The destination is mediated, and a mediation point is created for the destination on the bus member.

## What to do next

Next, you can configure properties that affect how messages are processed at the mediated destination; for example, whether it runs within a global transaction, or processes multiple messages concurrently. For more information, see “Configuring mediation properties” on page 1331.

## Unmediating a destination

Use this task to unmediate a selected bus destination.

### Before you begin

Before you start this task, you should consider whether you want to preserve message ordering at the bus destination you intend to unmediate.

### About this task

Unmediating a selected bus destination breaks the association between the bus destination and the mediation, and the mediation stops processing messages at the bus destination at run time. This task unmediates a bus destination, and optionally preserves message ordering at the bus destination.

To unmediate a bus destination use the administrative console to complete the following steps:

**Note:** If you want to preserve message ordering, complete all the following steps. If message ordering is not important, you can omit steps 2 and 4:

1. Display the bus destination you want to unmediate. Click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name*.
2. Optional: If you want to preserve message ordering at the destination, take the following steps:
  - a. Clear the **Send Allowed** check box (setting it to false) to stop sending messages to the message points for this destination.
  - b. Wait until there are no messages listed for the mediation points.
  - c. Stop all the mediation points, and wait for all the mediation points to enter the stopped state.
  - d. Optional: If it is not already selected, select the bus destination you want to unmediate.
3. Click **Unmediate** to unmediate the destination.
4. Optional: Select the **Send Allowed** check box (setting it to true) to resume sending messages to the mediation points for this destination.
5. Save your changes to the master configuration.

## Results

The destination is unmediated, and the mediation point is deleted from the destination.

If you did not preserve message ordering, any messages that remain on the mediation point after you have unmediated the destination are processed as for a non-mediated destination. Messages with an empty forward routing path are placed on the next appropriate message point for the destination. Messages with a non-empty forward routing path are sent to the destination specified in the forward routing path.

The unmediated destination now operates as a non-mediated destination, and new messages are sent to a message point on the destination.

## Configuring mediation points

In service integration technologies, messages are held at specialized message points called mediation points before they are processed by a mediation. Use the following tasks to set properties at mediation points to route messages and start and stop mediations:

### Configuring a mediation point

This task uses the administrative console to browse or change the configuration properties for a selected mediation point for a selected bus destination.

#### Before you begin

You must first create a mediation point on a bus destination. For more information, see “Mediating a destination” on page 1337.

#### About this task

A mediation point is a specialized message point on a bus location where messages are stored and mediated. Configuring the properties of a mediation point enables you to control some aspects of how messages are sent to and received from a bus destination. In this task you use the administrative console to configure the properties for a selected mediation point for a selected bus destination.

**Note:** You should be aware that the mediation point properties *Send allowed* and *Initial state* override the general properties defined for the bus destination.

To browse or change the properties for a selected mediation point, use the administrative console to complete the following steps:

1. Start the administrative console, and click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points** → *mediation\_point\_name*. The properties for the selected mediation point are displayed.
2. Optional: Browse or change the following properties for the mediation point:

#### Identifier

The identifier by which this message point is known for administrative purposes. This field is for display purposes only.

#### UUID

The universal unique identifier assigned to this mediation point for administrative purposes. This field is for display purposes only.

#### High message threshold

The maximum total number of messages that can be placed on this mediation point. This field is for display purposes only.

#### Send allowed

This property specifies whether or not messages are sent to this mediation point. By default,

True is selected, and messages are sent to this mediation point. Select False to prevent messages from being sent to this mediation point.

#### **Initial state**

This property specifies the state of the mediation point when the host messaging engine is started for the first time. Permitted values are Started or Stopped. The default state is Started. The mediation does not start mediating messages until Initial state is Started.

#### **Target UUID**

The UUID of the bus destination where this mediation point is created. This field is for display purposes only.

3. Click **OK**.
4. Save your changes to the master configuration.

### **Results**

You have browsed or changed the configuration properties for the selected mediation point.

### **Listing mediation points for a bus destination**

Use this task to list mediation points for a selected bus destination.

#### **About this task**

This task lists the mediation points for a selected bus destination. You might want to do this, for example, to check that a destination is mediated.

To display a list of mediation points for a bus destination, use the administrative console to complete the following steps:

1. Click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name*.
2. Click **[Message Points] Mediation Points**.

#### **Results**

All the mediation points for the selected bus destination are displayed.

### **Listing mediation points for a messaging engine**

This task displays a list of mediation points for a selected messaging engine.

#### **About this task**

This task uses the administrative console to list all the known mediation points for a selected messaging engine. You can then view the properties for a mediation point, administer messages for a mediation point, or operate mediations at a mediation point.

To list the mediation points for a selected messaging engine, use the administrative console to complete the following steps:

Start the administrative console, and click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points**.

#### **Results**

The Mediation points panel displays a list of all the mediation points for the selected messaging engine.

## What to do next

You can click the name of a mediation point in the list to work with its properties, administer its messages or operate mediations.

## Managing mediations with administrative commands

You can use wsadmin commands to administer service integration technologies mediations. For example you can create, delete and view mediations, configure mediation properties and mediate destinations.

### About this task

These commands provide an alternative to using the administrative console.

1. Open a wsadmin command session in local mode For example:

```
wsadmin -conntype none -lang jython
```

2. Type `AdminTask.command` where *command* is the command format as indicated in the related reference topics. For example:

```
wsadmin>AdminTask.listSIBMediations("-bus abus")
(cells/9994GKCCe1101/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCe1101/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```

## Operating mediations at mediation points

Use these tasks to start, stop and restart mediations at runtime at specialized message points called mediation points.

### Before you begin

These tasks assume that mediations are configured in the administrative console. For more information, see “Configuring mediations” on page 1328.

### Starting a mediation

Use this task to start a selected mediation at a mediation point.

### Before you begin

Before you can start a mediation, it must be associated with a destination. For more information, see “Mediating a destination” on page 1337.

### About this task

You start a mediation when you want the mediation to start mediating messages. Starting a mediation, like all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. A mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

**Note:** If you want to ensure that the mediation starts processing a specific message, remove existing messages from the mediation point before you start the mediation. For more information, see “Deleting messages on a mediation point” on page 1343.

To start a mediation, use the administrative console to complete the following steps:

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name* → **[Message Points] Mediation points**.

- To list the mediation points for a messaging engine, click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points**.
2. Select the mediation name.
  3. Click **Start**.

## Results

The mediation starts processing messages mediation point that arrive at the mediation point.

## Stopping a mediation

Use this task to stop a selected mediation at a mediation point.

## Before you begin

Before you can operate a mediation, it must be associated with a destination. For more information, see “Mediating a destination” on page 1337.

## About this task

Stopping a mediation, like all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. By stopping a mediation, you stop any further messages from being delivered to the mediation point. Messages sent to the destination are held at the pre-mediated part of the destination. The messages are not mediated and are not made available to message consumers until the mediation is restarted. Note that mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

To stop a selected mediation, use the administrative console to complete the following steps:

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name* → **[Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points**.
2. Select the mediation name.
3. Click **Stop**.

## Results

The mediation is stopped at the mediation point. Messages arriving at the mediation point are not processed by the mediation. The messages are stored at the mediation point until the mediation is restarted.

## Restarting a mediation that has stopped on error

This topic describes how to restart a mediation that has stopped on error.

## About this task

You need to restart a mediation that has stopped on error so that the mediation can continue processing messages. When the mediation is restarted, the mediation resumes mediating messages on the pre-mediated part of the destination.

Changes in the state of a mediation normally occur as the result of operations performed by the administrator. If the state of a mediation moves from Started to Stopped on error, and you have not stopped it intentionally, you should investigate the cause of the problem, and resolve it before attempting to restart the mediation.

To restart a mediation that has stopped on error, use the administrative console to complete the following steps:

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name* → **[Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points**.
2. In the content pane, select the mediation name.
3. Click the **Runtime** tab.
4. Under **General Properties**, view the information in the **Reason** field.
5. Resolve the problem.
6. Restart the mediation so that it can continue processing messages.

## Administering messages on mediation points

Use these tasks to list and delete runtime messages held at mediation points in a service integration bus.

### Listing messages at a mediation point

Use this topic to list messages at a mediation point.

#### About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. You can browse and delete messages on a mediation point for a selected bus destination or messaging engine.

To display a list of messages on a selected mediation point, use the administrative console to complete the following steps:

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration** → **Buses** → *bus\_name* → **[Destination resources] Destinations** → *destination\_name* → **[Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration** → **Buses** → *bus\_name* → **[Topology] Messaging engines** → *engine\_name* → **[Message points] Mediation points**.
2. Click the mediation point name. This displays the properties of the mediation point.
3. Click the **Runtime** tab.
4. Click **[Additional Properties] Messages**.

#### Results

A list of messages on the selected mediation point is displayed in the content pane.

### Deleting messages on a mediation point

Use this topic to delete messages that exist on a mediation point for a selected bus destination.

## About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. Like other message points, you can delete messages on a mediation point for a selected bus destination or messaging engine. For example, if you want to preserve message ordering at a destination before it is unmediated, you can delete all the messages at that destination.

1. List the messages at the mediation point. For more information, see “Listing messages at a mediation point” on page 1343.
2. In the content pane, click the check box next to each message you want to delete. Alternatively, select all the messages in the list by clicking **Select All Items**.
3. Click **Delete**.

## Results

The selected messages are removed from the destination.

## Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it simply extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
 SIMessageContext msgCtx = (SIMessageContext)context;
 SIMediationSession session = msgCtx.getSession();
 SIMessage msg = msgCtx.getMessage();
 String msgId = msg.getApiMessageId();
 String corrId = msg.getCorrelationId();
 String dest = session.getDestinationName();

 System.out.println(msgId+" (correlation id="+corrId) is passing through "+dest+".");

 return true;
}
```

---

## Security

This topic is an overview of the tasks for administering messaging security for a service integration bus.

### Before you begin

Review the security requirements for the bus. For guidance, see Planning your security requirements.

### About this task

Messaging security protects the bus from unauthorized access. By default, messaging security is enabled for the bus. Providing administrative security is also enabled, messaging security enforces a security policy that prevents unauthorized client applications from connecting to the bus, and accessing bus resources. There may be circumstances when you do not require messaging security, for example on a development system. In this case, you can disable messaging security.

You can customize the security configuration for the bus using the administrative console, or wsadmin scripting commands. The security configuration controls the following aspects of bus security:

- Authorizing groups of users in the user registry to perform selected operations on bus destinations.
- The transport policies that maintain the integrity of messages in transit on the bus.
- The use of global, and multiple custom security domains.
- The integrity of links between messaging engines, foreign buses and databases.

Use the following tasks to administer messaging security:

- “Securing buses”
- “Enabling client SSL authentication” on page 1352
- “Adding unique names to the bus authorization policy” on page 1354
- “Administering authorization permissions” on page 1354
- “Administering permitted transports for a bus” on page 1380
- “Securing messages between messaging buses” on page 1384
- “Securing access to a foreign bus” on page 1385
- “Securing links between messaging engines” on page 1386
- “Controlling which foreign buses can link to your bus” on page 1387
- “Securing database access” on page 1387
- “Securing mediations” on page 1327

## Securing buses

Securing a service integration bus provides the bus with an authorization policy to prevent unauthorized users from gaining access. If a bus is configured to use multiple security domains, the bus also has a security domain and user realm to further enforce its authorization policy.

### Before you begin

- If administrative security for the cell in which the bus resides is not already enabled, you must enable it. The tasks below use an administrative console wizard that detects if administrative security is not enabled, and takes you through the steps to enable it. You need to supply the type of user repository used by the server, and the administrative security username and password.
- If the bus contains a bus member at WebSphere Application Server Version 6.x, you must provide an authentication alias to establish trust between bus members, and to enable the bus to operate securely. The administrative console wizard detects if an authentication alias is required, and prompts you to supply one. If you want to specify a new authentication alias, you must provide a username and password.

### About this task

When you secure a bus, consider the following points:

- If you are securing a WebSphere Application Server Version 7.0 bus that contains only Version 7.0 bus members, you can use a non-global security domain for the bus. If the bus has a WebSphere Application Server Version 6.x bus member, or might have a Version 6.x bus member in the future, you must assign the bus to the global security domain.
- If you want to assign the bus to a custom domain, you can select an existing security domain, or create a new one.
- If you assign the bus to a custom domain, you must specify a user realm. You can select an existing user realm, or use the global user realm.

### What to do next

- The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.
- Use the administrative console to control access to the bus by administering users and groups in the bus connector role.

## Disabling bus security

If you do not want to protect the bus from unauthorized access, you can disable messaging security.

### Before you begin

- Ensure that there are no indoubt transactions on the messaging engine because incomplete transactions cannot be recovered after the bus security is disabled. For more information, refer to Resolving indoubt transactions.
- Stop all servers on which the SIB Service enabled before you disable bus security. This ensures that the bus security configuration is applied consistently when the servers are restarted. For more information, refer to Stopping an application server.

### About this task

Messaging security protects the bus from access by unauthorized client applications. Messaging security is enabled by default, providing administrative security for the cell is enabled. However, there may be circumstances when you do not require messaging security, for example on a development system. In this case, you can use the administrative console to disable messaging security. If you want to re-enable bus security, refer to “Securing buses” on page 1345.

1. In the navigation pane, click **Service integration** → **Buses**. A list of buses is displayed.
2. Find the bus for which you want to disable security, and click **Enabled** in the security column. The security settings for the selected bus are displayed.
3. Clear the checkbox **Enable bus security**.
4. Click **Apply**.
5. Save your changes to the master configuration.

### Results

You have disabled security for the selected bus.

### What to do next

You must propagate the bus security configuration to all the affected nodes, and restart the servers. For more information, refer to Synchronizing nodes with the wsadmin tool and Starting an application server.

## Adding a secured bus

This task uses an administrative console wizard to add a new service integration bus that uses a security domain. A bus can use the global security settings, inherit the security settings that exist at cell level, or use a set of customized settings that are unique to the bus, or shared with another resource.

### Before you begin

You must decide which type of security domain to use for the bus. For more information, refer to Planning your security requirements and Messaging security and multiple security domains.

### About this task

By default, administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, the wizard prompts you to enable it. You must specify the type of user repository, and the administrative security username and password.

Security settings are held in a security domain. If the bus might contain a WebSphere Application Server Version 6.x bus member, you must select the global domain. You can select any type of domain for a bus that contains only WebSphere Application Server Version 7.0 bus members.

1. Log into the administrative console.

2. Click **Service integration** → **Buses**. A list of buses is displayed.
3. In the content pane, click **New**.
4. Type a name for the new bus. It is advisable to choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after a bus is created, so if you need to interoperate with WebSphere MQ in the future, it will be much simpler if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
5. Ensure that the **Bus security** checkbox is checked.
6. Click **Next**. The Bus Security Configuration wizard is launched.
7. Read the Introduction panel, and click **Next**.
8. If administrative security is disabled, follow the instructions in the wizard to select, and configure the appropriate user repository.
9. Click **Next**. A summary of the administrative security settings for the bus is displayed.
10. Review the summary, and click **Finish**. Administrative security for the cell is now enabled.
11. By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports**.
12. Select a security domain for the bus. The domain you specify depends on the versions of the bus members. If the bus may contain a Version 6.x bus member, you must select the global domain. If the bus will only contain Version 7.0 bus members, you can select the cell-level or a custom domain. If you select a custom security domain, you must also follow the instructions to specify a user realm.
13. Review the summary of your choices, and click **Finish**.
14. Save your changes to the master configuration.

## Results

Administrative security is enabled, and a new bus is created with your chosen security settings.

## What to do next

You can now add bus members to the bus.

## Securing an existing bus using multiple security domains

You can configure an existing service integration bus so that it uses a security domain other than the default global security domain. Using non-global security domains provides the scope to use multiple security domains. The bus can inherit security settings from the cell, or have a unique security configuration.

## Before you begin

- For more information about using security domains, refer to Planning your security requirements and Messaging security and multiple security domains.
- The bus you want to secure must exist in the administrative console. If you want to create a new secured bus, refer to “Adding a secured bus” on page 1198.
- All the bus members must be at WebSphere Application Server Version 7.0; use of multiple security domains is not supported for earlier versions of WebSphere Application Server. If the bus you want to secure has a WebSphere Application Server Version 6.x bus member, refer to “Securing an existing bus using the global security domain” on page 1348.

## About this task

This task uses the Bus Security Configuration wizard to secure a selected bus, and assign it to a security domain. If administrative security for the cell is disabled, the wizard prompts you to enable it. You need to

know the type of user repository, and the administrative security username and password. If you specify a custom domain, you must also specify a user realm.

1. In the navigation pane, click **Service integration** → **Buses** → **security\_value**. The general properties for the selected bus are displayed.
2. Click **Configure Bus Security** to launch the Bus Security Configuration wizard.
3. Read the Introduction panel, and click **Next**.
4. If administrative security is disabled, follow the instructions to configure the appropriate user repository, and click **Next**.
5. Review the summary of your choices:
  - a. If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
  - b. Click **Finish** when you are ready to confirm your choices.

Administrative security for the cell is now enabled.

6. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports**. By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity.
7. Select the cell-level or custom security domain for the bus. You can only select a non-global security domain if all the bus members are at Version 7.0.
8. Optional: To create a new custom security domain:
  - a. Use the name suggested for the security domain, or type a new one.
  - b. Optional: Provide a description of the security domain.
  - c. Select a user realm for the domain. You can use the user realm configured in the global security domain, or follow the steps to configure a new user realm.
9. Click **Next**.
10. Review the summary of your choices:
  - a. Optional: If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
  - b. Click **Finish** to confirm your choices.
11. Save your changes to the master configuration.

## Results

You have specified that the selected bus uses a non-global security domain. The security settings configured for the bus are displayed in the updated Bus Security Settings panel. The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.

## What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

## Securing an existing bus using the global security domain

Use this task to secure an existing service integration bus using the global security domain.

### Before you begin

- The bus you want to secure must exist in the administrative console. If you want to create a new secured bus, refer to “Adding a secured bus” on page 1198.
- If administrative security for the cell in which the bus resides is disabled, the wizard prompts you to enable it. You need to know the type of user repository, and the administrative security username and password.

- If the service bus contains a bus member at WebSphere Application Server Version 6.x, the wizard prompts you to select an existing authentication alias, or specify a new one. If you want to specify a new authentication alias, you must provide a username and password.

## About this task

Use this task if you want to secure a bus that exists already in the administrative console, and you want to use the global (default) security domain. For example, you are securing a Version 7.0 bus that has a bus member at WebSphere Application Server Version 6.x; mixed version buses cannot use multiple security domains.

This task uses an administrative console wizard to guide you through the steps to secure a bus. The following steps are conditional, depending on the bus environment:

- If administrative security for the cell in which the bus resides is disabled, the wizard prompts you to enable administrative security.
- If the bus has a bus member at WebSphere Application Server Version 6.x, the wizard prompts you for an authentication alias to establish trust between bus members, and to enable the bus to operate securely.

Use the administrative console to secure a selected bus using the global security domain as follows:

1. In the navigation pane, click **Service integration** → **Buses** → **security\_value**. The general properties for the selected bus are displayed.
2. Click **Configure Bus Security** to launch the Bus Security Configuration wizard.
3. Read the Introduction panel, and click **Next**. The next step is conditional, depending on whether administrative security is enabled or disabled:
  - If administrative security is disabled, complete all the following steps.
  - If administrative security is already enabled, continue from step 7.
4. Select the appropriate user repository, and click **Next**.
5. Depending on the type of user registry you selected, do one of the following:
  - For a federated repository, specify a username and password for administrative security, and click **Next**.
  - For all other types of repository, follow the wizard prompts, and click **Next**.
6. Review the summary of your choices:
  - a. If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
  - b. Click **Finish** when you are ready to confirm your choices.

Administrative security for the cell is now enabled.
7. If you do not want clients to use SSL protected transports, clear the checkbox **Require clients use SSL protected transports**. By default, clients are required to use SSL protected transports to ensure data confidentiality and integrity.
8. Select the global security domain option, and click **Next**.
9. If at least one bus member is at Version 6.x, you must specify an authentication alias. Specify either an existing authentication alias, or create a new one:
  - Select **Specify existing authentication alias**, and select the alias name from the list box.
  - Select **Create a new authentication alias**, type a unique alias name and password.
10. Review the summary of your choices:
  - a. Optional: If you want to make changes, click **Previous** to return to an earlier panel, and make the changes you require.
  - b. Click **Finish** to confirm your choices.
11. Save your changes to the master configuration.

## Results

You have secured the bus using the global security domain. The new security settings for the bus are displayed in the updated Bus Security Settings panel. The bus is secured after you restart all the servers that are members of the bus, or in the case of a bus that has bootstrap members, servers for which the SIB service is enabled.

## What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

## Configuring bus security using an administrative console panel

Use this task to enable or disable messaging security, and configure security properties for an existing service integration bus.

## Before you begin

The bus must exist in the administrative console. If you want to create a new bus, refer to “Adding buses” on page 1197.

## About this task

This task uses the Bus Security administrative console panel. You can launch the Bus security wizard from the panel, or specify individual security properties directly in the panel. The bus security properties are effective only when administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, it prompts you to enable it.

The security properties available to a particular bus depend on the versions of the bus members. If the bus has a WebSphere Application Server Version 6.x bus member, you must specify the global security domain. The bus cannot use cell level, or custom security domains. You must also specify an inter-engine authentication alias to prevent unauthenticated messaging engines from establishing a connection with the bus. If the bus contains Version 7.0 bus members only, you can specify any type of security domain, and you do not need to specify an inter-engine or mediation authentication alias.

If you want to run mediations across multiple security domains, you can specify a single server identity for the bus, rather than specify a mediation authentication alias for each domain. You can also use a server identity to run mediations on the global domain.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → **security\_value**. *security\_value* is either Enabled or Disabled, depending on the security status of the bus.
3. Click **Launch Bus Security Wizard** to launch the wizard, or specify the following properties directly:

### Enable bus security

Bus security is enabled by default. Clear this check box if you do not want a secure bus. The check box is read-only if administrative security is disabled.

### Inter-engine authentication alias

The name of the authentication alias used to authorize communication between messaging engines on the bus. Specify an inter-engine authentication alias if the bus has a Version 6.x bus member, bus security is enabled, and you want to prevent unauthorized messaging engines from establishing a connection with the bus.

### Permitted transports

Specify one of the following transports for the bus:

- Any messaging transport chain defined to any bus member.

- Only messaging transport chains that are protected by an SSL chain.
- Only the transports specified in the list of permitted transports.

If you want to add and remove permitted transports, click **Service integration** → **Buses** → **security\_value** → **[Additional Properties] Permitted Transports**.

### Use the Server ID when running mediations

Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Mediations are deployed as applications, and run in the domain used by the application server, not the bus domain. If you want to run a mediation on multiple servers in different domains, you must ensure that the user identity in the mediation authentication alias exists in the configuration for each domain. Alternatively, you can choose to use the server identity option. You can use this option when multiple domains are not in use.

### Bus security domain

Specify one of the following security domains for the bus:

#### Global domain

You must specify the global domain if the bus contains a Version 6.x bus member, or you do not want the bus to use multiple domains.

#### Cell level domain

Specify the cell-level security domain if the bus has Version 7.0 bus members only, and you want the bus to share security settings with the administrative cell.

#### Custom domain

Specify a custom security domain if the bus has Version 7.0 bus members only, and you want the bus to use a security domain that is used by another resource, or you want to create a new security configuration for this bus.

4. Save your changes to the master configuration.

## Results

You have configured security properties for the selected bus.

## What to do next

You can use the administrative console to control access to the bus.

## Configuring a bus to run mediations in a multiple security domain environment

Use this task to configure a secured bus so that it can run mediations successfully on bus members in different security domains.

### Before you begin

The secured bus must be configured to use a non-global security domain. For more information about securing buses using multiple security domains, refer to “Securing buses” on page 1345.

### About this task

If your bus topology has bus members in different security domains, you can configure the bus to allow mediations to run under the server identity. This means that a mediation can run on any server in any domain. You do not have to add a dedicated user ID for each mediation to the user repository, or maintain a mediation authentication alias.

Use the administrative console to configure a secured bus to run mediations successfully as follows:

1. In the navigation pane, click **Service integration** → **Buses** → **security\_value**. The security settings for the selected bus are displayed.
2. Check the option **Use the Server ID when running mediations**.
3. Click **Apply**.
4. Save your changes to the master configuration.

## Results

You have configured the bus to run mediations successfully across servers in multiple security domains.

## What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

## Enabling client SSL authentication

You can configure a service integration bus to allow connecting client JMS applications to authenticate using Secure Sockets Layer (SSL) certificates.

### About this task

This is the parent task for the steps required to establish client SSL authentication for connections between messaging engines and JMS applications running in a client container. You need to configure the bus to allow client SSL authentication, and configure the JMS client application to perform client SSL authentication. See the following topics:

- “Configuring a bus to allow client SSL authentication.”
- “Configuring JMS client applications to perform client SSL authentication” on page 1353.

### Configuring a bus to allow client SSL authentication

This task describes how to configure a service integration bus to enable connecting client JMS applications to authenticate using Secure Sockets Layer (SSL) certificates.

### Before you begin

You must ensure that the following tasks have been completed:

- Administrative security is enabled. For more information, see [Enabling security](#).
- A standalone Lightweight Directory Access Protocol (LDAP) user registry has been configured for storing user and group IDs. To access the user registry, you must know a valid user ID that has the administrative role, and password, the server host and port of the registry server, and the base distinguished name (DN). For more information, see [Configuring Lightweight Directory Access Protocol user registries](#).
- Bus security is enabled. For more information, see “Disabling bus security” on page 1346.
- JMS client applications have been configured to authenticate using client SSL certificates.

### About this task

If you want to allow connecting JMS application clients to authenticate to the bus using client SSL certificates you need to define an SSL configuration. There are two parts to this task. First you use the administrative console to map SSL certificates to entries in the LDAP user registry. Secondly, you create a unique SSL configuration for each endpoint address for which you want to use client SSL authentication. Do not use the default SSL configuration for the bus.

1. Use the administrative console to define certificate filters to map an SSL certificate to an entry in the LDAP server. For more information, see *Creating a Secure Sockets Layer configuration*. The client SSL certificate is mapped to a user ID in the user registry.
2. Create a separate SSL configuration file for each endpoint address for server, bus member or cluster on the bus, and select that client authentication is required. For more information, see *Creating a Secure Sockets Layer configuration*

## Results

The bus is configured to allow client SSL authentication.

## What to do next

Connecting JMS client applications can now authenticate to the bus using client SSL certificates.

## Configuring JMS client applications to perform client SSL authentication

This task describes how to configure JMS client applications to authenticate to the bus using client Secure Sockets Layer (SSL) authentication.

### Before you begin

- You have already obtained a Secure Sockets Layer (SSL) certificate for the JMS client application.
- The JMS client application is already configured to use SSL. For more information, see *SSL client properties file*

### About this task

This task has two objectives. First, you install the SSL certificate for the client application in the key store for the application client. Secondly, you modify the `sib.client.ssl.properties` file to use client SSL authentication. You use the Key Management (iKeyman) utility to work with SSL certificates. The iKeyman user interface is Java-based and uses the Java support that is installed with IBM HTTP Server.

Take the following steps to configure a JMS client application to use client SSL authentication:

1. Start the iKeyman user interface. Refer to the *iKeyman User's Guide* available from IBM developer kits for more information about using iKeyman.
2. When prompted, select the key store for the JMS client application.
3. When prompted for the type of certificate to work with, select the option **Personal certificates**. A list of personal certificates is displayed.
4. Select that you want to import a certificate to the selected key store.
5. When prompted, type the location and name for the certificate. You can provide an alias for the certificate. The certificate is installed into the keystore of the client application.
6. Close the iKeyman user interface.
7. Open a text editor to work with the `sib.client.ssl.properties` properties file. This file is located in the `profile_root/properties` directory of the application server installation, where `profile_root` is the directory in which profile-specific information is stored.
8. Set the value for the property `com.ibm.ssl.client.clientAuthentication` to *True*.
9. Set the value for the property `com.ibm.ssl.client.keyStoreClientAlias` to the alias name for the certificate in the client key store.
10. Save the `sib.client.ssl.properties` properties file.

## Results

You have now configured a JMS client application to use client SSL authentication.

## Adding unique names to the bus authorization policy

How to update the authorization policy for the service integration bus with unique name entries.

### About this task

You should carry out this task if you are migrating from WebSphere Application Server Version 6.x to WebSphere Application Server Version 7.0. In this task, you manually run the `populateUniqueNames` command to query the user repository for a selected bus for unique names, and add them to the authorization policy. If you do not manually run this command, the messaging engine performs the query, and adds the missing unique names to the authorizations policy, which adversely affects the start up time.

When you migrate from a Version 6.x node to a Version 7.0 node, the authorization policy only contains the user and group security names; it does not contain the names in the user registry that uniquely define each user and group. If an LDAP user registry is in use, the unique name is the distinguished name (DN). By default, only missing unique names are added to the authorization policy. If you set the **-force** parameter, all unique name entries added to the authorization policy

1. Launch a scripting command. For more information, refer to Starting the wsadmin scripting client.
2. At the wsadmin command prompt, type the `populateUniquenames` command. The following example syntax queries the user repository for the unique names that match the security names for a bus called Bus 1, and adds the missing unique names to the authorization policy .

```
AdminTask.populateUniquenames('[-bus Bus1]')
```

3. Save your changes to the master configuration repository. The following example presents the syntax:

```
AdminConfig.save()
```

### Results

The authorization policy for the bus is updated with the missing unique names.

### Example

The following example updates all the unique name entries in the authorization policy for a bus called Bus 1.

```
AdminTask.populateUniqueNames(AdminTask.populateUniquenames('[-bus Bus1 -force TRUE]'))
```

### What to do next

Use the administrative console to administer bus security authorizations.

## Administering authorization permissions

Service integration messaging security uses role-based authorization. When a user is assigned to a role, the user is granted all of the permissions that the role contains. By administering authorization permissions, you can control user access to a bus and its resources when messaging security is enabled.

### Before you begin

For guidance on security authorization for a service integration bus, refer to Planning your security requirements.

### About this task

When a bus is created, a set of default authorization roles is created. Default roles provide authenticated users who have the bus connector role with full access to all local destinations on the bus. By default, only members of the Server group have the bus connector role. If a specific user needs to connect to the bus, you must explicitly add that user to the bus connector role.

You can make changes to authorization permissions when messaging security is enabled or disabled. Any changes that you make when security is disabled do not have any effect until security is enabled, as described in “Disabling bus security” on page 1346.

**Note:** When you specify the group authorization permissions, the group distinguished name (DN) must be used. If you specify a common name (CN) for the group name, users in that group do not have the specified authorities. For more details see Standalone Lightweight Directory Access Protocol registries.

When security is enabled, by default users cannot connect to a foreign bus. If a specific user needs to connect to a foreign bus, you must explicitly add that user to the foreign bus access list.

Use the following tasks to administer authorization permissions for a bus to meet your security requirements.

- “Administering the bus connector role”
- “Administering default roles” on page 1358
- “Administering destination roles” on page 1314
- “Administering foreign bus roles” on page 1365
- “Administering topic space root roles” on page 1372
- “Administering topic roles” on page 1375
- Listing security roles for service integration by using the wsadmin tool
- Removing users and groups by using the wsadmin tool
- Removing authorization data by using the wsadmin tool

## **Administering the bus connector role**

Service integration bus security uses role-based authorization. By administering groups of users in the bus connector role, you can control access to the local service integration bus and its resources when messaging security is enabled.

### **About this task**

Adding a group of users to the bus connector role for a local bus grants the members of the group permission to access local bus destinations. The users and groups you want to work with must exist in the user repository.

Use the following tasks to list, add and remove groups of users in the bus connector roles using the administrative console.

- “Listing users and groups in the bus connector role”
- “Adding users and groups in the bus connector role” on page 1356
- “Removing users and groups from the bus connector role” on page 1357

### ***Listing users and groups in the bus connector role:***

Service integration bus security uses role-based authorization. By listing the users and groups in the bus connector role, you can find out which users and group members are authorized to connect to a selected secured local bus, and its resources.

### **Before you begin**

Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1345.

### **About this task**

In this task you use the administrative console to list the users and groups in the bus connector role for a selected local bus. By default, the list is empty for a new bus.

1. Log into the administrative console.

2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Users and groups in the bus connector role**.

## Results

A list of the users and groups in the bus connector role for the selected bus is displayed. The list is empty for a new bus.

## What to do next

You can add and delete users and groups in the bus connector role for the selected bus.

### ***Adding users and groups in the bus connector role:***

Service integration bus security uses role-based authorization. By adding users and groups to the bus connector role for a secured bus, you can control which users and group members have access to the bus and its resources.

## Before you begin

- Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1345.
- The users and groups that you want to add to the bus connector role must exist already in the user repository.

## About this task

Adding users and groups to the bus connector role enables them to connect to the bus to carry out messaging operations. You can add a user directly to the bus connector role, or indirectly by adding a group to which the user belongs. You can also add special groups of users. There are three special groups:

### **Server**

The server identity is a WebSphere Application Server . You cannot specify the Server group for a JMS message-driven bean (MDB).

### **All Authenticated**

This group comprises all user identities that authenticate successfully to the bus.

### **Everyone**

The user identities in this group are anonymous, and connect to the bus without security authentication.

## Note:

- If the user registry is an LDAP registry, you must use the group distinguished name (DN) when you specify a group name to add to a bus connector role. Using the common name (CN) causes problems in security authorization. For more information, refer to *Service integration bus security: Troubleshooting tips and Standalone Lightweight Directory Access Protocol registries*.
- If you attempt to add a user or a group that is already a member of the bus connector role, a warning message is displayed.

In this task you use an administrative console wizard to add groups and users to the bus connector role for a selected local bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Users and groups in the bus connector role**. A list of the users and groups already in the bus connector role for the selected bus is displayed. By default, the list is empty for a new bus.

3. Click **New** to launch the Security Resource Wizard.
4. Choose whether you want to add groups or users:
  - If you want to add a special group, select **The built-in special groups** option.
  - If you want to add other groups or users in the user repository, select the appropriate option, and complete the following mandatory fields:

**Search pattern**

Specify a string to match against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. You can specify wildcard characters.

**Maximum number of search results to display**

Specify the maximum number of user IDs or group names to display.

5. Click **Next** to display a list of groups or users.
6. Select the names of the groups or users you want to add to the bus connector role, and click **Next**.
7. Click **Finish** to confirm you choices.
8. Save your changes to the master configuration.

**Results**

The selected users and groups are added to the bus connector role for the selected bus.

**What to do next**

You can perform other security administration tasks by using the administrative console.

***Removing users and groups from the bus connector role:***

Service integration bus security uses role-based authorization. By removing selected users and groups from the bus connector role for a selected secured bus you prevent those users and group members from connecting to the bus.

**About this task**

The users and groups that you remove from the bus connector role for a bus can no longer perform messaging operations on the bus. Note that removing a user from the bus connector role does not prevent that user from connecting to the bus if they are also a member of a group that is in the bus connector role.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → **security\_value** → **[Authorization Policy] Users and groups in the bus connector role**. A list of the users and groups in the bus connector role for the selected bus is displayed.
3. Select the check box next to the name of the user or group that you want to remove, and click **Delete**.
4. Save your changes to the master configuration.

**Results**

The selected users and groups are removed from the bus connector role.

**What to do next**

You can perform other security administration tasks by using the administrative console.

## Administering default roles

Service integration bus security uses role-based authorization. By adding a user or a group to the default roles for a secured bus, you can control which users and group members have access to the bus and its resources in the default roles when messaging security is enabled.

### About this task

The default roles are sender, receiver, browser, and creator. These roles apply to bus destinations that do not have a destination role, or have been configured to inherit the default roles. By default, all destinations inherit the default roles. Access in the default roles exists in addition to any specific access roles that have been configured for a destination.

Use the following tasks to list, add, and remove groups of users in default roles using the administrative console.

- “Adding users and groups to default roles”
- “Removing users and groups from default roles” on page 1359
- “Listing users and groups in default roles”

### *Listing users and groups in default roles:*

Service integration bus security uses role-based authorization. By listing the users and groups in the default roles for a selected secured bus, you can find out which users and group members are authorized to perform messaging operations on a local bus destinations that is allowed to inherit default roles.

### About this task

In this task you use the administrative console to list users and groups in the default access roles for a selected secured bus. The default role types are sender, receiver, browser and creator.

1. Log into the administrative console.
2. Click **Service integration** →  **Buses** → *security\_value* → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed. The information for the default access is displayed in a collapsed section.
3. Expand the Default access header.

### Results

A list of users and groups in default roles for the selected bus is displayed.

### What to do next

You can also add and remove users and groups in default roles.

### *Adding users and groups to default roles:*

Service integration bus security uses role-based authorization. By adding selected users and groups to the default roles for all the local bus destinations on a secured bus, you provide those users and group members with access to the local bus destinations that are allowed to inherit default roles.

### Before you begin

If a bus destination is not allowed to inherit the default roles, you must first add the user or group to the role that grants authorization permission for the specific local destination. For more information, see “Adding users and groups to destination roles” on page 1314.

