify(orb, [['connectionCacheMaximum', 252], ['noLocalCopies', 'true']])
```

where:

|                        |                                                                          |
|------------------------|--------------------------------------------------------------------------|
| \$                     | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig            | is an object representing the WebSphere Application Server configuration |
| modify                 | is an AdminConfig command                                                |
| orb                    | evaluates to the ID of ORB specified in step number 2                    |
| connectionCacheMaximum | is an attribute                                                          |
| 252                    | is the value of the connectionCacheMaximum attribute                     |
| noLocalCopies          | is an attribute                                                          |
| true                   | is the value of the noLocalCopies attribute                              |

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring processes using scripting

You can use scripting and the wsadmin tool to configure processes.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure a process:

1. There are two ways to perform this task. Choose one of the following:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask setProcessDefinition {-interactive}
```

- Using Jython:

```
AdminTask.setProcessDefinition (['-interactive'])
```

- Using the AdminConfig object:

- a. Identify the server and assign it to the s1 variable. For example:

- Using Jacl:

```
set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
s1 = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')  
print s1
```

where:

|             |                                                                          |
|-------------|--------------------------------------------------------------------------|
| set         | is a Jacl command                                                        |
| s1          | is a variable name                                                       |
| \$          | is a Jacl operator for substituting a variable name with its value       |
| AdminConfig | is an object representing the WebSphere Application Server configuration |
| getid       | is an AdminConfig command                                                |
| Cell        | is the object type                                                       |

|                |                                                 |
|----------------|-------------------------------------------------|
| <i>mycell</i>  | is the name of the object that will be modified |
| Node           | is the object type                              |
| <i>mynode</i>  | is the name of the object that will be modified |
| Server         | is the object type                              |
| <i>server1</i> | is the name of the object that will be modified |
| print          | a Jython command                                |

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

- b. Identify the process definition belonging to this server and assign it to the processDef variable. For example:

- Using Jacl:
- Using Jython:

Example output:

- c. Change the attributes.

-

- Using Jacl:

```
$AdminConfig modify $processDef {{workingDirectory /home/myProfile/temp/user1}}
```

- Using Jython:

```
AdminConfig.modify(processDef, [['workingDirectory', '/home/myProfile/temp/user1']])
```

- The following example modifies the stderr file name:

- Using Jacl:

```
set errFile [list stderrFilename \${LOG_ROOT}/server1/new_stderr.log]
set attr [list $errFile]
$AdminConfig modify $processDef [subst {{ioRedirect ${attr}}}]
```

- Using Jython:

```
errFile = ['stderrFilename', '\${LOG_ROOT}/server1/new_stderr.log']
attr = [errFile]
AdminConfig.modify(processDef, [['ioRedirect', [attr]]])
```

- The following example modifies the process priority:

- Using Jacl:

```
$AdminConfig modify $processDef {{execution {{processPriority 15}}}}
```

- Using Jython:

```
AdminConfig.modify(processDef, [['execution', [['processPriority', 15]]])
```

- The following example changes the maximum startup attempts. You can modify this example to change other attributes in the process definition object.

- Using Jacl:

```
$AdminConfig modify $processDef {{monitoringPolicy {{maximumStartupAttempts 1}}}}
```

- Using Jython:

```
AdminConfig.modify(processDef, [['monitoringPolicy', [['maximumStartupAttempts', 1]]])
```

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Configuring transaction properties for a server using scripting

Use scripting to configure transaction properties for servers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to configure the runtime transaction properties for an application server.

1. Identify the transaction service MBean for the application server. The following command returns the transaction service MBean for *server1*.

- Using Jacl:

```
set ts [$AdminControl completeObjectName cell=mycell,node=mynode,process=server1,type=TransactionService,*]
```

- Using Jython:

```
ts = AdminControl.completeObjectName('cell=mycell,node=mynode,process=server1,type=TransactionService,*')
print ts
```

where:

|                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| set                                                                                        | is a Jacl command                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ts                                                                                         | is a variable name                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| \$                                                                                         | is a Jacl operator for substituting a variable name with its value                                                                                                                                                                                                                                                                                                                                                                                                                     |
| AdminControl                                                                               | is an object that enables the manipulation of MBeans running in a WebSphere server process                                                                                                                                                                                                                                                                                                                                                                                             |
| completeObjectName                                                                         | is an AdminControl command                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| cell= <i>mycell</i> ,node= <i>mynode</i> ,process= <i>server1</i> ,type=TransactionService | is a fragment of the object name whose complete name is returned by this command. It is used to find the matching object name which is, in this case, the transaction object MBean for the node <i>mynode</i> , where <i>mynode</i> is the name of the node that you use to synchronize configuration changes. For example: type=TransactionService, process=server1. It can be any valid combination of domain and key properties. For example, type, name, cell, node, process, etc. |

Example output:

```
WebSphere:cell=mycell,name=TransactionService,mbeanIdentifier=TransactionService,
type=TransactionService,node=mynode,process=server1
```

2. Modify the attributes.

- Using Jacl:

```
$AdminControl setAttributes $ts {{clientInactivityTimeout 30} {totalTranLifetimeTimeout 180}}
```

- Using Jython:

```
AdminControl.setAttributes(ts, [['clientInactivityTimeout', 30], ['totalTranLifetimeTimeout', 180]])
```

where:

|                          |                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| \$                       | is a Jacl operator for substituting a variable name with its value                                                             |
| AdminControl             | is an object that enables the manipulation of MBeans running in a WebSphere server process                                     |
| setAttributes            | is an AdminControl command                                                                                                     |
| ts                       | evaluates to the ID of the transaction service specified in step number 1                                                      |
| clientInactivityTimeout  | is an attribute                                                                                                                |
| 30                       | is the value of the clientInactivityTimeout attribute specified in seconds. A value of 0 means that there is no timeout limit. |
| totalTranLifetimeTimeout | is an attribute                                                                                                                |

## Setting port numbers kept in the serverindex.xml file using scripting

This topic provides reference information about modifying port numbers in the serverindex.xml file.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

The end points of the serverindex.xml file are part of different objects in the configuration.

Use the following attributes to modify the end point information of the end point attributes for a process:

- **BOOTSTRAP\_ADDRESS** of server1 process

An attribute of the NameServer object that exists inside the server. It is used by the naming client to specify the naming server to look up the initial context. Use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName mynode -endPointName BOOTSTRAP_ADDRESS
-host myhost -port 2810}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', '[-nodeName mynode -endPointName
BOOTSTRAP_ADDRESS -host myhost -port 2810]')
```

- Using the AdminConfig object. To modify its end point, obtain the ID of the NameServer object and issue a **modify** command.

- Using Jacl:

```
set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set ns [$AdminConfig list NameServer $s]
$AdminConfig modify $ns {{BOOTSTRAP_ADDRESS {{port 2810} {host myhost}}}}
```

- Using Jython:

```
s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
ns = AdminConfig.list('NameServer', s)
AdminConfig.modify(ns, [['BOOTSTRAP_ADDRESS', [['host', 'myhost'], ['port', 2810]]])
```

- **SOAP\_CONNECTOR\_ADDRESS** of server1 process

An attribute of the SOAPConnector object that exists inside the server. It is the port that is used by HTTP transport for incoming SOAP requests. Use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName mynode -endPointName SOAP_CONNECTOR_ADDRESS
-host myhost -port 8881}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', '[-nodeName mynode -endPointName SOAP_CONNECTOR_ADDRESS
-host myhost -port 8881]')
```

- Using the AdminConfig object. To modify its end point, obtain the ID of the SOAPConnector object and issue a **modify** command, for example:

- Using Jacl:

```
set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set soap [$AdminConfig list SOAPConnector $s]
$AdminConfig modify $soap {{SOAP_CONNECTOR_ADDRESS {{host myhost} {port 8881}}}}
```

- Using Jython:

```
s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
soap = AdminConfig.list('SOAPConnector', s)
AdminConfig.modify(soap, [['SOAP_CONNECTOR_ADDRESS', [['host', 'myhost'], ['port', 8881]]]])
```

- **DRS\_CLIENT\_ADDRESS** of server1 process

An attribute of the SystemMessageServer object that exists inside the server. It is the port used to configure the Data Replication Service (DRS) which is a JMS-based message broker system for dynamic caching. The DRS\_CLIENT\_ADDRESS attribute is not available if a replication domain and a replicator entry have not been added to the server. Use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName mynode -endPointName
DRS_CLIENT_ADDRESS -host myhost -port 7874}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', ['-nodeName mynode -endPointName
DRS_CLIENT_ADDRESS -host myhost -port 7874'])
```

- Using the AdminConfig object. To modify the end point of the DRS\_CLIENT\_ADDRESS attribute, obtain the ID of the SystemMessageServer object and issue a **modify** command, for example:

- Using Jacl:

```
set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set sms [$AdminConfig list SystemMessageServer $s]
$AdminConfig modify $sms {{DRS_CLIENT_ADDRESS {{host myhost} {port 7874}}}}
```

- Using Jython:

```
s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
sms = AdminConfig.list('SystemMessageServer', s)
AdminConfig.modify(sms, [['DRS_CLIENT_ADDRESS', [['host', 'myhost'], ['port', 7874]]]])
```

- **JMSERVER\_QUEUED\_ADDRESS** and **JMSERVER\_DIRECT\_ADDRESS** of server1 process

An attribute of the JMSServer object that exists inside the server. These are ports used to configure the WebSphere Application Server JMS provider topic connection factory settings. Use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName mynode -endPointName JMSSERVER_QUEUED_ADDRESS
-host myhost -port 5560}
```

```
$AdminTask modifyServerPort server1 {-nodeName mynode -endPointName JMSSERVER_DIRECT_ADDRESS
-host myhost -port 5561}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', ['-nodeName mynode -endPointName JMSSERVER_QUEUED_ADDRESS
-host myhost -port 5560'])
```

```
AdminTask.modifyServerPort ('server1', ['-nodeName mynode -endPointName JMSSERVER_DIRECT_ADDRESS
-host myhost -port 5561'])
```

- Using the AdminConfig object. To modify its end point, obtain the ID of the JMSServer object and issue a **modify** command, for example:

- Using Jacl:

```
set s [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set jmss [$AdminConfig list JMSServer $s]
$AdminConfig modify $jmss {{JMSSERVER_QUEUED_ADDRESS {{host myhost} {port 5560}}}}
$AdminConfig modify $jmss {{JMSSERVER_DIRECT_ADDRESS {{host myhost} {port 5561}}}}
```

- Using Jython:

```
s = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
jmss = AdminConfig.list('JMSServer', s)
AdminConfig.modify(jmss, [['JMSSERVER_QUEUED_ADDRESS', [['host', 'myhost'], ['port', 5560]]]])
AdminConfig.modify(jmss, [['JMSSERVER_DIRECT_ADDRESS', [['host', 'myhost'], ['port', 5561]]]])
```

- **NODE\_DISCOVERY\_ADDRESS** of nodeagent process An attribute of the NodeAgent object that exists inside the server. It is the port used to receive the incoming process discovery messages inside a node agent process. Use one of the following examples:
    - Using the AdminTask object:
      - Using Jacl:
 

```
$AdminTask modifyServerPort nodeagent {-nodeName mynode -endPointName
NODE_DISCOVERY_ADDRESS -host myhost -port 7272}
```
      - Using Jython:
 

```
AdminTask.modifyServerPort ('nodeagent', '[-nodeName mynode -endPointName
NODE_DISCOVERY_ADDRESS -host myhost -port 7272]')
```
    - Using the AdminConfig object. To modify its end point, obtain the ID of the NodeAgent object and issue a **modify** command, for example:
      - Using Jacl:
 

```
set nodeAgentServer [$AdminConfig getid /Cell:mycell/Node:mynode/Server:nodeagent/]
set nodeAgent [$AdminConfig list NodeAgent $nodeAgentServer]
$AdminConfig modify $nodeAgent {{NODE_DISCOVERY_ADDRESS {{host myhost} {port 7272}}}}
```
      - Using Jython:
 

```
nodeAgentServer = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:nodeagent/')
nodeAgent = AdminConfig.list('NodeAgent', nodeAgentServer)
AdminConfig.modify(nodeAgent, [['NODE_DISCOVERY_ADDRESS', [['host', 'myhost'], ['port', 7272]]])
```
    - Using Jacl:
 

```
set nodeAgentServer [$AdminConfig getid /Cell:mycell/Node:mynode/Server:nodeagent/]
set nodeAgent [$AdminConfig list NodeAgent $nodeAgentServer]
$AdminConfig modify $nodeAgent {{NODE_DISCOVERY_ADDRESS {{host myhost} {port 7272}}}}
```
    - Using Jython:
 

```
nodeAgentServer = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:nodeagent/')
nodeAgent = AdminConfig.list('NodeAgent', nodeAgentServer)
AdminConfig.modify(nodeAgent, [['NODE_DISCOVERY_ADDRESS', [['host', 'myhost'], ['port', 7272]]])
```
- **CELL\_DISCOVERY\_ADDRESS** of dmgr process An attribute of the deploymentManager object that exists inside the server. It is the port used to receive the incoming process discovery messages inside a deployment manager process. Use one of the following examples:
  - Using the AdminTask object:
    - Using Jacl:
 

```
$AdminTask modifyServerPort dmgr {-nodeName managernode -endPointName
CELL_MULTICAST_DISCOVERY_ADDRESS -host myhost -port 7272}
```

```
$AdminTask modifyServerPort dmgr {-nodeName managernode -endPointName
CELL_DISCOVERY_ADDRESS -host myhost -port 7278}
```
    - Using Jython:
 

```
AdminTask.modifyServerPort ('dmgr', '[-nodeName managernode -endPointName
CELL_MULTICAST_DISCOVERY_ADDRESS -host myhost -port 7272]')
```

```
AdminTask.modifyServerPort ('dmgr', '[-nodeName managernode -endPointName
CELL_DISCOVERY_ADDRESS -host myhost -port 7278]')
```
  - Using the AdminConfig object. To modify its end point, obtain the ID of the deploymentManager object and issue a **modify** command, for example:
    - Using Jacl:
 

```
set netmgr [$AdminConfig getid /Cell:mycell/Node:managernode/Server:dmgr/]
set deploymentManager [$AdminConfig list CellManager $netmgr]
$AdminConfig modify $deploymentManager {{CELL_MULTICAST_DISCOVERY_ADDRESS {{host myhost} {port 7272}}}}
$AdminConfig modify $deploymentManager {{CELL_DISCOVERY_ADDRESS {{host myhost} {port 7278}}}}
```
    - Using Jython:

```

netmgr = AdminConfig.getid('/Cell:mycell/Node:managernode/Server:dmgr/')
deploymentManager = AdminConfig.list('CellManager', netmgr)
AdminConfig.modify(deploymentManager, [['CELL_MULTICAST_DISCOVERY_ADDRESS', [['host', 'myhost'],
['port', 7272]]])
AdminConfig.modify(deploymentManager, [['CELL_DISCOVERY_ADDRESS', [['host', 'myhost'], ['port', 7278]]])

```

- **WC\_defaulthost** of server1 process To modify a WC\_defaulthost end point use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName myNode -endPointName WC_defaulthost -host myhost -port 5555}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', '[-nodeName myNode -endPointName WC_defaulthost -host myhost -port 5555]')
```

- Using the AdminConfig object:

- Using Jacl:

```

set serverName server1
set node [$AdminConfig getid /Node:myNode/]
set serverEntries [$AdminConfig list ServerEntry $node]

foreach serverEntry $serverEntries {
  set sName [$AdminConfig showAttribute $serverEntry serverName]
  if {$sName == $serverName} {
    set specialEndpoints [lindex [$AdminConfig showAttribute $serverEntry specialEndpoints] 0]
    foreach specialEndPoint $specialEndpoints {
      set endPointNm [$AdminConfig showAttribute $specialEndPoint endPointName]
      if {$endPointNm == "WC_defaulthost"} {
        set ePoint [$AdminConfig showAttribute $specialEndPoint endPoint]
        $AdminConfig modify $ePoint [list [list host myhost] [list port 5555]]
        break
      }
    }
  }
}

```

- Using Jython:

```

serverName = "server1"
node = AdminConfig.getid('/Node:myNode/')
serverEntries = AdminConfig.list('ServerEntry', node).split(java.lang.System.getProperty('line.separator'))

for serverEntry in serverEntries:
  sName = AdminConfig.showAttribute(serverEntry, "serverName")
  if sName == serverName:
    specialEndpoints = AdminConfig.showAttribute(serverEntry, "specialEndpoints")
    [1:len(specialEndpoints)-1].split(" ")
    for specialEndPoint in specialEndpoints:
      endPointNm = AdminConfig.showAttribute(specialEndPoint, "endPointName")
      if endPointNm == "WC_defaulthost":
        ePoint = AdminConfig.showAttribute(specialEndPoint, "endPoint")
        AdminConfig.modify(ePoint, [{"host", "myhost"}, {"port", 5555}])
        break

```

- **WC\_defaulthost\_secure** of server1 process To modify a WC\_defaulthost\_secure end point use one of the following examples:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask modifyServerPort server1 {-nodeName myNode -endPointName WC_defaulthost_secure -host myhost -port 5544}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', '[-nodeName myNode -endPointName WC_defaulthost_secure -host myhost -port 5544]')
```

- Using the AdminConfig object:

- Using Jacl:

```

set serverName server1
set node [AdminConfig getid /Node:myNode/]
set serverEntries [AdminConfig list ServerEntry $node]

foreach serverEntry $serverEntries {
  set sName [AdminConfig showAttribute $serverEntry serverName]
  if {$sName == $serverName} {
    set specialEndpoints [lindex [AdminConfig showAttribute $serverEntry specialEndpoints] 0]
    foreach specialEndPoint $specialEndpoints {
      set endPointNm [AdminConfig showAttribute $specialEndPoint endPointName]
      if {$endPointNm == "WC_defaulthost_secure"} {
        set ePoint [AdminConfig showAttribute $specialEndPoint endPoint]
        AdminConfig modify $ePoint [list [list host myhost] [list port 5544]]
        break
      }
    }
  }
}

```

- Using Jython:

```

serverName = "server1"
node = AdminConfig.getid('/Node:myNode/')
serverEntries = AdminConfig.list('ServerEntry', node).split(java.lang.System.getProperty('line.separator'))

for serverEntry in serverEntries:
  sName = AdminConfig.showAttribute(serverEntry, "serverName")
  if sName == serverName:
    specialEndpoints [AdminConfig.showAttribute(serverEntry, "specialEndpoints")
    [1:len(specialEndpoints)-1].split(" ")
    for specialEndPoint in specialEndpoints:
      endPointNm = AdminConfig.showAttribute(specialEndPoint, "endPointName")
      if endPointNm == "WC_defaulthost_secure":
        ePoint = AdminConfig.showAttribute(specialEndPoint, "endPoint")
        AdminConfig.modify(ePoint, [{"host", "myhost"}, {"port", 5544}])
        break

```

• **WC\_adminhost** of server1 process

To modify a WC\_adminhost end point use one of the following examples:

– Using the AdminTask object:

- Using Jacl:

```
AdminTask modifyServerPort server1 {-nodeName myNode -endPointName WC_adminhost -host myhost -port 6666}
```

- Using Jython:

```
AdminTask.modifyServerPort ('server1', '[-nodeName myNode -endPointName WC_adminhost -host myhost -port 6666]')
```

– Using the AdminConfig object:

- Using Jacl:

```

set serverName server1
set node [AdminConfig getid /Node:myNode/]
set serverEntries [AdminConfig list ServerEntry $node]

foreach serverEntry $serverEntries {
  set sName [AdminConfig showAttribute $serverEntry serverName]
  if {$sName == $serverName} {
    set specialEndpoints [lindex [AdminConfig showAttribute $serverEntry specialEndpoints] 0]
    foreach specialEndPoint $specialEndpoints {
      set endPointNm [AdminConfig showAttribute $specialEndPoint endPointName]
      if {$endPointNm == "WC_adminhost"} {
        set ePoint [AdminConfig showAttribute $specialEndPoint endPoint]
        AdminConfig modify $ePoint [list [list host myhost] [list port 6666]]
        break
      }
    }
  }
}

```

```

    }
  }
}

```

- Using Jython:

```

serverName = "server1"
node = AdminConfig.getid('/Node:myNode/')
serverEntries = AdminConfig.list('ServerEntry', node).split(java.lang.System.getProperty('line.separator'))

for serverEntry in serverEntries:
    sName = AdminConfig.showAttribute(serverEntry, "serverName")
    if sName == serverName:
        specialEndpoints [AdminConfig.showAttribute(serverEntry, "specialEndpoints")
        [1:len(specialEndpoints)-1].split(" ")
        for specialEndPoint in specialEndpoints:
            endPointNm = AdminConfig.showAttribute(specialEndPoint, "endPointName")
            if endPointNm == "WC_adminhost":
                ePoint = AdminConfig.showAttribute(specialEndPoint, "endPoint")
                AdminConfig.modify(ePoint, [{"host", "myhost"}, {"port", 6666}])
                break

```

• **WC\_adminhost\_secure** of server1 process

To modify a WC\_adminhost\_secure end point use one of the following examples:

– Using the AdminTask object:

- Using Jacl:

```

$AdminTask modifyServerPort server1 {-nodeName myNode -endPointName WC_adminhost_secure -host myhost -port 5566}

```

- Using Jython:

```

AdminTask.modifyServerPort ('server1', '[-nodeName myNode -endPointName WC_adminhost_secure
-host myhost -port 5566]')

```

– Using the AdminConfig object:

- Using Jacl:

```

set serverName server1
set node [$AdminConfig getid /Node:myNode/]
set serverEntries [$AdminConfig list ServerEntry $node]

foreach serverEntry $serverEntries {
    set sName [$AdminConfig showAttribute $serverEntry serverName]
    if {$sName == $serverName} {
        set specialEndpoints [lindex [$AdminConfig showAttribute $serverEntry specialEndpoints] 0]
        foreach specialEndPoint $specialEndpoints {
            set endPointNm [$AdminConfig showAttribute $specialEndPoint endPointName]
            if {$endPointNm == "WC_adminhost_secure"} {
                set ePoint [$AdminConfig showAttribute $specialEndPoint endPoint]
                $AdminConfig modify $ePoint [list [list host myhost] [list port 5566]]
                break
            }
        }
    }
}

```

- Using Jython:

```

serverName = "server1"
node = AdminConfig.getid('/Node:myNode/')
serverEntries = AdminConfig.list('ServerEntry', node).split(java.lang.System.getProperty('line.separator'))

for serverEntry in serverEntries:
    sName = AdminConfig.showAttribute(serverEntry, "serverName")
    if sName == serverName:
        specialEndpoints [AdminConfig.showAttribute(serverEntry, "specialEndpoints")
        [1:len(specialEndpoints)-1].split(" ")
        for specialEndPoint in specialEndpoints:
            endPointNm = AdminConfig.showAttribute(specialEndPoint, "endPointName")

```

```

if endPointNm == "WC_adminhost_secure":
    ePoint = AdminConfig.showAttribute(specialEndPoint, "endPoint")
    AdminConfig.modify(ePoint, [{"host", "myhost"}, {"port", 5566}])
break

```

- Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Disabling components using scripting

You can disable components with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to disable the name server component of a configured server. You can modify this example to disable a different component.

1. Identify the server component and assign it to the nameServer variable.

- Using Jacl:

```
set nameServer [$AdminConfig list NameServer $server]
```
- Using Jython:

```
nameServer = AdminConfig.list('NameServer', server)
print nameServer
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
```

2. List the components belonging to the server and assign them to the components variable.

- Using Jacl:

```
set components [$AdminConfig list Component $server]
```
- Using Jython:

```
components = AdminConfig.list('Component', server)
print components
```

The components variable contains a list of components.

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#ApplicationServer_1)
(cells/mycell/nodes/mynode/servers/server1|server.xml#EJBContainer_1)
(cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
(cells/mycell/nodes/mynode/servers/server1|server.xml#WebContainer_1)
```

3. Identify the name server component and assign it to the nameServer variable.

Since the name server component is the third element in the list, retrieve this element by using index 2.

- Using Jacl:

```
set nameServer [lindex $components 2]
```
- Using Jython:

```
# get line separator
import java
lineSeparator = java.lang.System.getProperty('line.separator')
arrayComponents = components.split(lineSeparator)
nameServer = arrayComponents[2]
print nameServer
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#NameServer_1)
```

4. Disable the name server component by changing the nested initialState attribute belonging to the stateManagement attribute. For example:

- Using Jacl:

```
$AdminConfig modify $nameServer {{stateManagement {{initialState STOP}}}}
```

- Using Jython:

```
AdminConfig.modify(nameServer, [['stateManagement', [['initialState', 'STOP']]])
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Disabling services using scripting

You can disable the services of a configured server with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to disable the trace service of a configured server. You can modify this example to disable a different service.

1. Identify the server and assign it to the server variable. For example:

- Using Jacl:

```
set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print server
```

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. List all the services belonging to the server and assign them to the services variable. The following example returns a list of services:

- Using Jacl:

```
set services [$AdminConfig list Service $server]
```

- Using Jython:

```
services = AdminConfig.list('Service', server)
print services
```

3. Identify the trace service and assign it to the traceService variable.

Since trace service is the 7th element in the list, retrieve this element by using index 6.

- Using Jacl:

```
set traceService [$AdminConfig list TraceService $server]
```

- Using Jython:

```
traceService = AdminConfig.list('TraceService', server)
print traceService
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#TraceService_1)
```

4. Disable the trace service by modifying the enable attribute. For example:

- Using Jacl:

```
$AdminConfig modify $traceService {{enable false}}
```

- Using Jython:

```
AdminConfig.modify(traceService, [['enable', 'false']])
```

5. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

6. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Dynamic caching with scripting

You can configure dynamic caching with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

**Important:** If you use the wsadmin tool to enable servlet caching, you must make sure that portlet fragment caching is also enabled. Similarly if you use the wsadmin tool to disable servlet caching, you must make sure that portlet fragment caching is also disabled. The settings for these two caching functions must stay synchronized. If you enable or disable servlet caching using the administrative console, synchronization is automatically taken care of for you.

To see a list of parameters associated with dynamic caching, use the **attributes** command. For example:

```
$AdminConfig attributes DynamicCache
```

Perform the following steps to enable servlet caching:

1. Locate the server object. The following example selects the first server found:

Using Jacl:

```
set s1 [$AdminConfig getid /Server:server1/]
```

Using Jython:

```
s1 = AdminConfig.getid('/Server:server1/')
```

2. List the web containers and assign them to the wc variable, for example:

Using Jacl:

```
set wc [$AdminConfig list WebContainer $s1]
```

Using Jython:

```
wc = AdminConfig.list('WebContainer', s1)
```

3. Set the enableServletCaching attribute to true and assign it to the serEnable variable, for example:

Using Jacl:

```
set serEnable "{enableServletCaching true}"
```

Using Jython:

```
serEnable = [['enableServletCaching', 'true']]
```

4. Enable caching, for example:

Using Jacl:

```
$AdminConfig modify $wc $serEnable
```

Using Jython:

```
AdminConfig.modify(wc, serEnable)
```

## Modifying variables using scripting

Use scripting and the wsadmin tool to modify variables in WebSphere Application Server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to modify a WebSphere Application Server variable:

1. There are two ways to perform this task. Choose one of the following:
  - Using the AdminTask object:
    - Using Jacl:

```
$AdminTask setVariable {-interactive}
```

- Using Jython:

```
AdminTask.setVariable (['-interactive'])
```

- Using the AdminConfig object. The following examples modify the DB2\_JDBC\_DRIVER\_PATH variable on the node level:

- Using Jacl:

```
set varName DB2_JDBC_DRIVER_PATH
set newVarValue C:/SQLLIB/java

set node [$AdminConfig getid /Node:myNode/]

set varSubstitutions [$AdminConfig list VariableSubstitutionEntry $node]

foreach varSubst $varSubstitutions {
  set getVarName [$AdminConfig showAttribute $varSubst symbolicName]
  if {[string compare $getVarName $varName] == 0} {
    AdminConfig modify $varSubst [list [list value $newVarValue]]
    break
  }
}
```

- Using Jython:

```
varName = "DB2_JDBC_DRIVER_PATH"
newVarValue = "C:/SQLLIB/java"

node = AdminConfig.getid("/Node:myNode/")

varSubstitutions = AdminConfig.list("VariableSubstitutionEntry",node).split
(java.lang.System.getProperty("line.separator"))

for varSubst in varSubstitutions:
  getVarName = AdminConfig.showAttribute(varSubst, "symbolicName")
  if getVarName == varName:
    AdminConfig.modify(varSubst, [["value", newVarValue]])
    break
```

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Increasing the Java virtual machine heap size using scripting

For some servers, it may be required to specify a Java virtual machine (JVM) heap size greater than the default. You can increase the heap size of the JVM using the administrative console, the wsadmin tool, or a Java client. If the JVM platform is 32-bit AIX and it is required that the application server, deployment manager, or node agent have a heap size greater, perform the following steps:

1. Set attributes that control the heap size for the JVM associated with the server. This can be done using the administrative console, the wsadmin tool, or a Java client.
2. Perform one of the following to increase the heap size of the JVM:
  - Create a script to launch the server. Use the `-script` option with the command that you are using to start the target server, for example, the **startServer**, **startManager**, or **startNode** commands. This will generate a script for that you can use to launch the target server in the future.
  - Manually set the environment variables before starting the target server with the **startServer**, **startManager**, or **startNode** commands. With the following settings, you can specify a maximum heap size for the JVM of 11 multiplied by 256 megabytes:

```
export IBM_JVM_LDR_CNTRL_NEW_VALUE=MAXDATA=0XB0000000@DSA
export LDR_CNTRL=MAXDATA=0XB0000000@DSA
```

- Use the AdminTask object. For example:

- Using Jacl:  
\$AdminTask setJVMMaxHeapSize {-interactive}

- Using Jython:  
AdminTask.setJVMMaxHeapSize ('[-interactive]')

For additional information on AIX address space management, view the following sources:

- IBM 32-bit SDK for AIX, Java 2 Technology Edition, Version 1.4 - User Guide
- Getting more memory in AIX for your Java applications

## Commands for the PortManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the PortManagement group of the AdminTask object:

| Command name:        | Description:                                                                                               | Target object:           | Parameters and return values:                                                                                                                                                                                                                                                                                                                   | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Commands for the VariableConfiguration group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the VariableConfiguration group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                 |                                                                                                                                                                                                       |      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                           |

## Configuring connections to Webservers with scripting

Use these topics to learn about configuring a connection to Webservers using scripting and the wsadmin tool.

This topic contains the following tasks:

- “Regenerating the node plug-in configuration using scripting” on page 222
- “Creating new virtual hosts using templates with scripting” on page 222

## Regenerating the node plug-in configuration using scripting

You can use scripting and the wsadmin tool to regenerate the node plug-in configuration.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to regenerate the node plug-in configuration:

1. Identify the plug-in and assign it to the generator variable, for example:

Using Jacl:

```
set generator [$AdminControl completeObjectName type=PluginCfgGenerator,node=mynode,*]
```

Using Jython:

```
generator = AdminControl.completeObjectName('type=PluginCfgGenerator,node=mynode,*')
```

2. Regenerate the node plug-in:

Using Jacl:

```
$AdminControl invoke $generator generate "profile_root  
/config mycell mynode myWebServer false"
```

Using Jython:

```
AdminControl.invoke(generator, 'generate', "profile_root  
/config mycell mynode myWebServer false")
```

## Creating new virtual hosts using templates with scripting

Use scripting to create a new virtual host from a new or preexisting template.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Some configuration object types have templates that you can use when you create a virtual host. You can create a new virtual host using a preexisting template or by creating a new custom template. Perform the following steps to create a new virtual host using a template:

1. If you want to create a new custom template, perform the following steps:
  - a. Copy and paste the following file into a new file, *myvirtualhostname.xml*:  
`app_server_root/config/templates/default/virtualhosts.xml`
  - b. Edit and customize the new *myvirtualhostname.xml* file.
  - c. Place the new file in the following directory:  
`app_server_root/config/templates/custom/`

If you want the new custom template to appear with the list of templates, restart the deployment manager on a network deployment edition, or use the AdminConfig object **reset** command. For example:

- Using Jacl:

```
$AdminConfig reset
```

- Using Jython:

```
AdminConfig.reset()
```

The administrative console does not support the use of custom templates. The new template that you create will not be visible in the administrative console panels.

2. Use the AdminConfig object **listTemplates** command to list available templates, for example:

- Using Jacl:

```
$AdminConfig listTemplates VirtualHost
```

- Using Jython:

```
print AdminConfig.listTemplates('VirtualHost')
```

Example output:

```
default_host(templates/default:virtualhosts.xml#VirtualHost_1)
my_host(templates/custom:virtualhostname.xml#VirtualHost_1)
```

3. Create a new virtual host. For example:

- Using Jacl:

```
set cell [$AdminConfig getid /Cell:NetworkDeploymentCell/]
set vtempl [$AdminConfig listTemplates VirtualHost my_host]
$AdminConfig createUsingTemplate VirtualHost $cell {{name newVirHost}} $vtempl
```

- Using Jython:

```
cell = AdminConfig.getid('/Cell:NetworkDeploymentCell/')
vtempl = AdminConfig.listTemplates('VirtualHost', 'my_host')
AdminConfig.createUsingTemplate('VirtualHost', cell, [['name', 'newVirHost']], vtempl)
```

4. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.

5. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

---

## Managing servers with scripting

Use these topics to learn about managing servers with scripting.

This topic contains the following tasks:

- “Stopping a node using scripting”
- “Starting servers using scripting” on page 224
- “Stopping servers using scripting” on page 225
- “Querying server state using scripting” on page 225
- “Listing running applications on running servers using scripting” on page 226
- “Starting listener ports using scripting” on page 228
- “Managing generic servers using scripting” on page 229
- “Setting development mode for server objects using scripting” on page 230
- “Disabling parallel startup using scripting” on page 230
- “Obtaining server version information with scripting” on page 231

## Stopping a node using scripting

Use scripting to stop a node agent.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Stopping the node agent on a remote machine process is an asynchronous action where the stop is initiated, and then control returns to the command line. Perform the following task to stop a node:

1. Identify the node that you want to stop and assign it to a variable:

Using Jacl:

```
set na [$AdminControl queryNames type=NodeAgent,node=mynode,*]
```

Using Jython:

```
na = AdminControl.queryNames('type=NodeAgent,node=mynode,*')
```

2. Stop the node:

Using Jacl:

```
$AdminControl invoke $na stopNode
```

Using Jython:

```
AdminControl.invoke(na, 'stopNode')
```

## Starting servers using scripting

You can use scripting and the wsadmin tool to start servers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the **startServer** command to start the server. This command has several syntax options. For example:

- To start a server on a WebSphere Application Server single server edition, choose one of the following options:

- The following examples specify the server name only:

Using Jacl:

```
$AdminControl startServer serverName
```

Using Jython:

```
AdminControl.startServer('serverName')
```

- The following example starts an application server with the node specified:

- Using Jacl:

```
$AdminControl startServer server1 mynode
```

- Using Jython:

```
print AdminControl.startServer('server1', 'mynode')
```

Example output:

```
WASX7319I: The serverStartupSyncEnabled attribute is set to false. A start  
will be attempted for server "server1" but the configuration information for  
node "mynode" may not be current.
```

```
WASX7262I: Start completed for server "server1" on node "mynode"
```

- The following example specify the server name and wait time:

- Using Jacl:

```
$AdminControl startServer serverName 10
```

- Using Jython:

```
AdminControl.startServer('serverName', 10)
```

where *10* is the number of seconds that the process should wait before starting the server.

- To start a server on a WebSphere Application Server network deployment edition, choose one of the following options:

- The following example specifies the server name and the node name:

- Using Jacl:

```
$AdminControl startServer serverName nodeName
```

- Using Jython:

```
AdminControl.startServer('serverName', 'nodeName')
```

- The following example specifies the server name, the node name, and the wait time:

- Using Jacl:

```
$AdminControl startServer serverName nodeName 10
```

- Using Jython:

```
AdminControl.startServer('serverName', 'nodeName', 10)
```

where *10* is the number of seconds that the process should wait before starting the server.

## Stopping servers using scripting

You can stop servers using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the **stopServer** command to stop the server. This command has several syntax options. For example:

- To stop a server on a WebSphere Application Server single server edition, choose one of the following options:

- The following examples specify the server name only:

Using Jacl:

```
$AdminControl stopServer serverName
```

Using Jython:

```
AdminControl.stopServer('serverName')
```

- The following examples stop an application server with the node specified:

- Using Jacl:

```
$AdminControl stopServer serverName mynode
```

- Using Jython:

```
print AdminControl.stopServer('serverName', 'mynode')
```

Example output:

```
WASX7337I: Invoked stop for server "serverName" Waiting for stop completion.
```

```
WASX7264I: Stop completed for server "serverName" on node "mynode"
```

- The following examples specify the server name and immediate:

- Using Jacl:

```
$AdminControl stopServer serverName immediate
```

- Using Jython:

```
AdminControl.stopServer('serverName', immediate)
```

- To stop a server on a WebSphere Application Server network deployment edition, choose one of the following options:

- The following example specifies the server name and the node name:

- Using Jacl:

```
$AdminControl stopServer serverName nodeName
```

- Using Jython:

```
AdminControl.stopServer('serverName', 'nodeName')
```

- The following example specifies the server name, the node name, and immediate:

- Using Jacl:

```
$AdminControl stopServer serverName nodeName immediate
```

- Using Jython:

```
AdminControl.stopServer('serverName', 'nodeName', immediate)
```

## Querying server state using scripting

You can use the wsadmin tool and scripting to query server states.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to query the server state:

1. Identify the server and assign it to the server variable. The following example returns the server MBean that matches the partial object name string:

- Using Jacl:

```
set server [$AdminControl completeObjectName cell=mycell,node=mynode,
name=server1,type=Server,*]
```

- Using Jython:

```
server = AdminControl.completeObjectName('cell=mycell,node=mynode,
name=server1,type=Server,*')
print server
```

Example output:

```
WebSphere:cell=mycell,name=server1,mbeanIdentifier=server.xml#Server_1,
type=Server,node=mynode,process=server1,processType=ManagedProcess
```

## 2. Query for the state attribute. For example:

- Using Jacl:

```
$AdminControl getAttribute $server state
```

- Using Jython:

```
print AdminControl.getAttribute(server, 'state')
```

The **getAttribute** command returns the value of a single attribute.

Example output:

```
STARTED
```

## Listing running applications on running servers using scripting

Use the wsadmin tool and scripting to list all the running applications on all the running servers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Use the following example to list all the running applications on all the running servers on each node of each cell:

- Using Jacl:

\*Provide this example as a Jacl script file and run it with the "-f" option:

```
1 #-----
2 # lines 4 and 5 find all the cell and process them one at a time
3 #-----
4 set cells [$AdminConfig list Cell]
5 foreach cell $cells {
6     #-----
7     # lines 10 and 11 find all the nodes belonging to the cell and
8     # process them at a time
9     #-----
10    set nodes [$AdminConfig list Node $cell]
11    foreach node $nodes {
12        #-----
13        # lines 16-20 find all the running servers belonging to the cell
14        # and node, and process them one at a time
15        #-----
16        set cname [$AdminConfig showAttribute $cell name]
17        set nname [$AdminConfig showAttribute $node name]
18        set servs [$AdminControl queryNames type=Server,cell=$cname,node=$nname,*]
19        puts "Number of running servers on node $nname: [length $servs]"
20        foreach server $servs {
21            #-----
22            # lines 25-31 get some attributes from the server to display;
23            # invoke an operation on the server JVM to display a property.
24            #-----
25            set sname [$AdminControl getAttribute $server name]
26            set ptype [$AdminControl getAttribute $server processType]
27            set pid [$AdminControl getAttribute $server pid]
28            set state [$AdminControl getAttribute $server state]
29            set jvm [$AdminControl queryNames type=JVM,cell=$cname,
```

```

node=$nname,process=$sname,*)
30     set osname [${AdminControl invoke $jvm getProperty os.name}]
31     puts " $sname ($ptype) has pid $pid; state: $state; on $osname"
32
33     #-----
34     # line 37-42 find the applications running on this server and
35     # display the application name.
36     #-----
37     set apps [${AdminControl queryNames type=Application,
cell=$cname,node=$nname,process=$sname,*}]
38     puts " Number of applications running on $sname: [llength $apps]"
39     foreach app $apps {
40         set aname [${AdminControl getAttribute $app name}]
41         puts " $aname"
42     }
43     puts "-----"
44     puts ""
45
46 }
47 }
48 }

```

- Using Jython:

\* Provide this example as a Jython script file and run it with the "-f" option:

```

1 #-----
2 # lines 7 and 8 find all the cell and process them one at a time
3 #-----
4 # get line separator
5 import java.lang.System as sys
6 lineSeparator = sys.getProperty('line.separator')
7 cells = AdminConfig.list('Cell').split(lineSeparator)
8 for cell in cells:
9     #-----
10    # lines 13 and 14 find all the nodes belonging to the cell and
11    # process them at a time
12    #-----
13    nodes = AdminConfig.list('Node', cell).split(lineSeparator)
14    for node in nodes:
15        #-----
16        # lines 19-23 find all the running servers belonging to the cell
17        # and node, and process them one at a time
18        #-----
19        cname = AdminConfig.showAttribute(cell, 'name')
20        nname = AdminConfig.showAttribute(node, 'name')
21        servs = AdminControl.queryNames('type=Server,cell=' + cname +
',node=' + nname + ',*').split(lineSeparator)
22        print "Number of running servers on node " +
nname + ": %s \n" % (len(servs))
23        for server in servs:
24            #-----
25            # lines 28-34 get some attributes from the server to display;
26            # invoke an operation on the server JVM to display a property.
27            #-----
28            sname = AdminControl.getAttribute(server, 'name')
29            ptype = AdminControl.getAttribute(server, 'processType')
30            pid = AdminControl.getAttribute(server, 'pid')
31            state = AdminControl.getAttribute(server, 'state')
32            jvm = AdminControl.queryNames('type=JVM,cell=' +
cname + ',node=' + nname + ',process=' + sname + ',*')
33            osname = AdminControl.invoke(jvm, 'getProperty', 'os.name')
34            print " " + sname + " " + ptype + " has pid " + pid +
"; state: " + state + "; on " +
osname + "\n"
35
36            #-----
37            # line 40-45 find the applications running on this server and

```

```

38     # display the application name.
39     #-----
40     apps = AdminControl.queryNames('type=Application,cell=' +
    Cname + ',node=' + nname + ',process=' + sname + ',*').
    split(lineSeparator)
41     print "Number of applications running on " + sname +
    ": %s \n" % (len(apps))
42     for app in apps:
43         aname = AdminControl.getAttribute(app, 'name')
44         print aname + "\n"
45     print "-----"
46     print "\n"

```

#### Example output:

```

Number of running servers on node mynode: 2
mynode (NodeAgent) has pid 3592; state: STARTED; on Windows 2000
Number of applications running on mynode: 0
-----

```

```

server1 (ManagedProcess) has pid 3972; state: STARTED; on Windows 2000
Number of applications running on server1: 0
-----

```

```

Number of running servers on node mynodeManager: 1
dmgr (DeploymentManager) has pid 3308; state: STARTED; on Windows 2000
Number of applications running on dmgr: 2
adminconsole
filetransfer
-----

```

## Starting listener ports using scripting

These steps demonstrate how to start a listener port on an application server using scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to start a listener port on an application server. The following example returns a list of listener port MBeans:

1. Identify the listener port MBeans for the application server and assign it to the lPorts variable.

- Using Jacl:

```

set lPorts [$AdminControl queryNames type=ListenerPort,
cell=mycell,node=mynode,process=server1,*]

```

- Using Jython:

```

lPorts = AdminControl.queryNames('type=ListenerPort,
cell=mycell,node=mynode,process=server1,*')
print lPorts

```

#### Example output:

```

WebSphere:cell=mycell,name=ListenerPort,mbeanIdentifier=server.xml#
ListenerPort_1,type=ListenerPort,node=mynode,process=server1
WebSphere:cell=mycell,name=listenerPort,mbeanIdentifier=ListenerPort,
type=server.xml#ListenerPort_2,node=mynode,process=server1

```

2. Start the listener port if it is not started. For example:

- Using Jacl:

```

foreach lPort $lPorts {
    set state [$AdminControl getAttribute $lport started]
    if {$state == "false"} {
        $AdminControl invoke $lPort start
    }
}

```

- Using Jython:

```
# get line separator
import java
lineSeparator = java.lang.System.getProperty('line.separator')

lPortsArray = lPorts.split(lineSeparator)
for lPort in lPortsArray:
    state = AdminControl.getAttribute(lPort, 'started')
    if state == 'false':
        AdminControl.invoke(lPort, 'start')
```

These pieces of Jacl and Jython code loop through the listener port MBeans. For each listener port MBean, get the attribute value for the started attribute. If the attribute value is set to false, then start the listener port by invoking the start operation on the MBean.

## Managing generic servers using scripting

You can use WebSphere Application Server to define, start, stop, and monitor generic servers.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

A generic server is a server that the WebSphere Application Server manages but did not supply.

- To define a generic server, use the following example:

- Using Jacl:

```
$AdminTask createGenericServer mynode {-name generic1 -ConfigProcDef
  {[/mydir1/myStartCommand "arg1 arg2" "" "" "/tmp/workingDirectory"
  "/mydir2/stopCommand" "argz argz"]}}
$AdminConfig save
```

- Using Jython:

```
AdminTask.createGenericServer('mynode', '[-name generic1 -ConfigProcDef
  [[/mydir1/myStartCommand "a b c" "" "" "/tmp/workingDirectory
  /mydir2/myStopCommand "x y z"]]]')
AdminConfig.save()
```

- To start a generic server, use the launchProcess parameter, for example:

- Using Jacl:

```
set nodeagent [$AdminControl queryNames *:*,type=NodeAgent]
$AdminControl invoke $nodeagent launchProcess generic1
```

- Using Jython:

```
nodeagent = AdminControl.queryNames ('*:* ,type=NodeAgent')
AdminControl.invoke(nodeagent, 'launchProcess', 'generic1')
```

Example output:

true

or

false

- To stop a generic server, use the terminate parameter, for example:

- Using Jacl:

```
set nodeagent [$AdminControl queryNames *:*,type=NodeAgent]
$AdminControl invoke $nodeagent terminate generic1
```

- Using Jython:

```
nodeagent = AdminControl.queryNames ('*:* ,type=NodeAgent')
AdminControl.invoke(nodeagent, 'terminate', 'generic1')
```

Example output:

true

or  
false

- To monitor the server state, use the `getProcessStatus` parameter, for example:

– Using Jacl:

```
$AdminControl invoke $nodeagent getProcessStatus generic1
```

Using Jython:

```
AdminControl.invoke(nodeagent, 'getProcessStatus', 'generic1')
```

Example output:

RUNNING

or

STOPPED

## Setting development mode for server objects using scripting

You can use scripting and the `wsadmin` tool to configure development mode for server objects.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

Perform the following steps to set the development mode for a server object:

1. Locate the server object. The following example selects the first server found:
  - Using Jacl:

```
set server [$AdminConfig getid /Server:server1/]
```
  - Using Jython:

```
server = AdminConfig.getid('/Server:server1/')
```
2. Enable development mode:
  - Using Jacl:

```
$AdminConfig modify $server "{developmentMode true}"
```
  - Using Jython:

```
AdminConfig.modify(server, [['developmentMode', 'true']])
```
3. Save the configuration changes. See the “Saving configuration changes with the `wsadmin` tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the `wsadmin` tool” on page 99 article for more information.