## About this task

The default roles are sender, receiver, creator and browser. In this task you use an administrative console wizard, the Security wizard, to add selected users or groups to the default roles. The Security wizard requests information to enable it to retrieve selected users or groups from the potentially very large number of users and groups in the user repository.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed.
3. Expand the Default access header to list the users and groups that have been assigned to default access roles.
4. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to default access roles:
  - a. Search for the users or groups that you want to add to default access roles:

### Users or Groups

Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

### Search pattern

This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

### Maximum number of search results to display

This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

- b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
  - c. Select the check boxes next to the user IDs or group names that you want to add to the default access roles, and click **Next**. A list of user IDs or group names that you can add to the default access roles is displayed. Note that some users or groups may already be assigned to default access roles.
  - d. Select the role types that you want to assign to a user or group. For example, to assign a group to the sender role, click the sender icon for the appropriate group name. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
  - e. Complete the previous step for each user or group that you want to add to access roles, and then click **Next**. A summary of your role type assignments is displayed.
  - f. Click **Previous** to review and change your assignments, if required.
  - g. Click **Finish** to confirm your assignments. The Default access roles panel is redisplayed and shows the new role type assignments.
5. Save your changes to the master configuration.

## Results

The selected users and groups are added to selected default roles for the selected bus.

## What to do next

You can perform other security administration tasks by using the administrative console.

### **Removing users and groups from default roles:**

Service integration bus security uses role-based authorization. By removing selected users and groups from the default roles for a selected secured bus, you prevent those users and group members from accessing the bus using the default roles.

### About this task

When you remove users and groups from the default roles for a bus, they can no longer access local bus destinations that inherit default access permissions. Note that removing a user from the default roles does not prevent that user from accessing the bus if they are also a member of a group that has been assigned to the default roles for that bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage default access roles**. The Default access roles panel is displayed.
3. Expand the Default access header to list the users and groups that have been assigned to default access roles for the selected bus.
4. Select the users and groups that you want to remove from the default access roles for this bus, and click **Remove**.
5. Save your changes to the master configuration.

### Results

The selected users and groups are removed from the default roles for the selected bus. The Default access roles panel displays the changes to the default access role assignments.

### What to do next

You can perform other security administration tasks by using the administrative console.

## Administering destination roles

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups must have authority to perform messaging operations, at a bus destination. By administering destination roles, you can control which users and groups can perform operations at a bus destination, and the type of operation that they can perform.

### About this task

You use the administrative console to administer users and groups in access roles for a destination. The access roles available for a destination depend on the type of destination. The table below lists the roles that you can assign for each destination type:

Destination type	Access roles
queue	sender, receiver, browser, creator
port	sender, receiver, browser, creator
webService	sender, receiver, browser, creator
topicSpace	sender, receiver
foreignDestination	sender
alias	sender, receiver, browser

In addition to controlling which users and groups have access to a specific local or foreign destination, you can also control the inheritance of access roles for a specific local destination. In this case, the default access roles that apply to all the destinations in the local bus namespace are added to any access roles that have been added for a specific destination.

Use the following tasks to administer destination roles.

- Listing users and groups in bus destination roles by using the wsadmin tool
- Adding users and groups to bus destination roles by using the wsadmin tool
- Removing users and groups from bus destination roles by using the wsadmin tool
- Defining destination defaults inheritance by using the wsadmin tool
- Determining destination defaults inheritance by using the wsadmin tool

### ***Listing users and groups in destination roles:***

Service integration bus security uses role-based authorization. By listing the users and groups in the destination roles for a selected secured bus, you can find out which users and groups are authorized to access the bus, and its resources.

### **About this task**

In this task you use the administrative console to list all the users and groups in destination roles for selected destinations. The list includes users and groups that have references in the service integration role-based configuration; it does not include all the users and groups that exist in the user repository. The permitted destination roles are sender, receiver, browser and creator, depending on the destination type. Icons are used in the administrative console to represent the roles to which users and groups have been assigned. For example, if the role type set icon () is displayed in the sender role for a group called Group 1, it means that Group 1 has been assigned to the sender role for a selected destination. For a complete description of all the icons used to represent role assignments in the administrative console, refer to Access role assignments for bus security resources.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
  - Click the name of a single destination.
  - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.

4. Expand a destination header.

### **Results**

The Destination access roles panel lists the users and groups in access roles for the expanded destination.

### **What to do next**

You can now administer the users and groups in destination roles at this destination.

### ***Adding users and groups to destination roles:***

Service integration bus security uses role-based authorization. By adding users and groups to the destination roles for a secured bus, you can control which users and group members can perform messaging operations at a bus destination.

### **Before you begin**

Ensure that the following conditions are met:

- Security is enabled for the bus. For more information, refer to “Securing buses” on page 1345.

- The users and groups that you want to add to destination roles must exist already in the user repository.

### About this task

By adding users or groups to destination role, you grants the users or groups authority to perform the operation defined by the role at a selected destination. The destination roles are sender, receiver, browser, and creator, depending on the destination type.

In this task you use the administrative console Security wizard to retrieve selected users or groups from the user repository, and add them to destination roles for selected bus destinations.

**Note:** To add a large number of users to destination roles, it is advisable to create a group in the user repository, and add the group to the destination roles.

1. Start the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage destination access roles**. A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destination to work with:
  - Click a single destination name.
  - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.

4. Expand a destination header to list the users and groups that have been assigned to roles for this destination. You can verify that the user or group you want to add does not already have a role at this destination.
5. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to access roles for the expanded destination:
  - a. Search for the users or groups that you want to add to access roles for the expanded destination:

#### Users or Groups

Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

#### Search pattern

This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

#### Maximum number of search results to display

This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

- b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
- c. Select the check boxes next to the user IDs or group names that you want to add to access roles for the currently expanded destination, and click **Next**. A list of user IDs or group names that you can add to destination roles is displayed. Note that some users or groups may already be assigned to access roles for this destination.
- d. Select the appropriate access role icon for the user ID or group name that you want to add to the role at this destination. For example, select the **Receiver** icon for a user ID or group name that you want to add to the receiver role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
- e. Repeat the previous step to add more users or groups to access roles for the currently expanded destination, and then click **Next**. A summary of your access role assignments is displayed.

- f. Click **Previous** to review and change your assignments, if required.
  - g. Click **Finish** to confirm your assignments.
6. Repeat steps 4 and 5 for each destination you want to work with.
  7. Save your changes to the master configuration.

## Results

The selected users and groups are added to the access roles for the currently expanded destination. The new access role assignments are displayed in the Destination access roles panel.

## Example

A group called MyGroup receives messages from three queues, Queue 1, Queue 2, and Queue 3. If you want the group MyGroup to produce and consume messages at an additional destination, Queue 4, you add MyGroup to Queue 4, and then add MyGroup to the sender and receiver roles for Queue 4.

## What to do next

Use the administrative console to perform other security administrative tasks.

### ***Removing users and groups from destination roles:***

Service integration bus security uses role-based authorization. By removing users and groups from the destination roles for a secured bus, you can prevent those users and group members from performing messaging operations on the bus.

## About this task

When selected users and groups no longer require access to a destination, you can remove them from all the roles for that destination.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage destination access roles** A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destinations to work with:
  - Click a single destination name.
  - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.

4. Expand a destination header to list the users and groups that have been assigned to roles at this destination, and verify that the user or group that you want to remove has a role at this destination.
5. Select the users and groups that you want to remove from all role types at this destination, and click **Remove**.
6. Save your changes to the master configuration.

## Results

The selected users and groups are removed from all role types at the selected destination. The Manage access roles for users and groups panel displays the updated role type assignments.

## Example

The members of three groups, Group A, Group B, and Group C, belong to the sender role and the receiver role for two queue destination, Queue 1 and Queue 2. If Group B is no longer required to send and receive messages on Queue 2, you can use this task to remove Group B from all the role types on Queue 2.

## What to do next

You can perform other security administration tasks by using the administrative console.

### ***Enabling topic role inheritance:***

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, and users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If topic role inheritance has been disabled for a particular topic, you can restore it by using the administrative console.

## Before you begin

You must ensure that the following conditions are met:

- Messaging security is enabled. For more information, refer to “Disabling bus security” on page 1346.
- Topic level security is enabled for the topic space. Check the setting **Topic Access Check Required?** in the topic space destination configuration. For more information, refer to “Configuring bus destination properties” on page 1303.

## About this task

In this task you use the administrative console to restore topic role inheritance for selected topics. A topic can only inherit the sender and receiver roles from the parent topic in the topic hierarchy.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have one or more access roles for this topic.
4. Select the **Inherit sender role from parent topic** check box.
5. Select the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

## Results

The select topic inherits access roles from the parent topic. The Topic access roles panel displays the inherited access roles for the topic.

## What to do next

You can perform other security administration tasks by using the administrative console.

### ***Disabling topic role inheritance:***

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If you do not want topics to inherit topic roles from the parent topic in the topic hierarchy, you can override topic role inheritance by using the administrative console.

## Before you begin

### About this task

In this task you use the administrative console to prevent a selected topic from inheriting authorization roles from its parent topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have access one or more access roles for the selected topic.
4. Clear the **Inherit sender role from parent topic** check box.
5. Clear the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

### Results

The selected topic cannot inherit access roles from its parent topic. The Topic access roles panel displays the changed access roles for the selected topic.

### What to do next

You can perform other security administration tasks by using the administrative console.

## Administering foreign bus roles

Service integration bus security uses role-based authorization. When messaging security is enabled, groups of users require authority to send messages from a local bus destination to a foreign bus. By listing, adding and removing users and groups in foreign bus roles, you can control who can send messages to foreign buses.

## Before you begin

These tasks assumes that one or more foreign bus connections have been configured. For more information, refer to “Configuring foreign bus connections” on page 1223.

### About this task

The foreign bus connection represents another service integration bus. The bus is either in the same cell as the local bus, or in a different cell, or it represents a WebSphere® MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell. Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses. A member of a group that belongs to the sender role on the local bus and the foreign bus can send messages directly to the foreign bus. The sender role is the only foreign bus role.

For more information about how to list, add and remove groups of users in foreign bus roles using the administrative console, refer to the following tasks.

- “Adding users and groups to foreign bus roles”
- “Removing users and groups from foreign bus roles” on page 1368
- “Listing users and groups in foreign bus roles”

### ***Listing users and groups in foreign bus roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send messages from a secured local bus destination to a secured foreign bus. By listing all the users and groups in foreign bus roles for a selected foreign bus, you can find out who has authority to send messages from the local bus to the selected foreign bus.

### **About this task**

In this task you use the administrative console to list users and groups in the sender role for selected foreign buses. The list includes users and groups that have references in the service integration role-based configuration. It does not include all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage foreign bus access roles**. A list of all the foreign buses defined for the selected bus is displayed.
3. Select one or more foreign buses:
  - Click the name of a single foreign bus.
  - Select the check boxes next to multiple foreign buses and click **Manage Access Roles**.

The Foreign bus access roles panel is displayed. The access roles information for each foreign bus is displayed in a collapsible section.

4. Expand the section header for a foreign bus.

### **Results**

A list of all the users and groups that have been assigned to the sender role for the currently expanded foreign bus is displayed.

### **What to do next**

You can add and remove users and groups in the sender role for the selected foreign bus.

### ***Adding users and groups to foreign bus roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send messages from a secured local bus destination to a secured foreign bus. By adding selected users and groups to the sender role for a selected foreign bus, you can control who has authority to send messages to the selected foreign bus.

### **Before you begin**

This task assumes that the following conditions have been met:

- One or more foreign bus connections have been configured for the local bus. For more information, refer to “Configuring foreign bus connections” on page 1223.
- The users and groups that you want to add to foreign bus roles must exist in the user repository.

## About this task

By default, when security is enabled, users and groups cannot send messages to a foreign bus. You need to add them to the sender role for the foreign bus. In this task you use an administrative console wizard to select one or more foreign buses, retrieve selected users or groups from the potentially very large number of users and groups in the user repository, and add them to the sender role for the selected foreign buses.

1. Start the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage foreign bus access roles**. A list of the foreign buses defined for the selected bus is displayed in the Foreign buses panel.
3. Select one or more foreign buses to work with:
  - Click a single foreign bus name.
  - Select the check boxes next to multiple foreign bus names, and then click **Manage Access Roles**.

The Foreign bus access roles panel is displayed. The access roles information for each foreign bus you have selected is displayed in a collapsed section.

4. Expand a foreign bus header to list the users and groups that have been assigned to roles for this foreign bus. You can verify that the user or group you want to add does not already have a role for this foreign bus.
5. Click **Add** to launch the Security wizard. The wizard takes you through the following steps to add selected users or groups to the sender role for the selected foreign bus:
  - a. Search for the users or groups that you want to add to the sender role for the expanded foreign bus:

### Users or Groups

Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

### Search pattern

This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

### Maximum number of search results to display

This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

- b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
  - c. Select the check boxes next to the user IDs or group names that you want to add to the sender role for the currently expanded foreign bus, and click **Next**. A list of users IDs or group names that you can add to the sender role is displayed. Note that some users or groups may already be assigned to the sender role for this foreign bus.
  - d. Select the **Sender** icon for a user ID or group name that you want to add to the sender role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
  - e. Repeat the previous step for each user or group you want to add to the sender role, and then click **Next**. A summary of your role assignments is displayed.
  - f. Click **Previous** to review and change your assignments, if required.
  - g. Click **Finish** to confirm your assignments.
6. Save your changes to the master configuration.

## Results

The selected users and groups are added to the sender role for the selected foreign bus. The new access roles are displayed in the Foreign bus access roles panel.

## What to do next

You can perform other security administration tasks by using the administrative console.

### ***Removing users and groups from foreign bus roles:***

Service integration bus security uses role-based authorization. By removing users and groups from the foreign bus roles for a selected secured local bus, you prevent those users and groups from sending messages to the foreign bus.

## About this task

In this task you use the administrative console to remove selected users or groups from the sender role for a selected foreign bus.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage foreign bus access roles**. A list of all the foreign buses defined for the selected bus is displayed.
3. Select one or more foreign buses to work with:
  - Click a single foreign bus name.
  - Select the check boxes next to multiple foreign bus names, and then click **Manage Access Roles**.

The Foreign bus access roles panel is displayed. The access roles information for each selected foreign bus is displayed in a collapsed section.

4. Expand the section header for a foreign bus to display details for all the users and groups that have the sender role for this foreign bus.
5. Select the users and groups that you want to remove from the sender role, and click **Remove**. The selected users and groups are removed from the sender role for this foreign bus.
6. Save your changes to the master configuration.

## Results

The selected users and groups are removed from the sender role for the selected foreign bus. The Foreign bus access roles panel displays the changed access role assignments.

## What to do next

You can perform other security administration tasks by using the administrative console.

### **Administering temporary destination prefix roles**

Service integration bus security uses role-based authorization. A temporary destination prefix can have two role types: creator and sender. The messaging engine uses the temporary destination prefix at runtime to determine which users and groups have authority to create a temporary destination, and send messages to temporary destinations. By administering temporary destination prefix roles for a bus, you control which users and groups can create and send messages to temporary destinations for a selected bus.

## Before you begin

Ensure that security is enabled for the bus. For more information, refer to “Securing buses” on page 1345.

## About this task

By default, a bus does not contain any temporary destination prefixes. You use the administrative console to add a new temporary destination prefix to the bus, and then assign selected users and groups to the sender role for the new temporary destination prefix. The creator role is assigned by default. All authenticated users can create temporary destinations by default. You can remove selected users and groups from the sender role for a selected temporary destination prefix, and you can remove a selected temporary destination prefix.

Use the following tasks to administer temporary destination prefix roles.

- “Adding users and groups to temporary destination prefix roles”
- “Removing users and groups from temporary destination prefix roles” on page 1371
- “Listing users and groups in temporary destination prefix roles”
- “Removing a temporary destination prefix” on page 1371

### ***Listing users and groups in temporary destination prefix roles:***

Service integration bus security uses role-based authorization. Temporary destination prefix roles are used to authorize access to the temporary destinations for a bus. By listing the users and groups in the temporary destination prefix roles for a selected bus, you can find out which users and groups can create temporary destinations, and send messages to temporary destinations for a selected bus.

## About this task

In this task you use the administrative console to list users and groups in temporary destination prefix roles for the selected bus. The list includes users and groups that have references in the role-based security configuration for service integration. It does not include all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage temporary destination prefix access roles**. The Temporary destination prefixes panel lists all the temporary destination prefixes defined on the bus.
3. Select one or more temporary destination prefixes to work with:
  - Click the name of a single temporary destination prefix.
  - Select the check boxes next to multiple temporary destination prefixes, and click **Manage Access Roles**.

The Temporary destination prefix access roles panel is displayed. The access roles information for each temporary destination prefix is displayed in a collapsed section.

4. Expand the header for a selected temporary destination prefix to show its access roles.

## Results

The expanded section lists the users, groups and group members that are assigned to access roles for the selected temporary destination prefix.

## What to do next

You can now administer the users and groups in the sender role for a selected temporary destination prefix.

### ***Adding users and groups to temporary destination prefix roles:***

Service integration bus security uses role-based authorization. The messaging engine uses the temporary destination prefix at runtime to determine whether a client application is authorize to create, or send

messages to a particular temporary destination. By adding users and groups to temporary destination prefix roles for a selected bus, you can control which users and groups can create temporary destinations, and send messages to them.

## Before you begin

The users and groups that you want to add to temporary destination prefix roles must already exist in the user repository.

## About this task

By default, the bus security configuration does not contain any temporary destination prefixes. In this task, you use the administrative console Security wizard to first add a new temporary destination prefix, and then add users and groups to the sender role for the new temporary destination prefix. Note that the creator role is assigned by default to the creator of the temporary destination; you cannot use the administrative console to add users and groups to the creator role. By default, members of the All Authenticated group have authority in the creator role for temporary destination prefixes.

1. Log into the administrative console. The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus. By default, this list is empty.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage temporary destination prefix access roles**
3. Click **Add** to launch the Security wizard:
  - a. Define the name of the temporary destination prefix, and identify the users or groups that you want to add to the sender role for the temporary destination prefix:

### Resource

This field is mandatory. Specify a name for the new temporary destination prefix.

### Users or Groups

Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

### Search pattern

This field is mandatory. Specify a search string that is matched against user identities or group names in the user repository. Only user identities or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wild card characters are allowed.

### Maximum number of search results to display

This field is mandatory. Specify the maximum number of user identities or group names you want the administrative console to display.

- b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
- c. Select the check boxes for the user identities or group names that you want to assign to the sender role for the temporary destination prefix, and click **Next**. Note that you cannot assign users and groups to the creator role; it is assigned by default.
- d. Select the **Sender** icon for each user identity or group name that you want to add to the sender role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
- e. Click **Next**. A summary of your role type assignments is displayed.
- f. Click **Previous** to review and change your role type assignments. Make your changes on the Select role types page, and then click **Next**. Note that you cannot change the name of the temporary destination prefix.
- g. Click **Finish** to confirm your assignments. The role type assignments are saved to the master configuration, and the new assignments are displayed in the Temporary destination prefixes panel.

4. Save your changes to the master configuration.

## Results

The selected users, groups, and group members are added to the sender role for the selected temporary destination prefix roles. The Manage access roles panel displays the new access roles.

## What to do next

You can perform other security administration tasks by using the administrative console.

### ***Removing users and groups from temporary destination prefix roles:***

Service integration bus security uses role-based authorization. When security is enabled, a temporary destination prefix role is used to authorize access to temporary destinations. The temporary destination prefix is used at runtime to create temporary destinations on the bus. By removing users and groups from temporary destination prefix roles for a selected bus, you can prevent selected users and groups from sending messages to temporary destinations on the bus.

## About this task

In this task you use the administrative console to remove users, groups, and group members from the sender role for selected temporary destination prefixes. Note that you cannot use this task to remove users and groups from the creator role. If you want to remove the creator role from a user or group, refer to “Removing a temporary destination prefix.”

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage temporary destination prefix access roles** The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus.
3. Select one or more temporary destination prefixes to work with:
  - Click the name of a single temporary destination prefixes.
  - Select the check boxes next to multiple temporary destination prefixes, and click Manage Access Roles.

The Temporary destination prefix access roles panel is displayed. The access roles information for each temporary destination prefix is displayed in a collapsed section.

4. Expand the header for a selected resource to show its role type assignments.
5. Select the users and groups that you want to remove from the sender role for the currently selected temporary destination prefix, and click **Remove**.
6. Save your changes to the master configuration.

## Results

The selected users, groups, and group members are removed from the sender role for the selected temporary destination prefix. The Temporary destination prefix access roles panel is updated to show the changes to the access role assignments.

## What to do next

You can perform other security administration tasks by using the administrative console.

### ***Removing a temporary destination prefix:***

A temporary destination prefix is used by the service integration bus security model to determine what operations the creator of the temporary destination can perform. By removing a temporary destination prefix, you remove the creator role from the identity of the user that created the temporary destination.

### About this task

A temporary destination prefix can have two authorization role types: creator and sender. In this task you use the administrative console to remove a selected temporary destination prefix from a selected bus, which removes the creator role from the user identity that created the temporary destination.

If you want to remove users and groups from the sender role for a temporary destination prefix, refer to “Removing users and groups from temporary destination prefix roles” on page 1371.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → **security\_value** → **[Authorization Policy] Manage temporary destination prefix access roles**. The Temporary destination prefixes panel lists all the temporary destination prefixes defined for the selected bus.
3. Select the temporary destination prefix you want to remove.
4. Click **Remove**.
5. Save your changes to the master configuration.

### Results

The selected temporary destination prefix is removed, and the creator role is removed from the user identity that created the temporary destination.

### What to do next

You can perform other security administration tasks by using the administrative console.

## Administering topic space root roles

Service integration bus security uses role-based authorization. When messaging security is enabled, groups of users require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By adding and removing users and groups in topic space root roles, you can control access to the topic space root.

### About this task

Topic space root (/) is also called the virtual root, and it is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space, and it is a type of destination. Note that these tasks apply only to the topic space root; they do not apply to topics or a topic space. For information about administering topic access roles, refer to “Administering topic roles” on page 1375, and for information about administering topic space access roles, refer to “Administering destination roles” on page 1314.

You can add and remove users and groups in the sender and receiver roles for the topic space root. The topic space root can also inherit access in the sender and receiver roles from the topic space, providing the topic space is configured to inherit the default destination roles. For more information about topic inheritance, refer to Topic security.

For the topic space root roles to have an effect, the **Topic Access Check Required** checkbox must be set in the topic space configuration. For more information, refer to “Configuring bus destination properties” on page 1303.

Use the following tasks to list, add and remove users and groups in the topic space root roles using the administrative console.

- “Listing users and groups in topic space root roles” on page 1373

- “Adding users and groups to topic space root roles”
- “Removing users and groups from topic space root roles” on page 1375

### ***Listing users and groups in topic space root roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By listing the users and groups in topic space root roles, you can find out who has access to the topic space root for a selected topic space.

#### **About this task**

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. In this task you use the administrative console wizard to list users and groups in topic space root roles for a selected root topic.

This task applies to the topic space root only; it does not apply to the topics within the topic space, or to the topic space. If you want to list users and groups in topic roles, refer to “Listing users and groups in topic roles” on page 1376. If you want to list users and groups in a topic space (which is a type of destination), refer to “Listing users and groups in destination roles” on page 1317.

The users and groups listed in this task have references in the service integration bus security configuration. The list does not include all users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles**

#### **Results**

The Topic space root panel lists all the users and groups in topic space root roles for the selected bus.

#### **What to do next**

You can administer the role type assignments for the users and groups displayed.

### ***Adding users and groups to topic space root roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By adding users and groups to topic space root roles, you control access to the root topic in a selected topic space.

#### **Before you begin**

- The users and groups you want to add to topic space root roles must exist in the user repository.
- Topic space root roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1303.

#### **About this task**

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. Note that this task applies only to the topic space root; it does not apply to adding users and groups to topics or a topic space. For information about adding users and groups to topic access roles, refer to “Adding users and groups to topic roles” on page 1376, and for adding users and groups to topic space access roles, refer to “Adding users and groups to destination roles” on page 1314.

You can add users and groups to the sender and receiver roles for the topic space root. The topic space root can also inherit access in the sender and receiver roles from the topic space, providing the topic space is configured to inherit the default destination roles. For more information about topic inheritance, refer to Topic security.

By default, a topic space does not contain a root topic. In this task you use an administrative console wizard to add a root topic to an existing topic space, retrieve the users and groups from the user repository that you want to assign to roles on the new root topic, and add them to the root topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → **security\_value** → **[Authorization Policy] Manage topic access roles**. The Topic spaces panel lists the topic spaces defined on the selected bus.
3. Select the name of the topic space where you want to add a new root topic. The Topics panel displays the selected topic space in a collapsible section.
4. Click **Add** to launch the Security wizard:
  - a. Identify the users or groups that you want to add to the sender and receiver roles for the new root topic:

#### **Users or Groups**

Select either **Users** or **Groups** to specify whether you want to grant roles to users or groups.

#### **Search pattern**

This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. You can use wildcard characters in the search string.

#### **Maximum number of search results to display**

This field is mandatory. Specify the maximum number of user IDs or group names that you want the administrative console to display.

- b. Click **Next**. The wizard displays the new root topic, and lists the users IDs or group names in the user repository that match the information that you provided in the previous step.
  - c. Select the check boxes next to the user IDs or group names that you want to assign to roles on the new root topic.
  - d. Click **Next**. The wizard displays the topic role types that you can assign for the users or groups you selected in the previous step. Role types might already have been assigned for a specific user or group.
  - e. Select the role types for the selected users or groups. For example, to assign a user to the sender role, select the **Sender** icon for the appropriate user ID. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
  - f. Click **Next**. A summary of your role type assignments for the root topic is displayed.
  - g. If you want to change your assignments, click **Previous** to return to the Select role types page, change your assignments, and then click **Next**.
  - h. Click **Finish** to confirm your assignments. The role type assignments are saved to the master configuration, and the new assignments are displayed in the Topics panel.
5. Save your changes to the master configuration.

## **Results**

The selected users and groups are added to topic space root roles for the new root topic. The **Manage access roles** panel displays the new access role assignments.

## What to do next

You can perform additional security administration using the administrative console.

### ***Removing users and groups from topic space root roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to send and receive messages from the topic space root in a publish/subscribe topic hierarchy. By removing users and groups from topic space root roles, you prevent them from accessing the root topic in a selected topic space.

### **About this task**

Topic space root (/) is the highest level topic in a publish/subscribe topic hierarchy. The hierarchy itself is called the topic space. Note that this task applies only to the topic space root; it does not apply to removing users and groups from topics or a topic space. For information about removing users and groups from topic access roles, refer to “Removing users and groups from topic roles” on page 1377, and for removing users and groups from topic space roles, refer to “Removing users and groups from destination roles” on page 1316.

In this task you use the administrative console to remove selected users and groups from the sender and receiver roles for the selected root topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles**. The Topic spaces panel lists the topic spaces defined on the bus.
3. Select the topic space you want to work with. The selected topic space is displayed in the Topics panel. The root topic (/) is displayed by default.
4. Select the topic space root. The Topic access roles panel lists the role type assignments for the topic space root.
5. Select the names of the users, groups and group members that you want to remove from all role types for the selected root topic, and click **Remove**.
6. Save your changes to the master configuration.

### **Results**

The selected users and groups are removed from all roles for the selected root topic. The Topic access roles panel is updated to show the changes to the access roles assignments.

## What to do next

You can perform other security administration commands using the administrative console.

### **Administering topic roles**

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to access a topic in a publish/subscribe topic hierarchy. By adding and removing users and groups in topic roles, you can control access to the topic.

### **About this task**

You use the administrative console to list, add and remove users and groups in the sender and receiver roles, and to define topic role inheritance. By default, a child topic inherits its topic roles from its parent topic. You can change the default roles for a particular topic by adding or removing topic roles at the topic level. You can also allow or block inheritance of topic roles at topic level.

You can add access roles for a topic before it exists. Topics are created at runtime only, and exist only for as long as they are active.

For information about how to list, add, and remove users and groups in topic roles using the administrative console, refer to the following tasks.

- “Listing users and groups in topic roles”
- “Adding users and groups to topic roles”
- “Removing users and groups from topic roles” on page 1377
- “Enabling topic role inheritance” on page 1364
- “Disabling topic role inheritance” on page 1364

### ***Listing users and groups in topic roles:***

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups require authority to access topics in a publish/subscribe topic hierarchy. By listing the users and groups that are members of topic roles for a selected topic, you can find out who has authority to send messages to and from the topic.

#### **About this task**

In this task you use the administrative console to list users and groups that have access roles for a selected topic in a selected topic space. The list includes users, groups and group members that have references in the role-based security configuration for service integration. It does not list all the users and groups that exist in the external user repository.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topics panel displays the information for the topic in a collapsed section.
3. Expand the section header to display the users and groups that are assigned to role types for the selected topic.

#### **What to do next**

You can add and remove users and groups in the topic roles for the selected topic.

### ***Adding users and groups to topic roles:***

Service integration bus security uses role-based authorization. When messaging security, and topic level authorization is enabled, users and groups must be authorized to access topics in a publish/subscribe topic hierarchy. By adding users and groups to topic roles, you control access to a topic in a selected topic space.

#### **Before you begin**

- The users and groups you want to add to topic space root roles must exist in the user repository.
- Topic roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1303.

#### **About this task**

Topics are organized into one or more hierarchies within a topic space. If the **Topic Access Check Required** setting is enabled for the topic space, a user must have authorization to access the topic itself. You can add access roles to a topic before it is created at runtime. A topic inherits access roles from its parent unless you explicitly block the inheritance. For more information, refer to “Enabling topic role inheritance” on page 1364.

In this task you use an administrative console wizard to add users or groups to the sender and receiver roles for a selected topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic space root panel lists the users and groups that are assigned to role types for the selected topic.
3. Click **Add** to launch the Security wizard:
  - a. Provide the following information to enable the wizard to identify the users or groups that you want to add to role types for the selected topic:

**Resource**

Specify the name of the topic.

**Users or Groups**

Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

**Search pattern**

This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wild card characters are allowed.

**Maximum number of search results to display**

This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

- b. Click **Next**. The wizard lists the users IDs or group names that match the information that you provided in the previous step.
- c. Select the check boxes for the user IDs or group names that you want to assign to roles for the selected topic.
- d. Click **Next**. The wizard lists the topic role types that you can assign for the users or groups you selected in the previous step. Role types may already have been assigned for a specific user or group.
- e. Select the role types for each of the selected users or groups. For example, to assign a user ID to the sender role, select the **Sender** icon for that user ID. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
- f. Click **Next**. A summary of your role type assignments for the selected topic is displayed.
- g. If you want to change your assignments, click **Previous** to return to the Select role types step. Make changes to your assignments, and click **Next** to return to the Confirm step.
- h. Click **Finish** to confirm your assignments and save your changes to the master configuration.

**Results**

The updated role type assignments for the selected users or groups are displayed in the Topic access roles panel.

**What to do next**

You can perform other security administration tasks by using the administrative console.

**Removing users and groups from topic roles:**

Service integration bus security uses role-based authorization. When messaging security is enabled, and the **Topic access check required** setting is enabled for the topic space, users and groups require

authority to access a topic in the topic space. By removing users and groups from all topic roles for a selected topic, you prevent them from accessing the topic.

### Before you begin

Topic roles are effective only when the **Topic Access Check Required** setting is enabled in the configuration for a topic space. For more information, refer to “Configuring bus destination properties” on page 1303.

### About this task

This task uses the administrative console to remove users and groups from both the sender and receiver roles for a selected topic in a selected topic space.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic access roles panel is displayed. The information for the topic is displayed in a collapsed section.
3. Expand the section header to display the users and groups that are assigned to role types for the selected topic.
4. Select the users and groups that you want to remove from the sender and receiver roles for the selected topic, and click **Remove**.
5. Save your changes to the master configuration.

### Results

The selected users and groups are removed from the sender and receiver roles for the selected topic. The Topic access roles panel is updated to show that the selected users and groups have no topic role type assignments.

### *Enabling topic role inheritance:*

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, and users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If topic role inheritance has been disabled for a particular topic, you can restore it by using the administrative console.

### Before you begin

You must ensure that the following conditions are met:

- Messaging security is enabled. For more information, refer to “Disabling bus security” on page 1346.
- Topic level security is enabled for the topic space. Check the setting **Topic Access Check Required?** in the topic space destination configuration. For more information, refer to “Configuring bus destination properties” on page 1303.

### About this task

In this task you use the administrative console to restore topic role inheritance for selected topics. A topic can only inherit the sender and receiver roles from the parent topic in the topic hierarchy.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.

3. Expand the topic name header to display details of the users and groups that have one or more access roles for this topic.
4. Select the **Inherit sender role from parent topic** check box.
5. Select the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

## Results

The select topic inherits access roles from the parent topic. The Topic access roles panel displays the inherited access roles for the topic.

## What to do next

You can perform other security administration tasks by using the administrative console.

### *Disabling topic role inheritance:*

Service integration bus security uses role-based authorization. When messaging security, and topic level security are enabled, users and groups require access in the sender and receiver roles to access a topic in a publish/subscribe topic hierarchy. By default, topics inherit these roles from the parent topic. If you do not want topics to inherit topic roles from the parent topic in the topic hierarchy, you can override topic role inheritance by using the administrative console.

## Before you begin

### About this task

In this task you use the administrative console to prevent a selected topic from inheriting authorization roles from its parent topic.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage topic access roles** → *topic\_space\_name* → *topic\_name*. The Topic access roles panel lists users and groups that have been assigned role types for the selected topic.
3. Expand the topic name header to display details of the users and groups that have access one or more access roles for the selected topic.
4. Clear the **Inherit sender role from parent topic** check box.
5. Clear the **Inherit receiver role from parent topic** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

## Results

The selected topic cannot inherit access roles from its parent topic. The Topic access roles panel displays the changed access roles for the selected topic.

## What to do next

You can perform other security administration tasks by using the administrative console.

## Removing access roles from unknown users and groups

Service integration bus security uses role-based authorization. Users and groups are assigned to access roles for specific bus resources. If a user or a group that has access roles is removed from the user repository, it becomes an unknown user. You can identify the unknown users and groups for a selected bus, and removes their access roles.

### About this task

In this task, you use the administrative console to remove access roles from users and groups for unknown users and groups.

1. Click **Service integration** → **Buses** → *security\_value* → **[Authorization Policy] Manage users and groups not known to the user repository** The Unknown users and groups panel lists all the users and groups that have access roles assigned to them, but they are not known in the user registry.
2. Select the check boxes next to multiple user and group names.
3. Click **Remove all roles**. The access role assignments for the selected users and groups are removed.
4. Save your changes to the master configuration.

### Results

The access role assignments are removed from the selected users and groups. The Unknown users and groups panel is updated to show the changes to the role type assignments.

## Administering permitted transports for a bus

Use these tasks to configure a transport policy for a service integration bus, and to administer the transports chains that remote applications clients can use to connect to a service integration bus.

### About this task

- “Administering permitted transports for a bus”
- “Listing permitted transports for a bus” on page 1381
- “Adding a permitted transport to a bus” on page 1381
- “Removing a permitted transport from a bus” on page 1382

## Configuring a transport policy for a bus

By configuring a transport policy for the bus you can affect the security of messages in transit.

### Before you begin

There are no prerequisites for this task.

### About this task

The transport policy for a bus controls which transport mechanism remote application clients can use to connect to the bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → *security\_value*. The configuration panel for the selected bus is displayed
3. Choose one of the following transport policies for the bus:

#### **Allow the use of all defined transport channel chains**

Select this option to allow the bus to use unsecured ports.

#### **Restrict the use of defined transport channel chains to those protected by SSL**

Select this option to prevent the use of the InboundBasicMessaging port.

### **Restrict the use of defined transport channel chains to the list of permitted transports**

Select this option if you want connecting client applications to use named transport channel chains. This provides the highest level of control over the use of transport channel chains.

4. Click **Apply**.
5. Save your changes to the master configuration.

## **Results**

The transport policy you have configured for the selected bus controls how application clients connect to the bus.

## **What to do next**

You can use the administrative console to add and remove transport chains in the list of permitted transports for the bus.

## **Listing permitted transports for a bus**

Use this task to display a list of the transport chains that are available for a remote client application to use to connect to a selected service integration bus.

## **Before you begin**

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1380.

## **About this task**

A permitted transport is a transport chain that a remote client application can use to connect to the bus. In this task, you use the administrative console to list all the permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Additional Properties] Permitted Transports**.

## **Results**

The Permitted transports panel displays the list of permitted transports for the selected bus.

## **What to do next**

You can use the administrative console to add and remove transport chains in the list of permitted transports to control which transport chains a remote client application can use to connect to the bus.

## **Adding a permitted transport to a bus**

Use this task to make a new transport chain available to a remote client application to use to connect to a service integration bus.

## **Before you begin**

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1380.

## About this task

A permitted transport is a transport chain that a remote client application can use to connect to the bus. If you want to allow remote client applications to connect to the bus using a new transport chain, you must add the new transport chain to the list of permitted transports for the bus. In this task, you use the administrative console to add a new transport chain to the list of permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Additional Properties] Permitted Transports**. The Permitted transports panel displays the list of permitted transports for the selected bus.
3. Click **New**.
4. Select the name of the transport chain you want to add in the list box.
5. Click **OK**.
6. Save your changes to the master configuration.

## Results

The new transport name is displayed in the list of permitted transports, and its is available for use by a remote client application to connect to the bus.

## What to do next

You can use the administrative console to remove transport chains from a bus.

## Removing a permitted transport from a bus

Use this task to remove a selected transport chain from the list of permitted transport chains for a selected service integration bus.

## Before you begin

The transport policy for the bus must be set to the option **Restrict the use of defined transport channel chains to the list of permitted transports** for this task to have an effect. For more information about how to configure the transport policy for the bus, refer to “Configuring a transport policy for a bus” on page 1380.

## About this task

A permitted transport is a transport chain that a remote client application can use to connect to the bus. If you want to prevent a remote client application from using a particular transport chain to connect to the bus, you can remove the transport chain from the list of permitted transports for the bus. In this task, you use the administrative console to remove a transport chain from the list of permitted transports for a selected bus.

1. Log onto the administrative console.
2. Click **Service integration** → **Buses** → *security\_value* → **[Additional Properties] Permitted Transports**. The Permitted transports panel displays the list of permitted transports for the selected bus.
3. Select the name of the transport chain you want to remove.
4. Click **Delete**. The Permitted transports panel displays an updated list of permitted transports for the selected bus.
5. Save your changes to the master configuration.

## Results

The selected transport chain is removed from the list of permitted transports for the selected bus, and a remote client can no longer use it to connect to the bus.

## What to do next

You can use the administrative console to manage the transport policy for the bus.

## Configuring bus security using an administrative console panel

Use this task to enable or disable messaging security, and configure security properties for an existing service integration bus.

## Before you begin

The bus must exist in the administrative console. If you want to create a new bus, refer to “Adding buses” on page 1197.

## About this task

This task uses the Bus Security administrative console panel. You can launch the Bus security wizard from the panel, or specify individual security properties directly in the panel. The bus security properties are effective only when administrative security for the cell is enabled. If the wizard detects that administrative security is disabled, it prompts you to enable it.

The security properties available to a particular bus depend on the versions of the bus members. If the bus has a WebSphere Application Server Version 6.x bus member, you must specify the global security domain. The bus cannot use cell level, or custom security domains. You must also specify an inter-engine authentication alias to prevent unauthenticated messaging engines from establishing a connection with the bus. If the bus contains Version 7.0 bus members only, you can specify any type of security domain, and you do not need to specify an inter-engine or mediation authentication alias.

If you want to run mediations across multiple security domains, you can specify a single server identity for the bus, rather than specify a mediation authentication alias for each domain. You can also use a server identity to run mediations on the global domain.

1. Log into the administrative console.
2. Click **Service integration** → **Buses** → **security\_value**. *security\_value* is either Enabled or Disabled, depending on the security status of the bus.
3. Click **Launch Bus Security Wizard** to launch the wizard, or specify the following properties directly:

### Enable bus security

Bus security is enabled by default. Clear this check box if you do not want a secure bus. The check box is read-only if administrative security is disabled.

### Inter-engine authentication alias

The name of the authentication alias used to authorize communication between messaging engines on the bus. Specify an inter-engine authentication alias if the bus has a Version 6.x bus member, bus security is enabled, and you want to prevent unauthorized messaging engines from establishing a connection with the bus.

### Permitted transports

Specify one of the following transports for the bus:

- Any messaging transport chain defined to any bus member.
- Only messaging transport chains that are protected by an SSL chain.
- Only the transports specified in the list of permitted transports.

If you want to add and remove permitted transports, click **Service integration** → **Buses** → **security\_value** → **[Additional Properties] Permitted Transports**.

### Use the Server ID when running mediations

Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Mediations are deployed as applications, and run in the domain used by the application server, not the bus domain. If you want to run a mediation on multiple servers in different domains, you must ensure that the user identity in the mediation authentication alias exists in the configuration for each domain. Alternatively, you can choose to use the server identity option. You can use this option when multiple domains are not in use.

### Bus security domain

Specify one of the following security domains for the bus:

#### Global domain

You must specify the global domain if the bus contains a Version 6.x bus member, or you do not want the bus to use multiple domains.

#### Cell level domain

Specify the cell-level security domain if the bus has Version 7.0 bus members only, and you want the bus to share security settings with the administrative cell.

#### Custom domain

Specify a custom security domain if the bus has Version 7.0 bus members only, and you want the bus to use a security domain that is used by another resource, or you want to create a new security configuration for this bus.

4. Save your changes to the master configuration.

## Results

You have configured security properties for the selected bus.

## What to do next

You can use the administrative console to control access to the bus.

## Securing messages between messaging buses

Use these tasks to administer the access control security associated with sending messages between buses.

### About this task

- “Protecting messages transmitted between buses”
- “Administering access to foreign destinations” on page 1385

### Protecting messages transmitted between buses

Use this task to protect the integrity of the data that is transmitted between secured linked service integration buses.

### Before you begin

- Review the information in the topics *Secure transport considerations* and *Configuring transport chains*.
- Configure a transport policy for the bus, as described in the topic “Configuring a transport policy for a bus” on page 1380.

## About this task

In this task, you configure transport chains for the remote bus to ensure that only secured inbound transport chains can contact the messaging engines on the server. The remote bus may be a foreign bus, or an WebSphere MQ link.

1. Ensure that the linked buses are secured. For further information, see “Securing buses” on page 1345.
2. Configure the Target inbound transport chain property for the foreign bus, or WebSphere MQ link, as appropriate:
  - For connections to a foreign bus, refer to “Connecting service integration buses to use point-to-point messaging” on page 1233 or “Connecting service integration buses to use publish-subscribe messaging” on page 1235
  - For connections to WebSphere MQ, refer to “Creating a new WebSphere MQ link” on page 1710.

## Results

You have configured the Target inbound transport chains for the remote service integration bus.

## What to do next

### Administering access to foreign destinations

Use these tasks to administer the access control security associated with sending messages to foreign bus destinations.

## About this task

To define the authentication information used in the access control checks that are performed when a message is sent to a destination in a foreign bus, complete the following steps:

- Define the required authorization permissions to allow a sender to access a destination on a foreign bus. These can be defined using either a foreign bus definition, as described in “Administering foreign bus roles” on page 1365, or a foreign bus destination definition, as described in “Administering destination roles” on page 1314. These permissions are used when the message is sent, to check that the sender is allowed to access the foreign bus.
- The administrator of the foreign bus must define the required authorization permissions to allow the messages to access the destination on the foreign bus. These permissions are used when the message enters the foreign bus.
- Define the authorization permissions to allow any messages entering your bus from the foreign bus to access the required destinations.

## Securing access to a foreign bus

You can secure the link between a local bus and a foreign bus.

## Before you begin

Before you can secure the link between a local bus and a foreign bus, there must be foreign bus connection on the local bus, and therefore a link between the buses.

## About this task

This task summarizes the significant tasks to secure the link between a local bus and a foreign bus. For more general information about service integration bus security, see “Security” on page 1184.

When you create a foreign bus connection, there are some options to secure the connection during that procedure.

1. Enable security on the service integration bus and the foreign bus. See “Disabling bus security” on page 1346.
2. Secure the link between the buses. See “Securing messages between messaging buses” on page 1384.
3. Grant access to the local bus for users who will be sending messages to the foreign bus. See “Administering the bus connector role” on page 1355.
4. Grant access to the foreign bus for users who will be sending messages to it. See “Administering foreign bus roles” on page 1365.
5. Optional: Give users access to foreign or alias destinations that will forward messages to a foreign bus. See “Administering destination roles” on page 1314.

## Securing links between messaging engines

When security is enabled, messaging engines in a mixed version bus establish trust using an authentication alias.

### Before you begin

You must ensure that the user ID that you intend to use for the authentication alias meets the following conditions:

- It exists in the user registry
- It is used only for the purpose of messaging engine to messaging engine authentication.
- It has not been added to the bus connector access role.

### About this task

If you have a secure, mixed version bus, you must define an Inter-engine authentication alias for use in preventing unauthorized messaging engines from establishing a connection. The Inter-engine authentication alias is used by messaging engines to establish trust in the following scenarios:

- A WebSphere Application Server Version 6.x messaging engine initiates a link with a Version 7.0 messaging engine.
- A Version 7.0 messaging engine initiates a link with a Version 6.x messaging engine.

Trust between Version 7.0 messaging engines is established using a Lightweight Third Party Authentication (LTPA) token.

1. In the navigation pane, click **Service integration** → **Buses** → **security\_value**. The bus security configuration panel is displayed.
2. In the **Inter-engine authentication alias** field, select an authentication alias.
3. Click **OK**.
4. Save your changes to the master configuration.

### Results

You have selected an Inter engine authentication alias for the bus to use in establishing trust between mixed version messaging engines.

### What to do next

If you require additional security, you can configure the SSL certificate stores to restrict objects that can make an SSL connection, and thereby connect to the bus. For more information see Configuring secure sockets layer.

## Controlling which foreign buses can link to your bus

Use this task to control which foreign buses are allowed to link to your bus.

### About this task

When messaging security is enabled, it is important that only authorized foreign buses are allowed to link to your bus.

To control which foreign buses can create a link to your bus, complete the following steps:

1. Set the authentication alias property on the foreign bus connection to be used for authentication of the foreign bus joining your bus, as described in “Connecting service integration buses to use point-to-point messaging” on page 1233 or “Connecting service integration buses to use publish-subscribe messaging” on page 1235.
2. If you require extra security, configure the SSL certificate stores to restrict who can make an SSL connection, and hence link to the bus. For more information, see [Configuring secure sockets layer](#).

## Securing database access

How to protect the data store from access by unauthorized users.

### About this task

To secure access to the data store, you must configure a user name and password on the data store for the messaging engine. If you want to apply additional levels of security such as encrypting the contents of the database, use the specific security features provided by your database.

## Securing mediations

Use the following tasks to secure mediations at an operations level. For example, a mediation inherits its identity from a the messaging engine, but you might want to specify an alternative identity for the mediation to use.

---

## Chapter 7. Data access resources

---

### Task overview: Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases.

#### About this task

IBM WebSphere Application Server provides several options for accessing an information system's backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various Java EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using embedded Structured Query Language in Java (SQLJ) support with applications that use DB2 as a backend database.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

For all of these options, except for using the JCA 1.0 or 1.5 compliant connectors, the prerequisite Web site details which databases and drivers are currently supported.

1. Develop data access applications. Develop your application to access data using the various ways available through the application server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
2. Assemble data access applications using the assembly tool. Assemble your application by creating and mapping resource references.
3. Prepare for deployment: Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.
4. Install the application on your application server.

#### Resource adapters

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

WebSphere Application Server supports JCA versions 1.0 and 1.5 including additional, configurable features for JCA 1.5 resource adapters with activation specifications that handle inbound requests.

Data access for container-managed persistence (CMP) beans is indirectly managed by the WebSphere Persistence Manager. The JCA specification supports persistence manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, the persistence manager uses the relational resource adapter to access the data from the database.

You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

## Java EE Connector Architecture resource adapters

An application server vendor extends its system once to support the Java Platform, Enterprise Edition Connector Architecture (JCA) and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

The product supports any resource adapter that implements version 1.0 or 1.5 of this specification. IBM supplies resource adapters for many enterprise systems separately from the WebSphere Application Server package, including (but not limited to): the Customer Information Control System (CICS®), Host On-Demand (HOD), Information Management System (IMS™), and Systems, Applications, and Products (SAP) R/3 .

The general approach to writing an application that uses a JCA resource adapter is to develop EJB session beans or services with tools such as Rational Application Developer. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

## WebSphere Relational Resource Adapter

WebSphere Application Server provides the WebSphere Relational Resource Adapter implementation. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the JCA connection management architecture and provides connection pooling, transaction, and security support. The WebSphere RRA is installed and runs as part of WebSphere Application Server, and needs no further administration.

The RRA supports both the configuration and use of JDBC data sources and Java EE Connection Architecture (JCA) connection factories. The RRA supports the configuration and use of data sources implemented as either JDBC data sources or Java EE Connector Architecture connection factories. Data sources can be used directly by applications, or they can be configured for use by container-managed persistence (CMP) entity beans.

For more information about the WebSphere Relational Resource Adapter, see the following topics:

- For information about resource adapters and data access, see “Data access portability features” on page 1391
- For RRA settings, see “WebSphere relational resource adapter settings”
- For information about enterprise beans, see EJB applications

## WebSphere relational resource adapter settings

Use this page to view the settings of the WebSphere relational resource adapter. This adapter is preinstalled in the product to provide access to relational databases.

**Note:** Although the default relational resource adapter settings are viewable, you cannot make changes to them.

To view this administrative console page, click **Resources > Resource adapters > Resource adapters**. Expand the **Preferences** section at the top of the page. Select **Show built-in resources**. The table of configured resource adapters now displays the **WebSphere Relational Resource Adapter**.

### **Name:**

Specifies the name of the resource provider.

**Data type** String

**Description:**

Specifies a description of the relational resource adapter.

**Data type** String

**Archive path:**

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

**Data type** String

**Class path:**

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

**Data type** String

**Native path:**

Specifies a list of paths that forms the location for the resource provider native libraries.

**Data type** String

**Data access portability features**

These interfaces work with the relational resource adapter (RRA) to make database-specific functions operable on connections between the application server and that database.

In other words, your applications can access data from different databases, and use functions that are specific to the database, without any code changes. Additionally, WebSphere Application Server enables you to plug in a data source that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* type or the *ConnectionPoolDataSource* type, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

**DataStoreHelper interface**

With this interface, each data store platform can plug in its own private datastore specific functions that the relational resource adapter runtime uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

The interface also provides a *GenericDataStoreHelper* class for unsupported data sources to use. You can subclass the *GenericDataStoreHelper* class or other WebSphere provided helpers to support any new data source.

**Note:** If you are configuring data access through a user-defined JDBC provider, do not implement the *DataStoreHelper* interface directly. Either subclass the *GenericDataStoreHelper* class or subclass one of the *DataStoreHelper* implementation classes provided by IBM (if your database behavior or SQL syntax is similar to one of these provided classes).

For more information, see the API documentation **DataStoreHelper** topic (as listed in the API documentation index).

The following code segment shows how a new data store helper is created to add new error mappings for an unsupported data source.

```
public class NewDSHelper extends GenericDataStoreHelper
{
 public NewDSHelper(java.util.Properties dataStoreHelperProperties)
 {
 super(dataStoreHelperProperties);
 java.util.Hashtable myErrorMap = null;
 myErrorMap = new java.util.Hashtable();
 myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
 myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
 myErrorMap.put("S1000", MyTableNotFoundException.class);
 setUserDefinedMap(myErrorMap);
 ...
 }
}
```

### WSCallHelper class

This class provides two methods that enable you to use vendor-specific methods and classes that do not conform to the standard JDBC APIs (and are not part of WebSphere Application Server extension packages).

- **jdbcCall() method**

By using the static `jdbcCall()` method, you can invoke vendor-specific, nonstandard JDBC methods on your JDBC objects. (For more information, see the API documentation **WSCallHelper** topic.) The following code segment illustrates using this method with a DB2 data source:

```
Connection conn = ds.getConnection();
// get connection attribute
String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
 "getConnectionAttribute", null, null);
// setAutoClose to false
WSCallHelper.jdbcCall(java.sql.Connection.class,
 conn, "setAutoClose",
 new Object[] { new Boolean(false)},
 new Class[] { boolean.class });
// get data store helper
DataStoreHelper dsHelper = WSCallHelper.getDataStoreHelper(ds);
```

- **jdbcPass() method**

Use this method to exploit the nonstandard JDBC classes that some database vendors provide. These classes contain methods that require vendors' proprietary JDBC objects to be passed as parameters.

In particular, implementations of Oracle can involve use of nonstandard classes furnished by the vendor. Methods contained within these classes include:

```
oracle.sql.ArrayDescriptor ArrayDescriptor.createDescriptor(java.lang.String, java.sql.Connection)
oracle.sql.ARRAY new ARRAY(oracle.sql.ArrayDescriptor, java.sql.Connection, java.lang.Object)
oracle.xml.sql.query.OracleXMLQuery(java.sql.Connection, java.lang.String)
oracle.sql.BLOB.createTemporary(java.sql.Connection, boolean, int)
oracle.sql.CLOB.createTemporary(java.sql.Connection, boolean, int)
oracle.xdb.XMLType.createXML(java.sql.Connection, java.lang.String)
```

The following code sample demonstrates how to use `jdbcPass` to call the Oracle method `XMLType.createXML` on a connection. This Oracle function creates an XML type object out of the XML data that the database passes to your application.

```
XMLType poXML = (XMLType)WSCallHelper.jdbcPass(XMLType.class,
 "createXML", new Object[] {conn,poString},
 new Class[] {java.sql.Connection.class, java.lang.String.class},
 new int[] {WSCallHelper.CONNECTION,WSCallHelper.IGNORE});
```

For more examples of using `jdbcPass` and a complete list of method parameters, see the API documentation for the `WSCallHelper` class. In this information center, access the API documentation with the following steps:

1. Click **Reference > Developer API documentation > Application programming interfaces**
2. Click **com.ibm.websphere.rsadapter**
3. Under the Class Summary heading, click **WSCallHelper**

The first section on `jdbcPass` discusses using the method to call database static methods. The second section on `jdbcPass` addresses database non-static methods.

**Note:** Use of the `jdbcPass()` method causes the JDBC object to be used outside of the protective mechanisms of WebSphere Application Server. Performing certain operations (such as setting `autoCommit`, or transaction isolation settings, etc.) outside of these protective mechanisms will cause problems with the future use of these pooled connections. IBM does not guarantee stability of the object after invocation of this method; it is the user's responsibility to ensure that invocation of this method does not perform operations that harm the object. Use at your own risk.

Because of these potential problems, WebSphere Application Server strictly controls which methods are allowed to be invoked using the `jdbcPass()` method support. If you require support for a method that is not listed previously in this document, contact WebSphere Application Server Support with information on the method you require.

## Resource Recovery Services (RRS)

WebSphere Application Server for z/OS supports resource adapters that use Resource Recovery Services (RRS) to support global transaction processing. RRS is an z/OS extension to the JCA resource adapter specifications.

WebSphere Application Server for z/OS supports the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) 1.0., and because of this, any resource adapter that is designed to use the 1.0 level of the Java EE Connector Architecture (JCA) is supported.

In addition to the 3 types of transaction support defined by JCA, WebSphere Application Server for z/OS supports a fourth type, **RRSTransactional** support, which is a z/OS only extension to the architecture. Resource adapters that are capable of using RRS and that properly indicate to WAS z/OS they are **RRSTransactional** will be supported as RRS compliant resource adapters.

z/OS resource adapters that are capable of using RRS are:

- IMS Connector for Java
- CICS CTG ECI Java EE Connector
- IMS JDBC Connector
- DB2 for z/OS Local JDBC connector when used as aJDBC Provider under the WebSphere Relational Resource Adapter (RRA)

All RRS Compliant resource adapters are required to support the property **RRSTransactional** in their `ManagedConnectionFactory` and must support a getter method for the property.

```
java.lang.Boolean.RRSTransactional=true;

java.lang.Boolean getRRSTransactional(){
 // Determine if the adapter can run RRSTransactional based
 // on it's configuration, and set the RRSTransactional property
 // appropriately to true or false.
 return RRSTransactional;
}
```

RRS support is only applicable in a local environment, where the backend must reside on the system. CICS and IMS resources adapters may use **RRSTransactional** support only when these adapters are configured to use local interfaces to their backend resource manager, which as stated above must reside on the same system as the IBM WebSphere Application Server for z/OS. These adapters are also capable of being configured to a remote instance of their backend resource manager. In this case, the adapters will

respond "false" when the `getRRSTransactional()` method is invoked and instead of running as `RRSTransactional` will use whichever one of the three types of Java EE Transaction support they have chosen to support.

## JDBC providers

Installed applications use JDBC providers to interact with relational databases.

The JDBC provider object supplies the specific JDBC driver implementation class for access to a specific vendor database. To create a pool of connections to that database, you associate a data source with the JDBC provider. Together, the JDBC provider and the data source objects are functionally equivalent to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity with a non-relational database.

For a current list of supported providers, see the WebSphere Application Server prerequisite Web site. For detailed descriptions of the providers, including the supported data source classes and their required properties, refer to the topics on data source required minimum required settings, by vendor.

**Note:** WebSphere Application Server Version 7.0 no longer supports the DB2 for z/OS Local JDBC Provider (RRS). Version 6.1 and later of the product requires that you migrate your JDBC configurations to the DB2 Using IBM JCC Driver or DB2 Universal JDBC Driver. For instructions, consult the topic on migrating from the JDBC/SQLJ Driver for OS/390 and z/OS to the DB2 Universal JDBC Driver in the Information Management Software for z/OS Solutions Information Center, which is located at <http://publib.boulder.ibm.com/infocenter/dzichelp>.

## DB2 Universal JDBC Driver Support

This article lists the support details for using the DB2 Universal JDBC Driver with WebSphere Application Server for z/OS.

WebSphere Application Server for z/OS supports the DB2 Universal JDBC Driver. The capabilities available depend on the DB2 Universal JDBC Driver that you installed as follows:

- The z/OS Application Connectivity to DB2 for z/OS feature that provides DB2 Universal JDBC Driver Type 4 connectivity. This DB2 Universal JDBC Drive can be invoked only as a type 4 driver for z/OS. As a type 4 driver, it uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database.

When you install and configure this driver for WebSphere Application Server for z/OS, it permits your applications to use JDBC or Container Managed Persistence (CMP) support to access backend DB2 databases (DB2 V7 and up) residing on z/OS at any location. All global transactions are handled as Java Platform Enterprise Edition (Java EE) XA transactions.

- The DB2 Universal JDBC Driver in DB2 UDB for z/OS Version 8. This driver provides both Type 2 and Type 4 support.

Type 4 driver support uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database. This driver supports using Java EE XA transaction processing to process global transactions.

Type 2 driver support uses local API protocol to communicate requests from a z/OS application to a target DB2 running on the same z/OS system image as the application. When the Type 2 driver is used under z/OS, the driver supports the use of z/OS Resource Recovery Services (RRS) to coordinate global transactions across multiple resource manages using 2-phase commit processing.

When you install and configure this version of the driver, your applications can use JDBC or CMP support to access backend DB2 databases (DB2 V7 and up). These databases can reside on the same z/OS system image, or on a different z/OS system image. depending on the driver type used. Type 2 driver handles all global transactions as RRS-coordinated global transactions.

- The DB2 Universal JDBC Driver Provider by APAR PQ80841 on DB2 UDB for OS/390 and z/OS Version 7. This version provides both driver Type 2 and driver Type 4 support.

Type 4 driver support uses a communication protocol to communicate requests from a z/OS application to a remote DB2 database. This driver supports using Java EE XA transaction processing to process global transactions.

Type 2 driver support uses local API protocol to communicate requests from a z/OS application to a target DB2 running on the same z/OS system image as the application. When the Type 2 driver is used under z/OS, the driver supports the use of z/OS Resource Recovery Services (RRS) to coordinate global transactions across multiple resource managers using 2-phase commit processing.

When you install and configure this version of the driver, your applications can use JDBC or CMP support to access backend DB2 databases (DB2 V7 and up). These databases can reside on the same z/OS system image, or on a different z/OS system image, depending on the driver type used.

## Data sources

Installed applications use a *data source* to obtain connections to a relational database. A data source is analogous to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity to other types of enterprise information systems (EIS).

A data source is associated with a JDBC provider, which supplies the driver implementation classes that are required for JDBC connectivity with your specific vendor database. Application components transact directly with the data source to obtain connection instances to your database. The connection pool that corresponds to each data source provides connection management.

You can create multiple data sources with different settings, and associate them with the same JDBC provider. For example, you might use multiple data sources to access different databases within the same vendor database application. WebSphere Application Server requires JDBC providers to implement one or both of the following data source interfaces, which are defined by Sun Microsystems. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

- *ConnectionPoolDataSource* - a data source that supports application participation in local and global transactions, excepting two-phase commit transactions. When a connection pool data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.

**Note:** A connection pool data source does support two-phase commit transactions in these cases:  
– the JDBC provider is DB2 for z/OS Local JDBC provider (RRS).

For more information, consult the article [Using one-phase and two-phase commit resources in the same transaction](#).

- *XADataSource* - a data source that supports application participation in any single-phase or two-phase transaction environment. When this data source is involved in a global transaction, the product transaction manager provides transaction recovery.

Prior to version 5.0 of the application server, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available to support Java 2 Platform, Enterprise Edition (J2EE) 1.2 applications, but another connection manager architecture is provided, based on the JCA architecture supporting the J2EE 1.3 application style, J2EE 1.4 and Java EE applications.

These architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.

- Data source (WebSphere Application Server V4) - This data source runs under the original CM architecture. Applications using this data source behave as if they were running in Version 4.0.
- Data source - This data source uses the JCA standard architecture to provide support for J2EE version 1.3 and 1.4, as well as Java EE applications. It runs under the JCA connection manager and the relational resource adapter.

## Choice of data source

- J2EE 1.2 application - all EJB 1.1 enterprise beans, JDBC applications, or Servlet 2.2 components must use the **4.0** data source.
- J2EE 1.3 (and subsequent releases) application -
  - EJB 1.1 module - all EJB 1.x beans must use the **4.0** data source.
  - EJB 2.0 (and subsequent releases) module - enterprise beans that include container-managed persistence (CMP) Version 1.x, 2.0, and beyond must use the **new** data source.
  - JDBC applications and Servlet 2.3+ components - must use the **new** data source.

## Data access beans

Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the Enterprise JavaBeans specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *Rational Application Developer*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

### Feature

#### Details

#### Caching query results

You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

#### Updating through result cache

Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

#### Querying parameter support

The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

#### Supporting metadata

A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatype parameters are automatically converted to SQL data types as specified in the metadata mapping.

When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

## Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the Java Database Connectivity (JDBC) 2.0 (and later) Extensions specification.

To make data source connections manageable by the CM, the WebSphere Application Server provides a resource adapter (the WebSphere Relational Resource Adapter) that enables JDBC data sources to be managed by the same CM that manages JCA connections. From the CM point of view, JDBC data sources and JCA connection factories look the same. Users of data sources do not experience any programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the specification changes from various Java EE requirements levels. These differences are not related to the adoption of the JCA architecture.

If you have Java 2 Platform, Enterprise Edition (J2EE) 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 6.0 and later, the JDBC CM from Application Server version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 6.0 or later, using the latest migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.x modules in J2EE 1.3, J2EE 1.4 and Java Platform, Enterprise Edition (Java EE) applications cannot use the JDBC CM from WebSphere Application Server Version 4.0.

## Connection pooling

Using connection pools helps to both alleviate connection management overhead and decrease development tasks for data access.

Each time an application attempts to access a backend store (such as a database), it requires resources to create, maintain, and release a connection to that datastore. To mitigate the strain this process can place on overall application resources, the Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. Connection pooling spreads the connection overhead across several user requests, thereby conserving application resources for future requests.

The application server supports JDBC 4.0 APIs for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

## Benefits of connection pooling

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. Because users connect and disconnect frequently with applications on the Internet, the application requests for data access can surge to considerable volume. Consequently, the total datastore overhead quickly becomes high for Web-based applications, and performance deteriorates. When connection pooling capabilities are used, however, Web applications can realize performance improvements of up to 20 times the normal results.

With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnection is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

## When to use connection pooling

Use connection pooling in an application that meets any of the following criteria:

- It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
- It requires Java Transaction API (JTA) transactions within the Application Server.

- It needs to share connections among multiple users within the same transaction.
- It needs to take advantage of product features for managing local transactions within the application server.
- It does not manage the pooling of its own connections.
- It does not manage the specifics of creating a connection, such as the database name, user name, or password

**Note:** Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

## How connections are pooled together

When you configure a unique data source or connection factory, you must give it a unique Java Naming and Directory Interface (JNDI) name. This JNDI name, along with its configuration information, is used to create the connection pool. A separate connection pool exists for each configured data source or connection factory.

Furthermore, the application server creates a separate instance of the connection pool in each application server that uses the data source or connection factory. For example:

- Within a cluster, three z/OS controllers each contain three servants that use *myDataSource*, and for the connection pool that the Application Server creates for every instance of *myDataSource*, you can set a Maximum Connections value of 10. Therefore, you can generate up to 90 connections (9 servants times 10 connections).

Consider how this behavior potentially impacts the number of connections that your backend resource can support. See “Connection pool settings” on page 1476 for more information.

It is also important to note that when using connection sharing, it is only possible to share connections obtained from the same connection pool.

### **Connection and connection pool statistics:**

WebSphere Application Server supports use of PMI APIs to monitor the performance of data access applications.

Performance Monitoring Infrastructure (PMI) method calls that are supported in the two existing Connection Managers (JDBC and J2C) are supported in this version of WebSphere Application Server. The calls include:

- `ManagedConnectionsCreated`
- `ManagedConnectionsAllocated`
- `ManagedConnectionFreed`
- `ManagedConnectionDestroyed`
- `BeginWaitForConnection`
- `EndWaitForConnection`
- `ConnectionFaults`
- Average number of `ManagedConnections` in the pool
- Percentage of the time that the connection pool is using the maximum number of `ManagedConnections`
- Average number of threads waiting for a `ManagedConnection`
- Average percent of the pool that is in use
- Average time spent waiting on a request
- Number of `ManagedConnections` that are in use
- Number of Connection Handles

- FreePoolSize
- UseTime

Java Specification Request (JSR) 77 requires statistical data to be accessed through managed beans (Mbeans) to facilitate this. The Connection Manager passes the ObjectNames of the Mbeans created for this pool. In the case of Java Message Service (JMS) *null* is passed in. The interface used is:

```
PmiFactory.createJ2CPerf(
 String pmiName, // a unique Identifier for JCA /JDBC. This is the
 // ConnectionFactory name.

 ObjectName providerName, // the ObjectName of the J2CResourceAdapter
 // or JDBCProvider Mbean

 ObjectName factoryName // the ObjectName of the J2CConnectionFactory
 // or DataSourceMbean.
)
```

The following Unified Modeling Language (UML) diagram shows how JSR 77 requires statistics to be reported:

JCAConnectionPoolStats and JDBCConnectionPoolStats objects do not have a direct implementing Mbean; the statistics are gathered through a call to PMI. A J2C resource adapter, and JDBC provider each contain a list of ConnectionFactory or DataSource ObjectNames, respectively. The ObjectNames are used by PMI to find the appropriate connection pool in the list of PMI modules.

The JCA 1.5 Specification allows an exception from the matchManagedConnection() method that indicates that the resource adapter requests that the connection not be pooled. In that case, statistics for that connection are provided separately from the statistics for the connection pool.

### Connection life cycle

A ManagedConnection object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the DoesNotExist state. After a connection is created, it can be in either the InUse or the InFreePool state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the InFreePool state to InUse state only if:

- the application has called the data source or connection factory getConnection() method (the *getConnection* condition)
- a free connection is available in the pool with matching properties (the *freeConnectionAvailable* condition)
- and one of the two following conditions are true:
  - the getConnection() request is on behalf of a resource reference that is marked unsharable
  - the getConnection() request is on behalf of a resource reference that is marked shareable but no shareable connection in use has the same properties.

This transition description follows:

```
InFreePool > InUse:
getConnection AND
freeConnectionAvailable AND
NOT(shareableConnectionAvailable)
```

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older than its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on a data source or connection factory object.
markedStale	Connection is marked as stale, typically in response to a fatal error notification.
noOtherReferences	There is only one connection handle to the managed connection, and the Transaction Service is not holding a reference to the managed connection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection() request is for a shareable connection, and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection() request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

## Getting connections

The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

### DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
unshareableConnectionRequest)
```

This transition specifies that a connection object is not created unless the following conditions occur:

- The application calls the `getConnection()` method on the data source or connection factory
- No connections are available in the free pool (`NOT(freeConnectionAvailable)`)
- The pool size is less than the maximum pool size (`poolSizeLTMax`)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (`NOT(shareableConnectionAvailable)`) OR the request is for an unsharable connection (`unshareableConnectionRequest`)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

### InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:

- the application has issued a `getConnection()` call
- a connection is available for use in the connection pool (`freeConnectionAvailable`),
- and one of the following is true:
  - the request is for an unsharable connection (`unshareableConnectionRequest`)
  - no connection with the same sharing properties is already in use in the transaction. (`NOT(shareableConnectionAvailable)`).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any

number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

## InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition indicates that if an application requests a shareable connection (`getConnection`) with the **same** sharing properties as a connection that is already in use (`ShareableConnectionAvailable`), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolation level*, which is configurable on the resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the `ConnectionSpec` object. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

**Note:** It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

## Returning connections

All of the transitions discussed previously involve getting a connection for application use. With that goal, the transitions result in a connection closing, and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling `close()` on the connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:

- If the application or the container calls `close()` (producing the close condition) and there are no references (the `noOtherReferences` condition) either by the application (in the application sharing condition) or by the transaction manager (in the `NoTx` condition, meaning that the transaction manager holds a reference when the connection is enlisted in a transaction), the connection object returns to the free pool.
- If the connection was enlisted in a transaction but the transaction manager ends the transaction (the `txEnds` condition), and the connection was a shareable connection (the `ShareableConnection` condition), the connection closes and returns to the pool.

When the application calls `close()` on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls `close()` on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the

pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool, making it impossible for any application running on the server to get a connection.

When the application calls `close()` on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling `close()` can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently `InUse` connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to `close()` when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls `close()` on the connection and the connection is marked as stale during the pool cleansing step (`markedStale`), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.

1. If a fatal error notification is received from the resource adapter (or data source). A fatal error notification (`FatalErrorNotification`) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (`UnusedTimeoutExpired`) and the pool size is greater than the minimum number of connections (`poolSizeGTMin`), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.
3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

## Unshareable and shareable connections

The application server supports both unshareable and shareable connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

Access to a resource marked as unshareable means that there is a one-to-one relationship between the connection handle a component is using and the physical connection with which the handle is associated. This access implies that every call to the `getConnection` method returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring in another application that is sharing the connection (for example, unexpectedly changing the isolation level).

Marking a resource as shareable allows for greater scalability. Instead of creating new physical connections on every `getConnection()` invocation, the physical connection (that is, managed connection) is

shared through multiple connection handles, as long as each `getConnection` request has the same connection properties. However, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application that assumes sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

## Connection property requirements

To permit sharing of connections used within the same transaction, the following data source properties must be the same:

- Java Naming and Directory Interface (JNDI) name. While not actually a connection property, this requirement simply means that you can only share connections from the same data source in the same server.
- Resource authentication
- In relational databases:
  - Isolation level (corresponds to access intent policies applied to CMP beans)
  - Readonly
  - Catalog
  - TypeMap

For more information on sharing a connection with a CMP bean, see “Sharing a connection with a CMP bean.”

To permit sharing of connections within the same transaction, the following properties must be the same for the connection factories:

- JNDI name. While not actually a connection property, this requirement simply means that you can only share connections from the same connection factory in the same server.
- Resource authentication

In addition, the `ConnectionSpec` object that is used to get the connection must also be the same.

**Note:** Java Message Service (JMS) connections cannot be shared with non-JMS connections.

## Sharing a connection with a CMP bean

The application server allows you to share a physical connection among a CMP bean, a BMP bean, and a JDBC application to reduce the resource allocation or deadlock scenarios. There are several ways to ensure that all of these entity beans and the JDBC applications are sharing the same physical connection.

- **Sharing a connection between CMP beans or methods**

When all CMP bean methods use the same access intent, they all share the same physical connection. A different access intent policy triggers the allocation of a different physical connection. For example, a CMP bean has two methods; method 1 is associated with `wsPessimisticUpdate` intent, whereas method 2 has `wsOptimisticUpdate` access intent. Method 1 and method 2 cannot share the same physical connection within a transaction. In other words, an XA data source is required to run in a global transaction.

You can experience some deadlocks from a database if both methods try to access the same table. Therefore, sharing a connection is determined by the access intents that are defined in the CMP methods.

- **Sharing a connection between CMP and BMP beans**

Remember to first verify that the `getConnection` methods of both the BMP bean and the CMP bean set the same connection properties. To match the authentication type of the CMP bean resource, set the authentication type of the BMP bean resource to container-managed, which is designated in the deployment descriptor as `res-auth = Container`.

Additionally, use one of the following options to ensure connection-sharing between the bean types:

- Define the same access intent on both CMP and BMP bean methods. Because both use the same access intent, they share the same physical connection. The advantage to using this option is that the backend is transparent to a BMP bean. However, this option also makes the BMP non-portable because it uses the WebSphere extended API to handle the isolation level. For more information, refer to the code example in Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans.
- Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level that is specified on the resource reference to look up a data source and a connection. This option is more of a manual process, and the isolation level might be different from database to database. For more information refer to the isolation level and access intent mapping table: Access intent isolation levels and update locks and the Isolation level and resource reference section.
- **Sharing a connection between CMP and a JDBC application that is used by a servlet or a session bean**  
Determine the isolation level that the access intent uses on a CMP bean method, then use the corresponding isolation level specified on the resource reference to look up a data source and a connection. For more information refer to Access intent isolation levels and update locks and Isolation level and resource reference.

## Factors that determine sharing

The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref) that specifies the res-sharing-scope as shareable are candidates for sharing. The resource reference properties of res-sharing-scope and res-auth and the IBM extension isolationLevel help determine if it is possible to share a connection. IBM extension isolationLevel is stored in IBM deployment descriptor extension file; for example: ibm-ejb-jar-ext.xmi.
- You can only share connections that are requested with the same properties.
- Connection sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection sharing only occurs within a sharing boundary. Current® sharing boundaries include *Transactions* and *LocalTransactionContainment* (LTC) boundaries.
- Connection sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.  
The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true connection sharing does not take place. The term "*reuse*" is more accurate.  
**More importantly**, the *LocalTransactionContainment* boundary enclosing both *get* actions is not complete; no *cleanUp()* method is invoked on the *ManagedConnection* object. Therefore the second *get* action inherits all of the connection properties set during the first *getConnection()* call.
- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the Java Platform, Enterprise Edition (Java EE) standard.
  - General users of resource adapters can set the connection properties on the connection factory *getConnection()* call by passing them in a *ConnectionSpec*.

However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the isolation level specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.

- For JDBC users, the application server provides an extension to enable passing the connection properties through the ConnectionSpec.

Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.

- You cannot set the isolation level on a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

## Maximal connection sharing

To maximize connection sharing opportunities for an application, ensure that each component has the local transaction containment (LTC) Resolver attribute set to **ContainerAtBoundary**. This setting specifies that the component container, rather than the application code, resolves all resource manager local transactions (RMLTs) within the LTC scope. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope.

Consult the topic Configuring transactional deployment attributes for instructions on setting the transaction resolution control and other attributes.

## Connection sharing violations

There is a new exception, the sharing violation exception, that the resource adapter can issue whenever an operation violates sharing requirements. Possible violations include changing connection attributes, security settings, or isolation levels, among others. When such a mutable operation is performed against a managed connection, the sharing violation exception can occur when both of the following conditions are true:

- The number of connection handles associated with the managed connection is more than one.
- The managed connection is associated with a transaction, either local or XA.

Both the component and the J2C run time might need to detect this sharing violation exception, depending on when and how the managed connection becomes unshareable. If the managed connection becomes unshareable because of an operation through the connection handle (for example, you change the isolation level), then the component needs to process the exception. If the managed connection becomes unshareable without being recognized by the application server (due to some component interaction with the connection handle), then the resource adapter can reject the creation of a connection handle by issuing the sharing violation exception.

## Connection handles

A connection handle is a representation of a physical connection. To use a backend resource (such as a relational database) in WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. It is used within a single method and without calling another method that might get a connection from the same data source or connection factory. An application using this pattern does the following:

1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:

1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Keep in mind the following considerations for using cached handles:

- Cached handle support requires some additional connection handle management across these boundaries, which can impact performance. For example, in a JDBC application, *Statements*, *PreparedStatement*s, and *ResultSet*s are closed implicitly after a transaction ends, but the connection remains valid.
- You are encouraged **not** to cache the connection across the transaction boundary for shareable connections; the *get/use/close* pattern is preferred.
- Caching of connection handles across servlet methods is limited to JDBC and Java Message Service (JMS) resources. Other non-relational resources, such as Customer Information Control System (CICS) or IMS objects, currently cannot have their connection handles cached in a servlet; you need to get, use, and close the connection handle within each method invocation. (This limitation only applies to single-threaded servlets because multithreaded servlets do not allow caching of connection handles.)
- You **cannot** pass a cached connection handle from one instance of a data access client to another client instance. Transferring between client instances creates the problematic contingency of one instance using a connection handle that is referenced by another. This relationship can only cause problems because connection handle management code processes tasks for each client instance *separately*. Hence, connection handle transfers result in run-time scenarios that trigger exceptions. For example:
  1. The application code of a client instance that receives a transferred handle closes the handle.
  2. If the client instance that retains the original reference to the handle tries to reclaim it, the application server issues an exception.

The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
ut.begin();
conn.prepareStatement("...."); --> Connection runs in global transaction mode
...
ut.commit();
conn.prepareStatement("...."); ---> Connection still valid but runs in autoCommit(True);
...
```

## Unshareable connections

Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

- **The possible benefits of unshared connections**

- Your application always maintains a direct link with a physical connection (managed connection).
- The connection always has a one-to-one relationship between the connection handle and the managed connection.
- In most cases, the connection does not close until the application closes it.
- You can use a cached unshared connection handle across multiple transactions.
- The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.