## Disabling parallel startup using scripting

You can use scripting to disable parallel startup of servers.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

Perform the following steps to disable parallel startup:

1. Locate the server object. The following example selects the first server found:
  - Using Jacl:

```
set server[$AdminConfig getid /Server:server1/]
```
  - Using Jython:

```
server = AdminConfig.getid('/Server:server1/')
```
2. Enable development mode. For example:
  - Using Jacl:

```
$AdminConfig modify $server "{parallelStartEnabled false}"
```

- Using Jython:

```
AdminConfig.modify(server, [['parallelStartEnabled', 'false']])
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Obtaining server version information with scripting

Use the wsadmin tool and scripting to obtain server version information.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to query the server version information:

1. Identify the server and assign it to the server variable.

- Using Jacl:

```
set server [$AdminControl completeObjectName type=Server,name=server1,node=mynode,*]
```

- Using Jython:

```
server = AdminControl.completeObjectName('type=Server,name=server1,node=mynode,*')
print server
```

Example output:

```
WebSphere:cell=mycell,name=server1,mbeanIdentifier=server.xml#Server_1,
type=Server,node=mynode,process=server1,processType=ManagedProcess
```

2. Query the server version. The server version information is stored in the serverVersion attribute. The **getAttribute** command returns the attribute value of a single attribute, passing in the attribute name.

- Using Jacl:

```
$AdminControl getAttribute $server1 serverVersion
```

- Using Jython:

```
print AdminControl.getAttribute(server1, 'serverVersion')
```

Example output for a Network Deployment installation follows:

```
IBM WebSphere Application Server Version Report
```

```
-----
Platform Information
```

```
-----
Name: IBM WebSphere Application Server
Version: 5.0
```

```
Product Information
```

```
-----
ID: BASE
Name: IBM WebSphere Application Server
Build Date: 9/11/02
Build Level: r0236.11
Version: 5.0.0
```

```
Product Information
```

```
-----
ID: ND
Name: IBM WebSphere Application Server for Network Deployment
```

-----  
 End Report  
 -----

## Commands for the NodeGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the NodeGroupCommands group of the AdminTask object:

| Command name:        | Description:                                                                                                                                                                                                                                                                                                                                                                                                   | Target object:                                                                                               | Parameters and return values:                                                                                                                                                                                                                                                             | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addNode Group Member | <p>The <b>addNode Group Member</b> command adds a member to a node group. Nodes can be members of more than one node group. The command does validity checking to ensure the following:</p> <ul style="list-style-type: none"> <li>• Distributed and z/OS nodes are not combined in the same node group.</li> <li>• z/OS platform from different sysplex are not combined into the same node group.</li> </ul> | <p>The target object is the node group where the member will be created. This target object is required.</p> | <ul style="list-style-type: none"> <li>• Parameters:           <ul style="list-style-type: none"> <li>- <b>nodeName</b><br/>The name of the node that you want to add to a node group. This parameter is required.</li> </ul> </li> <li>• Returns: Node group member object ID</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/> <code>\$AdminTask addNodeGroupMember WBINodeGroup {-nodeName WBINode}</code></li> <li>• Using Jython string:<br/> <code>AdminTask.addNodeGroupMember ('WBINodeGroup', ['-nodeName WBINode'] )</code></li> <li>• Using Jython list:<br/> <code>AdminTask.addNodeGroupMember ('WBINodeGroup', ['-nodeName', 'WBINode'] )</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/> <code>\$AdminTask addNodeGroupMember {-interactive}</code></li> <li>• Using Jython string:<br/> <code>AdminTask.addNodeGroupMember ('[-interactive'] )</code></li> <li>• Using Jython list:<br/> <code>AdminTask.addNodeGroupMember (['-interactive'])</code></li> </ul> |

|                           |                                                                                                                                                                                                                                       |                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createNode Group          | The <b>createNode Group</b> command creates a new node group. A node group consists of a group of nodes that are referred to as node group members. Optionally, you can create a short name and a description for the new node group. | The node group name to be created. This target object is required. | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>shortName</b><br/>The short name of the node group. This parameter is optional.</li> <li>- <b>description</b><br/>The description of the node group. This parameter is optional.</li> </ul> </li> <li>Returns: The node group object ID.</li> </ul>                                                                                                    | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask createNodeGroup WBINodeGroup</code></li> <li>Using Jython string:<br/><code>AdminTask.createNodeGroup ('WBINodeGroup')</code></li> <li>Using Jython list:<br/><code>AdminTask.createNodeGroup ('WBINodeGroup')</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask createNodeGroup {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.createNodeGroup ('[-interactive]')</code></li> <li>Using Jython list:<br/><code>AdminTask.createNodeGroup (['-interactive'])</code></li> </ul>                                                                                                                                                                      |
| createNode Group Property | The <b>createNode Group Property</b> command creates custom properties for a node group.                                                                                                                                              | The name of the node group. This target object is required.        | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name of the custom property to create. This parameter is required.</li> <li>- <b>value</b><br/>The value of the custom property. This parameter is optional.</li> <li>- <b>description</b><br/>The description of the custom property. This parameter is optional.</li> </ul> </li> <li>Returns: The properties object ID.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask createNodeGroup Property WBINodeGroup {-name Channel -value "channel1"}</code></li> <li>Using Jython string:<br/><code>AdminTask.createNodeGroup Property('WBINodeGroup', '[-name Channel -value channel1]')</code></li> <li>Using Jython list:<br/><code>AdminTask.createNodeGroup Property('WBINodeGroup', ['-name', 'Channel', '-value', 'channel1'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask createNodeGroup Property {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.createNodeGroup Property ('[-interactive]')</code></li> <li>Using Jython list:<br/><code>AdminTask.createNodeGroup Property (['-interactive'])</code></li> </ul> |

|                           |                                                                                                                                                                                                                      |                                                                              |                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| listNode Group Properties | The <b>listNode Group Properties</b> command displays all of the custom properties of a node group.                                                                                                                  | The target object is name of the node group. This target object is required. | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A list of all of the custom properties of a node group.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask listNodeGroup Properties WBINodeGroup</li> <li>Using Jython string:<br/>AdminTask.listNodeGroup Properties ('WBINodeGroup')</li> <li>Using Jython list:<br/>AdminTask.listNodeGroup Properties ('WBINodeGroup')</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask listNodeGroup Properties {-interactive}</li> <li>Using Jython string:<br/>AdminTask.listNodeGroup Properties ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.listNodeGroup Properties (['-interactive'])</li> </ul>                                                      |
| listNode Groups           | The <b>listNode Groups</b> command returns the list of node groups from the configuration repository. You can pass an optional node name to the command that returns the list of node groups where the node resides. | The target object is name of the node. This target object is optional.       | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: A list of the node groups in the cell.</li> </ul>                  | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask listNodeGroups<br/><br/>\$AdminTask listNodeGroups <i>nodeName</i></li> <li>Using Jython string:<br/>AdminTask.listNodeGroups<br/><br/>AdminTask.listNodeGroups ('<i>nodeName</i>')</li> <li>Using Jython list:<br/>AdminTask.listNodeGroups<br/><br/>AdminTask.listNodeGroups ('<i>nodeName</i>')</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask listNodeGroups {-interactive}</li> <li>Using Jython string:<br/>AdminTask.listNodeGroups ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.listNodeGroups (['-interactive'])</li> </ul> |

## Commands for the Utility group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the Utility group of the AdminTask object:

| Command name:     | Description:                                                                                        | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                               | Examples:                                                                                                                                                                                                                                                                                                                    |
|-------------------|-----------------------------------------------------------------------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| changeHostName    | Use the <b>changeHostName</b> command to change the host name of a node.                            | None           | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>hostName</b><br/>The new host name. (String, required)</li> <li>- <b>nodeName</b><br/>The name of the node whose host name will be changed. (String, required)</li> </ul> </li> <li>Returns: None</li> </ul> | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask changeHostName {-interactive}</li> <li>Using Jython string:<br/>AdminTask.changeHostName ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.changeHostName (['-interactive'])</li> </ul>          |
| getDmgrProperties | Use the <b>getDmgrProperties</b> command to return the name of the deployment manager.              | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: The name of the deployment manager in a network deployment system. Returns an empty string if the system is a single server.</li> </ul>                                                                                           | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask getDmgrProperties {-interactive}</li> <li>Using Jython string:<br/>AdminTask.getDmgrProperties ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.getDmgrProperties (['-interactive'])</li> </ul> |
| isFederated       | Use the <b>isFederated</b> command to check if the system is a single server or network deployment. | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: Boolean. true if the system is a network deployment system. Otherwise it returns false.</li> </ul>                                                                                                                                | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/>\$AdminTask isFederated {-interactive}</li> <li>Using Jython string:<br/>AdminTask.isFederated ('[-interactive]')</li> <li>Using Jython list:<br/>AdminTask.isFederated (['-interactive'])</li> </ul>                   |

## Commands for the ManagedObjectMetadata group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ManagedObjectMetadata group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

|                       |                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| compareNodeVersion    | The <b>compareNodeVersion</b> command compares the WebSphere Application Server version given a node that you specify and an input version. | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li><b>- nodeName</b><br/>The name of the node associated with the metadata you want this command to return.</li> <li><b>- version</b><br/>A version number that you want to compare to the WebSphere Application Server version number.</li> </ul> </li> <li>Returns: <ul style="list-style-type: none"> <li>0 if node version matches the input version</li> <li>-1 if node version is smaller than the input version</li> <li>1 if node version is higher than the input version</li> </ul> </li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask compareNodeVersion {-nodeName <i>node1</i> -version 5}</code></li> <li>Using Jython string:<br/><code>AdminTask.compareNodeVersion(['-nodeName <i>node1</i> -version 5'])</code></li> <li>Using Jython list:<br/><code>AdminTask.compareNodeVersion(['-nodeName', '<i>node1</i>', '-version', '5'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask compareNodeVersion {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.compareNodeVersion (['-interactive'])</code></li> <li>Using Jython list:<br/><code>AdminTask.compareNodeVersion (['-interactive'])</code></li> </ul> |
| getMetadataProperties | The <b>getMetadataProperties</b> command obtains all metadata for the node that you specify.                                                | None | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li><b>- nodeName</b><br/>The name of the node associated with the metadata you want this command to return.</li> </ul> </li> <li>Returns: The list of metadata properties.</li> </ul>                                                                                                                                                                                                                                                                                                                     | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask getMetadataProperties {-nodeName <i>node1</i>}</code></li> <li>Using Jython string:<br/><code>AdminTask.getMetadataProperties(['-nodeName <i>node1</i>'])</code></li> <li>Using Jython list:<br/><code>AdminTask.getMetadataProperties(['-nodeName', '<i>node1</i>'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/><code>\$AdminTask getMetadataProperties {-interactive}</code></li> <li>Using Jython string:<br/><code>AdminTask.getMetadataProperties (['-interactive'])</code></li> <li>Using Jython list:<br/><code>AdminTask.getMetadataProperties (['-interactive'])</code></li> </ul>                      |

|                           |                                                                                                                                   |      |                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Commands for the ServerManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ServerManagement group of the AdminTask object:

| Command name: | Description: | Target object: | Parameters and return values: | Examples: |
|---------------|--------------|----------------|-------------------------------|-----------|
|---------------|--------------|----------------|-------------------------------|-----------|

## Commands for the UnmanagedNodeCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the UnmanagedNodeCommands group of the AdminTask object:

| Command name:       | Description:                                                                                                                                                                                                                                           | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createUnmanagedNode | Use the <b>createUnmanagedNode</b> command to create a new unmanaged node in the configuration. An unmanaged node is a node that does not have a node agent or a deployment manager. Unmanaged nodes can contain Web servers, such as IBM HTTP Server. | None           | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li><b>- nodeName</b><br/>The name that will represent the node in the configuration repository. (String, required)</li> <li><b>- hostName</b><br/>The host name of the system associated with this node. (String, required)</li> <li><b>- nodeOperatingSystem</b><br/>The operating system in use on the system associated with this node. Valid entries include the following: os400, aix, hpux, linux, solaris, windows, and os390. (String required)</li> </ul> </li> <li>Returns: null</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask createUnmanagedNode {-nodeName myNode -hostName myHost -nodeOperatingSystem linux}</pre> </li> <li>Using Jython string: <pre>AdminTask.createUnmanagedNode (['-nodeName jjNode -hostName jjHost -nodeOperatingSystem linux'])</pre> </li> <li>Using Jython list: <pre>AdminTask.createUnmanagedNode (['-nodeName', 'jjNode', '-hostName', 'jjHost', '-nodeOperatingSystem', 'linux'])</pre> </li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask createUnmanagedNode {-interactive}</pre> </li> <li>Using Jython string: <pre>AdminTask.createUnmanagedNode (['-interactive'])</pre> </li> <li>Using Jython list: <pre>AdminTask.createUnmanagedNode (['-interactive'])</pre> </li> </ul> |
| listManagedNodes    | Use the <b>listManagedNodes</b> command to list the managed nodes, nodes that have a node agent defined, in a configuration.                                                                                                                           | None           | <ul style="list-style-type: none"> <li>Parameters: None</li> <li>Returns: List</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask listManagedNodes</pre> </li> <li>Using Jython string: <pre>AdminTask.listManagedNodes()</pre> </li> <li>Using Jython list: <pre>AdminTask.listManagedNodes()</pre> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                  |      |                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Commands for the ConfigurationArchiveOperations group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ConfigurationArchiveOperations group of the AdminTask object:

| Command name: | Description:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|  |                                                                                                                                                                                                                                                                                       |  |  |  |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
|  | <p>The <b>exportServer</b> command exports the metadata file of the node where the server resides. You can use this information later when you import the configuration archive to verify that the target node is compatible to the node from which you are exporting the server.</p> |  |  |  |
|  |                                                                                                                                                                                                                                                                                       |  |  |  |

|              |                                                                                                                                                                                                                                      |      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

---

## Clustering servers with scripting

You can use scripting and the wsadmin tool to cluster servers.

This topic contains the following tasks:

- “Creating clusters using scripting”
- “Modifying cluster member templates using scripting”
- “Creating cluster members using scripting” on page 276
- “Creating clusters without cluster members using scripting” on page 278
- “Starting clusters using scripting” on page 278
- “Querying cluster state using scripting” on page 279
- “Stopping clusters using scripting” on page 280

## Creating clusters using scripting

You can create clusters using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to create a cluster:

1. Identify the server to convert to a cluster and assign it to the server variable:

Using Jacl:

```
set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

Using Jython:

```
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
```

2. Convert the existing server to a cluster by using the **convertToCluster** command passing in the existing server and the cluster name:

Using Jacl:

```
$AdminConfig convertToCluster $server myCluster1
```

This command converts a cluster named myCluster with server1 as its member.