- **The possible drawbacks of unshared connections**

- Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
- Wasted connections. It is important not to keep the connection handle open (that is, your application does not call the *close()* method) any longer than it is needed. As long as an unshareable connection is open, the physical connection is unavailable to any other component, even if your application is not currently using that connection. Unlike a shareable connection, an unshareable connection is not closed at the end of a transaction or servlet call.
- Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlock in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

In the same scenario, but with a *shared* connection, deadlock does not occur because all the work is done on the same connection. It is worth noting that when writing code that uses shared connections, you use a strategy that calls for multiple work items to be performed on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception might occur for waiting connection requests if you exceed the maximum connections value, and unshareable connections are not being closed before the connection wait time-out is exceeded.

## Shareable connections

Some characteristics of connection handles that are retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

- **The possible benefits of shared connections**

- Within an instance of connection sharing, application components can share a managed connection with one or more connection handles, depending on how the handle is retrieved and which connection properties are used.
- They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as a transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time ensures that the handle is reassociated with a managed

connection that is appropriate for the current sharing scope, and has the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Furthermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.

- **The possible drawbacks of shared connections**

- Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) that gets a connection handle to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle is not valid and triggers an exception at any attempt to use it.

**Note:** This exception occurs only when calling a utility object (a Java object).

Not all resource adapters have this limitation; it occurs only in certain implementations. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any data source used through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another (or close your handle before calling code that gets another handle), and before returning from a method, you can allow two pieces of code to share the same managed connection. You simply cannot use the connection for both events at the same time.

- Trying to change the *isolation level* on a shareable JDBC-based connection in a global transaction (that is supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.
- Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

## Lazy connection association optimization

The Java Platform, Enterprise Edition (Java EE) Connector (J2C) connection manager implemented *smart handle* support. This technology enables allocation of a connection handle to an application while the managed connection associated with that connection handle is used by other applications (assuming that the connection is not being used by the original application). This concept is part of the Java EE Connector Architecture (JCA) 1.5 specification. (You can find it in the JCA 1.5 specification document in the section entitled "Lazy Connection Association Optimization.") Smart handle support introduces use a method on the ConnectionManager object, the *LazyAssociatableConnectionManager()* method, and a new marker interface, the *DissociatableManagedConnection* class. You must configure the provider of the resource adapter to make this functionality available in your environment. (In the case of the RRA, WebSphere Application Server itself is the provider.) The following code snippet shows how to include smart handle support:

```
package javax.resource.spi;
import javax.resource.ResourceException;

interface LazyAssociatableConnectionManager { // application server
 void associateConnection(
 Object connection, ManagedConnectionFactory mcf,
 ConnectionRequestInfo info) throws ResourceException;
}

interface DissociatableManagedConnection { // resource adapter
 void dissociateConnections() throws ResourceException;
}
```

This `DissociatableManagedConnection` interface introduces another state to the `Connection` object: *inactive*. A `Connection` can now be active, closed, and inactive. The connection object enters the inactive state when a corresponding `ManagedConnection` object is cleaned up. The connection stays inactive until an application component attempts to re-use it. Then the resource adapter calls back to the connection manager to re-associate the connection with an active `ManagedConnection` object.

## Transaction type and connection behavior

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC) boundary. Each transaction type places different requirements on connections and impacts connection settings differently.

## Connection sharing and reuse

You can share connections within a global transaction scope (assuming other sharing rules are met). You can also share connections within a shareable LTC. You can *serially reuse* connections within an LTC scope. A `get/use/close` connection pattern followed by another instance of `get/use/close` (to the same data source or connection factory) enables you to reuse the same connection. See the “Unshareable and shareable connections” on page 1403 topic for more details.

## JDBC AutoCommit behavior

All JDBC connections, when first obtained through a `getConnection()` call, contain the setting `AutoCommit = TRUE` by default. However, different transaction scope and settings can result in changing, or simply overriding, the `AutoCommit` value.

- If you operate within an LTC and have its resolution-control set to *Application*, `AutoCommit` remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, the application must **not** touch the `AutoCommit` setting. The WebSphere Application Server run time sets the `AutoCommit` value to *FALSE* before work begins, then commits or rolls back the work, as appropriate, at the end of the LTC scope.
- If you use a connection within a global transaction, the database ignores the `AutoCommit` setting so that the transaction service that controls the commit and rollback processing can manage the transaction. This action takes place upon first use of the connection to do work, regardless of the user changing the `AutoCommit` setting. After the transaction completes, the `AutoCommit` value returns to the value it had before the first use of the connection. So even if the `AutoCommit` value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* because the value is ignored by the database. In this example, after the transaction completes, the `AutoCommit` value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

## One-phase commit and two-phase commit connections

The type and number of resource managers, such as a database server, that must be accessed by an application often determines the application transaction requirements. Consequently each type of resource manager places different requirements on connection behavior.

- A two-phase commit resource manager can support two-phase coordination of a transaction. That support is necessary for transactions that involve other resource managers; these transactions are global transactions. See “Transaction support in WebSphere Application Server” on page 2225 for further explanation.
- A one-phase commit resource manager supports only one-phase transactions, or LTC transactions, in which that resource is the sole participating datastore. Again, see “Transaction support in WebSphere Application Server” on page 2225 for further explanation.

One-phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done on all of the connections completes or fails atomically. The product does not allow more than one one-phase commit connection in a global transaction. Furthermore, it does not allow a one-phase commit connection in a global transaction with one or more two-phase commit connections. You can coordinate only multiple two-phase commit connections within a global transaction.

WebSphere Application Server provides *last participant support*, which enables a single one-phase commit resource to participate in a global transaction with one or more two-phase commit resources.

Note that any time that you do multiple `getConnection()` calls using a resource reference that specifies `res-sharing-scope=Unshareable`, you get multiple physical connections. This situation also occurs when `res-sharing-scope=Shareable`, but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two-phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an XA exception that logs the following message:

```
WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred.
```

## Application scoped resources

Use this page to view brief descriptions of the resources that are bundled with your application. You can view individual resource settings by clicking on the resource name.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application\_name* → **Application scoped resources**.

Each table row corresponds to a resource that is bundled with your application. Click a resource name or the corresponding provider name to view an administrative console page where you can edit the object configuration settings.

### **Name:**

Specifies the administrative name that was assigned to this resource.

Click this name to view a page where you can edit the configuration settings.

### **JNDI name:**

Specifies the Java Naming and Directory Interface (JNDI) name of the resource.

**Data type** String

### **Resource type:**

Specifies the type of resource, such as a data source or a J2C connection factory.

### **Provider:**

Specifies the resource provider that supplies the class information for this resource object.

Click the provider name to view a page where you can edit the configuration settings.

### **Description:**

Specifies a text description of the resource.

## Cache instances

An application uses a cache instance to store, retrieve, and share data objects within the dynamic cache.

Each cache instance can be configured independently for Java Naming and Directory Interface (JNDI) name, cache size, priority, and disk offload. Objects that are stored in a particular cache instance are not affected by other cache instances. This means that if you store an object named **object\_1** with a value of `object_data` in `cache_instance_x`, you can also store an object with the same name, but different value in `cache_instance_y`.

Objects that are stored in a particular cache instance are available to applications on other servers by accessing a cache instance of the same name. The two servers must be within the same replication domain to share data.

There are two types of cache instances, object cache instances and servlet cache instances.

An object cache instance is a location in addition to the default shared dynamic cache where Java 2 Platform, Enterprise Edition (J2EE) applications can store, distribute, and share objects. After configuring object cache instances, you can use the `DistributedMap` or `DistributedObjectCache` interfaces in the `com.ibm.websphere.cache` package to programmatically access your cache instances.

See the Additional Application Programming Interfaces (APIs) for more information about the `DistributedMap` or `DistributedObjectCache` interfaces.

Servlet cache instances are locations in addition to the default dynamic cache where dynamic cache can store, distribute, and share the output and the side effects of an invoked servlet. By configuring a servlet cache instance, your applications have greater flexibility and better tuning of cache resources. The Java Naming and Directory Interface (JNDI) name that is specified for the cache instance in the administrative console maps to the `<cache-instance>` element in the `cachespec.xml` configuration file. Any `<cache-entry>` elements that are specified within a `<cache-instance>` element are created in that specific cache instance. Any `<cache-entry>` elements that are specified outside of a `<cache-instance>` element are stored in the default dynamic cache instance.

See “Using servlet cache instances” on page 2397 for more information.

## Data access: Resources for learning

Use the following links to find relevant supplemental information about data access. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to this product, but it can be useful for understanding concepts or functions used by the application server. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

## Configuring data access with scripting

Use these topics to learn about using scripting to configure data access.

### About this task

This topic contains the following tasks:

- “Configuring a JDBC provider using scripting” on page 1414
- “Configuring new data sources using scripting” on page 1415
- “Configuring new connection pools using scripting” on page 1417
- “Changing connection pool settings with the wsadmin tool” on page 1418
- “Configuring new data source custom properties using scripting” on page 1424
- “Configuring new Java 2 Connector authentication data entries using scripting” on page 1425
- “Configuring new WAS40 data sources using scripting” on page 1426
- “Configuring new WAS40 connection pools using scripting” on page 1427
- “Configuring new WAS40 custom properties using scripting” on page 1428
- “Configuring new J2C resource adapters using scripting” on page 1430
- “Configuring custom properties for J2C resource adapters using scripting” on page 1431
- “Configuring new J2C connection factories using scripting” on page 1432

- “Configuring new J2C administrative objects using scripting” on page 1436
- “Configuring new J2C activation specifications using scripting” on page 1434
- “Managing the message endpoint lifecycle using scripting” on page 1437
- “Testing data source connections using scripting” on page 1438

## Configuring a JDBC provider using scripting

You can configure a JDBC provider using the wsadmin tool and scripting.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

**Note:** The product no longer supports the DB2 for 390 and z/OS Legacy JDBC driver and the corresponding JDBC provider, the DB2 for zOS Local JDBC provider (RRS). Now WebSphere Application Server for z/OS requires the DB2 Universal JDBC Driver to connect with DB2 for z/OS. Migrate your existing provider settings to the DB2 Universal JDBC Driver provider. Consult the topic “Migrating from the JDBC/SQLJ Driver for OS/390 and z/OS to the DB2 Universal JDBC Driver” in the Information Management Software for z/OS Solutions Information Center, which is located at <http://publib.boulder.ibm.com/infocenter/dzichelp>.

1. There are two ways to perform this task. Perform one of the following:

- Using the AdminTask object:

- Using Jacl:

```
$AdminTask createJDBCProvider {-interactive}
```

- Using Jython:

```
AdminTask.createJDBCProvider (['-interactive'])
```

- Using the AdminConfig object:

a. Identify the parent ID and assign it to the node variable. The following example uses the node configuration object as the parent. You can modify this example to use the cell, cluster, server, or application configuration object as the parent.

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

b. Identify the required attributes:

**Note:** For supported JDBC drivers, you can also script JDBC providers according to the same pre-configured templates that are used by the administrative console logic. Consult the article Creating configuration objects using the wsadmin tool for details.

- Using Jacl:

```
$AdminConfig required JDBCProvider
```

- Using Jython:

```
print AdminConfig.required('JDBCProvider')
```

Example output:

```
Attribute Type
name String
implementationClassName String
```

- c. Set up the required attributes and assign it to the jdbcAttrs variable. You can modify the following example to setup non-required attributes for JDBC provider.

- Using Jacl:

```
set n1 [list name JDBC1]
set implCN [list implementationClassName myclass]
set jdbcAttrs [list $n1 $implCN]
```

Example output:

```
{name {JDBC1}} {implementationClassName {myclass}}
```

- Using Jython:

```
n1 = ['name', 'JDBC1']
implCN = ['implementationClassName', 'myclass']
jdbcAttrs = [n1, implCN]
print jdbcAttrs
```

Example output:

```
[['name', 'JDBC1'], ['implementationClassName', 'myclass']]
```

- d. Create a new JDBC provider using node as the parent:

- Using Jacl:

```
$AdminConfig create JDBCProvider $node $jdbcAttrs
```

- Using Jython:

```
AdminConfig.create('JDBCProvider', node, jdbcAttrs)
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
```

2. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
3. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## What to do next

If you modify the class path or native library path of a JDBC provider: After saving your changes (and synchronizing the node in a network deployment environment), you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

## Configuring new data sources using scripting

You can configure new data sources using scripting and the wsadmin tool.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

In WebSphere Application Server, any JDBC driver properties that are required by your database vendor must be set as data source properties. Consult the article *Vendor-specific data sources minimum required settings* in the *Troubleshooting and support* PDF to see a list of these properties and setting options, ordered by JDBC provider type. Consult your database vendor documentation to learn about available optional data source properties. Script them as *custom properties* after you create the data source. In the Related links section of this article, click the "Configuring new data source custom properties using scripting" link for more information.

You can also learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS, if you use one of the following JDBC providers:

- DB2 for z/OS Local JDBC Provider (RRS) JDBC Provider (using the DB2 JDBC / SQLJ driver)
- DB2 Universal JDBC Driver provider

## About this task

There are two ways to perform this task; use either of the following wsadmin scripting objects:

- AdminTask object
- AdminConfig object

AdminConfig gives you more configuration control than the AdminTask object. When you create a data source using AdminTask, you supply universally required properties only, such as a JNDI name for the data source. (Consult the article “JDBCProviderManagement command group for the AdminTask object” on page 1440 for more information.) Other properties that are required by your JDBC driver are assigned default values by Application Server. You cannot use AdminTask commands to set or edit these properties; you must use AdminConfig commands.

- Using the AdminConfig object to configure a new data source:
  1. Identify the parent ID, which is the name and location of the JDBC provider that supports your data source.

– Using Jacl:

```
set newjdbc [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/]
```

– Using Jython:

```
newjdbc = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/')
print newjdbc
```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml#JDBCProvider_1)
```

2. Obtain the required attributes.

**Note:** For supported JDBC drivers, you can also script data sources according to the same pre-configured templates that are used by the administrative console logic. Consult the article [Creating configuration objects using the wsadmin tool](#) for details.

– Using Jacl:

```
$AdminConfig required DataSource
```

– Using Jython:

```
print AdminConfig.required('DataSource')
```

Example output:

```
Attribute Type
name String
```

**Note:** If the database vendor-required properties (which are referenced in the article “Data source minimum required settings, by vendor” on page 1510) are not displayed in the resulting list of required attributes, script these properties as data source custom properties after you create the data source.

3. Set up the required attributes.

– Using Jacl:

```
set name [list name DS1]
set dsAttrs [list $name]
```

– Using Jython:

```
name = ['name', 'DS1']
dsAttrs = [name]
```

4. Create the data source.

– Using Jacl:

```
set newds [$AdminConfig create DataSource $newjdbc $dsAttrs]
```

– Using Jython:

```
newds = AdminConfig.create('DataSource', newjdbc, dsAttrs)
print newds
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml#DataSource_1)
```

• Using the AdminTask object to configure a new data source:

– Using Jacl:

```
$AdminTask createDatasource {-interactive}
```

– Using Jython:

```
AdminTask.createDatasource (['-interactive'])
```

• Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

• Synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## What to do next

To set additional properties that are supported by your JDBC driver, script them as data source custom properties.

## Configuring new connection pools using scripting

You can use scripting and the wsadmin tool to configure new connection pools.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps:

1. Identify the parent ID:

• Using Jacl:

```
set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
```

• Using Jython:

```
newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
```

2. Creating connection pool:

• Using Jacl:

```
$AdminConfig create ConnectionPool $newds {}
```

• Using Jython:

```
print AdminConfig.create('ConnectionPool', newds, [])
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#ConnectionPool_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Changing connection pool settings with the wsadmin tool

You can use the wsadmin scripting tool to change connection pool settings.

### About this task

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages. To learn more about the wsadmin tool see Starting the wsadmin scripting client.

To use the wsadmin tool to change connection pool settings:

1. Launch a scripting command. There are several options for you to run scripting commands, ranging from running them interactively to running them in a profile.

To change connection pool settings, you use the *getAttribute* and *setAttribute* commands, run against the various settings objects.

For example, to change the connection timeout setting, the commands are:

```
$AdminControl getAttribute $objectname connectionTimeout
$AdminControl setAttribute $objectname connectionTimeout 200
```

where:

- \$ is a Jacl operator for substituting a variable name with its value
  - getAttribute and setAttribute are the commands
  - connectionTimeout is the object whose value you are resetting
2. For Jacl code examples of each of the connection pool settings, see “Example: Changing connection pool settings with the wsadmin tool”

### Example: Changing connection pool settings with the wsadmin tool

Using the wsadmin AdminControl object, you can script changes to connection pool settings.

The WebSphere Application Server wsadmin tool provides the ability to run scripts in the Jacl and Jython languages only. You must start the wsadmin scripting client to perform any scripting task. (See the article “Starting the wsadmin scripting client.”)

For more information about the AdminControl scripting object, refer to the article “Using the AdminControl object for scripted administration.” See the links section at the end of this article.

### Connection Timeout

The Connection timeout can be changed at any time while the pool is active. All connection requests that are waiting for a connection are changed to the new value minus the time already waited, and are returned to the wait state if there are no available connections.

For example, if the connection timeout is changed to 300 seconds and a connection request has waited 100 seconds, the connection request waits for 200 more seconds if no connection becomes available.

```
$AdminControl getAttribute $objectname connectionTimeout
$AdminControl setAttribute $objectname connectionTimeout 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

### Maximum Connections

The maximum connections can be changed at any time except in the case where stuck connection support is active.

If stuck connection support is active, an attempt to change the maximum connections is made. If the attempt fails, an `IllegalStateException` exception occurs. See the Connection pool advanced settings topic in the *Administering applications and their environment* PDF for more information.

If stuck connection support is not active, the maximum connections are changed to the new value. If the new value is greater than the current value, the number of connections increases to the new value and any requests waiting are notified. If the new value is less than the current value and Aged Timeout or Reap Time is used, the number of connections decreases to the new value depending on pool activity. If agedTimeout or Reap Time are not used, no automatic attempt will be made to reduce the total number of connections. To manually reduce the number of connections to the new maximum connections, use the Mbean function `purgePoolContents`.

```
$AdminControl getAttribute $objectname maxConnections
$AdminControl setAttribute $objectname maxConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Minimum Connections

The minimum connections can be changed at any time

```
$AdminControl getAttribute $objectname minConnections
$AdminControl setAttribute $objectname minConnections 200
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Reap Time

The reap time can be changed at any time. The reap time interval is changed to the new value at the next interval.

```
$AdminControl getAttribute $objectname reapTime
$AdminControl setAttribute $objectname reapTime 30
```

## Unused Timeout

The unused timeout can be changed at any time.

```
$AdminControl getAttribute $objectname unusedTimeout
$AdminControl setAttribute $objectname unusedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Aged Timeout

The Aged Timeout can be changed at any time.

```
$AdminControl getAttribute $objectname agedTimeout
$AdminControl setAttribute $objectname agedTimeout 900
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

## Purge Policy

The purge policy can be changed at any time.

```
$AdminControl getAttribute $objectname purgePolicy
$AdminControl setAttribute $objectname purgePolicy "Failing Connection Only"
```

For more information about this setting, see the Connection pool settings topic in the *Administering applications and their environment* PDF.

### Surge Protection Support

Surge connection support starts if surgeThreshold is > -1 and surgeCreationInterval is > 0. The surge protection properties can be changed at any time.

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

### Stuck connection Support

An attempt is made to change the stuckTime, stuckTimerTime or stuckThreshold properties. If the attempt fails, an IllegalState exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, all three stuck property values must be greater than 0, and the maximum connections value must be > 0.

If the connection pool is stuck, you cannot change the stuck or the maximum connection properties. If you are stuck, there are active connections.

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerTime
$AdminControl setAttribute $objectname stuckTimerTime 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

### Test Connection Support (This is only supported for a DataSource)

The test connection support starts when the testConnection property is set to true, and the interval is > 0. The test connection properties can be changed at any time.

```
$AdminControl getAttribute $objectname testConnection
$AdminControl setAttribute $objectname testConnection 30
$AdminControl getAttribute $objectname testConnectionInterval
$AdminControl setAttribute $objectname testConnectionInterval 15
```

For more information about this setting, see the Test connection service topic in the *Administering applications and their environment* PDF.

### Connection Pool Partition Support

```
$AdminControl invoke $objectname freePoolDistributionTableSize
$AdminControl invoke $objectname numberOfFreePoolPartitions
$AdminControl invoke $objectname numberOfSharedPoolPartitions
$AdminControl invoke $objectname gatherPoolStatisticalData
$AdminControl invoke $objectname enablePoolStatisticalData
```

For more information about this setting, see the Connection pool advanced settings topic in the *Administering applications and their environment* PDF.

## Show Pool Information Support

The show pool operations can be changed at any time.

```
$AdminControl invoke $ObjectName showAllPoolContents
$AdminControl invoke $ObjectName showPoolContents
$AdminControl invoke $ObjectName showAllocationHandleList
```

## Purge Connection Support

PurgePool can be changed at any time.

```
$AdminControl invoke $ObjectName purgePoolContents normal
$AdminControl invoke $ObjectName purgePoolContents immediate
```

## Pool Control Support

Pause and resume can be changed at any time.

```
$AdminControl invoke $ObjectName pause
$AdminControl invoke $ObjectName resume
```

## Example: Accessing MBean connection factory and data sources using wsadmin

Wsadmin commands are used to access connection factory and data source MBeans. MBeans can retrieve or update properties for a connection factory or data source.

To get a list of J2C connection factory or data source Mbean object names, from the wsadmin command line use one of the following administrative control commands:

```
$AdminControl queryNames *:type=J2CConnectionFactory,*
$AdminControl queryNames *:type=DataSource,*
```

Example output from DataSource query:

```
wsadmin>$AdminControl queryNames *:type=DataSource,*
"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Derby JDBC Provider,j2eeType=JDBCDataSource,J2EESe
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Derby JDBC Provider,cell=system1Node01Cell"
```

By using the J2C connection factory or data source MBean object name, you can access the MBean. The name follows the webSphere:name= expression. In the following example, for the first set, the default data source name is set on variable name. For the second set, the object name is set on variable *objectName*.

Example using the Default Datasource

```
- wsadmin>set name [list Default Datasource]
```

Default Datasource

```
- wsadmin>set objectName [$AdminControl queryNames *:name=$name,*]
```

```
"WebSphere:name=Default Datasource,process=server1,platform=dynamicproxy,node=
system1Node01,JDBCProvider=Derby JDBC Provider,j2eeType=JDBCDataSource,J2EESe
rver=server1,Server=server1,version=6.0.0.0,type=DataSource,mbeanIdentifier=cell
s/system1Node01Cell/nodes/system1Node01/servers/server1/resources.xml#DataSource
_1094760149902,JDBCResource=Derby JDBC Provider,cell=system1Node01Cell"
```

Now you can use the objectName for getting help on attributes and operations available for this mbean.

```
$Help attributes $ObjectName
$Help operations $ObjectName
```

To get or set an attribute or to use an operation, use one of the following commands:

```
$AdminControl getAttribute $ObjectName "attribute name"
$AdminControl setAttribute $ObjectName "attribute name" value
$AdminControl invoke $ObjectName "operation"
```

#### Attribute, operation examples:

Get and set a attribute maxConnections (Note, if you get no value, a null value, or a java.lang.IllegalStateException, the connection factory or data source for this MBean has not been created. The connection factory or data source is created at first JNDI lookup. For this example, the Default Datasource needs to be used before get, set and invoke will work.)

```
wsadmin>$AdminControl getAttribute $ObjectName maxConnections
10
```

```
wsadmin>$AdminControl setAttribute $ObjectName maxConnections 20
```

```
wsadmin>$AdminControl getAttribute $ObjectName maxConnections
20
```

Using invoke

```
wsadmin>$AdminControl invoke $ObjectName showPoolContents
```

```
PoolManager name:DefaultDatasource
PoolManager object:746354514
Total number of connections: 3 (max/min 20/1, reap/unused/aged 180/1800/0,
connectiontimeout/purge 1800/EntirePool)
(testConnection/inteval false/0, stuck timer/time
/threshold 0/0/0, surge time/connections 0/-1)
Shared Connection information (shared partitions 200)
 No shared connections
```

```
Free Connection information (free distribution table/partitions 5/1)
(2)(0)MCWrapper id 5c6af75b Managed connection WSRdbManagedConnectionImpl@4b5
a775b State:STATE_ACTIVE_FREE
(2)(0)MCWrapper id 3394375a Managed connection WSRdbManagedConnectionImpl@328
5f75a State:STATE_ACTIVE_FREE
(2)(0)MCWrapper id 4795b75a Managed connection WSRdbManagedConnectionImpl@46a
4b75a State:STATE_ACTIVE_FREE
```

```
Total number of connection in free pool: 3
UnShared Connection information
 No unshared connections
```

Here is an example Java program using the wsadmin tool to invoke showPoolContents: the Example: using wsadmin to invoke showPoolContents topic in the *Administering applications and their environment* PDF.

#### **Example: Invoking showPoolContents using the wsadmin tool:**

This example Java program uses the wsadmin tool to invoke showPoolContents.

```
/**
 * "This sample program is provided AS IS and may be used, executed, copied and modified without royalty payment
 * by customer (a) for its own instruction and study, (b) in order to develop applications designed to run with
 * an IBM WebSphere product, either for customer's own internal use or for redistribution by customer, as part
 * of such an application, in customer's own products. "
 *
 * Product 5724i63, (C) COPYRIGHT International Business Machines Corp., 2004
 *

### Related tasks

“Changing connection pool settings with the wsadmin tool” on page 1418  
You can use the wsadmin scripting tool to change connection pool settings.

## Configuring new data source custom properties using scripting

You can configure new data source custom properties using the wsadmin tool and scripting.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps to configure a new data source custom property:

#### 1. Identify the parent ID:

- Using Jacl:

```
set newds [$AdminConfig getid /Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/]
```

- Using Jython:

```
newds = AdminConfig.getid('/Cell:mycell/Node:mynode/JDBCProvider:JDBC1/DataSource:DS1/')
print newds
```

Example output:

```
DS1(cells/mycell/nodes/mynode|resources.xml$DataSource_1)
```

#### 2. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newds propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newds, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_8)
```

#### 3. Get required attribute:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

```
Attribute Type
name String
```

#### 4. Set up attributes:

- Using Jacl:

```
set name [list name RP4]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP4']
rpAttrs = [name]
```

5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new Java 2 Connector authentication data entries using scripting

You can configure new Java 2 Connector (J2C) authentication data entries with the wsadmin tool and scripting.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps to configure a new J2C authentication data entry:

1. Identify the parent ID:

- Using Jacl:

```
set security [$AdminConfig getid /Cell:mycell/Security:/]
```

- Using Jython:

```
security = AdminConfig.getid('/Cell:mycell/Security:/')
print security
```

Example output:

```
(cells/mycell|security.xml#Security_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required JAASAuthData
```

- Using Jython:

```
print AdminConfig.required('JAASAuthData')
```

Example output:

Attribute	Type
alias	String
userId	String
password	String

3. Set up required attributes:

- Using Jacl:

```

set alias [list alias myAlias]
set userid [list userId myid]
set password [list password secret]
set jaasAttrs [list $alias $userid $password]

```

Example output:

```
{alias myAlias} {userId myid} {password secret}
```

- Using Jython:

```

alias = ['alias', 'myAlias']
userid = ['userId', 'myid']
password = ['password', 'secret']
jaasAttrs = [alias, userid, password]
print jaasAttrs

```

Example output:

```
[['alias', 'myAlias'], ['userId', 'myid'], ['password', 'secret']]
```

#### 4. Create JAAS auth data:

- Using Jacl:

```
$AdminConfig create JAASAuthData $security $jaasAttrs
```

- Using Jython:

```
print AdminConfig.create('JAASAuthData', security, jaasAttrs)
```

Example output:

```
(cells/mycell|security.xml#JAASAuthData_2)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new WAS40 data sources using scripting

Use scripting to configure a new WAS40 data source.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps:

#### 1. Identify the parent ID:

- Using Jacl:

```
set newjdbc [$AdminConfig getid "/JDBCProvider:Apache Derby JDBC Provider/"]
```

- Using Jython:

```

newjdbc = AdminConfig.getid('/JDBCProvider:Apache Derby JDBC Provider/')
print newjdbc

```

Example output:

```
JDBC1(cells/mycell/nodes/mynode|resources.xml$JDBCProvider_1)
```

#### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WAS40DataSource
```

- Using Jython:

```
print AdminConfig.required('WAS40DataSource')
```

Example output:

```
Attribute Type
name String
```

### 3. Set up required attributes:

- Using Jacl:

```
set name [list name was4DS1]
set ds4Attrs [list $name]
```

- Using Jython:

```
name = ['name', 'was4DS1']
ds4Attrs = [name]
```

### 4. Create WAS40DataSource:

- Using Jacl:

```
set new40ds [$AdminConfig create WAS40DataSource $newjdbc $ds4Attrs]
```

- Using Jython:

```
new40ds = AdminConfig.create('WAS40DataSource', newjdbc, ds4Attrs)
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynode|resources.xml#WAS40DataSource_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new WAS40 connection pools using scripting

You can use scripting to configure a new WAS40 connection pool.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps to configure a new WAS40 connection pool:

#### 1. Identify the parent ID:

- Using Jacl:

```
set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
```

- Using Jython:

```
new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
Server:server1/JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynodes:resources.xml$WAS40DataSource_1)
```

#### 2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WAS40ConnectionPool
```

- Using Jython:

```
print AdminConfig.required('WAS40ConnectionPool')
```

Example output:

Attribute	Type
minimumPoolSize	Integer
maximumPoolSize	Integer
connectionTimeout	Integer
idleTimeout	Integer
orphanTimeout	Integer
statementCacheSize	Integer

### 3. Set up required attributes:

- Using Jacl:

```
set mps [list minimumPoolSize 5]
set minps [list minimumPoolSize 5]
set maxps [list maximumPoolSize 30]
set conn [list connectionTimeout 10]
set idle [list idleTimeout 5]
set orphan [list orphanTimeout 5]
set scs [list statementCacheSize 5]
set 40cpAttrs [list $minps $maxps $conn $idle $orphan $scs]
```

Example output:

```
{minimumPoolSize 5} {maximumPoolSize 30}
{connectionTimeout 10} {idleTimeout 5}
{orphanTimeout 5} {statementCacheSize 5}
```

- Using Jython:

```
minps = ['minimumPoolSize', 5]
maxps = ['maximumPoolSize', 30]
conn = ['connectionTimeout', 10]
idle = ['idleTimeout', 5]
orphan = ['orphanTimeout', 5]
scs = ['statementCacheSize', 5]
cpAttrs = [minps, maxps, conn, idle, orphan, scs]
print cpAttrs
```

Example output:

```
[[minimumPoolSize, 5], [maximumPoolSize, 30],
[connectionTimeout, 10], [idleTimeout, 5],
[orphanTimeout, 5], [statementCacheSize, 5]]
```

### 4. Create was40 connection pool:

- Using Jacl:

```
$AdminConfig create WAS40ConnectionPool $new40ds $40cpAttrs
```

- Using Jython:

```
print AdminConfig.create('WAS40ConnectionPool', new40ds, 40cpAttrs)
```

Example output:

```
(cells/mycell/nodes/mynode:resources.xml#WAS40ConnectionPool_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new WAS40 custom properties using scripting

You can use scripting and the wsadmin tool to configure a new WAS40 custom property.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

## About this task

Perform the following steps to configure a new WAS40 custom properties:

1. Identify the parent ID:

- Using Jacl:

```
set new40ds [$AdminConfig getid /Cell:mycell/Node:mynode/
JDBCProvider:JDBC1/WAS40DataSource:was4DS1/]
```

- Using Jython:

```
new40ds = AdminConfig.getid('/Cell:mycell/Node:mynode/
JDBCProvider:JDBC1/WAS40DataSource:was4DS1/')
print new40ds
```

Example output:

```
was4DS1(cells/mycell/nodes/mynodes|resources.xml$WAS40DataSource_1)
```

2. Get required attributes:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newds propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newds, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#J2EEResourcePropertySet_9)
```

3. Get required attribute:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

Attribute	Type
name	String

4. Set up required attributes:

- Using Jacl:

```
set name [list name RP5]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP5']
rpAttrs = [name]
```

5. Create J2EE Resource Property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP5(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_9)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new J2C resource adapters using scripting

Use the wsadmin tool to configure resource adapters with Resource Adapter Archive (RAR) files. A RAR file provides the classes and other code to support a resource adapter for access to a specific enterprise information system (EIS), such as the Customer Information Control System (CICS). Configure resource adapters for an EIS only after you install the appropriate RAR file.

### Before you begin

A RAR file, which is often called a J2EE Connector Architecture (JCA) connector, must comply with the JCA Specification. Meet these requirements by using a supported assembly tool (as described in the Assembly tools article) to assemble a collection of Java archive (JAR) files, other runnable components, utility classes, and so on, into a deployable RAR file. Then you are ready to install your RAR file in Application Server.

There are two ways to complete this task. This topic uses the AdminConfig object to install resource adapters. Alternatively, you can use the installJ2CResourceAdapter script in the AdminJ2C script library to install a J2C resource adapter in your configuration, as the following example demonstrates:

```
AdminJ2C.installJ2CResourceAdapter("myNode", "C:\temp\jca15cmd.rar", "J2CTest")
```

The scripting library provides a set of procedures to automate the most common administration functions. You can run each script procedure individually, or combine several procedures to quickly develop new scripts.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Identify the configuration ID of the node to which the resource adapter is installed, as the following examples demonstrate:

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

3. Identify the optional attributes.

The J2CResourceAdapter object does not require specific arguments. Use the following command to display the optional attributes for the J2CResourceAdapter object:

- Using Jacl:

```
$AdminConfig defaults J2CResourceAdapter
```

- Using Jython:

```
print AdminConfig.defaults('J2CResourceAdapter')
```

The following displays the command output that displays each optional attribute and the data type for the attribute, and denotes the default attributes:

Attribute	Type
name	String
description	String
classpath	String
nativepath	String
providerType	String
archivePath	String
threadPoolAlias	String
propertySet	J2EEResourcePropertySet
jaasLoginConfiguration	JAASConfigurationEntry
deploymentDescriptor	Connector
connectionDefTemplateProps	ConnectionDefTemplateProps

activationSpecTemplateProps	ActivationSpecTemplateProps
j2cAdminObjects	J2CAdminObject
adminObjectTemplateProps	AdminObjectTemplateProps
j2cActivationSpec	J2CActivationSpec

#### 4. Set up the attributes of interest.

Determine the attributes to configure for the J2C resource adapter. In the following examples, the commands set the RAR file path to the `rarFile` variable and the name and description configuration options to the option variable:

- Using Jacl:

```
set rarFile /currentScript/cicseci.rar
set option {-rar.name RAR1 -rar.desc "New resource adapter"}
```

- Using Jython:

```
rarFile = '/currentScript/cicseci.rar'
option = '[-rar.name RAR1 -rar.desc "New resource adapter"]'
```

#### 5. Create a resource adapter.

Use the `installResourceAdapter` command for the `AdminConfig` object to install the resource adapter with the previously set configuration options, as the following examples demonstrate:

- Using Jacl:

```
$AdminConfig installResourceAdapter $rarFile mynode $option
```

- Using Jython:

```
AdminConfig.installResourceAdapter(rarFile, 'mynode', option)
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

#### 6. Save the configuration changes.

#### 7. Synchronize the node.

Use the `syncActiveNode` or `syncNode` scripts in the `AdminNodeManagement` script library to propagate the configuration changes to node or nodes.