Using Jython:

```
print AdminConfig.convertToCluster(server, 'myCluster1')
```

Example output:

```
myCluster1(cells/mycell/cluster/myCluster1|cluster.xml#ClusterMember_1)
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Modifying cluster member templates using scripting

You can create cluster members using the AdminConfig object and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

A copy of the first cluster member that you create is stored in the cluster scope as a template. You can create the first cluster member using any existing server as a template or a default server template. You

can also create a first cluster member when you create the cluster by converting a server to a cluster. When you create a first cluster member, the template of the cluster member is stored under the scope of the cluster. Additional cluster members are created using the cluster member template stored in the cluster scope.

A cluster can be either homogeneous or heterogeneous in nature. A homogeneous cluster spans nodes that are of the same WebSphere Application Server version. A heterogeneous cluster spans nodes of different WebSphere Application Server versions. Since a cluster can contain members from nodes that run on different versions of WebSphere Application Server, one template will be stored for each version of the WebSphere Application Server node that is configured as a cluster member. The cluster member template will not exist for a given node version until you create a first member in a node of the same version. For example, if a cluster contains several V6.1 nodes and several V6 nodes, there will be one cluster member template for the V6.1 node and one for the V6 node, such as the following:

- The `$WAS_HOME/config/clusters/clusterName/servers/V6.1MemberTemplate` template will be used as the template for any member that is created in a V6.1 node.
- The `$WAS_HOME/config/clusters/clusterName/servers/V6MemberTemplate` template will be used as the template for any member that is created in a V6 node.
- The `$WAS_HOME/config/clusters/clusterName/servers/V5MemberTemplate` template will be used as the template for any member that is created in a V5 node.

Therefore, when you make a configuration change to cluster members, you should make the same configuration change to the corresponding template that is stored in the cluster scope in order to keep the template in synch with the existing members. Similarly, when you make a configuration change to the template, you should make the same configuration change to existing cluster members.

You can modify a cluster member template using the `wsadmin` tool similar to how you modify a server. You cannot modify a cluster member template using the administrative console. Perform the following steps to modify a cluster member template using the `wsadmin` tool:

1. Obtain the cluster template under the cluster scope. For example, the following example obtains the version 6.1 cluster member template for the `cluster1` cluster:

- Using `Jacl`:

```
set c [$AdminConfig getid /ServerCluster:Cluster1]
```

```
set s [$AdminConfig list Server $c]
```

Using `Jython`:

```
c = AdminConfig.listTemplates('Server','cluster1/servers/V6.1')
```

```
print AdminConfig.showall(c)
```

2. Modify the attributes of the template. For example:

- Using `Jacl`:

```
$AdminConfig modify $s {{attrName attrVal}}
```

Using `Jython`:

```
AdminConfig.modify(c, [[attrName, attrval]])
```

3. Save the configuration changes. See the “Saving configuration changes with the `wsadmin` tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the `wsadmin` tool” on page 99 article for more information.

## Creating cluster members using scripting

You can create cluster members using the `AdminConfig` object and scripting.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

The template options are available only for the first cluster member that you create. All cluster members that you create after the first member will be identical.

A template is stored in the cluster scope that you must use to create additional cluster members. For more information about this template, see the “Modifying cluster member templates using scripting” on page 275 article.

To create cluster members using the AdminConfig object, perform the following steps:

1. There are two ways to perform this task. Choose one of the following:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask createClusterMember {-interactive}
```

- Using Jython:

```
AdminTask.createClusterMember (['-interactive'])
```

- Using the AdminConfig object:

a. Identify the existing cluster and assign it to the cluster variable:

- Using Jacl:

```
set cluster [$AdminConfig getid /ServerCluster:myCluster1/]
```

- Using Jython:

```
cluster = AdminConfig.getid('/ServerCluster:myCluster1/')
print cluster
```

Example output:

```
myCluster1(cells/mycell/cluster/myCluster1|cluster.xml#ServerCluster_1)
```

b. Identify the node to create the new server and assign it to the node variable:

- Using Jacl:

```
set node [$AdminConfig getid /Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

c. (Optional) Identify the cluster member template and assign it to the serverTemplate variable:

- Using Jacl:

```
set serverTemplate [$AdminConfig listTemplates Server]
```

- Using Jython:

```
serverTemplate = AdminConfig.listTemplates('Server')
print serverTemplate
```

Example output:

```
server1(templates/default/nodes/servers/server1|server.xml#Server_1)
```

d. Create the new cluster member, by using the **createClusterMember** command.

- The following example creates the new cluster member, passing in the existing cluster configuration ID, existing node configuration ID, and the new member attributes:

- Using Jacl:

```
$AdminConfig createClusterMember $cluster $node {{memberName clusterMember1}}
```

- Using Jython:

```
AdminConfig.createClusterMember(cluster, node, [['memberName', 'clusterMember1']])
```

- The following example creates the new cluster member with a template, passing in the existing cluster configuration ID, existing node configuration ID, the new member attributes, and the template ID:

- Using Jacl:
 

```
$AdminConfig createClusterMember $cluster $node
  {{memberName clusterMember1}} $serverTemplate
```
- Using Jython:
 

```
print AdminConfig.createClusterMember(cluster, node,
  [['memberName', 'clusterMember1']], serverTemplate)
```

Example output:

```
clusterMember1(cells/mycell/clusters/myCluster1|cluster.xml$ClusterMember_2)
```

2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Creating clusters without cluster members using scripting

You can use scripting to create clusters without cluster members.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to create a cluster without a cluster member:

1. There are two ways to perform this task. Choose one of the following:
  - Using the AdminTask object:
    - Using Jacl:
 

```
$AdminTask createCluster {-interactive}
```
    - Using Jython:
 

```
AdminTask.createCluster (['-interactive'])
```
  - Using the AdminConfig object:
    - a. Identify the cell configuration ID and set it to the s1 variable:
      - Using Jacl:
 

```
set s1 [$AdminConfig getid /Cell:mycell/]
```
      - Using Jython:
 

```
s1 = AdminConfig.getid('/Cell:mycell/')
```
    - b. Create a new cluster without a cluster member:
      - Using Jacl:
 

```
$AdminConfig create ServerCluster $s1 {{name ClusterName}}
```
      - Using Jython:
 

```
print AdminConfig.create('ServerCluster', s1, '[[name ClusterName]]')
```
2. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
3. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Starting clusters using scripting

You can use scripting and the wsadmin tool to start clusters in an application server.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to start a cluster:

1. Identify the ClusterMgr MBean and assign it to the clusterMgr variable.

- Using Jacl:

```
set clusterMgr [$AdminControl completeObjectName cell=mycell,type=ClusterMgr,*]
```

- Using Jython:

```
clusterMgr = AdminControl.completeObjectName('cell=mycell,type=ClusterMgr,*')
print clusterMgr
```

This command returns the ClusterMgr MBean.

Example output:

```
WebSphere:cell=mycell,name=ClusterMgr,mbeanIdentifier=ClusterMgr,
type=ClusterMgr,process=dmgr
```

2. Refresh the list of clusters.

- Using Jacl:

```
$AdminControl invoke $clusterMgr retrieveClusters
```

- Using Jython:

```
AdminControl.invoke(clusterMgr, 'retrieveClusters')
```

This command calls the retrieveClusters operation on the ClusterMgr MBean.

3. Identify the Cluster MBean and assign it to the cluster variable.

- Using Jacl:

```
set cluster [$AdminControl completeObjectName cell=mycell,type=Cluster,name=cluster1,*]
```

- Using Jython:

```
cluster = AdminControl.completeObjectName('cell=mycell,type=Cluster,name=cluster1,*')
print cluster
```

This command returns the Cluster MBean.

Example output:

```
WebSphere:cell=mycell,name=cluster1,mbeanIdentifier=Cluster,type=Cluster,process=cluster1
```

4. Start or RippleStart the cluster.

- To start a cluster, use the following example. These commands invoke the start operation on the cluster MBean:

–

Using Jacl:

```
$AdminControl invoke $cluster start
```

- Using Jython:

```
AdminControl.invoke(cluster, 'start')
```

- Use the following example to RippleStart a cluster. RippleStart combines stopping and starting operations. It first stops and then restarts each member of the cluster. For example, your cluster contains 3 cluster members named server\_1, server\_2 and server\_3. When you click RippleStart, server\_1 stops and restarts, then server\_2 stops and restarts, and finally server\_3 stops and restarts. Use the RippleStart option instead of manually stopping and then starting all of the application servers in the cluster. The following commands invoke the rippleStart operation on the cluster MBean:

–

Using Jacl:

```
$AdminControl invoke $cluster rippleStart
```

- Using Jython:

```
AdminControl.invoke(cluster, 'rippleStart')
```

## Querying cluster state using scripting

You can query cluster states using the wsadmin tool and scripting.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to query cluster state:

1. Identify the Cluster MBean and assign it to the cluster variable.

- Using Jacl:

```
set cluster [$AdminControl completeObjectName cell=mycell,type=Cluster,name=cluster1,*]
```

- Using Jython:

```
cluster = AdminControl.completeObjectName('cell=mycell,type=Cluster,name=cluster1,*')
print cluster
```

This command returns the Cluster MBean.

Example output:

```
WebSphere:cell=mycell,name=cluster1,mbeanIdentifier=Cluster,type=Cluster,process=cluster1
```

2. Query the cluster state.

- Using Jacl:

```
$AdminControl getAttribute $cluster state
```

- Using Jython:

```
AdminControl.getAttribute(cluster, 'state')
```

This command returns the value of the run-time state attribute.

## Stopping clusters using scripting

Use scripting and the wsadmin tool to stop a cluster.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to stop a cluster:

1. Identify the Cluster MBean and assign it to the cluster variable.

- Using Jacl:

```
set cluster [$AdminControl completeObjectName cell=mycell,type=Cluster,name=cluster1,*]
```

- Using Jython:

```
cluster = AdminControl.completeObjectName('cell=mycell,type=Cluster,name=cluster1,*')
print cluster
```

This command returns the Cluster MBean.

Example output:

```
WebSphere:cell=mycell,name=cluster1,mbeanIdentifier=Cluster,type=Cluster,process=cluster1
```

2. Stop the cluster.

- Using Jacl:

```
$AdminControl invoke $cluster stop
```

- Using Jython:

```
AdminControl.invoke(cluster, 'stop')
```

This command invokes the stop operation on the Cluster MBean.

## Commands for the ClusterConfigCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ClusterConfigCommands group of the AdminTask object:

| <b>Command name:</b> | <b>Description:</b> | <b>Target object:</b> | <b>Parameters and return values:</b> | <b>Examples:</b> |
|----------------------|---------------------|-----------------------|--------------------------------------|------------------|
|----------------------|---------------------|-----------------------|--------------------------------------|------------------|

| <p>createClusterMember</p> | <p>The <b>createClusterMember</b> command creates a member of a server cluster. A cluster member is an application server that belongs to a cluster. If this is the first member of the cluster, you must specify a template to use as the model for the cluster member. The template can be either a default server template, or an existing application server.</p> <p>The first cluster member is used as a template to create subsequent members in the cluster. When you create a first cluster member, the template of the cluster member is stored under the scope of the cluster. Since a cluster can contain members from nodes that run different versions of WebSphere Application Server,</p> | <p>cluster Object ID configuration object ID of the cluster to which the new member will belong. If you do not specify the configuration ID, you must specify the clusterName parameter. You can obtain the object name programmatically through Java using the WebSphere Application Server ConfigService API or through wsadmin scripting using the AdminConfig object.</p> | <ul style="list-style-type: none"> <li>• <b>Parameters:</b> <ul style="list-style-type: none"> <li><b>-clusterName</b><br/>The name of the cluster to which the new member will belong. If you do not specify this parameter, you must specify the cluster object ID in the command target.</li> </ul> </li> <li>• <b>Parameters for step one:</b> <ul style="list-style-type: none"> <li><b>-memberConfig</b><br/>Specifies the attributes of the new cluster member to be created in the cluster. This command step is required. The following parameters can be specified for this step: <ul style="list-style-type: none"> <li><b>memberNode</b><br/>The name of the node where the new cluster member will be created. This parameter is required.</li> <li><b>memberName</b><br/>The name of the server to be created for the new cluster member. This parameter is required.</li> <li><b>memberWeight</b><br/>The weight of the new cluster member. This controls the amount of work directed to the application server. If the weight is greater than the weight assigned to other cluster members, the server will receive a larger share of the workload. The value is a number between 0 and 100. The default value is 2.</li> </ul> </li> </ul> </li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl: <ul style="list-style-type: none"> <li>First member creation using template name: <pre>\$AdminTask createClusterMember {-clusterName cluster1 -member Config {{node1 member1 "" "" true false}} -firstmember {{serverTemplateName "" "" "" ""}}}</pre> </li> <li>First member creation using server and node for template: <pre>\$AdminTask createClusterMember {-clusterName cluster1 -member Config {{node1 member1 "" "" true false}} -firstmember {{ "" node1 server1 "" ""}}}</pre> </li> <li>Second member creation: <pre>\$AdminTask createClusterMember {-clusterName cluster1 -member Config {{node1 member2 "" "" true false}}}</pre> </li> </ul> </li> </ul> |

|  | <p>one template will be stored for each version of the WebSphere Application Server node that is already configured as cluster members.</p> <p>The cluster member template will not exist for a given version of node until a first member is created in any node of the same version. For example, if a cluster contains some V6.1 nodes and some V6.0.x nodes, there will be one cluster member template for the V6.1 node and one cluster member template for the V6.0.x node.</p> <p>The following template will be used for members that are created for a V6.1 node:<br/> <code>\$WAS_HOME/<br/> config/<br/> templates/<br/> clusters/<br/> clusterName/<br/> servers/<br/> V6.1MemberTemplate.</code></p> |  | <p><b>genUniquePorts</b><br/> Generates unique port numbers for each HTTP transport defined in the server. The new server will not have HTTP transports which conflict with any other servers defined on the same node. The value is true or false. The default value is true .</p> <p><b>replicatorEntry</b><br/> Specifies a replicator entry for the new cluster member will be created in the cluster's replication domain. A replicator entry is used to provide HTTP session data replication. This command parameter is optional. The value is true or false which indicates whether the entry will be created. The default value is false. You can specify this parameter only if a replication domain has been created for the cluster.</p> <ul style="list-style-type: none"> <li>• <b>Parameters for step two:</b> <ul style="list-style-type: none"> <li><b>-firstMember</b><br/> Specifies additional information necessary to create the first cluster member. This command step is required when creating the first member of the cluster, and is executable only when creating the first member of the cluster. The target of this command step is a Boolean value indicating whether or not to perform this step. The default value is true if any of the step parameters are specified; otherwise the default value is false. The following parameters can be specified for this step:</li> </ul> </li> </ul> | <ul style="list-style-type: none"> <li>• Using Jython string:<br/> First member creation using template name:<br/> <pre>AdminTask.createClusterMember ('[-clusterName cluster1 -memberConfig [[node1 member1 "" "" true false]] -firstMember [[serverTemplateName "" "" "" ""]])'</pre> First member creation using server and node for template:<br/> <pre>AdminTask.createClusterMember ('[-clusterName cluster1 -memberConfig [[node1 member1 "" "" true false]] -firstMember [["" node1 server1 "" ""]]')</pre> Second member creation:<br/> <pre>AdminTask.createClusterMember ('[-clusterName cluster1 -memberConfig [[node1 member2 "" "" true false]]')</pre> </li> <li>• Using Jython list:<br/> First member creation using template name:<br/> <pre>AdminTask.createClusterMember (['-clusterName', 'cluster1', '-memberConfig', [['node1', 'member1', "", "", 'true', 'false']], '-firstMember', [['serverTemplateName', "" "" "" ""]])</pre> </li> </ul> |

## Configuring security with scripting

You can configure security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

If you enable security for a WebSphere Application Server cell, supply authentication information to communicate with servers.

The `sas.client.props` and the `soap.client.props` files are located in the properties directory for each WebSphere Application Server profile, `* profile_root/properties`, where `profile_root` is the directory that contains your profile.

- The nature of the properties file updates required for running in secure mode depend on whether you connect with a Remote Method Invocation (RMI) connector, or a SOAP connector:

- If you use a Remote Method Invocation (RMI) connector, set the following properties in the `sas.client.props` file with the appropriate values:

```
com.ibm.CORBA.loginUserId=
com.ibm.CORBA.loginPassword=
```

Also, set the following property:

```
com.ibm.CORBA.loginSource=properties
```

The default value for this property is `prompt` in the `sas.client.props` file. If you leave the default value, a dialog box appears with a password prompt. If the script is running unattended, it appears to hang.

- If you use a SOAP connector, set the following properties in the `soap.client.props` file with the appropriate values:

```
com.ibm.SOAP.securityEnabled=true
com.ibm.SOAP.loginUserId=
com.ibm.SOAP.loginPassword=
```

- To specify user and password information, choose one of the following methods:
  - Specify user name and password on a command line, using the **-user** and **-password** commands. For example:
 

```
wsadmin -conntype RMI -port 2809 -user u1 -password secret1
```
  - Specify user name and password in the `sas.client.props` file for a RMI connector or the `soap.client.props` file for a SOAP connector.

If you specify user and password information on a command line and in the `sas.client.props` file or the `soap.client.props` file, the command line information overrides the information in the props file.

**Note:** On UNIX system, the use of `-password` option may result in security exposure as the password information becomes visible to the system status program such as `ps` command which can be invoked by other user to display all the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

## Enabling and disabling administrative security using scripting

You can use scripting to enable or disable administrative security.

Before starting this task, the `wsadmin` tool must be running. See the “Starting the `wsadmin` scripting client” on page 134 article for more information.

The default profile sets up procedures so that you can enable and disable administrative security based on LocalOS registry.

- To determine if application security is enabled or disabled by looking at the value of the `appEnabled` field in the WCCM security model, use the **isAppEnabled** command, for example:
  - Using Jacl:
 

```
$AdminTask isAppSecurityEnabled {-interactive}
```
  - Using Jython:
 