- Use the `syncActiveNodes` script to propagate the changes to each node in the cell, as the following example demonstrates:

```
AdminNodeManagement.syncActiveNodes()
```

- Use the `syncNode` script to propagate the changes to a specific node, as the following example demonstrates:

```
AdminNodeManagement.syncNode("myNode")
```

## Configuring custom properties for J2C resource adapters using scripting

You can configure custom properties for J2C resource adapters with scripting and the `wsadmin` tool.

### Before you begin

Before starting this task, the `wsadmin` tool must be running. See the [Starting the wsadmin scripting client](#) article for more information.

### About this task

Perform the following steps to configure a new custom property for a J2C resource adapters:

#### 1. Identify the parent ID and assign it to the `newra` variable.

- Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

## 2. Get the J2EE resource property set:

- Using Jacl:

```
set propSet [$AdminConfig showAttribute $newra propertySet]
```

- Using Jython:

```
propSet = AdminConfig.showAttribute(newra, 'propertySet')
print propSet
```

Example output:

```
(cells/mycell/nodes/mynode|resources.xml#PropertySet_8)
```

## 3. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2EEResourceProperty
```

- Using Jython:

```
print AdminConfig.required('J2EEResourceProperty')
```

Example output:

Attribute name	Type
	String

## 4. Set up the required attributes:

- Using Jacl:

```
set name [list name RP4]
set rpAttrs [list $name]
```

- Using Jython:

```
name = ['name', 'RP4']
rpAttrs = [name]
```

## 5. Create a J2EE resource property:

- Using Jacl:

```
$AdminConfig create J2EEResourceProperty $propSet $rpAttrs
```

- Using Jython:

```
print AdminConfig.create('J2EEResourceProperty', propSet, rpAttrs)
```

Example output:

```
RP4(cells/mycell/nodes/mynode|resources.xml#J2EEResourceProperty_8)
```

## 6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

## 7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

# Configuring new J2C connection factories using scripting

Use scripting and the wsadmin tool to configure new J2C connection factories.

## Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

## About this task

Perform the following steps to configure a new J2C connection factory:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C connection factory. Perform one of the following:

- Using the AdminTask object:

- a. List the connection factory interfaces:

- Using Jacl:

```
$AdminTask listConnectionFactoryInterfaces $newra
```

- Using Jython:

```
AdminTask.listConnectionFactoryInterfaces(newra)
```

Example output:

```
javax.sql.DataSource
```

- b. Create a J2CConnectionFactory:

- Using Jacl:

```
$AdminTask createJ2CConnectionFactory $newra { -name cf1
-jndiName eis/cf1 -connectionFactoryInterface
avax.sql.DataSource
```

- Using Jython:

```
AdminTask.createJ2CConnectionFactory(newra, ['-name', 'cf1',
'-jndiName', 'eis/cf1', '-connectionFactoryInterface',
'avax.sql.DataSource'])
```

- Using the AdminConfig object:

- a. Identify the required attributes:

- Using Jacl:

```
$AdminConfig required J2CConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('J2CConnectionFactory')
```

Example output:

```
Attribute Type
connectionDefinition ConnectionDefinition@
```

- b. If your resource adapter is JCA1.5 and you have multiple connection definitions defined, it is required that you specify the ConnectionDefinition attribute. If your resource adapter is JCA1.5 and you have only one connection definition defined, it will be picked up automatically. If your resource adapter is JCA1.0, you do not need to specify the ConnectionDefinition attribute. Perform the following command to list the connection definitions defined by the resource adapter:

- Using Jacl:

```
$AdminConfig list ConnectionDefinition $newra
```

- Using Jython:

```
print AdminConfig.list('ConnectionDefinition', $newra)
```

- c. Set up the required attributes:

– Using Jacl:  
set name [list name J2CCF1]  
set jname [list jndiName eis/j2ccf1]  
set j2ccfAttrs [list \$name]

– Using Jython:  
name = ['name', 'J2CCF1']  
jname = ['jndiName', 'eis/j2ccf1']  
j2ccfAttrs = [name, jname]

d. If you are specifying the ConnectionDefinition attribute, also set up the following:

– Using Jacl:  
set cdatr [list connectionDefinition \$cd]

– Using Jython:  
cdatr = ['connectionDefinition', \$cd]

e. Create a J2C connection factory:

– Using Jacl:  
\$AdminConfig create J2CConnectionFactory \$newra \$j2ccfAttrs

– Using Jython:  
print AdminConfig.create('J2CConnectionFactory', newra, j2ccfAttrs)

Example output:

```
J2CCF1(cells/mycell/nodes/mynode|resources.xml#J2CConnectionFactory_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new J2C activation specifications using scripting

You can configure new J2C activation specifications using scripting and the wsadmin tool.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps to configure a J2C activation specifications:

1. Identify the parent ID and assign it to the newra variable.

• Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

• Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:

• Using the AdminTask object:

a. List the administrative object interfaces:

Using Jacl:

```
$AdminTask listMessageListenerTypes $newra
```

Using Jython:

```
AdminTask.listMessageListenerTypes(newra)
```

Example output:

```
javax.jms.MessageListener
```

- b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CActivationSpec $newra { -name ac1
-jndiName eis/ac1 -messageListenerType
javax.jms.MessageListener}
```

Using Jython:

```
AdminTask.createJ2CActivationSpec(newra, ['-name', 'ac1',
'-jndiName', 'eis/ac1', '-messageListenerType',
'javax.jms.MessageListener'])
```

- Using the AdminConfig object:

- a. Using Jacl:

```
$AdminConfig required J2CActivationSpec
```

Using Jython:

```
print AdminConfig.required('J2CActivationSpec')
```

Example output:

```
Attribute Type
activationSpec ActivationSpec@
```

- b. If your resource adapter is JCA V1.5 and you have multiple activation specifications defined, it is required that you specify the activation specification attribute. If your resource adapter is JCA V1.5 and you have only one activation specification defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the activationSpec attribute. Perform the following command to list the activation specifications defined by the resource adapter:

Using Jacl:

```
$AdminConfig list ActivationSpec $newra
```

Using Jython:

```
print AdminConfig.list('ActivationSpec', $newra)
```

- c. Set the administrative object that you need to a variable:

Using Jacl:

```
set ac [$AdminConfig list ActivationSpec $newra]
set name [list name J2CAC1]
set jname [list jndiName eis/J2CAC1]
set j2cacAttrs [list $name $jname $cdcttr]
```

Using Jython:

```
ac = AdminConfig.list('ActivationSpec', $newra)
name = ['name', 'J2CAC1']
jname = ['jndiName', 'eis/j2cac1']
j2cacAttrs = [name, jname, cdattr]
```

- d. If you are specifying the ActivationSpec attribute, also set up the following:

Using Jacl:

```
set cdcttr [list activationSpec $ac]
```

Using Jython:

```
cdattr = ['activationSpec', ac]
```

- e. Create a J2C activation specification object:

Using Jacl:

```
$AdminConfig create J2CActivationSpec $newra $j2cacAttrs
```

Using Jython:

```
print AdminConfig.create('J2CActivationSpec', newra, j2cacAttrs)
```

Example output:

```
J2CAC1(cells/mycell/nodes/mynode|resources.xml#J2CActivationSpec_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Configuring new J2C administrative objects using scripting

You can use scripting and the wsadmin tool to configure new J2C administrative objects.

### Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

### About this task

Perform the following steps to configure a J2C administrative object:

1. Identify the parent ID and assign it to the newra variable.

- Using Jacl:

```
set newra [$AdminConfig getid /Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/]
```

- Using Jython:

```
newra = AdminConfig.getid('/Cell:mycell/Node:mynode/J2CResourceAdapter:RAR1/')
print newra
```

Example output:

```
RAR1(cells/mycell/nodes/mynode|resources.xml#J2CResourceAdapter_1)
```

2. There are two ways to configure a new J2C administrative object. Perform one of the following:

- Using the AdminTask object:

- a. List the administrative object interfaces:

Using Jacl:

```
$AdminTask listAdminObjectInterfaces $newra
```

Using Jython:

```
AdminTask.listAdminObjectInterfaces(newra)
```

Example output:

```
com.ibm.test.message.FVTMessageProvider
```

- b. Create a J2C administrative object:

Using Jacl:

```
$AdminTask createJ2CAdminObject $newra { -name ao1 -jndiName eis/ao1
-adminObjectInterface com.ibm.test.message.FVTMessageProvider }
```

Using Jython:

```
AdminTask.createJ2CAdminObject(newra, ['-name', 'ao1', '-jndiName', 'eis/ao1',
'-adminObjectInterface', 'com.ibm.test.message.FVTMessageProvider'])
```

- Using the AdminConfig object:

- a. Using Jacl:

```
$AdminConfig required J2CAdminObject
```

Using Jython:

```
print AdminConfig.required('J2CAdminObject')
```

Example output:

Attribute Type  
adminObject AdminObject@

- b. If your resource adapter is JCA V1.5 and you have multiple administrative objects defined, it is required that you specify the administrative object attribute. If your resource adapter is JCA V1.5 and you have only one administrative object defined, it will be picked up automatically. If your resource adapter is JCA V1.0, you do not need to specify the administrative object attribute. Perform the following command to list the administrative objects defined by the resource adapter:

Using Jacl:

```
$AdminConfig list AdminObject $newra
```

Using Jython:

```
print AdminConfig.list('AdminObject', $newra)
```

- c. Set the administrative objects that you need to a variable:

Using Jacl:

```
set ao AdminObjectId
set name [list name J2CA01]
set jname [jndiName eis/j2cao1]
set j2caoAttrs [list $name $jname]
```

Using Jython:

```
ao = AdminObjectId
name = ['name', 'J2CA01']
set jname = ['jndiName', eis/j2cao1]
j2caoAttrs = [name, jname]
```

- d. If you are specifying the AdminObject attribute, also set up the following:

Using Jacl:

```
set cdatr [list adminObject $ao]
```

Using Jython:

```
cdatr = ['adminObject', ao]
```

- e. Create a J2C administrative object:

Using Jacl:

```
$AdminConfig create J2CAdminObject $newra $j2caoAttrs
```

Using Jython:

```
print AdminConfig.create('J2CAdminObject', newra, j2caoAttrs)
```

Example output:

```
J2CA01(cells/mycell/nodes/mynode|resources.xml#J2CAdminObject_1)
```

3. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
4. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

## Managing the message endpoint lifecycle using scripting

Use the Jython scripting language to manage your message endpoints with the wsadmin tool. Use this topic to query your configuration for message endpoint properties, and to deactivate or reactivate a message endpoint.

### About this task

The Java EE Connector Architecture (JCA) allows the application server to link inbound requests from messaging resource adapters to message endpoints. The message endpoint managed bean (MBean) is a Java Management Extensions (JMX) framework MBean that the application server associates with a message endpoint instance.

Use this topic to manage situations where messaging providers fail to deliver messages to their intended destinations. For example, a provider might fail to deliver messages to a message endpoint when its underlying Message Driven Bean attempts to commit transactions against a database server that is not responding. To troubleshoot the problem, use the wsadmin tool to temporarily disable the message endpoint from handling messages. After troubleshooting the issue, use the wsadmin tool to reactivate the message endpoint.

The steps in this topic display how to use the AdminControl object and the wsadmin tool to invoke a Message Endpoint MBean to:

- Display properties of the a message endpoint
- Temporarily deactivate a message endpoint
- Reactivate a message endpoint

**Note:** Starting in Version 7.0, you can use the AdminControl object and the wsadmin tool to deactivate message endpoints to pause the endpoints from receiving messages, and to reactivate message endpoints to resume message handling. Previously, the application server activated and deactivated message endpoints when the application or resource adapter was started and stopped.

- Display properties of a message endpoint.

Use the following command to display a list of all message endpoints in your configuration:

```
AdminControl.queryNames('*:type=J2CMessageEndpoint,*')
```

For the previous example, the command returns the following information for the JMSMDB\_MessageEndpoint:

```
WebSphere:name=JMSMDB_J2CMessageEndpoint,
process=myServer,
platform=dynamicproxy,
cell=myNode01Cell,
node=myNode01,
version=6.1.0.0,
type=J2CMessageEndpoint,
mbeanIdentifier=cells/myNode01Cell/nodes/myNode01/servers/myServer/resources.xml#example#example.jar#JMSMDB_J2CMessageEndpoint,
spec=1.0,
Server=server1,
diagnosticProvider=false,
j2eeType=JCAMessageEndpoint,
J2EEApplication=example
J2EEServer=myServer,
J2CResourceAdapter=SIB JMS Resource Adapter,
MessageDrivenBean=example#example.jar#JMSMDBActivationSpec=3727AS1
```

- Temporarily deactivate the message endpoint.

Use the following commands to cache the instance and deactivate the message endpoint:

```
objectName=AdminControl.queryNames('*:name=JMSMDB_MessageEndpoint,*')
AdminControl.invoke(objectName, 'pause')
```

The command returns the following output:

```
Message Endpoint JMSMDB_J2CMessageEndpoint is deactivated
```

- Reactivate the message endpoint.

Use the following commands to cache the instance and reactivate the message endpoint:

```
objectName=AdminControl.queryNames('*:name=JMSMDB_MessageEndpoint,*')
AdminControl.invoke(objectName, 'resume')
```

The command returns the following output:

```
Message Endpoint JMSMDB_J2CMessageEndpoint is activated
```

## Testing data source connections using scripting

You can test connections for data sources with the wsadmin tool and scripting. After you have defined and saved a data source, you can test the data source connection to ensure that the parameters in the data source definition are correct.

## About this task

You can use the `testConnection` command for the `AdminControl` object to test data source connections for a cell, node, server, application, or cluster scope. This topic provides an example that tests the data source connection for the application scope.

- Test the data source connection for a cell, node, or server scope.
  1. Launch the `wsadmin` scripting tool using the Jython scripting language.
  2. Identify the `DataSourceCfgHelper` MBean and assign it to the `dshelper` variable.
    - Using Jacl:

```
set ds [$AdminConfig getid /DataSource:DS1/]
$AdminControl testConnection $ds
```
    - Using Jython:

```
ds = AdminConfig.getid('/DataSource:DS1/')
AdminControl.testConnection(ds)
```
  3. Test the connection. The following example invokes the `testConnectionToDataSource` operation on the MBean, passing in the classname, userid, password, database name, JDBC driver class path, language, and country.
    - Using Jacl:

```
$AdminControl invoke $dshelper testConnectionToDataSource
"COM.ibm.db2.jdbc.DB2XADataSource db2admin db2admin
{{databaseName sample}} /sqllib/java/db2java.zip en US"
```
    - Using Jython:

```
print AdminControl.invoke(dshelper, 'testConnectionToDataSource',
'COM.ibm.db2.jdbc.DB2XADataSource dbuser1 dbpwd1
"{{databaseName jtest1}}" /sqllib/java12/db "\'\'\'\'')

```
- Test the data source connection for an application scope.
  1. Launch the `wsadmin` scripting tool using the Jython scripting language.
  2. Get the data source for the application of interest.

Use the `AdminConfig` object to determine the configuration IDs of the `myApplication` application and `DSA1` data source, as the following examples demonstrate:

    - Using Jacl:

```
set appID [$AdminConfig getid /Deployment:myApplication/]
set ds [$AdminConfig list DataSource $appID]
```
    - Using Jython:

```
appID = AdminConfig.getid("/Deployment:myApplication/")
ds = AdminConfig.list("DataSource", appID)
```
  3. Test the connection.

Use the `AdminConfig` object to test the connection for the data source of interest, as the following examples demonstrate:

    - Using Jacl:

```
$AdminControl testConnection $ds
```
    - Using Jython:

```
AdminControl.testConnection(ds)
```

The command returns output that indicates whether the connection is successful, as demonstrated in the following sample output:

WASX7467I: Connection to provided datasource on node myNode processnodeagent was successful.  
WASX7217I: Connection to provided datasource was successful.

- Test the data source connection for a cluster scope.

In the following example, the Cluster1 server cluster contains cluster members on the node1, node2, and node3 nodes. The Cluster1 server cluster contains the DSC1 data source.

1. Launch the wsadmin scripting tool using the Jython scripting language.
2. Get the data source configuration ID for the cluster of interest.

Use the AdminConfig object to determine the configuration IDs of the Cluster1 cluster and DSA1 data source, as the following examples demonstrate:

- Using Jacl:

```
set cluster [$AdminConfig getid /ServerCluster:Cluster1/]
set ds [$AdminConfig list DataSource $cluster]
```

- Using Jython:

```
cluster = AdminConfig.getid("/ServerCluster:Cluster1/")
ds = AdminConfig.list("DataSource", cluster)
```

3. Test the connection.

Use the AdminConfig object to test the connection for the data source of interest, as the following examples demonstrate:

- Using Jacl:

```
$AdminControl testConnection $ds
```

- Using Jython:

```
AdminControl.testConnection(ds)
```

The command returns output that indicates whether the connection is successful, as demonstrated in the following sample output:

```
WASX7467I: Connection to provided datasource on node node1 process nodeagent was successful.
WASX7467I: Connection to provided datasource on node node2 process nodeagent was successful.
WASX7467I: Connection to provided datasource on node node3 process nodeagent was successful.
WASX7217I: Connection to provided datasource was successful.
```

## JDBCProviderManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages in interactive mode to configure data access and data sources with scripting. The commands and parameters in the JDBCProviderManagement group can be used to create or list data sources and Java database connectivity (JDBC) providers.

The JDBCProviderManagement command group for the AdminTask object includes the following commands:

- “createDataSource”
- “createJDBCProvider” on page 1442
- “listDatasources” on page 1443
- “listJDBCProviders” on page 1444

### createDataSource

The createDataSource command creates a new data source to access the back end data store. Application components use the data source to access connection instances to your database.

Target object

JDBC Provider Object ID - The configuration object of the JDBC provider to which the new data source will belong.

Required parameters

**- name**

The name of the data source. (String, required)

**-jndiName**

The Java Naming and Directory Interface (JNDI) name. (String, required)

**-dataStoreHelperClassName**

The name of the DataStoreHelper implementation class that extends the capabilities of the selected JDBC driver implementation class to perform data-specific functions. WebSphere Application Server provides a set of DataStoreHelper implementation classes for each of the JDBC provider drivers it supports. (String, required)

**configureResourceProperties**

This command step configures the resource properties that are required by the data source. (Required) You can specify the following parameters for this step:

**name**

The name of the resource property. (String, required)

**type**

The type of the resource property. (String, required)

**value**

The value of the resource property. (String, required)

Optional parameters

**-description**

The description of the data source. (String, optional)

**-category**

The category that you can use to classify a group of data sources. (String, optional)

**-componentManagedAuthenticationAlias**

The alias used for database authentication at run time. This alias is only used when the application resource reference is using res-auth=Application. (String, optional)

**-containerManagedPersistence**

Specifies if the data source is used for container managed persistence for enterprise beans. The default value is true. (Boolean, optional)

Examples

**Batch mode example usage:**

- Using Jacl:

```
$AdminTask createDataSource "DB2 Universal JDBC Driver Provider (XA) (cells/myCell|resources.xml#JDBCProvider_1180538152781)" {-name
"DB2 Universal JDBC Driver XA DataSource" -jndiName ds1 -dataStoreHelperClassName com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
-componentManagedAuthenticationAlias myCellManager01/a1 -xaRecoveryAuthAlias myCellManager01/a1 -configureResourceProperties
{{databaseName java.lang.String db1} {driverType java.lang.Integer 4} {serverName java.lang.String dbserver1} {portNumber java.lang.Integer 50000}}
```

- Using Jython string:

```
AdminTask.createDataSource('DB2 Universal JDBC Driver Provider(XA) (cells/myCell|resources.xml#JDBCProvider_1180501752515)', ['-name
"DB2 Universal JDBC Driver XA DataSource 2" -jndiName ds2 -dataStoreHelperClassName com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
-componentManagedAuthenticationAlias myCellManager01/a1 -xaRecoveryAuthAlias myCellManager01/a1 -configureResourceProperties
[[databaseName java.lang.String db1] [driverType java.lang.Integer 4] [serverName java.lang.String dbserver1] [portNumber java.lang.Integer 50000]]')
```

- Using Jython list:

```
AdminTask.createDataSource('DB2 Universal JDBC Driver Provider(XA) (cells/myCell|resources.xml#JDBCProvider_1180501752515)', ['-name', '
DB2 Universal JDBC Driver XA DataSource 2', '-jndiName', 'ds2', '-dataStoreHelperClassName',
'com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper', '-componentManagedAuthenticationAlias', 'myCellManager01/a1',
'-xaRecoveryAuthAlias', 'myCellManager01/a1', '-configureResourceProperties', '[[databaseName java.lang.String db1]
[driverType java.lang.Integer 4] [serverName java.lang.String dbserver1] [portNumber java.lang.Integer 50000]]')
```

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask createDataSource {-interactive}
```

- Using Jython:

```
AdminTask.createDatasource('-interactive')
```

## createJDBCProvider

The createJDBCProvider command creates a new Java database connectivity provider (JDBC) that you can use to connect to a relational database for data access.

Target object

None

Required parameters

### **-scope**

The scope for the new JDBC provider. Provide the scope in the form type=name. Type can be Cell, Node, Server, Application, or Cluster, and name is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is none. (String, required)

### **-databaseType**

The type of database that will be used by the JDBC provider. For example, DB2, Derby, Informix, Oracle, and so on. (String, required)

### **-providerType**

The JDBC provider type that will be used by the JDBC provider. (String, required)

### **-implementationType**

The implementation type for this JDBC provider. Use Connection pool data source if your application runs in a single phase or a local transaction. Otherwise, use XA data source to run in a global transaction. (String, required)

Optional parameters

### **-classpath**

Specifies a list of paths or JAR file names that form the location for the resource provider classes. (String, optional)

### **-description**

The description for the JDBC provider. (String, optional)

### **-implementationClassName**

Specifies the Java class name for the JDBC driver implementation. (String, optional)

### **-isolated**

Specifies that the JDBC provider will load in its own class loader. The default value is false. You cannot specify a native path for an isolated JDBC provider. (Boolean, optional)

### **-name**

The name of the JDBC provider. The default is the value from the provider template. (String, optional)

### **-nativePath**

Specifies a list of paths that form the location for the resource provider native libraries. (String, optional)

### **-isolated**

Specifies whether the JDBC provider loads within the class loader. The default value is false. You cannot specify a native path for an isolated JDBC provider. (Boolean, optional)

Examples

**Batch mode example usage:**

- Using Jacl:

```
$AdminTask createJDBCProvider {-scope Cell=my02Cell -databaseType DB2 -providerType "DB2 Universal JDBC Driver Provider"
-implementationType "XA data source" -name "DB2 Universal JDBC Driver Provider (XA)" -description "XA DB2 Universal JDBC Driver-compliant
Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of driver type 2 on WAS z/OS is not
supported for datasources created under this provider." -classpath
${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar -nativePath ${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}}
```

- Using Jython string:

```
AdminTask.createJDBCProvider(['-scope Cell=myCell -databaseType DB2 -providerType "DB2 Universal JDBC Driver Provider"
-implementationType "XA data source" -name "DB2 Universal JDBC Driver Provider (XA)" -description "XA DB2 Universal JDBC
Driver-compliant Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of driver
type 2 on WAS z/OS is not supported for datasources created under this provider." -classpath
${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar -nativePath ${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}'])
```

- Using Jython list:

```
AdminTask.createJDBCProvider(['-scope', 'Cell=myCell', '-databaseType', 'DB2', '-providerType', 'DB2 Universal JDBC Driver Provider',
'-implementationType', 'XA data source', '-name', 'DB2 Universal JDBC Driver Provider (XA)', '-description', 'XA DB2 Universal
JDBC Driver-compliant Provider. Datasources created under this provider support the use of XA to perform 2-phase commit processing. Use of
driver type 2 on WAS z/OS is not supported for datasources created under this provider.', '-classpath',
'${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar;${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar;${DB2UNIVERSAL_JDBC_DRIVER_PATH}/
db2jcc_license_cisuz.jar', '-nativePath', '${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}'])
```

## Interactive mode example usage:

- Using Jacl:

```
$AdminTask createJDBCProvider {-interactive}
```

- Using Jython:

```
AdminTask.createJDBCProvider('-interactive')
```

## listDatasources

Use the listDatasources command to list data sources that are contained in the specified scope.

Target object

None

Required parameters

None.

Optional parameters

### -scope

The scope for the data sources that will be listed. Provide the scope in the form type=name. Type can be Cell, Node, Server, Application, or Cluster, and name is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is All. (String, optional)

Examples

## Batch mode example usage:

- Using Jacl:

```
$AdminTask listDatasources {-scope Cell=my02Cell}
```

- Using Jython string:

```
AdminTask.listDatasources(['-scope Cell=my02Cell'])
```

- Using Jython list:

```
AdminTask.listDatasources(['-scope', 'Cell=my02Cell'])
```

## Interactive mode example usage:

- Using Jacl:

```
$AdminTask listDatasources {-interactive}
```

- Using Jython:

```
AdminTask.listDatasources('-interactive')
```

## listJDBCProviders

The listJDBCProviders command lists JDBC providers that are contained in the specified scope.

Target object

None

Required parameters

None.

Optional parameters

### -scope

The scope for the JDBC providers that will be listed. Provide the scope in the form type=name. Type can be Cell, Node, Server, Application, or Cluster, and name is the name of the specific instance of the cell, node, server, application, or cluster that you are using. The default is All. (String, optional)

Examples

### Batch mode example usage:

- Using Jacl:

```
$AdminTask listJDBCProviders {-scope Cell=my02Cell}
```

- Using Jython string:

```
AdminTask.listJDBCProviders('-scope Cell=my02Cell')
```

- Using Jython list:

```
AdminTask.listJDBCProviders(['-scope', 'Cell=my02Cell'])
```

### Interactive mode example usage:

- Using Jacl:

```
$AdminTask listJDBCProviders {-interactive}
```

- Using Jython:

```
AdminTask.listJDBCProviders('-interactive')
```

## Configuring Persistence Provider support in the application server

Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

### About this task

The Enterprise JavaBeans (EJB) 3.0 specifications require that an application server container that supports the EJB 3.0 programming model must provide a JPA implementation. This is also referred to as a

persistence provider. There are two built-in JPA persistence providers: the JPA persistence provider for the application server and the OpenJPA persistence provider. If an explicit provider element is not specified in the persistence unit definitions, the application server will use the default persistence provider, which is the JPA persistence provider for the application server.

The application server provides both the default persistence provider and the Apache OpenJPA persistence provider to support the open source implementation of JPA and allow for easy migration of existing OpenJPA applications to the application server's solution for JPA.

- **Configuring a default persistence provider**

Use the default persistence provider, or specify a persistence provider for your application. With the application server's JPA persistence provider, you can take advantage of the stability and application extensions that are provided with the application server's implementation of JPA. You can decide which persistence implementation best fits your needs. If an application relies on a specific persistence provider for certain functions and settings, you should specify the provider in the persistence unit definition to avoid any incompatibilities.

- **Using third-party persistence providers**

Use third-party persistence providers in the application server environment.

## Configuring the Java Persistence API (JPA) default persistence provider

Two persistence providers are included in WebSphere Application Server: *JPA for WebSphere Application Server persistence provider* and *Apache OpenJPA persistence provider*. The JPA for WebSphere Application Server persistence provider is the default provider for WebSphere Application Server. You can use one of the two providers, or a third-party persistence provider, as the default provider.

### About this task

On the application server's feature pack for enterprise beans (EJB) 3.0 the default persistence provider, default Java Transaction API (JTA) datasource Java Naming and Directory Interface (JNDI) name, and default non-JTA datasource JNDI name, values are set through the following Java virtual machine (JVM) properties: `com.ibm.websphere.jpa.default.provider`, `com.ibm.websphere.jpa.default.jta.datasource`, and `com.ibm.websphere.jpa.default.nonjta.datasource`. Support for these properties has been deprecated. Any values that were set through these properties will be displayed as default values on this panel. Any change to these values through the Administrative Console panel will override any values set via the JVM properties.

While built from the Apache OpenJPA persistence provider, the JPA for WebSphere Application Server persistence provider contains the following enhancements and differences:

- Enhanced tracing support
- Version ID generation
- ObjectGrid cache plug-in support
- WebSphere product-specific commands and scripts
- Translated message files
- Static SQL support using the DB2 pureQuery feature
- Access intent support
- The following table shows how the default values for the JPA for WebSphere Application Server provider configuration properties are different from the Apache OpenJPA provider:

Property	Apache OpenJPA default value	JPA for WebSphere Application Server default value
<code>openjpa.Compatibility</code>	<code>StrictIdentityValues=false</code>	<code>StrictIdentityValues=true</code>

Property	Apache OpenJPA default value	JPA for WebSphere Application Server default value
openjpa.RuntimeUnenhancedClasses	supported	warn

If no JPA provider is configured in the <provider> element of the persistence.xml file within an EJB module, the default JPA provider that is currently configured for this server is used. The WebSphere Application Server is packaged with the JPA for WebSphere Application Server persistence provider defined as the default provider. However, it is possible to override this default and specify a different default via the Websphere Administrative Console.

You can set your default persistence provider in one of two ways. Use one of the following procedures.

1. Select the default JPA provider from a list of providers included with WebSphere Application Server.
  - a. Open the administrative console.
  - b. From the left-hand navigation, navigate to **Servers** → **Application Servers**
  - c. Select a *server*.
  - d. Navigate to **Container Services** → **Default Java Persistence API Settings**
  - e. Select **Select a default persistence provider that is included with WebSphere Application Server**.
  - f. Click the slider and select from the list.
  - g. Click **Apply** and save the configuration.
2. Specify an alternative default persistence provider via the Administrative Console
  - a. Open the administrative console.
  - b. From the left-hand navigation, navigate to **Servers** → **Application Servers**
  - c. Select a *server*.
  - d. Navigate to **Container Services** → **Default Java Persistence API Settings**
  - e. Select **Specify an alternative default persistence provider** .
  - f. Enter the fully qualified JPA implementation class name of a JPA persistence provider in the box.
  - g. Click **Apply** and save the configuration.

### Related tasks

“Configuring Persistence Provider support in the application server” on page 1444

Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

“Using third-party persistence providers” on page 1448

Java Persistence API (JPA) for WebSphere Application Server allows users to specify third-party persistence providers in their application server environment.

### Default Java Persistence API settings

The Java Persistence API (JPA) specification requires a default provider to be defined. If you have applications that use JPA, it is recommended you use this page to provide default values. To increase the portability of your applications, you can use this page to configure the default JPA settings for applications running on this server instead of defining the <provider> element in each persistence unit in your applications. The JPA settings defined here are used for the persistence unit of an application only when the application does not define the JPA settings for that persistence unit.

**Note:** Application JPA settings always override the settings on this page.

To view this administrative console page, click **Applications** → **server** → **Container Services** → **Default Java Persistence API settings**.

**Default persistence provider:**

Specify the default persistence provider for the application server container. The default persistence provider can be selected either from a list of providers that are included with the product or a user-specified alternate persistence provider.

Select a persistence provider from the product list or specify a fully package qualified JPA implementation class name of an alternate persistence provider.

**Default**

com.ibm.websphere.persistence.PersistenceProviderImpl

**Note:** If an alternate persistence provider is specified as the default, make sure the alternate persistence provider is created in the server. See the information center topic on using a third-party persistence provider.

**Default Java Transaction API (JTA) data source Java Naming and Directory Interface (JNDI) name:**

Specify the default JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The JTA data sources that are currently configured and visible to the application server are available in the drop down box selection.

**Default**

None

**Note:** If a default JTA data source is not specified, ensure an appropriate JTA data source is specified in the <jta-data-source> or connection properties field in the <properties> element in the persistence unit.

**Default non-JTA data source JNDI name:**

Specify the default non-JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The data sources that are currently configured, visible to the application server, and are set to "non-transactional" are available in the drop down box selection.

**Default**

None

**Note:** Some JPA entity features will require a non-JTA data source to be specified. An example of this is automatic entity identity generation. Ensure a non-JTA data source is configured to match your application needs. For information on configuring a non-JTA data source, see the information center topic on associating persistence units and data sources.

**Configuring the default JTA and non-JTA data source JNDI Names**

The Java Transaction API (JTA) and non-JTA data sources to be used for an application can be specified through the <jta-data-source> and <non-jta-data-source> elements of the persistence.xml file within an Enterprise JavaBeans (EJB) module.

**About this task**

If these elements are not configured in the persistence.xml file, then the default JTA and non-JTA data sources configured for the server are used. These values are null by default. However, the default JTA and non-JTA data source Java Naming and Directory Interface (JNDI) names to be used by applications running on this server can be defined using the administrative console.

1. Open the administrative console.
2. Select **Servers** → **Application server** → **server** → **Container Services**.

3. Click **Default Java Persistence API settings**.
4. Select the **Default JTA data source JNDI name** or the **Default non-JTA data source JNDI name** field.
5. Click **Apply** to save the configuration.

#### Related tasks

“Configuring the Java Persistence API (JPA) default persistence provider” on page 1445

Two persistence providers are included in WebSphere Application Server: *JPA for WebSphere Application Server persistence provider* and *Apache OpenJPA persistence provider*. The JPA for WebSphere Application Server persistence provider is the default provider for WebSphere Application Server. You can use one of the two providers, or a third-party persistence provider, as the default provider.

## Using third-party persistence providers

Java Persistence API (JPA) for WebSphere Application Server allows users to specify third-party persistence providers in their application server environment.

### About this task

Java EE applications that use JPA functions can employ third-party persistence providers other than those that are included with the application server. Applications can also specify an Apache OpenJPA provider that is other than the version that is included with the application server. There are two basic means to incorporate third-party providers into an application:

- Embedding the persistence provider inside an application
- Making use of shared libraries.

Depending on your requirements, you can embed a persistence provider inside an application, or place the persistence provider into a shared library.

- **Embedding a third-party persistence provider within an application** Sometimes an application design must rely on the implementation of a specific persistence provider. The JPA specification permits embedding of a specific JPA provider within a persistence archive. When building the application, you can assemble a specific version of a provider's implementation in the application enterprise archive (EAR) file or in a web application (WAR) file. To embed a third-party persistence provider into an application, you need to inspect the application design and all dependent prerequisites. Use the following steps to embed a persistence provider inside an application:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.
  2. Build the specific version of the third-party persistence provider into the application. To manage the persistence correctly, verify that the EntityManagerFactory and the EntityManager are calling the correct provider. Many providers write startup and version information to standard output, which gets included in the SystemOut.log of the application server. This information can be helpful to determine if a third-party provider is being used by your application.
  3. To use a third-party JPA provider that was not bundled with the application server, configure the class loader order for your application to load the classes with the application class loader first. This is also required if the third-party JPA provider is defined in a shared library that is assigned to a user-defined classloader on the server. If the class loader is not configured properly, the third-party JPA provider that is included with the application server will be loaded and used by your application.
  4. Depending on how you packaged the provider, perform one of the following steps:
    - If you packaged the provider in an EAR file, specify the third-party persistence provider binaries in the Manifest.mf classpath in those application modules that needs JPA access.
    - If the provider was bundled in a WAR file, include the necessary provider binaries in the WEB-INF/lib directory of the web application.
  5. Install your application normally.

This configuration localizes the availability of the provider and limiting it to the application alone. While sometimes necessary, embedding persistence providers will increase the application's memory footprint accordingly.

- **Using shared libraries to implement a third-party persistence provider** Persistence providers accessed by applications in a global environment can be installed as a shared library for the application server. Depending on your requirements, you can share the library to the server and application. Use the following steps to implement a third-party persistence provider using shared libraries:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.
  2. Define the persistence provider in a shared library. See the topic on creating shared libraries for more information.
  3. Associate the shared library with the application class loader, or associate the shared library with the server class loader if the library is accessed by many applications.
  4. Configure the class loader order for your application to load the classes with the application class loader first. This is required if the third-party JPA provider is included in the application or if it is defined in a shared library. If the class loader is not configured properly, the JPA provider that is included with the application server will be used by your application instead of the third-party JPA provider.

When the application starts, the specified persistence provider will be resolved. From this point on, all persistence requests will be handled by this provider.

- If the shared library persistence provider is overriding an existing persistence provider that is the same type and exists in your application's classloader hierarchy (example: attempting to override the version of OpenJPA that is shipped with WebSphere), using an isolated classloader for the shared library is recommended. See the topic on creating shared libraries for more information.

### Related tasks

Creating shared libraries

Shared libraries are files used by multiple applications. Create a shared library to reduce the number of duplicate library files on your system.

Configuring class loaders of a server

You can configure the application class loaders for an application server. Class loaders enable applications that are deployed on the application server to access repositories of available classes and resources.

## Task overview: Data Studio pureQuery

Data Studio pureQuery provides Java Persistence API (JPA) users an alternative way to access a DB2 database. PureQuery supports static Structured Query Language (SQL).

### About this task

**Note:** JPA in the Java EE and Java SE environments provides optional support for the DB2 pureQuery runtime environment. PureQuery is a high performance Java data access platform that helps manage applications that access data. PureQuery provides an alternate set of APIs that can be used instead of Java Database Connectivity (JDBC) to access the DB2 database.

To use this feature on the application server, Data Studio pureQuery runtime version 1.2 must be installed. If you plan on performing the DB2 bind command from the administrative console or with the wsadmin tool, you must have pureQuery v1.2 or later. Refer to the Data Studio information center topic on installing pureQuery Runtime for more information.

The application server offers support for static SQL for Enterprise JavaBeans (EJB) 2.x entity beans with the ejbdeploy SQLj option. With JPA, this feature is offered through pureQuery.

DB2 pureQuery offers a number of benefits over JDBC and SQLJ. Static SQL offers greater security and control over access to data because applications are only granted authority to execute known SQL. Static SQL offers better resource utilization on the DB2 server because it avoids runtime parsing and optimizing of the SQL statements.

PureQuery makes use of DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. To create the packages, the user must first run the `wfdb2gen` command on a JPA application. The `wfdb2gen` command creates a `persistence_unit_name.pdqxml` file. This file contains pre-generated SQL statements for Create, Update, Delete, and Retrieve, NamedQueries and NamedNativeQueries of JPA entities. The `persistence_unit_name.pdqxml` file must be bound against database. Associated DB2 packages are generated and the SQL statement is executed statically at runtime. This `persistence_unit_name.pdqxml` file must be included into the application Java archive (JAR) file.

When doing the bind process and when you define your JDBC provider, the following four JAR files must be in the class path:

- `db2jcc_license_cisuz.jar`
- `db2jcc_license_cu.jar`
- `pdq.jar`
- `pdqmgmt.jar`

### WebSphere Application Server support for pureQuery

#### Note:

- There is no support for the `QueryTimeout` property specified either through the `FetchPlan` API or through the property plug-in string for `wsjpa.ConnectionFactoryProperties`. The `QueryTimeout` value is ignored if specified.
- OpenJPA large result processing uses JDBC APIs for scrollable cursors.

#### Note:

- JPA sets the `pureQuery` property, `pdq.executionMode`, to the value `STATIC`.
- In addition to the JDBC driver JAR file, the JDBC provider configuration must include the JAR file for the pureQuery runtime environment.
- OpenJPA provides support to allow application programs to programmatically access and alter the `FetchPlan` at run time. Altering the fetch plan might result in SQL that has not been generated by the `wfdb2gen` command at application build time. If this occurs, the SQL is executed dynamically rather than using static SQL from the DB2 package.
- If the user makes changes to the application queries, entity mapping or persistence properties, then run the `wfdb2gen` command and bind again. This process generates and binds the updated DB2 packages.
- Input parameter values in JPA queries (with both EJB SQL queries and native SQL queries) cannot be NULL values except in the case of update statements `SET` expression values. To search for NULL values in a `WHERE` clause of `SELECT`, `UPDATE` or `DELETE`, then enter the `is null` predicate instead.

The command allows users to utilize the `pureQuery` feature in Java Persistence API (JPA) applications.

`wsenhancer` command

The entity enhancer tool for Java Persistence API (JPA) applications in the application server inserts bytecode into an entity class file that allows the JPA provider to manage the state of an entity.

Developing and packaging JPA applications for a Java EE environment

Containers in the application server can provide many of the necessary functions for the Java Persistence API (JPA) in a Java Enterprise Edition (Java EE) environment. The application server also provides JPA tools to assist you with developing applications in a Java EE environment.

Developing and packaging JPA applications for a Java SE environment

Prepare and package persistence applications to test outside of the application server container in a Java SE environment.

## Configuring to use `pureQuery` in a Java EE environment

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use `pureQuery` to access DB2.

### Before you begin

If you need to use multiple DB2 package collections, see the information center topic `configure pureQuery to use multiple package collections` before continuing with this task.

### About this task

`PureQuery` makes use of DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. You must first run the `wfdb2gen` command on a JPA application to create the packages. The `wfdb2gen` command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 `bind` command uses this file as input to create the DB2 package .

#### Note:

- JPA sets the `pureQuery` property `pdq.executionMode` to the value `STATIC`.
  - The JDBC provider configuration must include the JAR file for the `pureQuery` runtime environment. This JAR file is in addition to the JDBC driver JAR file. See the information center topic on installing `pureQuery` runtime for more information.
  - If this is an XA data source, define a new custom property on the data source where *property\_name* = `downgradeHoldCursorsUnderXa` and boolean value = `true`.
1. Update the application data source JDBC provider configuration to include the `pureQuery` runtime JAR file. Either define a new JDBC provider or modify an existing provider to include the following JAR files. See information center topics on JDBC provider settings and installing `pureQuery` Runtime for more information.
    - `pdq.jar`
    - `pdqmgmt.jar`
  2. Using the DB2 `bind` command, bind the XML file to the database. This creates the DB2 packages. There are three ways to do this:
    - Use the `wsadmin` command. Refer to the information center topic on application management command group for the `AdminTask` object for more information.
    - Using the administrative console. Refer to the information center topic on SQLj profiles and `pureQuery` bind files settings for more information.

- Using the DB2 bind command provided by Data Studio. Refer to the information center topic on the pureQuery Bind utility for more information.

## What to do next

If you want to reconfigure the data source for JDBC, just remove the pdq.jar and pdqmgmt.jar from the class path.

### ***Configuring pureQuery to use multiple package collections:***

Set up a pureQuery Java Persistence API (JPA) application to use multiple DB2 package collections.

### **About this task**

It is possible for multiple copies of a database schema to exist. This situation might happen in a partitioned database schema where there is one database for east coast employee data and another database for west coast employee data. In this case, the two databases have the same schema. There might be two databases with two database catalogs. Or there might be only one database, in which case, the high-level qualifier of the table names (the schema name) must be different. Since the schemas are the same, there can be a single set of JPA entities that are used to access both sets of data. There are several ways to configure JPA to handle these situations.

**Note:** When there are multiple persistence units, either with separate databases or a single database, you must run the wfdb2gen command once for each persistence unit.

The following three scenarios exist that require the use of multiple DB2 package collections. If you need more information on configuring pureQuery, read about configuring an application to use pureQuery.

1. When there are two persistence units with different data source names, using static SQL, two sets of DB2 packages exist: one DB2 package in each database. Since two persistence units exist, two *persistence\_unit\_name*.pdqxml files for the JPA runtime environment exist.
2. If the tables are in a single database, then two persistence units can also be used. In this case, the data source is the same in both persistence units. However, the schema name property, `wsjpa.jdbc.Schema` must be different. There are two sets of DB2 packages. Each DB2 package must have a different package name or a different package collection name. Both the `wscdb2gen` and the DB2 bind command have options to specify the package collection and package names.
3. You can create a single persistence unit, which will eliminate the need to maintain two persistence unit configurations and run the `wscdb2gen` command multiple times. This configuration requires a common package name. Thus the package collection names must be different. Use the `createEntityManager(Map map)` method, where the map contains the values for the `wsjpa.jdbc.Schema` and `wsjpa.jdbc.CollectionId` properties to specify the package collection name and schema name.

### Related tasks

“Configuring to use pureQuery in a Java EE environment” on page 1451

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

### Related reference

`wscdb2gen` command

The command allows users to utilize the pureQuery feature in Java Persistence API (JPA) applications.

## Configuring to use pureQuery in Java SE environment

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

### Before you begin

If you need to use multiple DB2 package collections, see the information center topic configure pureQuery to use multiple package collections before continuing with this task.

### About this task

PureQuery makes use of DB2 packages. These packages consist of information for one or more Structured Query Language (SQL) statements and are stored in the DB2 catalog. You must first run the `wscdb2gen` command on a Java Persistence API (JPA) application to create the packages. The `wscdb2gen` command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 bind command uses this file as input to create the DB2 package .

### Note:

- JPA sets the pureQuery property `pdq.executionMode` to the value `STATIC`.
- The class path must include the install location for the pureQuery Runtime. See the information center topic on installing pureQuery Runtime for more information.
- The JPA provider implementation must be JPA for the application server (`com.ibm.websphere.persistence.PersistenceProviderImpl`). The OpenJPA persistence provider does not provide support for pureQuery.
- The `wscdb2gen` command requires the URL of a database. The `wscdb2gen` command forces a synchronize mapping function that creates or alters the required tables. For DB2 z/OS, V8 unique indexes and LOB tables must be manually created prior to executing the `wscdb2gen` command.

PureQuery properties are specified in a `pdq.properties` file in the META-INF directory of the application jar. The `pdq.ExecutionMode` property is defaulted to `STATIC` for JPA applications. PDQ properties, if specified, pass on to the pureQuery runtime. See Data Studio pureQuery runtime documentation for list of properties and valid values.

- **wsjpa.jdbc.CollectionId** : String value specifying the collection id to use. This overrides any collection id used during `wfdb2gen`.
1. Update the application data source JDBC provider configuration to include the pureQuery Runtime JAR files. Include the `pdq.jar` and `pdqmgmt.jar` files on the class path in addition to the JDBC driver jar files. Either define a new JDBC provider or modify an existing provider to include the JAR files. The class path must include the install location for the pureQuery Runtime. See the information center topics on JDBC provider settings and installing pureQuery Runtime for more information.
  2. Using the DB2 bind command provided by Data Studio, bind the XML file to the database. This creates the DB2 packages. Refer to the information center topic on the pureQuery Bind utility for more information.

## What to do next

If you want to reconfigure the data source for JDBC, remove the `pdq.jar` and `pdqmgmt.jar` from the class path.

## Associating persistence units and data sources

Java Persistence API (JPA) applications allow you to specify the underlying data source used by the persistence provider to access the database.

### About this task

The application server provides three methods for defining the data sources in the `persistence.xml` file.

- Explicitly specify the Java Naming and Directory Interface (JNDI) name in the `persistence.xml` file, and the application will directly reference the data source. Switching to another data source requires an update to the `persistence.xml` file.

JPA has two transactional patterns for accessing a data source:

- The Java Transaction API (JTA) resource pattern depends on global transactions. The JTA resource pattern is typically used within the scope of an Enterprise JavaBeans (EJB) session facade. This allows the session bean to control transaction and security contexts while JPA handles the persistence mappings. In this case, the application does not use the `EntityTransaction` interface but relies on the `EntityManager` enlisted with the global transaction when it is accessed.

- The non-JTA resource pattern is generally used when dealing with a single resource in the absence of global transactions. The non-JTA resource pattern is typically used within the scope of a web application or an application client. The application controls the transaction with the data source with the EntityTransaction interface.

Within the application server, the use of the <non-jta-data-source> element requires a special configuration for a non-transactional data source. Data sources that are configured for the application server will not function as a <non-jta-data-source>, because all data sources that are configured by the application server are automatically enlisted with the current transactional context. To prevent this automatic enlistment, add an additional data source custom property `nonTransactionalDataSource=true`:

1. Select **Resources** → **JDBC** → **Data sources**
2. Select the name of the data source that you want to configure.
3. Select **WebSphere Application Server data source properties** from the **Additional Properties** heading.
4. Select **Non-transactional data source**.
5. Click **OK**.

**Note:** The JPA specification assumes that connections will be obtained with an isolation level that does not hold long term locks in the database, such as `READ_COMMITTED`. This may not match the WebSphere Application Server default isolation level, which is `REPEATABLE_READ` for most databases. You can check the level which is used for your database by referring to the topic Requirements for setting isolation level.

If the default for your database is not `READ_COMMITTED`, you may change the default by adding an additional data source custom property `webSphereDefaultIsolationLevel`. The following table shows the valid values.

Table 9. Isolation level values

Value	Isolation Level
1	READ_UNCOMMITTED
2	READ_COMMITTED (JPA default)
4	REPEATABLE_READ (WebSphere Application Server default)
8	SERIALIZABLE

If the isolation level is set to a value that will hold long-term read locks, you need to configure the JPA provider to use Pessimistic Locking instead of the default Optimistic Locking. For the JPA provider included with WebSphere Application Server, you may do this by adding the following properties to `persistence.xml` file:

```
<property name="openjpa.Optimistic"="false"/>
<property name="openjpa.LockManager"="pessimistic"/>
```

The JPA specification mandates that the data sources that are defined in the <jta-data-source> and <non-jta-data-source> elements of a persistence unit register in the JNDI name space. For example, the `persistence.xml` file should contain an entry similar to the following:

```
<jta-data-source>jdbc/FooBarDataSourceJNDI</jta-data-source>
```

- The JPA solution for the application server extends the implementation to allow you to reference data sources in component name space. In the EJB or Web module deployment descriptor file, this is the <resource-ref> element. You can prefix the data source with `java:comp/env/` so the application indirectly references the data source by using the local JNDI name. In this association, the application does not require updates, you change the <resource-ref> to use another data source. See the following example:

```
<jta-data-source>java:comp/env/jdbc/FooBarDataSourceJNDI</jta-data-source>
```

**Note:** JPA specifications do not require implementations to include data sources referenced through local JNDI names, so this method of reference may not be portable to other implementations of JPA.

- You can declare `openjpa.Connection*` properties in the persistence unit. If you are not using JPA inside the application server, you need to use this method:

**Example**

```
<property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
<property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
```

## What to do next

For information about configuring data sources, see the topic on creating and configuring a data source.

For information about data sources and JPA, see the section on persistence in the Apache OpenJPA User's Guide.

---

## Configuring OpenJPA caching to improve performance

The OpenJPA implementation allows users the option of storing frequently used data in the memory to improve performance. OpenJPA provides concurrent data and concurrent query caches that allow applications to save persistent object data and query results in memory to share among threads and for use in future queries.

### About this task

#### OpenJPA data cache functionality

The OpenJPA data cache is a cache of persistent object data that operates at the `EntityManagerFactory` level. This optional-use cache is designed to increase performance while remaining in full compliance with the Java Persistence API (JPA) standard. This means that enabling the caching option can increase the performance of your application, with no changes to your code. The OpenJPA data cache is designed to provide significant performance increases over cacheless operations and ensures that behavior will be identical in both cache-enabled and cacheless operations.

When enabled, the cache is examined before accessing the datastore. The cache stores data when objects are committed and when persistent objects are loaded from the datastore. If operating in a single Java virtual machine (JVM) environment, the JVM maintains and shares a data cache across all `EntityManager` instances obtained from a particular `EntityManagerFactory`. The OpenJPA data cache cannot do this in a distributed environment because caches in different JVMs, created from different `EntityManagerFactory` objects will not be synchronized. Using the OpenJPA cache in a multi-JVM environment requires either using the event notification framework or through custom integrations with a third-party distributed cache utilities such as IBM ObjectGrid.

#### Enabling and configuring the OpenJPA data cache

You can enable the OpenJPA data cache for a single or a multiple JVM environment, set its default element size, including soft references, and specify timeout values.

To set up and configure the OpenJPA data cache, do the following:

1. To enable the cache for a single JVM, set the `openjpa.DataCache` property to true, and set the `openjpa.RemoteCommitProvider` property to `sjvm`:

```
<property name="openjpa.DataCache" value="true"/>
<property name="openjpa.RemoteCommitProvider" value="sjvm"/>
```

To enable the data cache in a distributed environment, the `openjpa.RemoteCommitProvider` must be configured specifically for the environment, or a third-party cache management utility can be used.

2. The maximum cache size can be adjusted by setting the `CacheSize` property:

```
<property name="openjpa.DataCache" value=true(CacheSize=5000...)
```

By default, the OpenJPA data cache holds 1000 elements. Objects that are pinned into the cache are not counted when determining if the cache size exceeds its maximum size. If the cache overflows, it evicts random elements. You can preserve evicted elements longer with the `SoftReferenceSize` property. By default, soft references are unlimited. If you need to, you can limit the number of soft references or set to 0 to disable soft references completely:

```
<property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 ...)
```

3. You can specify that a cache should be cleared at certain times. The `EvictionSchedule` property of the OpenJPA cache implementation accepts a cron style eviction schedule. The cron format specifies the minute, hour of day, day of month, day of month, and day of the week beginning with 1 for Sunday; the \* symbol (asterisk), indicates match all. To schedule a cache to evict at 45 minutes past 3 PM on Sunday every month you would add this property:

```
<property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 EvictionSchedule='15,45 * * 1')/>
```

**Note:** You also can specify a cache timeout value for a single class by setting the timeout metadata extension to the amount of time in milliseconds that the data of the class is valid. Refer to the `org.apache.openjpa.persistence.DataCache` Javadoc for more information.

After configuring your data cache, you can use it after you restart your application.

### Refresh with active DataCache

Refreshing an entity may lead to different behavior with or without a `DataCache` when a separate process or part of the same application are updated or even deleted the corresponding record in the database. By default, entities are refreshed from the database even when `DataCache` is active. Therefore, with the default configuration the refresh behaves identically with or without a `DataCache`. However, a persistence unit can be configured to refresh entities from `DataCache` with the property `openjpa.RefreshFromDataCache` for improved performance. Under this configuration, any out-of-band changes that occur in the database record will not appear in the refreshed state of the entity.

**Note:** Regardless of the `openjpa.RefreshFromDataCache` setting, the `DataCache` is always bypassed for refresh when locks are active, such as for a pessimistic transaction, in a persistence context. An application may activate `openjpa.RefreshFromDataCache` but can still bypass the `DataCache` while refreshing an entity by explicitly evicting the entity from `DataCache` prior to refresh.

### Query Caching functions

OpenJPA provides a concurrent query cache that allows applications to save persistent object data and query results in memory to share among threads and for use in future queries. The query cache stores the object ids returned by query executions. When you run a query, OpenJPA assembles a key based on the query properties and the parameters used at execution time, and checks for a cached query result. If one is found, the object ids in the cached result are looked up, and the resultant persistence-capable objects are returned. Otherwise, the query is executed against the database, and the object ids loaded by the query are put into the cache.

### Configuring or disabling the query cache

You can configure the query cache settings in a similar way to the data cache. The interface provided to the query cache is the `org.apache.openjpa.persistence.QueryResultCache` class. You can access this class through the `OpenJPAEntityManagerFactory`.

The default query cache implementation caches 100 query executions in a least-recently-used cache. This can be changed by setting the cache size in the `CacheSize` plugin property. Like the data cache, the query cache also has a backing soft reference map that can be changed using the `SoftReferenceSize` property. To keep queries in the cache at all times, you can pin them to a cache. To change the query cache properties do the following:

1. Modify the `CacheSize` property of the `openjpa.QueryCache`:

```
<property name="openjpa.QueryCache" value=("CacheSize=1000, ...
```

2. Change the `SoftReferenceSize` property to enable and control the size of this map:

```
<property name="openjpa.QueryCache" value=("CacheSize=1000, SoftReferenceSize=100")/>
```

The `SoftReferenceSize` table is disabled by default. Setting the size enables it.

3. Pin or unpin queries in the cache through the `QueryResultCache` with this syntax:

```
public void pin(Query q);
public void unpin(Query q);
```

Modifying these properties allows you to make better use of the query cache.

## Extending a cache

OpenJPA provides classes that may be extended for further functionality.

- As previously mentioned, if you want to implement a distributed cache that uses an unsupported method for communications, create an implementation of `org.apache.openjpa.event.RemoteCommitProvider`.
- If you are adding new behavior, you should extend `org.apache.openjpa.datacache.DataCacheImpl`.
- To use your own storage mechanism, extend `org.apache.openjpa.datacache.AbstractDataCache`.
- To add query functionality, you can extend the default `org.apache.openjpa.datacache.QueryCacheImpl`.
- Implement your own storage mechanism for query results by extending `org.apache.openjpa.datacache.AbstractQueryCache`

## OpenJPA query SQL cache

OpenJPA provides a cache that provides caching of SQL strings used by find operations performed on the entity manager and some queries to manage eagerly fetched relationships. When this cache is enabled, SQL queries used by these operations are generated once per entity manager factory and may be reused. This cache is enabled by default but can also be configured through the `openjpa.jdbc.QuerySQLCache` configuration property.

## Configuring or disabling the SQL query cache

The query SQL cache can be configured or disabled through the `openjpa.jdbc.QuerySQLCache` property. By default, this property is set to `true`. When set to `true` the cache is enabled and uses the `org.apache.openjpa.util.CacheMap` class for its cache store. The `CacheMap` is a managed cache, meaning that it limits the number of cache entries and has a cache eviction scheme to manage memory usage. If the cache is set to `all` the `org.apache.openjpa.lib.util.ConcurrentHashMap` class is used as a cache store. The `ConcurrentHashMap` is not a managed cache so entries will remain in the cache for the lifetime of an entity manager factory. This caching mechanism may provide better performance at the expense of increased memory usage. A custom cache store class can also be specified provided that it implements the `java.util.Map` interface. To disable the cache, specify the value `false`. See the following examples on how to configure or disable the SQL query cache:

- To use an unmanaged cache:

```
<property name="openjpa.jdbc.QuerySQLCache" value="all"/>
```

- To specify a custom cache class:

```
<property name="openjpa.jdbc.QuerySQLCache" value="com.mycompany.MyCustomCache"/>
```

- To use an unmanaged cache:

```
<property name="openjpa.jdbc.QuerySQLCache" value="false"/>
```

## What to do next

Refer to chapter 10, Caching in the OpenJPA reference for all caching extensions.

### Related tasks

Developing and packaging JPA applications for a Java SE environment

Prepare and package persistence applications to test outside of the application server container in a Java SE environment.

---

## Troubleshooting Java Persistence API (JPA) applications

Use this information to find various known problems with JPA applications.

- Review messages that are related to transactions.

Under certain conditions, a message similar to the following might be logged:

```
Unable to execute {0} on a WebSphere managed transaction. WebSphere does not support direct manipulation of managed transactions.
```

This error is probably caused by a data source that is not configured correctly as `<non-jta-data-source>`. See the information center topic on how to configure a data source to be used as a `<non-jta-data-source>`.

- Troubleshoot classes that have not been enhanced by run time.

It is difficult to diagnose these situations. Sometimes you can trace the problem back to a lack of OpenJPA enhancement of entity classes. Examples of these situations might be detecting when entities are not "persistence capable". Look for a message similar to the following in the log:

```
This configuration disallows runtime optimization, but the following listed types were not enhanced at build time or at class load time with a javaagent: "{0}".
```

This message indicates that the expected runtime enhancement did not take place on the listed entity types. In most cases, this is just a build time failure and the PCEnhancer needs to be run on the listed classes. It can also indicate a more involved problem, especially if you are expecting the container classloader transform to do the entity enhancement.

- Troubleshoot issues with closed cursors.

The following is an exception from DB2 in the log  
org.apache.openjpa.persistence.PersistenceException:

```
[ibm][db2][jcc][10120][10898] Invalid operation: result set is closed can be a WebSphere Application Server configuration problem.
```

By default, the application server configures the `resultSetHoldability` custom property with a value of 2 (CLOSE\_CURSORS\_AT\_COMMIT). This property causes DB2 to close its `resultSet/cursor` at transaction boundaries. Despite DB2's default `resultSetHoldability` value of 1 (HOLD\_CURSORS\_OVER\_COMMIT), the application server retains the default value of 2 to avoid breaking compatibilities with previous releases of the application server. You can change the default if the need arises.

**Note:** If this is an XA datasource, define a new custom property on the datasource where `property_name = downgradeHoldCursorsUnderXa` and `boolean value = true`.

**Note:** In Version 7.0, if a DB2 XA Data source is used, the following configuration are required to overcome the "result set closed" problem:

1. Apply DB2 Version 8.1 FP17 for APAR IZ18070 or Version 9 FP4 for APAR IZ18072.
2. Add custom property `name="downgradeHoldCursorsUnderXa", value="true"` and `type="java.lang.Boolean"`

3. Add custom property name="resultSetHoldability", value="1", and type="java.lang.Integer"

- Avoid multi-threaded EntityManager usage. If you experience an exception with the following message text, you might be accidentally allowing the usage of an EntityManager across multiple threads.

Per the JPA specification, EntityManagers are meant to be used by a single thread. You might receive an exception message that is similar to the following (in this context, brokers and EntityManagers are essentially the same thing):

Multiple concurrent threads attempted to access a single broker. By default brokers are not thread safe; if you require and/or intend a broker to be accessed by more than one thread, set the openjpa.Multithreaded property to true to override the default behavior. There are some ways to address this issue:

- As documented in this exception text, an easy workaround to the situation is to tell OpenJPA that you are requiring multi-threaded access to the EntityManagers through the openjpa.Multithreaded property. This can introduce unnecessary overhead if multi-threaded access occurs that is not intentional.

–

**Note:** Utilize the get-use-close pattern when using application-managed (extended) persistence contexts. Remember to close the EntityManager before leaving the method that used the EntityManager. Leaving the EntityManager open can accidentally allow other threads to use the same EntityManager instance at the same time.

- Change the application to use container-managed persistence contexts by injecting the EntityManager instance through the @PersistenceContext annotation, if the programming model for the application is amenable to this change. Essentially, this enforces the get-use-close pattern by allowing the container to do the management.
- Be aware of versioning conditions if you are using optimistic locking. In the JPA architecture, the persistence provider uses the version property to perform optimistic locking and concurrency semantics for a persisting entity. For example:

```
@Entity
public class VersionedTimestampEntity
{
 @Id private int id;
 @Version private java.sql.Timestamp version;

}
```

The provider updates the versioned property to a new value when an entity is written to the database. During an entity merge operation, the persistence provider examines this versioned property to determine if the entity that is being merged is a stale copy of the entity. If the operation failed due to the stale versioning condition, an OptimisticLockException will be thrown. The versioned property can be one of these types:

- int
- Integer
- short
- Short
- long
- Long
- Timestamp.

**Note:** If you use the Timestamp type for the versioned property, the application needs to be aware of behavior that can be exhibited due from the implementation precision that is used for creating the Timestamp object. The typical implementation uses System.currentTimeMillis(), and the time precision of this method is platform specific. For example, the precision is approximately 15ms for 32-bit Windows and 2ms for z/OS.

If an entity is persisted, and the entity is then fetched and updated in a separate persistence context

that is within the precision window of the platform, the persistence provider will not be able to detect the optimistic locking and concurrent condition. As a result, an `OptimisticLockException` may not be thrown and data integrity could be compromised.

- Troubleshoot database constraint violations when working with entities.

The JPA providers included with WebSphere Application Server use a constraint update manager to determine the order of SQL requests to the database based on each entity's configuration. This update manager may rearrange the order of SQL requests to the database. This alleviates an application from knowing the order of entity manager operations required to perform its business logic and optimizes database performance using underlying batching support.

Since the JPA provider does not assume that there are implied database constraints for relationships between entities, if there are constraints in the database (for example, a foreign key constraint) the JPA provider may not issue SQL statements in the desired order. Under these conditions, the following or similar exception may be observed:

```
com.ibm.db2.jcc.b.SqlException: DB2 SQL error: SQLCODE: -530, SQLSTATE: 23503, SQLERRMC: xxxxxx
```

There are some ways to address this issue:

- The JPA provider can be configured to read constraint information from the database and apply to the update manager at runtime by adding the following configuration property to the persistence unit.

```
<property name="openjpa.jdbc.SchemaFactory" value="native(ForeignKeys=true)" />
```

- The application can enhanced entity to use `@ForeignKey` annotation to indicate to the JPA provider which relationships have foreign key constraints.

```
public class Person {
 @ManyToOne
 @ForeignKey
 private Address address;

}
```

- The application can take on the responsibility of ordering the SQL statements by adding the following configuration property to the persistence unit.

```
<property name="openjpa.jdbc.UpdateManager" value="operation-order" />
```

With this configuration option present, the JPA provider will execute the SQL statements in the same order as the entity operations were requested. The application must be aware of any interdependencies between entities.

- Remove the constraints from the database.

- Troubleshoot using the OpenJPA MappingTool ANT task.

The MappingTool ANT task provided by OpenJPA uses a temporary classloader to load the JDBC driver classes. This temporary classloader may have trouble loading some JDBC drivers such as DB2.

When you run the MappingTool ANT task, you could see something similar to the following error:  
[mappingtool] java.lang.UnsatisfiedLinkError: com/ibm/jvm/Trace.initTrace([Ljava/lang/String;[Ljava/lang/String;)V [mappingtool] at  
com.ibm.jvm.Trace.initializeTrace(Trace.java:94) [mappingtool] at  
com.ibm.jvm.Trace.<clinit>(Trace.java:59) [mappingtool] at  
java.lang.J9VMInternals.initializeImpl(Native Method) [mappingtool] at  
java.lang.J9VMInternals.initialize(J9VMInternals.java:200) [mappingtool] at  
java.lang.Class.forNameImpl(Native Method) [mappingtool] at  
java.lang.Class.forName(Class.java:136) [mappingtool] at com.ibm.db2.jcc.a.o.n(o.java:577)  
[mappingtool] at com.ibm.db2.jcc.a.o.<clinit>(o.java:329)

In order to use the mapping tool, you can disable the temporary classloader by adding the `tmpClassLoader=false` argument to the ANT task. Two example ANT scripts follow :

This example will exhibit the problem:

```
<taskdef name="mapping" classname="org.apache.openjpa.jdbc.ant.MappingToolTask" classpathref="jpa.cp"/>
. . .
<target name="map.broken">
 <mapping>
```

```

 <!-- this will exhibit the problem -->
 . . .
 </mapping>
</target>

```

This example will prevent the problem:

```

<taskdef name="mapping" classname="org.apache.openjpa.jdbc.ant.MappingToolTask" classpathref="jpa.cp"/>
. . .
<target name="map.fixed">
 <mapping tmpClassLoader="false">
 <!-- this will work -->
 . . .
 </mapping>
</target>

```

- Impact of DataCache on inconsistent domain models

When an application persists an inconsistent domain model and later retrieves the entities in a separate persistence context, the retrieved entities will differ depending on whether DataCache is active or not.

For example, consider bi-directional, one-to-one relationship between two entities mapped by a single foreign key column in the database. It is possible for an application to set the relation fields in the entities inconsistently. When such inconsistent values are mapped to the database, the database records become consistent only because a single foreign key column expresses the bi-directional relationships. DataCache is active, however, then DataCache captures the inconsistent in-memory entity states. Therefore, when an application persists a pair of entities related in a bi-directional relation but their relation fields are set to inconsistent values and later retrieves the entities in a different persistence context, the bi-directional relationship either remains inconsistent or becomes consistent depending on whether DataCache is used or not.

When multiple fields are mapped to the same column but set to different values is another example where an inconsistent entity state is persisted but retrieved as consistent in a separate persistence context. In this case, the introduction of DataCache will also cause an entity realized in a separate persistence context to retain different and inconsistent values while without a DataCache, an entity will hold the same value for both the fields.

**Note:** The best practice is to avoid populating the application domain model inconsistently. It is also possible to configure `openjpa.InverseManager` property to detect certain inconsistencies such as bi-directional relationship.

### Related tasks

Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)

The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

## Logging with the Java Persistence API (JPA) and the application server

Logging allows you to view, trace, and troubleshoot the runtime behavior of an application. JPA provides a flexible logging system that is integrated with the application server to assist you in troubleshooting problems.

### About this task

#### Logging channels

**Note:** Logging can have a negative impact on performance. Limit or disable logging when you run any performance tests.

In addition to the channels used by OpenJPA, a trace group named `openjpa` enables channels that are prefixed with “`openjpa.`” Specifying “`openjpa`” for a trace group will override any other trace group specification that is specific to a channel. **Example**

```
openjpa.Runtime=debug:openjpa.jdbc.SQL=all
```

```
openjpa=all
```

**Note:** The `openjpa.Log` property will be ignored if it is defined in a container-managed persistence unit that uses the persistence providers that are provided with the application server. In this case, you must use the standard trace specification for the application server.

OpenJPA and JPA for WebSphere Application Server implement logging channels to which message data, trace data, and debugging data can be recorded to a configurable repository. The JPA component creates the logging channel at run time and assigns a channel name for identification. The component writes information to the configured repository through the channel. OpenJPA and JPA for WebSphere Application Server create the following channels:

- **openjpa.Tools** - Command line and Ant server tools
- **openjpa.MetaData** - Meta data information
- **openjpa.Enhance** - Enhancement and runtime class generation
- **openjpa.Runtime** - Messages generated during runtime
- **openjpa.Query** - Query information
- **openjpa.DataCache** - L2 data cache plugin information
- **openjpa.jdbc.JDBC** - JDBC connection information
- **openjpa.jdbc.SQL** - Detailed SQL execution statements and information
- **wsjpa.pdq** - Trace of all interactions between store manager and PDQ runtime
- **wsajpa.SqlGen** - Diagnostic trace for `wsdb2gen` program

## Logging levels

Each of the logging channels use logging levels to control which messages are recorded. The following logging levels are supported by the JPA architecture:

- **TRACE** - the most detailed option
- **INFO** - information related to the specific channel
- **WARN** - warning messages
- **ERROR** - error condition messages
- **FATAL** - fatal condition messages

By using a particular logging channel together with logging levels, you can control the types of logging messages and the amount of logging messages that are recorded.

**Note:** These logging functions only apply to OpenJPA and JPA for the application server. Logging functions that are provided in implementations of a third-party persistence provider are not covered. However, if the logging output from a third-party persistence provider is directed to the Java `System.out` or `System.err` output streams, the messages are handled by the environment accordingly at run time.

## Logging in the application server

The default JPA persistence provider that is supported by the application server records messages and tracing data that are automatically integrated into the RAS component. Alternatively, OpenJPA implements a custom logger to route messages from OpenJPA channels to the channels of the application server.

The channel names that are supported by OpenJPA are used as the trace group names in the trace level for the application server. The mappings of OpenJPA logging levels to trace levels in the application server are:

OpenJPA logging level	Trace level for the application server
TRACE	debug
INFO	info
WARN	warning
ERROR	error
FATAL	fatal

### Logging in a client container and standalone Java application

OpenJPA logging uses the basic logging framework and output format:

```
millis [persistence-unit name]level[thread identifier] channel - message
```

.

**Note:** When using pureQuery, the PDQ store manager also uses JDBC in some situations, such as for large result set processing. When tracing all calls to the database, you will need to trace both JDBC and PDQ.

#### Example:

```
property name="wsjpa.Log" value="SQL=TRACE"/
```

This will trace the SQL and input parameter values.

```
property name="wsjpa.Log" value="pdq=TRACE, JDBC=TRACE"/
```

This will perform a detailed trace of calls to the pureQuery runtime as well as any calls to JDBC. If you are using pureQuery and need to trace calls to the database, you will need to perform both traces.

The default logging system accepts the following parameters:

- **File:** The name of the file to which the application server will log information. You can also use standard output stdout or standard error stderr to send messages. By default, JPA sends log messages to standard error.
- **DefaultLevel:** The default logging level for channels that are not configured. The values can be TRACE, INFO, WARN, and ERROR. The default setting is INFO.
- **DiagnosticContext:** A string that will be placed at the beginning of all log messages. If a DiagnosticContext is not supplied and an openjpa.id property is available, the openjpa.id value is used.
- **<channel>:** The channel that is being logged. This parameter can be used to configure the logging level of the channel.

1. Open the persistence.xml file for the application that you want to modify.
2. Add a property name tag to the XML schema named openjpa.log. For example:

```
<property name="openjpa.log" .../>
```

3. Add additional parameters. For example:

```
<property name="openjpa.log" value="DefaultLevel=WARN .../>
```

**Note:** To reduce overhead by disabling logging, set the openjpa.log property to NONE and proceed to Step 5.

4. Designate the logging channels and the logging level. For example:

```
<property name="openjpa.log" value="DefaultLevel=WARN, Runtime=INFO, Tool=INFO" .../>
```

5. Save changes to the file.

## Results

The next time the application is started the JPA component will log all channels at the WARN logging level and the Runtime and Tool channels at the INFO level.

## What to do next

OpenJPA allows users to substitute other logging methods. Consult the logging section of the Apache OpenJPA User's Guide for more information and examples.

### Related tasks

Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)

The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

## Enabling Enhanced Tracing for Java Persistence API (JPA)

In some situations the trace information generated by the JPA providers shipped with WebSphere Application Server may not be adequate to diagnose a problem. In these situations, an extended trace mechanism can be enabled to generate additional information in the trace file. Extended trace will only function with IBM-shipped persistence providers. It will not work with 3rd party providers, including versions of OpenJPA bundled within an application or configured as a shared library.

### About this task

#### Enabling enhanced tracing in a WebSphere Application Server environment

Enhanced JPA tracing for an application running on WebSphere Application Server can be enabled with a few simple steps using wsadmin scripting or the administration console. The steps below describe how to configure enhanced tracing using the administration console. This process changes server settings so it is good practice to backup your server configuration before proceeding.

1. Enable the trace agent. A trace agent must be enabled per application server by passing an argument to the server Java virtual machine (JVM). The trace agent can be enabled using the Administration console by following these steps:
  - a. In the navigation pane, select **Servers**. Select **Application Servers**.
  - b. In the server list pane, select the server that needs the enhanced JPA trace. If multiple servers provide JPA functionality to your application, these steps must be followed for every server.
  - c. Under the Server Infrastructure heading, select **Java and Process Management**. Select **Process Definition**.
  - d. Under the Additional Properties heading, select **Java virtual machine**.
  - e. Add the following argument to the Generic JVM arguments field, where <WAS install path> is the fully qualified path of your application server install directory. Make sure to use the path separator character appropriate for your operating system.  