```
AdminTask.isAppSecurityEnabled ('[-interactive]')
```

This command returns a value of `true` if `appEnabled` is set to `true`. Otherwise, returns a value of `false`.

- To determine if administrative security is enabled or disabled by looking at the value of the `enabled` field in the WCCM security model, use the **isGlobalSecurity** command, for example:
  - Using Jacl:
 

```
$AdminTask isGlobalSecurity {-interactive}
```
  - Using Jython:
 

```
AdminTask.isGlobalSecurity ('[-interactive]')
```

Returns a value of `true` if `enabled` is set to `true`. Otherwise, returns a value of `false`.

- To set administrative security based on the passed in value, use the **setGlobalSecurity** command. For example:
  - Using Jacl:
 

```
$AdminTask setGlobalSecurity {-interactive}
```
  - Using Jython:
 

```
AdminTask.setGlobalSecurity ('[-interactive]')
```

Returns a value of `true` if the `enabled` field in the WCCM security model is successfully updated. Otherwise, returns a value of `false`.

- You can use the **help** command to find out the arguments that you need to provide with this call, for example:
  - Using Jacl:

```
securityon help
```

Example output:

```
Syntax: securityon user password
```

- Using Jython:

```
securityon()
```

Example output:

```
Syntax: securityon(user, password)
```

- To enable administrative security based on the LocalOS registry, use the following procedure call and arguments:

- Using Jacl:

```
securityon user1 password1
```

- Using Jython:

```
securityon('user1', 'password1')
```

- To disable administrative security based on the LocalOS registry, use the following procedure call:

- Using Jacl:

```
securityoff
```

- Using Jython:

```
securityoff()
```

### Enabling and disabling LTPA authentication

There are sample scripts located in the <WAS\_ROOT>/bin directory on how to enable and disable LTPA authentication. The scripts are:

- LTPA\_LDAPSecurityProcs.py (python script)
- LTPA\_LDAPSecurityProcs.jacl (jacl script)

**Note:** The scripts hard code the type of LDAP server and base distinguished name (baseDN). The LDAP server type is hardcoded as IBM\_DIRECTORY\_SERVER and the baseDN is hardcoded as o=ibm,cn=us.

## Enabling and disabling Java 2 security using scripting

You can enable or disable Java 2 security with scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

Perform the following steps to enable or disable Java 2 security:

1. Identify the security configuration object and assign it to the security variable:

- Using Jacl:

```
set security [$AdminConfig list Security]
```

- Using Jython:

```
security = AdminConfig.list('Security')  
print security
```

Example output:

```
(cells/mycell|security.xml#Security_1)
```

2. Modify the enforceJava2Security attribute to enable or disable Java 2 security. For example:

- To enable Java 2 security:

- Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security true}}
```

- Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'true']])
```

- To disable Java 2 security:

- Using Jacl:

```
$AdminConfig modify $security {{enforceJava2Security false}}
```

- Using Jython:

```
AdminConfig.modify(security, [['enforceJava2Security', 'false']])
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

## Enabling authentication in the file transfer service using scripting

You can enable authentication in the file transfer service using scripting and the wsadmin tool.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

In WebSphere Application Server Network Deployment, V5.0.1 or later, the file transfer service is enhanced to provide role-based authentication. Two versions of the file transfer Web application are provided. By default, the version that does not authenticate its caller is installed. This default supports compatibility between the WebSphere Application Server Network Deployment, V5.0 and V5.0.1 or later.

Turning the file transfer authentication on is recommended to prevent unauthorized use of the file transfer application; however, if you have any V5.0 clients in your Network Deployment environment, they cannot communicate with the secured file transfer application if global security is turned on.

In WebSphere Application Server V6.x, mixed cells are supported and file transfer has become a system application. If all of the nodes in the cell are of V5.0.1 or later, you can activate authentication in the file transfer service by redeploying the file transfer application at the deployment manager. The compatible version is shipped in the *app\_server\_root/systemApps/filetransfer.ear* directory. The secured version is provided in the *app\_server\_root/systemApps/filetransferSecured.ear* directory.

- A wsadmin Jacl script is provided to help you redeploy the file transfer. The script is called *redeployFileTransfer.jacl* and is located in the *app\_server\_root/bin* directory. After the deployment manager and all the nodes are upgraded to WebSphere Application Server Network Deployment, version 5.0.1 or later, you can deploy the secured file transfer service by running the script. The syntax for running the script from the bin directory is the following:

–

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationXxx cellName nodeName serverName"
```

where Xxx is **On** or **Off**.

For Windows systems, use *wsadmin* or *wsadmin.bat*. For Linux and UNIX systems, use *wsadmin.sh*. For OS/400 systems, use *wsadmin*.

- For example, when running the script to enable use of the *filetransferSecured.ear* file, the syntax is similar to the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOn managedCell managedCellManager dmgr"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOn baseCell base server1"
```

- If you want to go return to running the file transfer service without authentication, you can run the script as shown in the following example:

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOff baseNodeCell baseNode server1"
```

or

```
wsadmin -profile redeployFileTransfer.jacl -c "fileTransferAuthenticationOff managedCell managedCellManager dmgr"
```

You must restart the server for the change to take affect.

## Propagating security policy of installed applications to a JACC provider using wsadmin scripting

It is possible that you have applications installed prior to enabling the Java Authorization Contract for Containers (JACC)-based authorization. You can start with default authorization and then move to an external provider-based authorization using JACC later.

Also, during application installation or modification you might have had problems propagating the security policy information to the JACC provider. For example, network problems might occur, the JACC provider might not be available, and so on. For these cases, the security policy of the previously installed applications does not exist in the JACC provider to make the access decisions. One choice is to reinstall the applications involved. However, you can avoid reinstalling by using the wsadmin scripting tool. Use this tool to propagate information to the JACC provider independent of the application installation process. The tool eliminates the need for reinstalling the applications.

The tool uses the SecurityAdmin MBean to propagate the policy information in the deployment descriptor of any installed application to the JACC provider. You can invoke this tool using wsadmin at the base application server for base and deployment manager level for Network Deployment. Note that the SecurityAdmin MBean is available only when the server is running.

Use `propagatePolicyToJACCProvider(String appNames)` to propagate the policy information in the deployment descriptor of the enterprise archive (EAR) files to the JACC provider. If the `RoleConfigurationFactory` and the `RoleConfiguration` interfaces are implemented by the JACC provider, the authorization table information in the binding file of the EAR files is also propagated to the provider. See the *Securing applications and their environment* PDF for more information about these interfaces.

The `appNames` String contains the list of application names, delimited by a colon (:), whose policy information must be stored in the provider. If a null value is passed, the policy information of the deployed applications is propagated to the provider.

Also, be aware of the following items:

- Before migrating applications to the Tivoli Access Manager JACC provider, create or import the users and groups that are in the applications to Tivoli Access Manager.
- Depending on the application or the number of applications that are propagated, you might have to increase the request time-out period either in the `soap.client.props` file in the directory `profile_root/properties` (if using SOAP) or in the `sas.client.props` file (if using RMI) for the command to complete. You can set the request time-out value to 0 to avoid the timeout problem, and change it back to the original value after the command is run.

1. Configure your JACC provider in WebSphere Application Server.  
See the *Securing applications and their environment* PDF for more information.
2. Restart the server.
3. Enter the following commands:

```
//use the SecurityAdmin MBean at the Deployment Manager or the unmanaged base
//application server connect to the appropriate process (Deployment Manager or
//base application server)
wsadmin -user serverID -password serverPWD
// To get the SecurityAdmin MBean for Deployment Manager
wsadmin> set secadm [${AdminControl} queryNames type=SecurityAdmin,process=dmgr,*]
// or to get the SecurityAdmin MBean for a unmanaged base application server
//(replace the process name to match your configuration)
wsadmin> set secadm [${AdminControl} queryNames
```

```

        type=SecurityAdmin,process=server1,*]
// to propagate specific applications security policy information
wsadmin>set appNames [list app1:app2]
// or to propagate all applications installed
wsadmin>set appNames [list null]

// Run the command to propagate
wsadmin>$AdminControl invoke $secadm propagatePolicyToJACCProvider $appNames

```

## Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility

You can use the wsadmin utility to configure Tivoli Access Manager security for WebSphere Application Server.

Verify that all the managed servers, including node agents, are started. The following configuration is performed once on the deployment manager server. The configuration parameters are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own restart for the configuration changes to take effect.

1. Start WebSphere Application Server.
2. At the **wsadmin** prompt, enter the following command:

```
$AdminTask configureTAM -interactive
```

You are prompted to enter the following information:

| Option                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WebSphere Application Server node name</b>                          | Specify a single node or enter an asterisk (*) to choose all nodes including the deployment manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Tivoli Access Manager Policy Server</b>                             | Enter the name of the Tivoli Access Manager policy server and the connection port. Use the format, <i>policy_server : port</i> . The policy server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7135.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Tivoli Access Manager Authorization Server</b>                      | Enter the name of the Tivoli Access Manager authorization server. Use the format <i>auth_server : port : priority</i> . The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default port is 7136. More than one authorization server can be specified by separating the entries with commas. Having more than one authorization server configured is useful for failover and performance. The priority value is the order of authorization server use. For example: <i>auth_server1:7136:1,auth_server2:7137:2</i> . A priority of 1 is still required when configuring against a single authorization server. |
| <b>WebSphere Application Server administrator's distinguished name</b> | Enter the full distinguished name of the WebSphere Application Server security administrator ID, as created in the "Creating the security administrative user" topic in the <i>Securing applications and their environment</i> PDF. For example: <i>cn=wasadmin,o=organization,c=country</i>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Tivoli Access Manager user registry distinguished name suffix</b>   | For example: <i>o=organization,c=country</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Tivoli Access Manager administrator's user name</b>                 | Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, <i>sec_master</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Option                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Tivoli Access Manager administrator's user password</b> | Enter the password for the Tivoli Access Manager administrator.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Tivoli Access Manager security domain</b>               | Enter the name of the Tivoli Access Manager security domain that is used to store users and groups. If a security domain is not already established at the time of Tivoli Access Manager configuration, click <b>Return</b> to accept the default.                                                                                                                                                                                                                 |
| <b>Embedded Tivoli Access Manager listening port set</b>   | WebSphere Application Server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine so a list of ports is required for the processes. Enter the ports that are used as listening ports by Tivoli Access Manager clients, separated by a comma. If you specify a range of ports, separate the lower and higher values by a colon. For example, 7999, 9990:9999. |
| <b>Defer</b>                                               | Set to <i>yes</i> , this option defers the configuration of the management server until the next restart. Set to <i>no</i> , configuration of the management server occurs immediately. Managed servers are configured on their next restart.                                                                                                                                                                                                                      |

- When all information is entered, select **F** to save the configuration properties or **C** to cancel from the configuration process and discard entered information.

Now enable the JACC provider for Tivoli Access Manager- Enabling the JACC provider for Tivoli Access Manager topic in the *Securing applications and their environment* PDF.

## Disabling embedded Tivoli Access Manager client using wsadmin

Follow these steps to unconfigure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager.

In a Network Deployment architecture, ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Details of the unconfiguration are forwarded to managed servers, including node agents, when a synchronization is performed. The managed servers require their own reboot for the configuration changes to take effect.

- Restart the deployment manager process.
- Start the wsadmin command-line utility. The wsadmin command is found in the *install\_dir/bin* directory
- From the **wsadmin** prompt, enter the following command:

```
WSADMIN>$AdminTask unconfigureTAM -interactive
```

You are prompted to enter the following information:

| Option                                                   | Description                                                                                                                                                      |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WebSphere Application Server node name</b>            | Enter an asterisk (*) to select all nodes.                                                                                                                       |
| <b>Tivoli Access Manager administrator user name</b>     | Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This name is usually, <i>sec_master</i> . |
| <b>Tivoli Access Manager administrator user password</b> | Enter the password for the Tivoli Access Manager administrator.                                                                                                  |

| Option       | Description                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Force</b> | Enter <i>yes</i> , if you want to ignore errors when unconfiguring the JACC provider for Tivoli Access Manager. Enter this option as <i>yes</i> only when the Tivoli Access Manager domain is in an irreparable state. |
| <b>Defer</b> | Enter <i>no</i> , to force the unconfiguration of the connected server. Enter <i>No</i> for the unconfiguration to proceed correctly.                                                                                  |

4. When all information is entered, enter F to save the properties or C to cancel from the unconfiguration process and discard the entered information.
5. **Optional:** Synchronize all nodes.
6. Restart all WebSphere Application Server instances for the changes to take effect.

## Creating an SSL configuration at the node scope using scripting

An Secure Socket Layer (SSL) configuration references many other configuration objects. To help you make valid selections for the new SSL configuration before you create it, view information about existing configuration objects. Information about existing objects is also useful when you create a node scoped SSL configuration using the **createSSLConfig** command of the AdminTask object.

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

To use the information in this task effectively, familiarize yourself with the instructions in the Creating a Secure Sockets Layer configuration topic in the *Securing applications and their environment* PDF. Perform the following task to create an Secure Socket Layer (SSL) configuration at the node scope:

1. List the existing configuration objects. Perform any of the following:
  - List some of the configuration objects that you may need when you create a new SSL configuration. For example, you want to see which management scopes have already been defined. If the one you need does not exist you will need to create it.

– Using Jacl:

```
$AdminTask listManagementScopes {-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02}
```

– Using Jython:

```
AdminTask.listManagementScopes ('[-scopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02]')
```

This shows an existing cell scope and existing node scope that you can use. If you want to create a different scope, use the **createManagementScope** command of the AdminTask object to define a different one. The valid scope parameters are cell, nodegroup, node, server, cluster, and endpoint. See the Central management of Secure Sockets Layer configurations topic in the *Securing applications and their environment* PDF for more information on scope definitions.

- List the key stores that exist in the configuration including key stores and trust stores.

– Using Jacl:

```
$AdminTask listKeyStores
```

– Using Jython:

```
AdminTask.listKeyStores()
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell02|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell02|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell02|security.xml#KeyStore_3)
```

The previous example only lists the key stores for the default management scope which is also known as the cell scope. To obtain key stores for other scopes, specify the `scopeName` parameter, for example:

- Using Jacl:
 

```
$AdminTask listKeyStores {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02 }
```
- Using Jython:
 

```
$AdminTask listKeyStores ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02]')
```

Example output:

```
CellDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1)
CellDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_2)
CellLTPAKeys(cells/BIRKT40Cell102|security.xml#KeyStore_3)
NodeDefaultKeyStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924357)
NodeDefaultTrustStore(cells/BIRKT40Cell102|security.xml#KeyStore_1134610924377)
```

- List specific trust or key managers. Be sure to display the object name for the trust managers. You will need the object name for the SSL configuration because you can specify multiple trust manager instances.

- Using Jacl:
 

```
$AdminTask listTrustManagers {-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02 -displayObjectName true }
```
- Using Jython:
 

```
AdminTask.listTrustManagers ('[-scopeName (cell):BIRKT40Cell102:(node):BIRKT40Node02 -displayObjectName true]')
```

Example output:

```
IbmX509(cells/BIRKT40Cell102|security.xml#TrustManager_1)
IbmPKIX(cells/BIRKT40Cell102|security.xml#TrustManager_2)
IbmX509(cells/BIRKT40Cell102|security.xml#TrustManager_1134610924357)
IbmPKIX(cells/BIRKT40Cell102|security.xml#TrustManager_1134610924377)
```

2. Create the node-scoped SSL configuration in interactive mode. Now that we have the information we need to choose from, we need to decide if these objects are sufficient or if we need to create new ones. For now, we will reuse what we've already got in the configuration and save creating new instances to task documents specific to those objects.

- Using Jacl:
 

```
$AdminTask createSSLConfig -interactive
```
- Using Jython:
 

```
AdminTask.createSSLConfig ('[-interactive]')
```

Example output:

Create a SSL Configuration.

```
*SSL Configuration Alias (alias): BIRKT40Node02SSLConfig
Management Scope Name (scopeName): (cell):BIRKT40Cell102:(node):BIRKT40Node02
Client Key Alias (clientKeyAlias): default
Server Key Alias (serverKeyAlias): default
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH]
Enabled Ciphers SSL Configuration (enabledCiphers):
JSSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS]
Trust Manager Object Names (trustManagerObjectNames): (cells/BIRKT40Cell102|security.xml#TrustManager_1)
*Trust Store Name (trustStoreName): NodeDefaultTrustStore
Trust Store Scope (trustStoreScopeName): (cell):BIRKT40Cell102:(node):BIRKT40Node02
*Key Store Name (keyStoreName): NodeDefaultKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):BIRKT40Cell102:(node):BIRKT40Node02
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):BIRKT40Cell102:(node):BIRKT40Node02
```

Create SSL Configuration

F (Finish)  
C (Cancel)

Select [F, C]: [F] F

```
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias BIRKT40Node02SSLConfig -scopeName
(cell):BIRKT40Cell02:(node):BIRKT40Node02 -clientKeyAlias default -serverKeyAlias default
-trustManagerObjectNames (cells/BIRKT40Cell02|security.xml#TrustManager_1) -trustStoreName
NodeDefaultTrustStore -trustStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyStoreName
NodeDefaultKeyStore -keyStoreScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 -keyManagerName
IbmX509 -keyManagerScopeName (cell):BIRKT40Cell02:(node):BIRKT40Node02 }
```

3. Save the configuration changes. See the “Saving configuration changes with the wsadmin tool” on page 115 article for more information.
4. In a network deployment environment only, synchronize the node. See the “Synchronizing nodes with the wsadmin tool” on page 99 article for more information.

The name of the SSL configuration object that you created, for example, (cells/BIRKT40Cell02|security.xml#SSLConfig\_1136652770753), appears in the security.xml file.

Example security.xml file output:

```
<repertoire xmi:id="SSLConfig_1136652770753" alias="BIRKT40Node02SSLConfig" type="JSSE"
managementScope="ManagementScope_1134610924357">
<setting xmi:id="SecureSocketLayer_1136652770924" clientKeyAlias="default" serverKeyAlias="default"
clientAuthentication="false" securityLevel="HIGH" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1134610924357" trustStore="KeyStore_1134610924377" trustManager="TrustManager_1"
keyManager="KeyManager_1134610924357"/>
</repertoire>
```

Once you create the SSL configuration object, the next step is to use it. There are several different ways that you can associate SSL configurations with protocols, for example:

- Set the SSL configuration on the thread programmatically.
- Associate the SSL configuration with an outbound protocol or a target host and port.
- Directly associating the SSL configuration using the alias.
- Centrally managing the SSL configurations by associating them with SSL configuration groups or zones so that they are used based upon the group from where the end point exists.

## Creating self-signed certificates using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

You can create self-signed certificates using the scripting and the AdminTask object. You can run the commands in interactive or batch mode. Interactive mode provides a way to discover the flags that you need to run the task in batch mode.

Certificates reside inside of key stores. To run the commands, you will need the name of the key store to be supplied. Use the **listKeyStore** command of the AdminTask object to get a list of key stores. If you need a new key store, use the **createKeyStore** command of the AdminTask object.

To create a personal key store, use the following examples:

- Interactive mode:
  - Using Jacl:

```
$AdminTask createSelfSignedCertificate -interactive
```
  - Using Jython:

```
AdminTask.createSelfSignedCertificate ('[-interactive]')
```

Example output:

```
*Key Store Name (keyStoreName): keyStore
Key Store Scope Name (keyStoreScope):
*Certificate Alias (certificateAlias): newCert
"Certificate Version" (certificateVersion): 3
```

```
*Key Size (certificateSize): [1024]
*Common Name (certificateCommonName): localhost
*Organization (certificateOrganization): workgroup
Organizational Unit (certificateOrganizationalUnit): testing
certLocality (certificateLocality): austin
State (certificateState): Texas
Zip (certificateZip): 78757
Country (certificateCountry): [US]
Validity Period (certificateValidDays): [365]
Create Self-Signed Certificate
```

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
WASX7278I: Generated command line: $AdminTask createSelfSignedCertificate
{-keyStoreName keyStore -certificateAlias newCert -certificateVersion 3
-certificateCommonName localhost -certificateOrganization ibm
-certificateOrganizationalUnit testing -certificateLocality austin
-certificateState Texas -certificateZip 78757 }
true
```

At the end of the output, the batch mode parameters are provided.

- Batch mode:

- Using Jacl:

```
$AdminTask createSelfSignedCertificate {-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757 }
```

- Using Jython:

```
AdminTask.createSelfSignedCertificate ('[-keyStoreName keyStore
-certificateAlias newCert -certificateVersion 3 -certificateCommonName localhost
-certificateOrganization ibm -certificateOrganizationalUnit testing
-certificateLocality austin -certificateState Texas -certificateZip 78757]')
```

## Automating SSL configurations using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

SSL configuration is needed for WebSphere to perform SSL connections with other servers. A SSL configuration can be configured through the Admin Console. But if an automated way to create a SSL configuration is desired then AdminTask should be used.

AdminTask can be used in a interactive mode and batch mode. For automation the batch mode options should be used. AdminTask batch mode can be called in a JACL or Python script. Interactive mode will step through all the parameter the task needs, requires ones are marked with a ‘\*’. Before the interactive task executes the task it echoes the batch mode syntax of the task to the screen. This can be helpful when writing batch mode scripts.

There attributes needed to create an ssl configurations:

- A key store
- Default client certificate alias
- Default server certificate alias
- Trust store
- The handshake protocol
- The ciphers needed during handshake
- Supporting client authentication or not

If automating the creation of a SSL Configuration it may be needed to create some of the attribute values needed like the key store, trust store, key manager, and trust managers.

- To create a SSL configuration the createSSLConfig AdminTask can be used. To make changes to the SSL configurations use the modifySSLConfig AdminTask.

- Interactive mode:

Interactive mode steps you through all attributes and tell you the default value of the attribute if there is one. The default value is in '[']' on the prompt line. The actual flag used in batch mode is in '(')' on each prompt line. If you are using the default value then the flag will not show up on the batch command line.

Using Jacl:

```
$AdminTask createSSLConfig -interactive
```

- Using Jython:

```
AdminTask.createSSLConfig ('[interactive]')
```

Example output:

```
*SSL Configuration Alias (alias): testSSLConfig
Management Scope Name (scopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
Client Key Alias (clientKeyAlias): clientCert
Server Key Alias (serverKeyAlias): serverCert
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH] HIGH
Enabled Ciphers SSL Configuration (enabledCiphers):
JSSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS] SSL_TLS
Trust Manager Object Names (trustManagerObjectNames):
*Trust Store Name (trustStoreName): testTrustStore
Trust Store Scope (trustStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
*Key Store Name (keyStoreName): testKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
```

Create SSL Configuration

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
```

```
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01 }
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

At the end of the output, the batch mode parameters are provided.

- Batch mode:

Using Jacl:

```
$AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01}
```

- Using Jython:

```
AdminTask.createSSLConfig ('[-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
```

```
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01]
```

Example output:

```
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

- **Key Stores and Trust Stores** The key store and trust store may already exist or a new one may need to be created. To create a new key store or trust store use the `createKeyStore AdminTask`. It will create a key store file and store the configuration object in the system configuration. A trust store is just a key store that usually only has signer certificates in it. To create a key store enter:

– Using Jacl:

```
$AdminTask createKeyStore {-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false}
```

– Using Jython:

```
AdminTask.createKeyStore ('[-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false]')
```

To populate the key store with certificates see “Managing Certificates using AdminConsole and Admin Task” The key store and trust store are required to create a SSL configuration. Use the ‘-keyStoreName’ and ‘-trustStoreName’ flags on the `createSSLConfig`. There scopes can be added with the ‘-keyStoreScope’ flag and ‘-trustStoreScope’ flags.

- **Key Manager** Key manager are used to determine how a certificate is selected. The IbmX509 key manager is in the security configuration by default. If a different key manager is needed then use `createKeyManager AdminTask` to create it. To create a key manager enter:

– Using Jacl:

```
$AdminTask createKeyManager {-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

– Using Jython:

```
AdminTask.createKeyManager ('[-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

To supply a key manager on the `createSSLConfig AdminTask` use the ‘-keyManagerName’ along with the ‘-keyManagerScope’ flag.

- **Trust Manager** Trust managers are use to determine how trust is established during ssl communication. The IbmX509 and IbmPKIX are trust managers are in the security configuration by default. If a different or additional trust manager is needed then use the `createTrustManger AdminTask` to create it. To create a trust manager enter:

– Using Jacl:

```
$AdminTask createTrustManager {-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

– Using Jython:

```
AdminTask.createTrustManager ('[-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

The SSL Configuration can have multiple trust managers. To supply multiple trust managers give a comma separated list of the trust managers configuration IDs with the `-trustManagerObjectNames` flag. When you create a trust manager the configuration object ID is returned. To get a list of trust managers object IDs use the **listTrustManagers** command of the `AdminTask` object with the `-displayObjectName true` flag. For example:

```

wsadmin>$AdminTask listTrustManagers -interactive
List Trust Managers

List trust managers.

Management Scope Name (scopeName):
Display list in ObjectName Format (displayObjectName): [false] true

List Trust Managers

F (Finish)
C (Cancel)

Select [F, C]: [F]
Inside generate script command
WASX7278I: Generated command line: $AdminTask listTrustManagers {-displayObjectName true }
IbmX509(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_1)
IbmPKIX(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_2)

```

## Updating default key store passwords using scripting

Before starting this task, the wsadmin tool must be running. See the “Starting the wsadmin scripting client” on page 134 article for more information.

When you install WebSphere Application Server, each server creates a key store and trust store for the default SSL configuration with the default password WebAS. To protect the security of the key store files and the SSL configuration, you must change the password. The following examples update the default password:

- Change multiple key stores passwords. The **changeMultipleKeyStorePasswords** command updates all of the key stores that have the same password. For example:
  - Using Jacl:
 

```
$AdminTask changeMultipleKeyStorePasswords {-keyStorePassword WebAS
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd}
```
  - Using Jython:
 

```
AdminTask.changeMultipleKeyStorePasswords ['(-keyStorePassword WebAS
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd)']
```
- Change the password of a single key store. The **changeKeyStorePassword** command updates the password of an individual key store. For example:
  - Using Jacl:
 

```
$AdminTask changeKeyStorePassword {-keyStoreName testKS
-keyStoreScope (cell):localhost:(server):server1
-keyStorePassword WebAS -newKeyStorePassword secretPwd
-newKeyStorePasswordVerify secretPwd}
```
  - Using Jython:
 