```
-javaagent:<WASinstall path>/optionalLibraries/IBM/wsjava/wsjava.jar
```
2. Enable additional trace components and adjust trace file options. You can accomplish this with wsadmin scripting or the Administration Console. These steps describe how to adjust trace file settings and enable components using the Administration Console:
  - a. In the navigation pane, select **Troubleshooting**. Click **Logs and Trace**.
  - b. Select the name of the server to trace.
  - c. Under the General Properties heading, select **Diagnostic Trace**.

- d. Make sure **Enable Log** is checked and optionally increase the Maximum File Size and Maximum Number of Historical Files. Depending on the number of additional trace categories and the trace levels chosen, the trace file can become extremely large.
- e. Under the Additional Properties heading, select **Change Log Detail Levels**.

**Note:** The use of generic JVM arguments in the Administrative console does not currently support spaces within arguments. If spaces are specified in this field, the server may fail to start. This is more likely to occur in a Windows environment because the default install path is C:\Program Files\IBM\WebSphere\AppServer, which contains a space in the path. To work around this problem in a Windows environment use an abbreviated path name for the <WAS install path>. For example, C:\Progra~1\IBM\WebSphere\AppServer. On Unix-type systems a symbolic link can be used to eliminate spaces in the <WAS install path>. For example, if the WebSphere Application Server installation path is /opt/WAS Install/AppServer, a symbolic link can be created in /opt from WAS Install to WASInstall, eliminating the space. Then, specify /opt/WASInstall/AppServer as the <WAS install path> in the generic JVM argument.

- f. Enable various extended trace categories by specifying one or more trace categories from the table below. An example trace string is: \*=info:JPA=all:openjpa.\*=finer:openjpa.kernel=finest. Extended trace traces at the FINER or FINEST trace levels. The FINEST level includes more detail than FINER. When ALL is specified, extended trace traces at the FINEST level.

Category	Relevant trace levels	Description
JPA	OFF, ALL, FINER, FINEST	Adds extended trace to the JPA trace group.
openjpa.*	OFF, ALL, FINER, FINEST	Normal OpenJPA trace in addition to extended trace for all categories in OpenJPA when extended trace is enabled.
openjpa.xtrace.*	OFF, ALL, FINER, FINEST	Extended trace for all categories in OpenJPA when extended trace is enabled.
openjpa.xtrace.Jdbc	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA JDBC classes when extended trace is enabled.
openjpa.xtrace.Lib	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA library classes when extended trace is enabled.
openjpa.xtrace.Persist	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA persistence classes when extended trace is enabled.
openjpa.xtrace.Kernel	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA kernel classes when extended trace is enabled.
openjpa.xtrace.General	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA classes not included in the JDBC, Lib, Persist, or Kernel categories when extended trace is enabled.
openjpa.xtrace.ApiSpi	OFF, ALL, FINER, FINEST	Extended trace for public API/SPI interfaces defined for WsJPA, OpenJPA and JPA when extended trace is enabled.

3. Save the application server configuration and restart the application server.

## Results

After you restart the application server, the new trace settings are picked up.

## What to do next

**Note:** Tracing can degrade performance significantly and should be disabled when not in use. To disable trace, remove the Generic JVM argument and any trace detail levels added for enhanced tracing.

## Enabling Enhanced Tracing for Java Persistence API (JPA) in a Java SE environment

In some cases it may be necessary to run a JPA trace from a Java SE environment.

### About this task

#### Enabling enhanced tracing for a Java SE environment

Enhanced trace can also be used gather additional JPA trace information in a Java SE environment. In the WebSphere Application Server environment, the application server takes care of coupling the standard OpenJPA trace with the enhanced trace function to produce a single trace output. This must be done manually in a Java SE environment. Here are the steps to use enhanced tracing in a Java SE environment:

1. Create a logging configuration properties file. This file must use the standard `java.util.logging` configuration file format. Below is a sample configuration file. The trace categories defined in the table below can also be used in the configuration file. As standard for `java.util.logging` configuration files, trace categories must be suffixed with `.level`.

```
Sample logger.properties file # Enable the file handler handlers =
java.util.logging.FileHandler # Set a trace file pattern - this pattern will write a file named # jpa_jse.log into the current
directory java.util.logging.FileHandler.pattern = jpa_jse.log # Setup the basic logging level of the file handler
java.util.logging.FileHandler.level = ALL # Set the standard OpenJPA jdbc.SQL category to trace level to ALL
openjpa.jdbc.SQL.level = ALL # Set the enhanced OJPA_General category to trace at FINEST openjpa.OJPA_General.level = FINEST #
Set the enhanced OJPA_Kernel category to trace at FINER openjpa.OJPA_Kernel.level = FINER
```

Category	Relevant trace levels	Description
JPA	OFF, ALL, FINER, FINEST	Adds extended trace to the JPA trace group.
openjpa.*	OFF, ALL, FINER, FINEST	Normal OpenJPA trace in addition to extended trace for all categories in OpenJPA when extended trace is enabled.
openjpa.xtrace.*	OFF, ALL, FINER, FINEST	Extended trace for all categories in OpenJPA when extended trace is enabled.
openjpa.xtrace.Jdbc	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA JDBC classes when extended trace is enabled.
openjpa.xtrace.Lib	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA library classes when extended trace is enabled.
openjpa.xtrace.Persist	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA persistence classes when extended trace is enabled.
openjpa.xtrace.Kernel	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA kernel classes when extended trace is enabled.

Category	Relevant trace levels	Description
openjpa.xtrace.General	OFF, ALL, FINER, FINEST	Extended trace for OpenJPA classes not included in the JDBC, Lib, Persist, or Kernel categories when extended trace is enabled.

2. Modify your persistence.xml file to use Apache commons logging instead of the default OpenJPA logger. Add this property to your persistence unit:

```
<property name="openjpa.Log" value="commons"/>
```

3. Add the apache commons logging Java archive (JAR) file to your class path. You can download the JAR file from the Apache Web site.
4. Add the following argument to the Java virtual machine (JVM), where <WAS install path> is the fully qualified path of your application server install directory. Be sure to use the path separator character appropriate for your operating system. This parameter must be specified before the name of the class or JAR file to be executed.

```
-javaagent:<WAS install path>/optionalLibraries/IBM/wsjava/wsjpgatrace.jar
```

5. Add this additional argument to the JVM which specifies the path to your logging configuration file. This option must also be specified before the name of the class or jar to be executed.

```
-Djava.util.Logging.config.file=Logger.properties
```

6. Run your Java SE application. Here is a sample Java SE application invocation with enhanced trace enabled:

```
java -javaagent:"C:\Program Files\IBM\WebSphere\AppServer\optionalLibraries\IBM\wsjava\wsjpgatrace.jar" -Djava.util.logging.config.file=logger.properties my.JPAApplication
```

## Results

Enhanced tracing is now functioning in your Java SE environment.

## What to do next

**Note:** Use of extended trace agent should not be used in combination with the OpenJPA PCEnhancer agent in a Java SE environment. If enhanced tracing is used, the OpenJPA PCEnhancer must be used at compile time. If the enhancer and enhanced trace agents are used together the results are unpredictable.

## Troubleshooting Java Persistence API (JPA) deadlocks and transaction time-outs

If an application encounters deadlocks and locked time-outs from the database, you can adjust the locking or transaction type to resolve the problem. Transactions are critical to maintaining data integrity. They are used to group operations into units of work that act together in an all-or-nothing fashion. There are two types of transactions, *optimistic* and *pessimistic*. JPA for WebSphere Application Server uses optimistic transactions by default, however, OpenJPA also supports pessimistic transactions. This topic includes the steps to configure these transactions.

### Before you begin

*Pessimistic* transactions prevent all other concurrent transactions from using or modifying the same data by locking the datastore records that they are using. The advantage of a pessimistic transaction is that conflicts between multiple transactions are avoided. However, preventing these conflicts consumes more database resources than optimistic transactions. Because pessimistic transactions lock their records, it is possible that two transactions can wait for the other to release its lock before continuing. This results in a deadlock. The result is that one transaction is forced to unlock its records after a specified timeout interval and an exception is generated.

*Optimistic* transactions operate with the assumption that transactions do not conflict with each other. Optimistic transactions do not lock datastore records. Therefore, it is possible for two transactions to access and change the persistent information at the same time. Optimistic transactions consume less database resources than pessimistic transactions but they can be less reliable.

These changes are not detected until one transaction attempts to commit its changes. At that time, the transaction realizes that the data has been changed by another transaction and an `OptimisticLockException` exception displays. Despite this disadvantage, optimistic transactions are typically a better choice for applications because of performance and a low risk of deadlock.

## Locking

Servers use objects called locks to maintain transaction and data integrity. Locks are managed automatically by lock management programs. Locking is handled on a per-transaction basis. When you obtain a lock on an entity, the lock indicates that you have the right to use the entity. The lock indicates that no other user can alter the data of the entity until the lock is released. Locking management ensures that no other user can obtain a lock that conflicts with a lock already in place. A lock cannot be used by more than one user. Locking management automatically assigns and releases locks, according to the actions of the user.

To manage locks with JPA for WebSphere Application Server, you need to use the `LockManager` plug-in. The `LockManager` controls how the JPA application locks the data involved in the transaction. Depending on the setting used, `LockManager` determines if locking takes place, and if so, optimistic or pessimistic. In addition to `LockManager`, you need to control the level of isolation that the lock places on the entities and determine when the locking takes place in the transaction.

JPA for WebSphere Application Server contains advanced locking and versioning APIs for more control over database resources and object versions. The implementation works with the application server container for managed transactions. This allows the use of the declarative transaction demarcation and Java Transaction API (JTA) implementations within the container.

## JPA Access Intent

JPA Access Intent in JPA for WebSphere Application Server provides an application improved control over the settings of isolation level and read lock when accessing data. This ability allows the data access criteria to be set based on the entity use and the `taskName` associated to the current transaction. By refining the scope of access, the deadlock condition is further minimized.

## About this task

The following steps show you how to enable optimistic or pessimistic locking:

- Enable Optimistic locking by setting the isolation and `LockManager` levels: Optimistic locking should be used when the chance of contention between updating transactions is low or when you have to read and update transaction across multiple transactions.
  1. Ensure that the `LockManager` is set to the following version: `openjpa.LockManager = "version"`. This is the default setting.
  2. Ensure that the isolation level is set to `Read_Committed`: `openjpa.TransactionIsolation = "Read_Committed"`. This is the default setting.
  3. Place the `@Version` annotation column in the entity class definition.
  4. Set the `LockMode` API for the `EntityManager` to guarantee repeatable read on a per entity instance, if needed: `EntityManager.setLock(LockMode.READ)` or `EntityManager.setLock(LockMode.WRITE)`.

Optimistic locking is now in place with versions enabled to monitor the entities involved in transactions and repeatable read permitted in case of `OptimisticLockException` exceptions. If you still experience frequent `OptimisticLockException` exceptions because transactions are rolled back and reinitiated, you should use pessimistic locking.

- Enable pessimistic locking by modifying the `LockManager` and isolation levels:
  1. Change the `LockManager` from version to pessimistic: `openjpa.LockManager="pessimistic"`
  2. Set the isolation level to `Repeatable_Read`: `openjpa.TransactionIsolation="Repeatable_Read"`. For more information about this property, see the OpenJPA documentation.

The locking type is now pessimistic. You might experience deadlocks if two transactions access read data, obtain read locks and attempt to update the data concurrently.

- If you encounter frequent deadlocks, you can modify your pessimistic locking as follows:
  1. Set the isolation level to `Serializable`: `openjpa.TransactionIsolation="Serializable"`.
  2. Modify the `ReadLockLevel` property to "write": `openjpa.ReadLockLevel="write"`. You can also use query hint with this property: `openjpa.FetchPlan.ReadLockLevel="write"`.

After your modifications are done, transactions acquire an update lock on data and cause other update transactions to serialize. The transaction throughput is less because transactions are serialized, but they execute without deadlock.

## Results

For more information, consult chapter 9 of the JPA Reference guide.

### Related tasks

JPA Access Intent

Java Persistence API (JPA) Access intent specifies the isolation level and lock level used when reading data from a data source. Access intent controls the JDBC isolation level and whether read, update or exclusive locks are acquired when retrieving data.

## wsjpa version command

Use this command line tool to find out information about the installed version of Java Persistence API (JPA) for WebSphere Application Server.

## Syntax

The command syntax is as follows:

```
wsjpa version.sh
```

## Usage

The version tool can be very useful when debugging problems with JPA in applications and for providing customer support teams with the information about the current JPA environment.

## Examples

Find the version information of your JPA installation:

```
WSJPA 1.2.0-SNAPSHOT
version id: WSJPA-1.2.0-SNAPSHOT-r1118:1319
revision: 1118:1319

OpenJPA 1.2.0-SNAPSHOT
version id: openjpa-1.2.0-SNAPSHOT-r420667:634150
Apache svn revision: 420667:634150

os.name: Linux
os.version: 2.6.9-55.0.9.ELsmp
```

```
os.arch: x86

java.version: 1.6.0
java.vendor: IBM Corporation

java.class.path:
app_server_root\dev\JavaEE\5.0\j2ee.jar
app_server_root\plugins\com.ibm.ws.jpa.jar

user.dir: /opt/WebSphere70/AppServer9/bin
```

On Windows operating systems the output looks like this:

```
C:\a.was.src\WASX Iww0811.63 S11.48 F11.32>wsjpaersion
WSJPA 1.2.0-SNAPSHOT
version id: WSJPA-1.2.0-SNAPSHOT-r1118:1356
revision: 1118:1356
```

```
OpenJPA 1.2.0-SNAPSHOT
version id: openjpa-1.2.0-SNAPSHOT-r420667:638667M
Apache svn revision: 420667:638667M
```

```
os.name: Windows XP
os.version: 5.1 build 2600 Service Pack 2
os.arch: x86
```

```
java.version: 1.6.0
java.vendor: IBM Corporation
```

---

## Using object cache instances

Perform this task so that your application can access dynamic cache object cache instances with the `DistributedMap` or `DistributedObjectCache` interfaces.

### Before you begin

Before you begin, enable the dynamic cache service. See “Using the dynamic cache service” on page 2324 for more information.

### About this task

Using object cache instances can improve the performance of your application because you can programmatically store and share frequently used objects. By using object cache instances, you also have the necessary control over the dynamic cache when you are running multiple applications in an application server. See “Cache instances” on page 1412 for more information.

1. Configure one or more cache instances.
  - a. In the administrative console, click **Resources > Cache instances > Object cache instances**.
  - b. Specify the scope for the cache instance.

Cell scope makes the cache instance available to all servers within the cell. Node scope makes the cache instance available to all servers on the particular node. Cluster scope makes the cache instance available to all members in a specified cluster. Server scope makes the cache instance available to only the selected server. You can mix scopes, if necessary.

- c. Click **Apply** after changing the scope.
  - d. Click **New**.
  - e. Enter the Java Naming and Directory Interface (JNDI) name for this cache instance.  
This is name that you pass to the InitialContext lookup() method from within your application. For example, services/cache/instance\_one.
  - f. Enter or modify other properties as needed.
2. Update your application. To store and retrieve objects in an object cache instance, you need a DistributedMap or DistributedObjectCache reference for the named object cache instance. See “Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache” on page 2373 for more information.

## Results

You configured object cache instances that you can access programmatically with the DistributedMap and DistributedObjectCache interfaces.

---

## Administering data access applications

These administrative tasks consist primarily of configuring the objects, or resources, through which applications connect with a backend, and tuning those resources to handle the volume of connection requests.

1. If your application contains Web modules or EJB modules that require access to a backend, configure resources according to your type of enterprise information system (EIS):
  - For a relational database, follow the steps outlined in the “Configuring a JDBC provider and data source” on page 1509 topic. If you are using a DB2 database, the “Configuring an application to use pureQuery” topic found in the related links section is another option. PureQuery provides an alternative to JDBC as a way to access the DB2 database.
  - For a non-relational database, or another type of EIS such as the Customer Information Control System (CICS), you must configure a resource adapter and connection factories. The topic Accessing data using Java EE Connector Architecture connectors provides information on setting up these objects.

**Note:** When you specify the Java Naming and Directory Interface (JNDI) name for resources, adhere to the following requirements:

- Do not assign duplicate JNDI names across different resource types (such as data sources versus J2C connection factories or JMS connection factories).
  - Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.
2. Configure an authentication alias for the new Web module resource or EJB module resource only if the application code, rather than WebSphere Application Server, authenticates connections with the backend. This security configuration is called component-managed authorization, and is indicated in the application deployment descriptor as res-auth = Application.

Container-managed authorization, which is designated as res-auth = Container, indicates that Application Server performs signon for backend connections. The container-managed authentication alias must be specified on the application resource reference. This task can be done during application assembly or deployment, along with mapping the resource reference to a data source or connection factory resource. After application deployment, however, you can alter the container-managed authentication alias using the administrative console. Click **Applications** → **Websphere enterprise applications** → **application\_name**, and select the link to the appropriate mapping page. For example, if you want to alter the alias of an EJB module resource, you might click **Map data sources for all 2.x CMP beans**. For a Web module resource, click **Resource References**.

Consult the “J2EE connector security” on page 1503 topic for detailed reference on resource authentication.

3. If your application contains a client module that requires data access, see *Configuring data access for application clients*. In this single configuration process, you can define authentication data for either component-managed or container-managed signon.
4. Specify connection pool settings.
5. Test a connection to the new data source. See the article “Test connection service” on page 1608 for information on the available methods for testing connections. This article also addresses important data source settings that can affect the accuracy of your test connection results.
6. Set the JDBC trace service. The JDBC trace log information augments the JVM log data for data source failures.  
To activate the trace using the administrative console, consult *Enabling trace at server startup*. Specify **WAS.database** as the trace group and select **com.ibm.ws.db2.logwriter** as the trace string.
7. Gather connection pool statistics by activating the JDBC connection pool counters or the J2C connection pool counters. Alternatively, you can use Performance Monitoring Infrastructure (PMI) method calls to gather connection statistics; consult the article “Connection and connection pool statistics” on page 1398.
8. Tune the resources to manage connection volume. Consult the topic “Data access tuning parameters” on page 1638.

## Results

If your z/OS application connects to a z/OS version of DB2 that serves multiple platform versions of WebSphere Application Server, the z/OS application might incur an EC3 dump during run time. To resolve the problem, set the CMTSTAT parameter to INACTIVE when you plan to run distributed workloads.

**Note:** For DB2 Version 7.0 on a z/OS system, the default value for CMTSTAT is ACTIVE. For DB2 Version 8.0 on a z/OS system, the default setting is set to INACTIVE.

Distributed workloads are generally large. The CMTSTAT=INACTIVE setting triggers DB2 to free up resources to counteract the drain that can be caused by large workloads. DB2 will deactivate threads after the threads successfully commit or roll back database tasks and release cursors.

If you set CMTSTAT=INACTIVE, you might need to adjust the CONDBAT and MAXDBAT parameters as well. Try the following combination of values to maximize the performance of DB2 and minimize suspended connection requests:

- Set MAXDBAT to a low number, like 100, which DB2 can support as active threads. MAXDBAT indicates the maximum number of threads that can remain active at the same time and continue running tasks in DB2.
- Set CONDBAT to a high number, like 5000. CONDBAT indicates the maximum number of connection request threads that your DB2 server can receive. When you set CMTSTAT to INACTIVE, DB2 will deactivate many threads after fulfilling the initial connection requests. When the number of threads that require further processing reaches the MAXDBAT setting, DB2 can queue other threads until it can handle them.

## Configuring Java EE Connector connection factories in the administrative console

To access an enterprise information system (EIS), configure connection factories, which instantiate resource adapter classes for establishing and maintaining resource connections.

### About this task

An application component uses a connection factory to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

1. Click **Resources** → **Resource Adapters** → **Resource adapters**.
2. In the **Resource adapters** panel, select the resource adapter that you want to configure.
3. From the **Additional Properties** heading, click **J2C connection factories**.
  - a. Click **New**.
  - b. Specify any properties for the connection factory in the **General Properties** panel.
  - c. Select the authentication preference.
  - d. Select the aliases for **Component-managed authentication**, **Container-managed authentication**, or both. Some choices for the mapping-configuration alias do not use a container-managed authentication alias, so you will not be able to select a container-managed alias if one of those mapping-configuration aliases is selected.

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Note:** If the resource adapter supports XA, an option for **Authentication alias for XA recovery** will be available.

If there are no aliases that are available, or you want to define a different alias:

- 1) Click **Apply** to save the current settings.
- 2) Click **JAAS - J2C authentication data** from the **Related Items** heading.
- 3) Click **New**.
- 4) Define the properties for the alias in **General Properties**.
- 5) Click **OK**.
- e. Click **OK**.
4. Click the name of the J2C connection factory that you created.
5. From the **Additional Properties** heading, click **Connection pool properties**.
  - a. Change any values by clicking the property name. For more information on the settings for connection pools, read “Tuning connection pools” on page 1547 or “Connection pool settings” on page 1476.
  - a. Click **OK**.
6. Click **Custom properties** from the **Additional Properties** heading.
  - a. Click any property name to change its value. If the **UserName** and **Password** properties are defined, they will be overridden by the component-managed authentication alias that you specified in the previous step.
  - b. Click **Save**.
7. Restart the Deployment Manager and the node agent for the changes to take effect.

## Configuring connection factories for resource adapters within applications

To access an enterprise information system (EIS), configure connection factories, which instantiate resource adapter classes for establishing and maintaining resource connections.

### About this task

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

1. Optional: Install the application if it is not already installed on the application server.
  - a. Click **Applications** > **Install New Application**.

- b. Browse to find the appropriate EAR file, which contains an RAR file.
- c. Click **Next**.
- d. Complete the installation process for the application. For more information on installing applications, refer to Installing enterprise application files with the console.
2. Select the application that you want to configure.
3. Click **Modules > Manage Modules**.
4. Select the name of the RAR file in the **Manage Modules** panel.
5. Click **Resource Adapter** under the **Additional Properties** heading.
6. Under the **Additional Properties** heading, click **J2C connection factories**.
  - a. Click **New**.
  - b. Specify any properties for the connection factory in the **General Properties** panel.
  - c. Select the authentication preference.
  - d. Select an alias for **Component-managed authentication** if any application components with *Application* or *Per connection factory* authentication specified in the resource reference are going to be getting connections from this connection factory using the empty-argument getConnection() method. For resources that support XA, you can specify an Authentication alias for XA recovery. If there are no aliases that are available, or you want to define a different alias:
    - 1) Click **Apply** to save the current settings.
    - 2) Click **JAAS - J2C authentication data** under the **Related Items** heading.
    - 3) Click **New**.
    - 4) Define the properties for the alias in **General Properties**.
    - 5) Click **OK**.
  - e. Click **OK**.
7. Click the name of the J2C connection factory that you created.
8. Under the **Additional Properties** heading, click **Connection pool properties**.
  - a. Change any values by clicking on the property name. For more information on the settings for connection pools, refer to “Tuning connection pools” on page 1547 or “Connection pool settings.”
  - a. Click **OK**.
9. Click **Custom properties** under the **Additional Properties** heading.
  - a. Click any property name to change its value. If the **UserName** and **Password** properties are defined, they will be overridden by a **component-managed authentication** alias that you might have configured.
  - b. Click **Save**.

## Connection pool settings

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types, like JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**.

**Note:** Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

For example: click **Resources** → **JDBC** → **JDBC Providers** → *JDBC\_provider* → **Data Sources** → *data\_source* → **Connection pool properties**

The path for JMS queue connection factories is: **Resources** → **JMS** → **Queue connection factories** → *JMS\_queue\_connection\_factory* → **[Additional properties]** **Connection pool properties**.

### ***Connection timeout:***

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection Timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	0 to max int

### ***Maximum connections:***

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown. For example: If the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend (such as a DB2 database or a CICS server) helps you determine a value for the Maximum Connections property.

Consider the number of servants that access the same resource; at runtime, this number essentially multiplies your Maximum Connections setting. When servants invoke the same JDBC data source or J2C connection factory configuration, WebSphere Application Server implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your Maximum Connections setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a Maximum Connections value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

<b>Data type</b>	Integer
<b>Default</b>	10
<b>Range</b>	0 to maximum integer

If Max Connections is set to 0, the Connection Timeout value is ignored.

**Note:** For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli® Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

#### ***Minimum connections:***

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused Timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged Timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

<b>Data type</b>	Integer
<b>Default</b>	1
<b>Range</b>	0 to max int

#### ***Reap time:***

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused Timeout and Aged Timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	0 to max int

#### ***Unused timeout:***

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	0 to max int

#### ***Aged timeout:***

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged Timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance.

For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	0
<b>Range</b>	0 to max int

#### ***Purge policy:***

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

**Data type**  
**Defaults**

String

- EntirePool for J2C connection factories and JMS-related connection factories
- EntirePool for WebSphere Version 4.0 data sources
- EntirePool for current version data sources that you create through the administrative console
- EntirePool for current version data sources that you script through wsadmin AdminConfig commands, invoking JDBC templates that are built into WebSphere Application Server (For information on the command **createUsingTemplate**, see the information center article "Commands for the AdminConfig object.")
- FailingConnectionOnly for data sources that you script in wsadmin without invoking JDBC templates

**Range**

:

#### **EntirePool**

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

#### **FailingConnectionOnly**

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

## **Connection pool advanced settings**

Use this page to specify connection pooling related settings.

This administrative console page is common to a range of resource types: for example, JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection pool properties** → **Advanced connection pool properties**.

For example, click:

- **Resources** → **JDBC** → **JDBC providers** → *JDBC\_provider* → **Data sources** → *data\_source* → **Connection pool properties** → **Advanced connection pool properties**
- **Resources** → **JMS** → **JMS provider** → **Default messaging** → **Queue connection factory** → *JMS\_queue\_connection\_factory* → **Connection pool properties** → **Advanced connection pool properties**.

The number of shared partitions, the number of free pool partitions, and the free pool distribution table size are properties related to reducing the time a thread needs to wait for a synchronization lock. On systems with a single processor, these values make no difference. On systems with multiple processors, these settings can reduce the performance cost associated with managing multiple threads.

### **Related concepts**

“Resource adapters” on page 1389

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

“JDBC providers” on page 1394

Installed applications use JDBC providers to interact with relational databases.

### ***Number of shared partitions:***

Specifies the number of partitions that are created in each of the shared pools.

Partition support is always enabled. The default values of 0 should be used to enable the connection pool to pick the best values for performance. In some cases where large multiprocessor systems are used, adjusting the partition support properties might help performance.

<b>Data type</b>	integer
<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Number of free pool partitions:***

Specifies the number of partitions that are created in each of the free pools.

<b>Data type</b>	integer
<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Free pool distribution table size:***

Determines the distribution of Subject and CRI hash values in the table that indexes connection usage data.

These hash values are used to match connection request credentials with the connections. A free pool distribution table size larger than 1 can yield more efficient distribution of hash values, to help minimize search collisions within the table. Fewer collisions can result in faster retrieval of a connection that matches a request. Use a larger value for free pool distribution table size if your resource receives many incoming requests with varying credentials. Smaller values (1) should be used if the same credentials

apply to all incoming requests for the resource. The value of 0 means random distribution.

<b>Data type</b>	integer
<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Surge threshold:***

Specifies the number of connections created before surge protection is activated.

Surge protection is designed to prevent overloading of a data source when too many connections are created at the same time. Surge protection is controlled by two properties, *surge threshold* and *surge creation interval*.

The surge threshold property specifies the number of connections created before surge protection is activated. After you reach the specified number of connections, you enter *surge mode*.

The surge creation interval property specifies the amount of time, in seconds, between the creation of connections when in surge mode.

For example, assume the follow settings:

- maxConnections = 50
- surgeThreshold = 10
- surgeCreationInterval = 30 seconds

If the connection pool receives 15 connection requests, 10 connections are created at about the same time. The 11th connection is created 30 seconds after the first 10 connections. The 12th connection is created 30 seconds after the 11th connection. Connections continue to be created every 30 seconds until there are no more new connections needed or you reach the maxConnections value.

Surge connection support starts if the surge threshold is > -1 and the surge creation interval is > 0. The surge threshold property has a default value of -1, which indicates that it is turned off.

### **wsadmin examples**

```
$AdminControl getAttribute $objectname surgeCreationInterval
$AdminControl setAttribute $objectname surgeCreationInterval 30
$AdminControl getAttribute $objectname surgeThreshold
$AdminControl setAttribute $objectname surgeThreshold 15
```

<b>Data type</b>	integer
<b>Default value</b>	-1
<b>Range</b>	-1 to max int

### ***Surge creation interval:***

Specifies the amount of time between connection creates when you are in surge protection mode.

When the number of connections specified for the surge threshold property is reached, the surge creation interval property dictates how much time each new connection request must wait before fulfillment.

**Note:** Surge protection does not work for a connection pool that is managed through an activation specification that coordinates with a JMS queue connection factory and default messaging provider. To control incoming connections for JMS calls such as **onMessage**, refer to the help article for the administrative console page **JMS > Activation specification > activation\_specification\_name**.

<b>Data type</b>	integer
------------------	---------

<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Stuck timer interval:***

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck timer interval property is the interval for the timer. This is how often the connection pool checks for stuck connections. The default value is 0 seconds.

If an attempt to change the stuck time, stuck timer interval, or stuck threshold properties using the wsadmin scripting tool fails, an `IllegalState` exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, the stuck time and the stuck threshold property values must be greater than 0 and maximum connections must be greater than 0.

Also, the stuck timer interval, if it is set, must be less than the stuck time value. In fact, it is suggested that the stuck timer interval should be one-quarter to one-sixth the value of stuck time so that the connection pool checks for stuck connections 4 to 6 times before a connection is declared stuck. This reduces the likelihood of false positives.

### **wsadmin examples**