```
AdminTask.changeKeyStorePassword ('[-keyStoreName testKS
-keyStoreScope (cell):localhost:(server):server1
-keyStorePassword WebAS -newKeyStorePassword secretPwd
-newKeyStorePasswordVerify secretPwd]')
```

## Commands for the IdMgrConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the Commands for the IdMgrRepositoryConfig group of the AdminTask object and the Commands for the IdMgrRealmConfig group of the AdminTask object articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrConfig group of the AdminTask object:

Table 3.

| Command name:                           | Description:                                                                                                                                                             | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| showId MgrConfig                 | The <b>showId MgrConfig</b> command returns the current configuration XML in string format.                                 | <ul style="list-style-type: none"> <li>• Parameters: None</li> <li>• Returns: None</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask showIdMgrConfig</li> <li>• Using Jython string:<br/>AdminTask.showIdMgrConfig()</li> <li>• Using Jython list:<br/>AdminTask.showIdMgrConfig()</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask showIdMgrConfig {-interactive}</li> <li>• Using Jython string:<br/>AdminTask.showIdMgrConfig ('[-interactive]')</li> <li>• Using Jython list:<br/>AdminTask.showIdMgrConfig (['-interactive'])</li> </ul>                                                                                                                                                                             |
| updateIdMgr Supported EntityType | The <b>updateIdMgr Supported EntityType</b> command updates the configuration that you specify for a supported entity type. | <ul style="list-style-type: none"> <li>• Parameters: <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required)</li> <li>- <b>defaultParent</b><br/>The default parent node for the supported entity type. (String, optional)</li> <li>- <b>rdnProperties</b><br/>The RDN attribute name for the supported entity type in the entity domain name. To reset all the values of the rdnProperties parameter, specify a blank string (""). (String, optional)</li> </ul> </li> <li>• Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask updateIdMgrSupported EntityType {-name <i>entity1</i>}</li> <li>• Using Jython string:<br/>AdminTask.updateIdMgrSupported EntityType ('[-name <i>entity1</i>]')</li> <li>• Using Jython list:<br/>AdminTask.updateIdMgrSupported EntityType (['-name', '<i>entity1</i>'])</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask updateIdMgrSupported EntityType {-interactive}</li> <li>• Using Jython string:<br/>AdminTask.updateIdMgrSupported EntityType ('[-interactive]')</li> <li>• Using Jython list:<br/>AdminTask.updateIdMgrSupported EntityType (['-interactive'])</li> </ul> |

## Commands for the IdMgrRepositoryConfig group of the AdminTask object

Use the commands in the IdMgrRepositoryConfig to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the “Commands for the IdMgrConfig group of the AdminTask object” on page 305 and the “Commands for the IdMgrRealmConfig group of the AdminTask object” on page 399 articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrRepositoryConfig group of the AdminTask object:

Table 4.

| Command name:            | Description:                                                                     | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                        | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addIdMgrLDAPBackupServer | The <b>addIdMgrLDAPBackupServer</b> command adds or updates backup LDAP servers. | <ul style="list-style-type: none"> <li>• Parameters:</li> <li>- <b>id</b><br/>The ID of the repository. (String, required)</li> <li>- <b>primary_host</b><br/>The host name for the primary LDAP server. (String, required)</li> <li>- <b>host</b><br/>The host name for the LDAP server. (String, required)</li> <li>- <b>port</b><br/>The port number for the LDAP server. |               |              | <p><b>- serverTTLAttribute</b></p> <p>The name of the ttl attribute that is supported by the LDAP server. The attributes cache uses the value of this attribute to determine when the cached entries in the attributes cache will time out.</p> <p>The ttl attribute contains the time, in seconds, that any information from the entry should be kept by a client before it is considered stale and a new copy is fetched. A value of 0 implies that the object will not be cached.</p> <p>For more information about this attribute, go to:</p> <p><a href="http://www.ietf.org/proceedings/98aug/I-D/draft-ietf-asis-ldap-cache-01.txt">http://www.ietf.org/proceedings/98aug/I-D/draft-ietf-asis-ldap-cache-01.txt</a>.</p> <p>The ttl attribute is not supported by all LDAP servers. If this attribute is supported by an LDAP server, you can set the value of the serverTTLAttribute parameter to the name of the ttl attribute in order to allow the value of the ttl attribute to determine when cached entries will time out. The time out value for different entries in attributes cache can be different.</p> | <p>Chapter 3. Using scripting (wsadmin) <b>373</b></p> |

|               |              | <p><b>- maxPoolSize</b></p> <p>The maximum number of context instances that can be maintained concurrently by the context pool. Both in-use and idle context instances contribute to this number. When the pool size reaches this number, new context instances cannot be created for new requests. The new request is blocked until a context instance is released by another request or is removed. The request checks periodically if there are context instances available in the pool according to the value defined for the poolWaitTime parameter. The minimum value of the maxPoolSize parameter is 0. There is no maximum value. A maximum pool size of 0 means that there is no maximum size and that a request for a pooled context instance will use an existing pooled idle context instance or a newly created pooled context instance. The default value is 20. (Integer, optional)</p> |           |

Table 4. (continued)

| updateIdMgr Repository BaseEntry | The <b>updateIdMgr Repository BaseEntry</b> command updates a base entry to the specified repository. | <ul style="list-style-type: none"> <li>• Parameters:</li> <li>- <b>id</b><br/>The ID of the repository. (String, required)</li> <li>- <b>name</b><br/>The distinguished name of a base entry. (String, required)</li> <li>- <b>nameInRepository</b><br/>The distinguished name in the repository that uniquely identifies the base entry name. (String, optional)</li> <li>• Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask updateIdMgrRepositoryBaseEntry {-id <i>id1</i> name <i>name1</i>}</code></li> <li>• Using Jython string:<br/><code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-id <i>id1</i> name <i>name1</i>]')</code></li> <li>• Using Jython list:<br/><code>AdminTask.updateIdMgrRepositoryBaseEntry (['-id', '<i>id1</i>', 'name', '<i>name1</i>'])</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask updateIdMgrRepositoryBaseEntry {-interactive}</code></li> <li>• Using Jython string:<br/><code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-interactive]')</code></li> <li>• Using Jython list:<br/><code>AdminTask.updateIdMgrRepositoryBaseEntry (['-interactive'])</code></li> </ul> |

## Commands for the IdMgrRealmConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the member manager realm and realms. The commands for this group do not require a target object. To see the additional commands related to the member manager, see the `Commands for the IdMgrRepositoryConfig group of the AdminTask object and the Commands for the IdMgrConfig group of the AdminTask object articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrRealmConfig group of the AdminTask object:

Table 5.

| Command name:          | Description:                                                                                    | Parameters and return values:                                                                                                                                                                                                                                                               | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Commands for the WIMManagementCommands group of the AdminTask object

Use the commands in the WIMManagementCommands group to configure the virtual member manager. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WIMManagementCommands group of the AdminTask object:

Table 6.

| Command name:    | Description:                                                                  | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addMemberToGroup | <p>The <b>addMemberToGroup</b> command adds a user or a group to a group.</p> | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>memberUniqueName</b><br/>Specifies the unique name value for the user or group that you want to add to the specified group. This parameter maps to the uniqueName property in the virtual member manager. (String, required)</li> <li>- <b>groupUniqueName</b><br/>Specifies the unique name value for the group to which you want to add the user or group that you specified in the memberUniqueName parameter. This parameter maps to the uniqueName property in virtual member manager. (String, required)</li> </ul> </li> <li>• Returns: Void if the command is successful. Returns an exception if the command fails.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:           <pre>\$AdminTask addMemberToGroup {-memberUniqueName uid= meyersd,cn=users,dc=yourco, dc=com -groupUniqueName cn=admins,cn=groups, dc=yourco,dc=com}</pre> </li> <li>• Using Jython string:           <pre>AdminTask.addMemberToGroup (['-memberUniqueName uid=meyersd,cn=users, dc=yourco,dc=com -group UniqueName cn=admins, cn=groups,dc=yourco, dc=com']')</pre> </li> <li>• Using Jython list:           <pre>AdminTask.addMemberToGroup (['-memberUniqueName', 'uid=meyersd,cn=users,dc= yourco,dc=com', '-group UniqueName', 'cn=admins, cn=groups,dc=yourco,dc=com'])</pre> </li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:           <pre>\$AdminTask addMemberToGroup {-interactive}</pre> </li> <li>• Using Jython string:           <pre>AdminTask.addMemberToGroup (['-interactive']')</pre> </li> <li>• Using Jython list:           <pre>AdminTask.addMemberToGroup (['-interactive'])</pre> </li> </ul> |

Table 6. (continued)

| Command name: | Description:                                                                                                                                                                                                                                                                                                                                                                                                                                | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createGroup   | <p>The <b>createGroup</b> command creates a new group in the virtual member manager. After the command completes, the new group will appear in the repository. For LDAP, a group must contain a member. The <code>memberUniqueName</code> parameter is optional in this case. If you set the <code>memberUniqueName</code> parameter to the unique name of a group or a user, the group or user will be added as a member of the group.</p> | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>cn</b><br/>Specifies the common name for the group that you want to create. This parameter maps to the <code>cn</code> property in virtual member manager. (String, required)</li> <li>- <b>description</b><br/>Specifies additional information about the group that you want to create. This parameter maps to the <code>description</code> property in a virtual member manager object. (String, optional)</li> <li>- <b>parent</b><br/>Specifies the repository in which you want to create the group. This parameter maps to the <code>parent</code> property in the virtual member manager. (String, optional)</li> <li>- <b>memberUniqueName</b><br/>Specifies the unique name value for the user or group that you want to add to the new group. This parameter maps to the <code>uniqueName</code> property in the virtual member manager. (String, optional)</li> </ul> </li> <li>• Returns: The unique name of the group that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><pre>\$AdminTask createGroup {-cn groupA -description a group of admins}</pre></li> <li>• Using Jython string:<br/><pre>AdminTask.createGroup (['-cn groupA -description a group of admins'])</pre></li> <li>• Using Jython list:<br/><pre>AdminTask.createGroup (['-cn', 'groupA', '-description', 'a group of admins'])</pre></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><pre>\$AdminTask createGroup {-interactive}</pre></li> <li>• Using Jython string:<br/><pre>AdminTask.createGroup (['-interactive'])</pre></li> <li>• Using Jython list:<br/><pre>AdminTask.createGroup (['-interactive'])</pre></li> </ul> |

Table 6. (continued)

| Command name: | Description:                                                                                                                                                                                                                                  | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createUser    | <p>The <b>createUser</b> command creates a new user in the default repository or a repository that the parent command parameter specifies. This command creates a person entity and a login account entity in the virtual member manager.</p> | <ul style="list-style-type: none"> <li>• Parameters:</li> <li>- <b>uid</b><br/>Specifies the unique ID for the user that you want to create. Virtual member manager then creates a uniqueId value and a uniqueName value for the user. This parameter maps to the uid property in the virtual member manager. (String, required)</li> <li>- <b>password</b><br/>Specifies the password for the user. This parameter maps to the password property in the virtual member manager. (String, required)</li> <li>- <b>confirmPassword</b><br/>Specifies the password again to validate how it was entered for the password parameter. This parameter maps to the password property in virtual member manager. (String, optional)</li> <li>- <b>cn</b><br/>Specifies the first name or given name of the user. This parameter maps to the cn property in virtual member manager. ## Commands for the KeyStoreCommands group of the AdminTask object

Use the commands in the KeyStoreCommands group to create or delete key stores. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeyStoreCommands group of the AdminTask object:

Table 7.

| Command name:                   | Description:                                                                              | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Commands for the SSLConfigCommands group of the AdminTask object

Use the commands in the SSLConfigCommands group to create and delete SSL configurations. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigCommands group of the AdminTask object:

Table 8.

| Command name:   | Description:                                                                                                                                                                                        | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| modifyDescriptiveProp | The <b>modifyDescriptiveProp</b> command modifies the settings of an existing key manager. | None           | <ul style="list-style-type: none"> <li>Parameters: <ul style="list-style-type: none"> <li>- <b>parentDataType</b> (String, required)</li> <li>- <b>parentClassName</b> (String, required)</li> <li>- <b>parentScopeName</b> (String, optional)</li> <li>- <b>name</b> (String, required)</li> <li>- <b>value</b> (String, optional)</li> <li>- <b>type</b> (String, optional)</li> <li>- <b>displayNameKey</b> (String, optional)</li> <li>- <b>nlsRangeKey</b> (String, optional)</li> <li>- <b>hoverHelpKey</b> (String, optional)</li> <li>- <b>range</b> (String, optional)</li> <li>- <b>inclusive</b> (Boolean, optional)</li> <li>- <b>firstClass</b> (Boolean, optional)</li> </ul> </li> <li>Returns: None</li> </ul> | <b>Interactive mode example usage:</b> <ul style="list-style-type: none"> <li>Using Jacl: <pre>\$AdminTask modifyDescriptiveProp {-interactive}</pre> </li> <li>Using Jython string: <pre>AdminTask.modifyDescriptiveProp ('[-interactive]')</pre> </li> <li>Using Jython list: <pre>AdminTask.modifyDescriptiveProp (['-interactive'])</pre> </li> </ul> |

## Commands for the TrustManagerCommands group of the AdminTask object

Use the commands in the TrustManagerCommands group to create and delete a trust manager. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the TrustManagerCommands group of the AdminTask object:

Table 10.

| Command name:      | Description:                                                                                                                                                                         | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createTrustManager | The <b>createTrustManagerInfo</b> command creates trust manager settings in the configuration. Use this command during SSL handshake to make trust decisions about remote endpoints. | None           | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name that uniquely identifies the trust manager. (String, required)</li> <li>- <b>scopeName</b><br/>The name of the scope. (String, optional)</li> <li>- <b>provider</b><br/>The provider name of the trust manager. (String, optional)</li> <li>- <b>algorithm</b><br/>The algorithm name of the trust manager. (String, optional)</li> <li>- <b>trustManagerClass</b><br/>Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional)</li> </ul> </li> <li>• Returns: The configuration object name of the trust manager object that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask createTrustManager {-name testTM -provider IBMJSSE2 -algorithm IbmX509}</li> <li>• Using Jython string:<br/>AdminTask.createTrustManager ('[-name testTM -provider IBMJSSE2 -algorithm IbmX509]')</li> <li>• Using Jython list:<br/>AdminTask.createTrustManager (['-name', 'testTM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509'])</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask createTrustManager {-interactive}</li> <li>• Using Jython string:<br/>AdminTask.createTrustManager ('[-interactive]')</li> <li>• Using Jython list:<br/>AdminTask.createTrustManager (['-interactive'])</li> </ul> |

Table 10. (continued)

| Command name:      | Description:                                                                                     | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                      | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

(String, optional)</li> <li><b>- trustManagerClass</b><br/>Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional)</li> </ul> </li> <li>Returns: None</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/> <pre>\$AdminTask modifyTrustManager {-name testTM -trustManagerClass test.trust.manager}</pre> </li> <li>Using Jython string:<br/> <pre>AdminTask.modifyTrustManager (['-name testTM -trustManagerClass test.trust.manager'])</pre> </li> <li>Using Jython list:<br/> <pre>AdminTask.modifyTrustManager (['-name', 'testTM', '-trustManagerClass', 'test.trust.manager'])</pre> </li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>Using Jacl:<br/> <pre>\$AdminTask modifyTrustManager {-interactive}</pre> </li> <li>Using Jython string:<br/> <pre>AdminTask.modifyTrustManager (['-interactive'])</pre> </li> <li>Using Jython list:<br/> <pre>AdminTask.modifyTrustManager (['-interactive'])</pre> </li> </ul> |

## Commands for the keyManagerCommands group of the AdminTask object

Use the commands in the `keyManagerCommands` group to manage key managers. You can use these commands to create, modify, list, or obtain information about key managers. For more information about the `AdminTask` object, see the [Commands for the AdminTask object](#) article.

The following commands are available for the `keyManagerCommands` group of the `AdminTask` object:

Table 11.

| Command name:    | Description:                                                                                                                                                                         | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createKeyManager | <p>The <b>createKeyManager</b> command creates the key manager settings in the configuration. Use this command during SSL handshake to determine which certificate alias to use.</p> | None           | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>name</b><br/>The name that uniquely identifies the key manager. (String, required)</li> <li>- <b>scopeName</b><br/>The name of the scope. (String, optional)</li> <li>- <b>provider</b><br/>The provider name of the key manager. (String, optional)</li> <li>- <b>algorithm</b><br/>The algorithm name of the key manager. (String, optional)</li> <li>- <b>keyManagerClass</b><br/>The name of the key manager implementation class. You can not use this parameter with the provider or the algorithm parameter. ## Commands for the SSLConfigGroupCommands group of the AdminTask object

Use the commands in the SSLConfigGroupCommands group to create or delete a SSL configuration group. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigGroupCommands group of the AdminTask object:

Table 12.

| Command name:        | Description:                                                               | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Commands for the DynamicSSLConfigSelections group of the AdminTask object

Use the commands in the DynamicSSLConfigSelections group to create or delete a dynamic SSL configuration selection. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the DynamicSSLConfigSelections group of the AdminTask object:

Table 13.

| Command name:                                | Description:                                                                                                                                | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>createDynamic<br/>SSLConfig Selection</p> | <p>The <b>createDynamic SSLConfig Selection</b> command creates the configuration settings for the dynamic SSL configuration selection.</p> | <p>None</p>    | <ul style="list-style-type: none"> <li>• Parameters:</li> <li>- <b>dynSSLConfigSelectionName</b><br/>The name that uniquely identifies the dynamic SSL configuration selection. (String, required)</li> <li>- <b>scopeName</b><br/>The name of the scope. (String, optional)</li> <li>- <b>dynSSLConfigSelectionDescription</b><br/>The description of the dynamic SSL configuration selection. (String, optional)</li> <li>- <b>dynSSLConfigSelectionInfo</b><br/>The information for the dynamic SSL configuration selection. (String, required)</li> <li>- <b>sslConfigName</b><br/>The name of the SSL configuration. (String, required)</li> <li>- <b>sslConfigScope</b><br/>The scope of the SSL configuration. (String, optional)</li> <li>- <b>certificateAlias</b><br/>The alias name to identify the certificate. (String, required)</li> <li>• Returns: The configuration object name of the dynamic SSL configuration selection object that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask createDynamicSSLConfigSelection</code></li> <li>• Using Jython:<br/><code>AdminTask.createDynamicSSLConfigSelection()</code></li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/><code>\$AdminTask createDynamicSSLConfigSelection {-interactive}</code></li> <li>• Using Jython string:<br/><code>AdminTask.createDynamicSSLConfigSelection ('[-interactive]')</code></li> <li>• Using Jython list:<br/><code>AdminTask.createDynamicSSLConfigSelection (['-interactive'])</code></li> </ul> |

Table 13. (continued)

| Command name:                                | Description:                                                                                                                         | Target object: | Parameters and return values:                                                                 | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Commands for the ManagementScopeCommands group of the AdminTask object

Use the commands in the ManagementScopeCommands group to create or delete a management scope. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ManagementScopeCommands group of the AdminTask object:

Table 14.

| Command name:         | Description:                                                                                      | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|---------------------------------------------------------------------------------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| createManagementScope | The <b>createManagementScope</b> command creates a management scope setting in the configuration. | None           | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>scopeName</b><br/>The name that uniquely identifies the management scope. (String, required)</li> <li>- <b>scopeType</b><br/>The type of the management scope. Valid types include cell, node, nodegroup, cluster, server, and endpoint. (String, optional)</li> </ul> </li> <li>• Returns: The configuration object name of the management scope object that you created.</li> </ul> | <p><b>Batch mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask createManagementScope {-name (cell):localhostNode01Cell -scopeType cell}</li> <li>• Using Jython string:<br/>AdminTask.createManagementScope [('-name (cell):localhostNode01Cell -scopeType cell)']</li> <li>• Using Jython list:<br/>AdminTask.createManagementScope [('-name', '(cell):localhostNode01Cell', '-scopeType', 'cell')]</li> </ul> <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask createManagementScope {-interactive}</li> <li>• Using Jython string:<br/>AdminTask.createManagementScope ('[-interactive]')</li> <li>• Using Jython list:<br/>AdminTask.createManagementScope (['-interactive'])</li> </ul> |

## Commands for the WSCertExpMonitorCommands group of the AdminTask object

Use the commands in the WSCertExpMonitorCommands group to start or update the certificate expiration monitor. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSCertExpMonitorCommands group of the AdminTask object:

Table 15.

| Command name:                      | Description:                                                                                                                | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Examples:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Commands for the SignerCertificateCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SignerCertificateCommands group of the AdminTask object:

Table 21.

| Command name:        | Description:                                                                                              | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Examples:                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| addSignerCertificate | The <b>addSignerCertificate</b> command adds a signer certificate from a certificate file to a key store. | None           | <ul style="list-style-type: none"> <li>• Parameters:               <ul style="list-style-type: none"> <li>- <b>keyStoreName</b><br/>The name of the key store where the signer certificate is located. (String, required)</li> <li>- <b>keyStoreScope</b><br/>The management scope of the key store. (String, optional)</li> <li>- <b>certificateFilePath</b><br/>The full path name of the file that contains the signer certificate. (String, required)</li> <li>- <b>certificateAlias</b><br/>The alias name of the signer certificate in the key store. (String, required)</li> <li>- <b>base64Encoded</b><br/>Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (String, required)</li> </ul> </li> <li>• Returns: The configuration object name of the key store object that you created.</li> </ul> | <p><b>Interactive mode example usage:</b></p> <ul style="list-style-type: none"> <li>• Using Jacl:<br/>\$AdminTask addSignerCertificate {-interactive}</li> <li>• Using Jython string:<br/>AdminTask.addSignerCertificate (['-interactive'])</li> <li>• Using Jython list:<br/>AdminTask.addSignerCertificate (['-interactive'])</li> </ul> |

Table 21. (continued)

| Command name:           | Description:                                                                              | Target object: | Parameters and return values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Examples:                                                                                                                                                                                                                                                                                                                                            |