```
$AdminControl getAttribute $objectname stuckTime
$AdminControl setAttribute $objectname stuckTime 30
$AdminControl getAttribute $objectname stuckTimerInterval
$AdminControl setAttribute $objectname stuckTimerInterval 15
$AdminControl getAttribute $objectname stuckThreshold
$AdminControl setAttribute $objectname stuckThreshold 10
```

<b>Data type</b>	integer
<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Stuck time:***

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck time property is the interval, in seconds, allowed for a single active connection to be in use to the backend resource before it is considered to be stuck.

<b>Data type</b>	integer
<b>Default value</b>	0
<b>Range</b>	0 to max int

### ***Stuck threshold:***

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool appears to be stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. An application can explicitly catch this exception and continue processing. The pool will continue to periodically check for stuck connections when the number of stuck connections is past the threshold. If the number of stuck connections drops below the stuck threshold, the pool will detect this during its periodic checks and enable the pool to begin servicing requests again. The stuck threshold is the number of connections that need to be considered stuck for the pool to be in stuck mode.

<b>Data type</b>	integer
------------------	---------

<b>Default value</b>	0
<b>Range</b>	0 to max int

## Connection pool (Version 4) settings

Use this page to create a connection pool for a Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources > JDBC > JDBC Providers > *JDBC\_provider* > Data sources (WebSphere Application Server V4) > *data\_source* > Connection pool properties (version 4)**
- **Resources > JDBC > Data sources (WebSphere Application Server V4) > *data\_source* > Connection pool properties (version 4)**

**Scope:** Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

For general information, see *Administrative console scope settings* in the Related Reference section.

<b>Data type</b>	String
------------------	--------

### **Minimum pool size:**

Specifies the minimum number of connections to maintain in the pool.

The minimum pool size can affect the performance of an application. Smaller pools require less overhead when the demand is low because fewer connections are held open to the database. When the demand is high, the first applications experience a slow response because new connections are created if all others in the pool are in use.

<b>Data type</b>	Integer
<b>Default</b>	1
<b>Range</b>	Any non-negative integer.

### **Maximum pool size:**

Specifies the maximum number of connections to maintain in the pool.

If the maximum number of connections is reached and all connections are in use, additional requests for a connection wait up to the number of seconds specified as the connection timeout. The maximum pool size can affect the performance of an application. Larger pools require more overhead when demand is high because there are more connections open to the database at peak demand. These connections persist until idled out of the pool. If the maximum value is smaller, longer wait times or possible connection timeout errors during peak times can occur. Ensure that the database can support the maximum number of connections in the application server, in addition to any load that it has outside of the application server.

<b>Data type</b>	Integer
<b>Default</b>	10
<b>Range</b>	Any positive integer

***Connection timeout:***

Specifies the maximum number of seconds an application waits for a connection from the pool before timing out and triggering a `ConnectionWaitTimeout` exception. WebSphere Application Server acts on this value only if you set the maximum pool size property, in which case the number of maximum connections serves as a trigger for enforcing the wait timeout property.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	Any non-negative integer

Setting this value to 0 disables the connection timeout.

If you accept the default value, Application Server issues the `ResourceAllocation` exception immediately after the pool manager indicates that the maximum number of connections are in use. If you disable connection timeout, Application Server does not issue an exception. Instead, the pool manager queues subsequent connection requests until it can allocate a connection.

***Idle timeout:***

Specifies the maximum number of seconds that an idle (unallocated) connection can remain in the pool before being removed to free resources.

Connections need to idle out of the pool because keeping connections open to the database can cause database memory problems. However, not all connections are idled out of the pool, even if they are older than the Idle Timeout setting. A connection is not idled if removing the connection would cause the pool to shrink below its minimum size. Setting this value to 0 disables the idle timeout.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	Any non-negative integer

***Orphan timeout:***

Specifies the maximum number of seconds that an application can hold a connection without using it before the connection returns to the pool

If there is no activity on an allocated connection for longer than the Orphan Timeout setting, the connection is marked for orphaning. After another Orphan Timeout number of seconds, if the connection still has no activity, the connection returns to the pool. If the application tries to use the connection again, it is issued a stale connection exception. Connections that are enlisted in a transaction are not orphaned. Setting this value to 0 disables the orphan timeout.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	Any non-negative integer

### **Statement cache size:**

Specifies the number of cached prepared statements to keep per connection.

The largest value you would need to set your cache size to if you do not want any cache discards is determined as follows: for each application that uses this data source on a particular server, add up the number of unique prepared statements (as determined by the *sql* string, concurrency, and the scroll type). This is the maximum number of possible prepared statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. This provides better performance. However, because of potential resource limitations, this might not always be possible.

<b>Data type</b>	Integer
<b>Default</b>	10
<b>Range</b>	Any non-negative integer

### **Disable auto connection cleanup:**

Specifies whether the connection pooling software automatically closes connections from the data source at the end of a transaction. Set this property if you want to maintain and reuse the same connection across multiple transactions.

The default is *false*, which indicates that when a transaction completes, the application server closes the connection and returns it to the pool. Any use of the connection after the transaction has ended results in a stale connection exception, because the connection is closed and has returned to the pool. This mechanism ensures that connections are not held indefinitely by the application. If the value is set to true, the connection is not returned to the pool at the end of a transaction. In this case, the application must return the connection to the pool by calling the `close()` method. If the application does not close the connection, the pool can run out of connections for other applications to use.

<b>Data type</b>	Boolean (check box)
<b>Default</b>	False (clear)

## **J2C Connection Factories collection**

Use this page to view Java 2 Connector (J2C) connection factories, which represent sets of connection configuration values.

Application components such as enterprise beans have resource reference descriptors that refer to the connection factory, not the resource adapter. The connection factory is really a configuration properties list holder. In addition to the arbitrary set of configuration properties defined by the vendor of the resource adapter, there are several standard configuration properties that apply to the connection factory. These standard properties are used by the Java 2 Connectors connection pool manager in the application server run time and are not known by the vendor-supplied resource adapter code.

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > J2C connection factories**
- **Resources > Resource Adapters > Resource Adapters > *resource\_adapter* > J2C connection factories**

### **Name:**

Specifies a list of the connection factory display names.

<b>Data type</b>	String
------------------	--------

**JNDI name:**

Specifies the Java Naming and Directory Interface (JNDI) name of this connection factory.

**Data type** String

**Scope:**

Specifies the scope of the connection factory. Only applications that are installed within this scope can use this connection factory.

**Provider:**

Specifies the resource adapter that WebSphere Application Server uses for this connection factory.

**Description:**

Specifies a text description of this connection factory.

**Data type** String

**Connection factory interface:**

Specifies the fully qualified name of the interface that provides the implementation class for the connection factory.

**Category:**

Specifies a string that you can use to classify or group this connection factory.

**Data type** String

**J2C connection factories settings:**

Use this panel to specify settings for a connection factory.

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **J2C connection factories** → **J2C\_connection\_factory**
- **Resources** → **Resource Adapters** → **Resource adapters** → **resource\_adapter** → **J2C connection factories** → **J2C\_connection\_factory**

**Scope:**

Specifies the scope of the resource adapter that connects applications to an enterprise information system (EIS) through this connection factory. Only applications that are installed within this scope can use this connection factory.

**Provider:**

Specifies the resource adapter that WebSphere Application Server uses for this connection factory.

**Provider** is displayed in this location only when you create a new connection factory. The list shows all of the existing resource adapters that are defined at the relevant scope. Select one from the list if you want to use an existing resource adapter as Provider.

*Create new provider:*

Provides the option of configuring a new resource adapter for the new connection factory.

**Create New Provider** is displayed only when you create, rather than edit, a connection factory.

Clicking **Create New Provider** triggers the console to display the resource adapter configuration page, where you create a new adapter. After you click **OK** to save your settings, you see the connection factory collection page. Click **New** to define a new connection factory for use with the new resource adapter; the console now displays a configuration page that lists the resource adapter as the new connection factory Provider.

*Name:*

Specifies the name of this connection factory.

This is a required property.

**Data type** String

*JNDI name:*

Specifies the JNDI name of this connection factory.

For example, the name could be *eis/myECIConnection*.

After you set this value, save it and restart the server. You can see this string when you run the *dumpNameSpace* tool. This is a required property. If you do not specify a JNDI name, it is filled in by default using the Name field.

**Data type** String  
**Default** *eis/display name*

**Note:** Adhere to the following requirements for JNDI names:

- Do not assign duplicate JNDI names across different resource types (such as data sources versus J2C connection factories or JMS connection factories).
- Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

*Description:*

Specifies a text description of this connection factory.

**Data type** String

*Connection factory interface:*

Specifies the fully qualified name of the Connection Factory Interfaces supported by the resource adapter.

This is a required property. For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the connection factory, the field is a read only text field.

**Data type** Drop-down list or text

*Category:*

Specifies a string that you can use to classify or group this connection factory.

**Data type** String

*Component-managed authentication alias:*

Specifies authentication data for component-managed signon to the resource.

Select an alias from the list.

To define a new alias that is not displayed in the list:

- Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
- Click **J2EE Connector Architecture (J2C) authentication data entries**.
- Click **New**.
- Define an alias.
- Click **OK**. The console now displays an alias collection page. This page contains a table that lists all of your configured aliases. Before the table, this page also displays the name of your connection factory.
- Click the name of your J2C connection factory. You now see the configuration page for the connection factory.
- Select the new alias in the Component-managed authentication alias list.
- Click **Apply**.

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** List

The alias that you configure for component-managed authentication does not apply to all clients that must access the secured resource. External Java clients with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component-managed authentication alias defined on the resource. This alias is the default value that is used when the `getConnection()` method does not specify any authentication data, like *user* and *password*, or a value for `ConnectionSpec`. If an external client needs to get a connection, it must assume responsibility for the authentication by passing it through arguments on the `getConnection()` call.

However, if clients such as servlets or enterprise beans run in processes within the same cell of the application server, and the clients can look up a resource in the JNDI namespace, these clients can obtain connections without explicitly providing authentication data on the `getConnection()` call. In this case, if the component's `res-auth` setting is **Application**, authentication is taken from the component-managed authentication alias that is defined on the connection factory. When you set `res-auth` to **Container**, authentication is taken from the login configuration that is defined on the component's resource-reference. If the resource reference for the component does not define a login configuration, authentication will be taken from the Container-managed authentication alias that is defined on the connection factory.

**Note:** The J2C authentication alias is per **cell**. An enterprise bean or servlet in one application server cannot look up a resource in another server process that is in a different cell, because the alias would not be resolved.

*Authentication alias for XA recovery:*

This field is used to specify the authentication alias that should be used during XA recovery processing. If this alias name is changed after a server failure, the subsequent XA recovery processing will use the original setting that was in effect before the failure.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** Drop-down list

#### *Mapping-configuration alias:*

Specifies the authentication alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

Click **Security** → **Global security** → **Java Authentication and Authorization Service** → **Application logins**, and select an alias from the table.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

**Note:** Some mapping-configuration aliases do not use a container-managed authentication aliases, so you will not be able to select a container-managed authentication alias if one of those mapping-configuration aliases is selected.

**Data type** Pick-list

#### *Container-managed authentication alias:*

Specifies authentication data, which is a JAAS - J2C authentication data entry, for container-managed signon to the resource.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **J2EE Connector Architecture (J2C) authentication data entries**.
3. Click **New**.
4. Define an alias.
5. Click **OK**. The console now displays an alias collection page. This panel contains a table that lists all of your configured aliases. Before the table, this page also displays the name of your connection factory.
6. Click the name of your J2C connection factory. You now see the configuration panel for the connection factory.
7. Select the new alias in the container-managed authentication alias list.
8. Click **Apply**.

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** Pick-list

*Authentication preference (deprecated):*

Specifies the authentication mechanisms defined for this connection factory.

**Note:** Beginning with WebSphere Application Server Version 6.0, the authentication preference is superseded by the combination of the <res-auth> application component deployment descriptor setting and the specification of a login configuration on the resource-reference mapping at deployment time.

This setting specifies which of the authentication mechanisms defined for the corresponding resource adapter applies to this connection factory. Common values, depending on the capabilities of the resource adapter, are: *KERBEROS*, *BASIC\_PASSWORD*, and *None*.

If *None* is chosen, the application component is expected to manage authentication (<res-auth>Application</res-auth>). In this case, the user ID and password are taken from one of the following:

- The component-managed authentication alias
- UserName, Password Custom Properties
- Strings passed on the getConnection method

For example, if two authentication mechanism entries are defined for a resource adapter in the *ra.xml* document:

- <authentication-mechanism-type>BasicPassword</authentication-mechanism-type>
- <authentication-mechanism-type>Kerbv5</authentication-mechanism-type>

the authentication preference specifies the mechanism to use for container-managed authentication. An exception is issued during server startup if a mechanism that is not supported by the resource adapter is selected.

**Data type** Pick-list  
**Default** BASIC\_PASSWORD

**J2C Connection Factory advanced settings:**

Use this page to specify settings for a connection factory.

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > J2C connection factories > J2C\_connection\_factory > Advanced connection factory properties**
- **Resources > Resource Adapters > Resource Adapters > resource\_adapter > J2C connection factories > J2C\_connection\_factory > Advanced connection factory properties**

## Related concepts

“Resource adapters” on page 1389

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

“JDBC providers” on page 1394

Installed applications use JDBC providers to interact with relational databases.

*Log missing transaction contexts:*

Specifies whether or not the container logs that there is a missing transaction context when a connection is obtained.

<b>Data type</b>	Boolean
<b>Default</b>	True (enabled)

*Cached handles:*

Specifies whether cached handles (handles held in inst vars in a bean) should be tracked by the container.

<b>Data type</b>	Boolean
<b>Default</b>	False (clear)

## Connection factory JNDI name practices

Observe the conventions of the Java Naming and Directory Interface (JNDI) service in WebSphere Application Server when you create connection factory JNDI names.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services use name-to-object mappings to associate names with objects such locations, services, information, and resources. The Java Naming and Directory Interface (JNDI) provides a common interface that is used to access the various naming and directory services.

## Naming your resources indirectly

When creating a connection factory or data source, a JNDI name is given by which the connection factory or data source can be looked up by a component. WebSphere Application Server uses an *indirect* name with the `java:comp/env` prefix:

- When you create a WebSphere Application Server data source, the default JNDI name is set to `jdbc/data_source_name`.
- When you create a connection factory, its default name is `eis/j2c_connection_factory_name`.

If you override these values by specifying your own, retain the `java:comp/env` prefix. An indirect name makes any resource-reference data associated with the application available to the connection management runtime, to better manage resources based on the `res-auth`, `res-isolation-level`, `res-sharing-scope`, and `res-resolution-control` settings.

## Naming your resources for use with CMP

In addition, if you click the checkbox for the **Use this data source for container managed persistence (CMP)** option when you create the data source, another reference is created with the name of `eis/jndi_name_of_datasource_CMP`. For example, if a data source has a JNDI name of `jdbc/myDataSource`,

the CMP JNDI name is `eis/jdbc/myDatasource_CMP`. This name is used internally by CMP and is provided simply for informational purposes.

## Installing a resource adapter archive

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

### Before you begin

A RAR file, which is often called a Java EE Connector Architecture (JCA) connector, must comply with the JCA Specification. Meet these requirements by using a supported assembly tool to assemble a collection of Java archive (JAR) files, other runnable components, utility classes, and so on, into a deployable resource adapter archive (RAR). You can then install the RAR file in the application server.

### About this task

A resource adapter archive provides the classes and other code to support a resource adapter for access to a specific enterprise information system (EIS), such as the Customer Information Control System (CICS). Therefore, you can only configure resource adapters for an EIS after you install the appropriate RAR file.

1. Navigate to the **Resource adapter** panel. Click **Resources** → **Resource Adapters** → **Resource adapters**.
2. Install a new resource adapter archive.
  - a. Click **Install RAR**. A dialog opens for installing a RAR file and configuring the associated resource adapter. Only click **New** if you want to configure a new resource adapter for a previously installed RAR file.

**Note:** When installing a RAR file using this dialog, the scope you define on the **Resource adapters** panel has no effect on where the RAR file is installed. You can install RAR files only at the *node* level, which you specify on the **Install RAR** panel.

- b. Browse to find the appropriate RAR file.
    - If your RAR file is located on your local workstation, select **Local path**, and browse to find the file.
    - If your RAR file is located on your server, select **Server path**, and specify the fully qualified path to the file.
  - c. Click **Next**.
3. Enter the resource adapter name and any other properties needed under *General Properties*. For more details on the settings that you can configure, see the topic on configuring a resource adapter in the administrative console.
  4. Click **OK**.

### Results

You have installed a resource adapter archive that will provide access to the EIS when it is properly configured. If you need to configure more settings, or change some settings that were configured during the installation process, refer to the topic on configuring a resource adapter in the administrative console for more information.

## Installing resource adapters within applications

Install resource adapters in your applications so they can access outside data sources.

1. Assemble an application with resource adapter archive (RAR) modules in it. See *Assembling applications*.

2. Install the application following the steps in Installing a new application. In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the Web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each Web server is generated based on the applications that are routed through it.

**Note:** When installing a RAR file onto a server, WebSphere Application Server looks for the manifest (MANIFEST.MF) for the connector module. It looks first in the `connectorModule.jar` file for the RAR file and loads the manifest from the `_connectorModule.jar` file. If the class path entry is in the manifest from the `connectorModule.jar` file, then the RAR uses that class path.

To ensure that the installed connector module finds the classes and resources that it needs, check the **Class path** setting for the RAR using the console. For more information, see “Resource adapter settings” on page 1498 and “WebSphere relational resource adapter settings” on page 1390

3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.
  - a. Open the administrative console.
  - b. Click **Resources** → **Resource Adapters** → **Resource adapters** → **resource\_adapter** → **J2C connection factories**.
  - c. Click **New** to create a new connection factory, or click on an existing connection factory to update it.

After you create and save the connection factories, you can modify the resource references defined in various modules of the application and specify the Java Naming and Directory Interface (JNDI) names of the connection factories wherever appropriate.

**Note:** A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own classloader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

## Install RAR

Use this page to install a RAR file in one of two ways. You can either upload a RAR file from the local file system, or specify an existing RAR file on a server. The RAR file must be installed at the node level, and you can select the node below.

For information on installing a resource adapter, see the article “Installing a Resource Adapter Archive (RAR) file.”

## Related tasks

“Installing a resource adapter archive” on page 1493

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

## Related reference

Administrative console buttons

This page describes the button choices that are available on various pages of the administrative console, depending on which product features you enable.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs.

Administrative console preference settings

Use the preference settings to specify how you want information to display on an administrative console panel. The preference settings vary from one administrative console panel to another.

## *Local path:*

Specifies the local path of the RAR.

**Data type** String

## *Server path:*

Specifies the server path where the RAR is located.

**Data type** String

## *Scope:*

Specifies the scope of the resource adapter. Only applications that are installed within this scope can use this adapter.

## Configuring resource adapters

You can view a list of installed and configured resource adapters in the administrative console, as well as use the administrative console to install new resource adapters, create additional configurations of installed resource adapters, or delete resource adapter configurations. You can also configure a single instance resource adapter.

## Before you begin

A resource adapter is an implementation of the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. It can provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of .rar. A resource adapter can be provided as a standalone adapter or as part of an application, in which case it is referred to as an embedded adapter.

## About this task

Use this task to configure a standalone resource adapter archive file. Embedded adapters are installed as part of the application installation. This panel can be used to work with either kind of adapter.

1. Open the administrative console.
2. Select **Resources** → **Resource Adapters** → **Resource adapters** → **resource\_adapter**.
3. Set the scope setting. This field specifies the level to which this resource definition is visible. For general information, see the topic on administrative console scope settings in the Related Reference section. The Scope field is a read-only string field that shows where the particular definition for a resource adapter is located. This is set either when the resource adapter is installed, which can only be at the node level, or when a new resource adapter definition is added.
4. Configure the description. This field specifies a text description of the resource adapter. Use a free-form text string to describe the resource adapter and its purpose.
5. Set the archive path. Use this field to specify the path to the RAR file containing the module for this resource adapter. This property is required.
6. Set the classpath. The class path includes the list of paths or JAR file names that, together, form the location for the resource adapter classes. This list includes any additional libraries needed by the resource adapter. The resource adapter code base itself is automatically added to the class path, but you can use this field to specify anything that is needed and is not within the RAR.
7. Set the native path. The list of paths which forms the location for the resource adapter native libraries is set here. The resource adapter code base itself is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.
8. Optional: Isolate the class loading for the resource adapter.

**Note:** You can isolate a resource adapter to allow different versions of the same resource provider to be loaded in the same Java Virtual Machine (JVM). For example, you might want to deploy multiple applications on a single server, and each application requires different versions or implementations of the same resource adapter. You can now isolate each version or implementation of the resource adapter so that the classes of each adapter will be loaded by its own class loader, and the class loader will not inadvertently link with classes of the other versions or implementations of the adapter.

- a. Select **Isolate this resource provider**.

**Note:** Be aware of the following conditions:

- You cannot isolate a resource adapter if you specify a native library path. If you specify a native path manually, using wsadmin or editing the XML descriptors, the native paths are ignored and Application Server will issue a warning at run time. The Application Server will define a value for the native library path for some JDBC providers; this behavior is intended to help you configure your provider when a native library path is necessary. If you do not require the native library path, delete the value, and you will be able to select the option to isolate the resource provider.
- If you are running a mixed cell environment, the application server will remove any isolated JDBC providers from nodes that are running at versions earlier than 7.0 if the provider is scoped for a version 7.0 cell, and you have not migrated the provider from an older release. If you want to use isolated resources at the cell level, do not use the resources in nodes that are running at versions earlier than 7.0. Define a resource at the node level, or avoid using the resource in nodes that are earlier than version 7.0, because there will be a "Naming not found" exception when the application server attempts to perform a lookup on an isolated resource at the cell level.

There are other general considerations that you should take into account when isolating any type of resource provider. Refer to the topic on considerations for isolated resource providers for more information.

- b. Give the resource adapter a unique class path that is appropriate for that version.
9. Optional: Restrict the JVM to allow only one instance of the resource adapter. This setting prevents more than one instance of a resource adapter enterprise bean with a unique resource adapter implementation class name from existing in the same Java Virtual Machine (JVM). Enabling this setting imposes a highly restrictive environment on the system and should be used with caution. For example, if two applications use the same embedded resource adapter, only the first application to start will be able to access resources through its embedded resource adapter. If a standalone resource adapter is configured for a single instance, no applications that embed that same resource adapter will be able to access resources.
  - a. Click **Advanced resource adapter properties**.
  - b. Select **Restrict the JVM to allow only one instance of the resource adapter**.
10. Optional: Register this resource adapter with the high availability manager.

**Note:** Registering the resource adapter with the high availability manager specifies that the high availability (HA) manager will manage the lifecycle of a JCA 1.5 resource adapter in a cluster, ensuring that applications using resource adapters for inbound communication remain highly available. To that end, appropriate use of the HA capability options enable you to set up an environment that will be able to implement failover for inbound activity when a server goes down.

Do not select this option without first consulting the product documentation for the resource adapter, because this option requires the resource adapter to support high availability of inbound messaging. This field is only available on resource archives that allow definitions for activation specifications.

- a. Click **Advanced resource adapter properties**.
- b. Select **Register this resource adapter with the high availability manager**. This setting can be implemented with:
  - **Endpoint failover:** allows only one resource adapter in an HA group to receive messages across multiple servers. The result is that only one resource adapter can have endpoints active at one time.
  - **Resource adapter instance failover:** allows only one resource adapter in an HA group to be started across multiple servers. Inbound or outbound communication is limited to one resource adapter in the cluster, and the result is that only one runtime resource adapter instance can exist at one time.

## Resource adapters collection

Use this panel to view the list of installed and configured resource adapters that you can use, install new resource adapters, create additional configurations of installed resource adapters, or delete resource adapter configurations. You can install a stand-alone resource adapter archive (RAR) file, or manage embedded adapters that are installed as part of the installation of an application.

You can configure a single instance resource adapter after a resource adapter archive (RAR) file is installed. The RAR file can either be stand-alone or embedded in an application through the administrative console or through the scripting tool. A checkbox is located on the console for you to specify that you want a single instance to be created at run time.

To view this administrative console page, click **Resources** → **Resource Adapters** → **Resource adapters**.

A resource adapter is an implementation of the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification that provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. Resource adapters can provide application access to resources such as DB2, CICS, SAP and PeopleSoft. A resource adapter can provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter

archive file; this file has an extension of .rar. A resource adapter can be provided as a stand-alone adapter or as part of an application, in which case the resource adapter is referred to as an embedded adapter.

To view the resource adapters that are provided with the application server, select **Show built-in resources** in **Preferences**.

#### **Scope:**

Specifies the level at which this resource adapter is visible. For general information, read about administrative console scope settings.

Some considerations that you should keep in mind for this particular panel are:

- Changing the scope enables you to see which resource adapter definitions exist at that level.
- Changing the scope does not have any effect on installation. Installations are always done under a scope of node, no matter what you set the scope to.
- When you create a new resource adapter from this panel, you must change the scope to what you want it to be before clicking New.

#### **Install RAR:**

Specifies to install a resource archive (RAR). You can upload a RAR file from the local file system, or specify an existing RAR file on a server.

The RAR file must be installed at the node level.

#### **New:**

Specifies to create a copy of a resource archive that is already installed in the application server. This will create a copy of the resource adapter that you select in the table.

If you wish to create a copy of an installed resource adapter, specify a server for the scope, and click **New**. You cannot create a copy of a resource adapter at the node scope. If you want to install a new resource adapter, click **Install RAR**.

#### **Delete:**

Specifies to delete the copy of a resource adapter. This will delete the copy that you select in the table.

#### **Update RAR:**

Specifies to update the resource adapter that you select in the table. Update a resource adapter archive (RAR) file when you determine that a resource adapter, or a set of resource adapters, needs to be updated with a different version or implementation.

Different versions or implementations of resource adapters can include different settings, so updating your adapter might be beneficial if you require a certain set of configuration options. You can choose if you would like to update the resource adapter for all of the nodes in a cell or all the nodes in a cluster. If some of your nodes are earlier than Version 7.0, the RAR update will not be supported until those nodes are migrated to Version 7.0.

#### **Name:**

Specifies the name of the resource adapter.

#### **Resource adapter settings:**

Use this page to specify settings for a resource adapter.

A resource adapter is an implementation of the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification that provides access for applications to resources outside of the server, provides access for applications to an enterprise information system (EIS), or provides access for an EIS to applications on the server. Resource adapters provide applications access to resources such as DB2, CICS, SAP and PeopleSoft. Resource adapters can provide an EIS with the ability to communicate with message driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file (RAR); this file has an extension of .rar. A resource adapter can be provided as a stand alone adapter or as part of an application, in which case the resource adapter is referred to as an embedded adapter. Use this panel to install a stand alone resource adapter archive file. Embedded adapters are installed as part of the application installation.

To view this administrative console page, click one of the following paths:

- **Resources** → **Resource Adapters** → **Resource adapters** → **New**.
- **Resources** → **Resource Adapters** → **Resource adapters** → *resource\_adapter*.
- Install a new resource adapter archive:
  1. Click **Resources** → **Resource Adapters** → **Resource adapters** → **Install RAR**.
  2. Specify a full path for the local file system or remote file system, and click **Next**.

*Scope:*

Specifies the highest topological level at which application servers can use this adapter.

The Scope field is a read-only string field that specifies where the particular definition for a resource adapter is located. The Scope field is set when the resource adapter is installed, which can only be at the node level, or when a new resource adapter definition is added.

*Name:*

Specifies the name of the resource adapter definition.

This property is a required string containing no spaces that is a meaningful text identifier for the resource adapter.

*Description:*

Specifies a text description of the resource adapter.

This description is a free-form text string to describe the resource adapter and its purpose.

*Archive path:*

Specifies the path to the installed resource archive file that contains the module for this resource adapter.

You can only select RAR files that are installed on the nodes within the selected scope, preventing you from configuring a selection that might fail for some of your nodes.

**Note:** For resources at the cell scope, the RAR files that are available are those that are installed on each individual node in the entire cell. For resources at a cluster scope, the RAR files that are available are those that are installed on each individual node in that particular cluster.

This property is required.

**Data type** String

*Class path:*

Specifies a list of paths or Java archive file (JAR) names that together form the location for the resource adapter classes.

Class path entries are separated by using the ENTER key and must not contain path separator characters like ';' or ':'. Class paths can contain variable (symbolic) names that can be substituted using a variable map. Check your driver installation notes for specific JAR file names that are required.

*Native library path:*

Specifies an optional path to any native libraries, which are .dll or .so files.

Native path entries are separated by using the ENTER key and must not contain path separator characters like ';' or ':'. Native paths can contain variable (symbolic) names that can be substituted using a variable map.

*Isolate this resource provider:*

Specifies that this resource provider will be loaded in its own class loader. This allows different versions of the same resource provider to be loaded in the same Java Virtual Machine. Give each version of the resource provider a unique class path that is appropriate for that version.

Ensure that all copies of a resource adapter have the same value for this option. For example, if you create a resource adapter at the cluster scope, the value of this option will be taken from the resource adapter archive (RAR) that you copy. When you create the copy, you cannot modify the value for any instances of that RAR, which would be the copies at the node or cluster scope in this example. If you need to modify the value, you have to delete the copies of the RAR until there is only one instance of that particular RAR that is left.

**Note:** You cannot isolate a resource provider if you specify a native library path.

***Advanced resource adapter properties:***

Use this page to specify advanced settings for resource adapters that comply with the Version 1.5 Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification.

A resource adapter is an implementation of the Java EE Connector Architecture (JCA) specification that provides access for applications to an enterprise information system (EIS), like DB2, CICS, SAP and PeopleSoft, or provides access for an EIS to applications on the server. A resource adapter can also provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM, but third party vendors can provide their own resource adapters.

A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of .rar. A resource adapter can be provided as a stand-alone adapter or as part of an application, in which case it is referred to as an embedded adapter. Use this panel to install a stand-alone resource adapter archive file. Embedded adapters are installed as part of the application installation.

To view this administrative console page, click **Resources** → **Resource Adapters** → **Resource adapters** → **resource\_adapter** → **Advanced resource adapter properties**.

*Restrict the JVM to allow only one instance of this resource adapter:*

Prevents more than one instance of a resource adapter JavaBean with a unique resource adapter implementation class name from existing in the same Java Virtual Machine (JVM). This field is only available on resource archives that allow definitions for activation specifications.

**Note:** Enabling this setting imposes a restrictive condition on the inbound communications. For example, if two applications embed the same resource adapter, only the first application to start will be able to access resources through its embedded resource adapter. If a stand-alone resource adapter is configured for a single instance, no applications that embed that same resource adapter will be able to access resources.

<b>Data type</b>	Boolean (checkbox)
<b>Default</b>	False (disabled)

*Register this resource adapter with the high availability manager:*

Specifies that the high availability (HA) manager will manage the lifecycle of a JCA 1.5 resource adapter in a cluster. Do not select this option without first consulting the product documentation for the resource adapter, because this option requires the resource adapter to support high availability of inbound messaging. This field is only available on resource archives that allow definitions for activation specifications.

**Note:** Enabling this setting imposes a restrictive condition on the inbound communications.

This setting can be implemented with:

- **Endpoint failover:** allows only one resource adapter in an HA group to receive messages across multiple servers. The result is that only one resource adapter can have endpoints active at one time.
- **Resource adapter instance failover:** allows only one resource adapter in an HA group to be started across multiple servers. Inbound or outbound communication is limited to one resource adapter in the cluster.

<b>Data type</b>	Boolean (checkbox with implementation options)
<b>Default</b>	False (disabled)

## Updating a resource adapter archive

Use the resource adapter archive (RAR) update wizard to update RAR files to a newer version. The application server uses the classes and other code that comprise a resource adapter archive to support the resource adapters that you configure.

### Before you begin

A resource adapter must be installed on the application server, and you must have a new version of the resource adapter that is compatible with the old version. You can create the new RAR file with an assembly tool, or the vendor for the resource adapter can provide the new version. If the new version of a RAR file is not compatible with the old version of the resource adapter, an update is not possible.

### About this task

Update a RAR file when you determine that a resource adapter or a set of resource adapters needs to be updated with a different version. Different versions of resource adapters can include different settings, so updating your adapter might be beneficial if you require a certain set of configuration options. You can

choose if you would like to update the resource adapter for all of the nodes in a cell or all the nodes in a cluster. If some of your nodes are earlier than Version 7.0, the RAR update will not be supported until those nodes are migrated to Version 7.0.

If you prefer to have more than one version of a resource adapter active in a given Java Virtual Machine (JVM), the update wizard will not provide the option of creating a new version and keeping the old. In this case, you will need to create an isolated resource adapter and configure it accordingly. Refer to the topic on configuring a resource adapter for more information.

1. Save all configuration changes.
2. Backup your configuration settings with the backupConfig tool. The backupConfig tool is located in the app\_server\_root/bin directory. Read the topic on the backupConfig command for more information on how to use this command.
3. Synchronize any of the nodes that will be updated.
4. Ensure that the node agents are running if they are associated with the resource adapter that you are updating.
5. Stop any servers that contain the RAR file that you will update. You must stop all of the servers in the node or cluster to which the RAR file is associated. Refer to Administering applications and their environment for information on how to stop or start an application server.
6. Click **Resources** → **Resource Adapters**.
7. Select the checkbox next to the RAR file to update, and click **Update RAR**.
8. Specify the installation path for the RAR file, and click **Next**.
  - If your RAR file is located on the same workstation as your browser, select **Local file system**, and browse to find the file.
  - If your RAR file is located on the server workstation where the application server is installed, select **Remote file system**, and specify the fully qualified path to the file.
9. Review the configuration information that is provided for the RAR file. The following information is displayed for the RAR file:
  - Name
  - Current RAR version
  - New RAR version
  - Scope
  - Any existing copies of the resource adapter. The resource adapters with an asterisk (\*) are copies of the resource adapter and must also be updated at the same time.

Click **Next** when you are finished.

10. Optional: Edit any properties that were added by the new version of the resource adapter. You can also edit these properties after completing the update.
  - a. Select a resource in the list to edit the new properties. Only resources with new properties are included in the list.
  - b. Edit the resource properties. Use the table that is provided to set the values for the selected resource's new properties.
    - Select the **Set for all** checkbox to apply the property value to all of the resources of the same type.
    - Click the **Reset to Default** button to reset all of the properties to the default values that are defined in the RAR file. This only affects the selected resource.
  - c. Click **Next**.
11. Review the summary panel, and click **Finish** when you are satisfied with the configuration settings. When you click Finish, all of the configuration changes will be automatically saved. To revert to an older version of the resource adapter you must perform the update process again, and specify the older version of the RAR file.

## What to do next

If you are not satisfied with the results, and you backed up your configuration with backupConfig tool, use the restoreConfig tool to restore your backup configuration. Read the topic on the restoreConfig command for more information on how to use this command.

## J2EE connector security

The Java 2 Platform, Enterprise Edition (J2EE) connector architecture defines a standard architecture for connecting J2EE to heterogeneous enterprise information systems (EIS). Examples of EIS include Enterprise Resource Planning (ERP), mainframe transaction processing (TP) and database systems.

The connector architecture enables an EIS vendor to provide a standard resource adapter for its EIS. A resource adapter is a system-level software driver that is used by a Java application to connect to an EIS. The resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application. Accessing information in EIS typically requires access control to prevent unauthorized accesses. J2EE applications must authenticate to the EIS to open a connection.

The J2EE connector security architecture is designed to extend the end-to-end security model for J2EE-based applications to include integration with EIS environments. An application server and an EIS collaborate to ensure the correct authentication of a resource principal, which establishes a connection to an underlying EIS. The connector architecture identifies the following mechanisms as the commonly supported authentication mechanisms, although other mechanisms can be defined:

- **BasicPassword:** Basic user-password-based authentication mechanism that is specific to an EIS

Applications define whether to use application-managed sign-on or container-managed sign-on in the resource-ref elements in the deployment descriptor. Each resource-ref element describes a single connection factory reference binding. The res-auth element in a resource-ref element, whose value is either `Application` or `Container`, indicates whether the enterprise bean code can perform sign-on or whether application server can sign-on to the resource manager using the principal mapping configuration. The resource-ref element is typically defined at application assembly time with an assembly tool. The resource-ref can also be defined, or redefined, at deployment time.

## Application managed sign-on

To access an EIS system, applications locate a connection factory from the Java Naming and Directory Interface (JNDI) namespace and invoke the getConnection method on that connection factory object. The getConnection method might require a user ID and password argument. A J2EE application can pass in a user ID and password to the getConnection method, which subsequently passes the information to the resource adapter. Specifying a user ID and password in the application code might compromise some security, however.

The user ID and password, if coded into the Java source code, are available to developers and testers in the organization. Also, the user ID and password are visible to users if they decompile the Java class.

The user ID and password cannot be changed without first requiring a code change. Alternatively, application code might retrieve sets of user IDs and passwords from persistent storage or from an external service. This approach requires that IT administrators configure and manage a user ID and password using the application-specific mechanism.

To access this authentication data, the application server supports a component-managed authentication alias to be specified on a resource. This authentication data is common to all references to the resource. Click **Resources > Resource Adapters > J2C connection factories > configuration\_name** . Select **Use component-managed authentication alias**.

When `res-auth=Application`, the authentication data is taken from the following elements, in order:

1. The user ID and password that are passed to the `getConnection` method
2. The component-managed authentication alias in the connection factory or the data source
3. The custom properties user name and password in the data source

The user name and password properties can be initially defined in the resource adapter archive (RAR) file.

These properties can also be defined in the administrative console or using `wsadmin` scripting from custom properties.

## Container-managed sign-on

The user ID and password for the target enterprise information systems (EIS) can be supplied by the application server. The product provides container-managed sign-on functionality. The application server locates the proper authentication data for the target EIS to enable the client to establish a connection. Application code does not have to provide a user ID and password in the `getConnection` call when it is configured to use container-managed sign-on, and authentication data does not have to be common to all references to a resource. The uses a Java Authentication and Authorization Service (JAAS) pluggable authentication mechanism to use a pre-configured JAAS login configuration, and `LoginModule` to map a client security identity and credentials on the running thread to a pre-configured user ID and password.

The product supports a default many-to-one credential mapping `LoginModule` module that maps any client identity on the running thread to a preconfigured user ID and password for a specified target EIS. The default mapping module is a special purpose JAAS `LoginModule` module that returns a `PasswordCredential` credential that is specified by the configured Java 2 connector (J2C) authentication data entry. The default mapping `LoginModule` module performs a table lookup, but does not perform actual authentication. The user ID and password are stored together with an alias in the J2C authentication data list.

The J2C authentication data list is located on the Global security panel from **Java Authentication and Authorization Service > J2C Authentication data**. The default principal and credential mapping function is defined by the `DefaultPrincipalMapping` application JAAS login configuration.

J2C authentication data that is modified using the administrative console takes effect when the modification is saved into the repository, and Test Connection is performed. Also, J2C authentication data that is modified using `wsadmin` scripting takes effect when any application is started or restarted for a given the application server server process. J2C authentication data modification takes effect by invoking the `SecurityAdmin` MBean method, `updateAuthDataCfg`. Set the `HashMap` parameter to null to enable the `Securityadmin` MBean to refresh the J2C authentication data using the latest values in the repository.

Do not modify the `DefaultPrincipalMapping` login configuration because the product includes performance enhancements to this frequently used default mapping configuration. The product does not support modifying the `DefaultPrincipalMapping` configuration, changing the default `LoginModule` module, or stacking a custom `LoginModule` module in the configuration.

On the z/OS platform, if a user ID and password are not present or defaulted by an alias, the WebSphere Application Server runtime searches for a System Authorization Facility (SAF) user ID in the subject.

For most systems, the default method with a many-to-one mapping is sufficient. However, the product does support custom principal and credential mapping configurations. Custom mapping modules can be added to the application logins JAAS configuration by creating a new JAAS login configuration with a unique name. For example, a custom mapping module can provide one-to-one mapping or Kerberos functionality.

Trusted connections also provide a one-to-one mapping while supporting client identity propagation. In addition by utilizing the DB2 trusted context object, trusted connections can take advantage of connection pooling to reduce the performance penalty of closing and reopening connections with a different identity. Using trusted connections also enhances the security of your DB2 database by eliminating the need to assign all privileges to a single user. The connection is established by a user whose credentials are trusted by the DB2 server to open the connection and the same user is also then trusted to assert the identity of the other users accessing the DB2 server from the application. A new mapping configuration called `TrustedConnectionMapping` has been created to implement trusted connections.

You also can use the WebSphere Application Server administrative console to bind the resource manager connection factory references to one of the configured resource factories. If the value of the `res-auth` element is `Container` within the deployment descriptor for your application, you must specify the mapping configuration. To specify the mapping configuration, use the **Resource references** link under References on the **Applications > Application Types > WebSphere enterprise applications > *application\_name*** panel. See Mapping resource references to references for additional directions.

## J2C mapping modules and mapping properties

Mapping modules are special JAAS login modules that provide principal and credential mapping functionality. You can define and configure custom mapping modules using the administrative console.

You also can define and pass context data to mapping modules by using login options in each JAAS login configuration. In the product, you also can define context data using mapping properties on each connection factory reference binding.

Login options that are defined for each JAAS login configuration are shared among all resources that use the same JAAS login configuration and mapping modules. Mapping properties that are defined for each connection factory reference binding are used exclusively by that resource reference.

Consider a usage scenario where an external mapping service is used.

For example, you might use the Tivoli Access Manager global sign-on (GSO) service. Use the Tivoli Access Manager GSO to locate authentication data for both backend servers.

You have two EIS servers: DB2 and MQ. The authentication data for DB2 is different from that for MQ, however. Use the login option in a mapping JAAS login configuration to specify the parameters that are required to establish a connection to the Tivoli Access Manager GSO service. Use the mapping properties in a connection factory reference binding to specify which EIS server requires the user ID and password.

For more detailed information about developing a mapping module, see the J2C principal mapping modules article.

### Note:

- The mapping configuration at the connection factory has moved to the resource manager connection factory reference. The mapping login modules that are developed using WebSphere Application Server Version 5 JAAS callback types can be used by the resource manager connection factory reference, but the mapping login modules cannot take advantage of the custom mapping properties feature.
- Connection factory reference binding supports mapping properties, and passes those properties to mapping login modules by way of a new `WSMappingPropertiesCallback` callback. In addition, the `WSMappingPropertiesCallback` callback and the new `WSManagedConnectionFactoryCallback` callback are defined in the `com.ibm.wsspi` package. Use the new mapping login modules with the new callback types.

## Mapping resource references to references

You can use the administrative console to bind the resource manager connection factory references to one of the configured resource factories.

### About this task

If the value of the res-auth element is Container within the deployment descriptor for your application, then you must specify the mapping configuration.

1. Click **Applications** > **Enterprise applications** > *application\_name*.
2. From Additional Properties, select **Resource references**.
3. Select the application module and specify an authentication method for the selected connection factory reference binding. Select either **Use default method**, **Use custom login configuration** or **Use trusted connections**. If you select the **Use default method** option, the DefaultPrincipalMapping login configuration is selected. If you select the **Use trusted connections** option, then the TrustedConnectionMapping login configuration is selected. You must select an authentication data alias from the list.
4. After you make a selection, click **Apply** for the configuration to take effect.
5. If you select the **Use trusted connection option**, then you must select an authentication data alias from the menu list. The alias that is specified is what the application server uses to get the initial trusted connection.
6. Click **Apply**. The selected login configuration name and an **Mapping properties** button is displayed in the Login configuration field of the particular connection factory reference binding.
7. Click **Mapping properties** > **New** to specify the properties for your configuration. Click **OK** after specifying the properties on the Mapping properties panel.
8. If you select the **Use trusted connection** option, then you must select an authentication data alias from the menu list.
9. Click **Apply**. The **Mapping properties** button is displayed in the login configuration field of the particular connection factory reference binding.
10. Click **Mapping properties** to modify the properties of the trusted connection. Read about “Setting the security properties for trusted connections” on page 1589 for information on tuning the mapping properties for the trusted connection.
11. Click **OK** and **Save** on the Resource references panel to save your changes to the master configuration.

## Managing messages with message endpoints

Manage message delivery for message-driven beans (MDB) that are deployed as message endpoints. The message endpoints are managed beans (MBeans) for inbound resource adapters that are compliant with Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5.

### About this task

The application server provides message endpoint MBeans to assist you in managing the delivery of a message to your message-driven beans that are acting as listeners on specific endpoints, which are destinations, and in managing the enterprise information system (EIS) resources that are utilized by these message-driven beans. Message-driven beans that are deployed as message endpoints are not the same as message-driven beans that are configured against a listener port. Message-driven beans that are used as message endpoints must be deployed using an ActivationSpecification that is defined within a resource adapter configuration for JCA Version 1.5.

With message endpoint MBeans, you can activate and deactivate specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy EIS resources. This capability allows you to optimize the performance of your JMS

applications in situations where an EIS resource is not behaving as expected. Message delivery to an endpoint typically fails when the message driven bean that is listening invokes an operation against a resource that is not healthy. For example, a messaging provider, which is an inbound resource adapter that is JCA Version 1.5 compliant, might fail to deliver messages to an endpoint when its underlying message-driven bean attempts to commit transactions against a database server that is not responding.

**Note:** Design your message-driven beans to delegate business processing to other enterprise beans. Do not access the EIS resources directly in the message-driven bean, but do so indirectly through a delegate bean.

Message endpoint MBeans alleviate two problems that are inherent to applications that provide message endpoints that access resources:

- Failed messages require additional processing, such as delivering them to the listening endpoint again or redirecting them to alternate destinations that process failed messages. In addition, a resource adapter might redeliver a message to an endpoint an infinite number of times.
- Message redirection requires the implementation of specialized destinations (queues and listeners) to process failed messages, as well as the logic to detect message failures. Message redirection is potentially error prone and computationally expensive due to its complexity.

The capability to deactivate (pause) and reactivate (resume) a specific message endpoint alleviates these problems by enabling the administrator to deactivate the endpoint from processing messages that are destined to fail. When the message endpoint is deactivated, you can repair the resource that is causing the problems and reactivate the endpoint to resume handling message requests. In the course of troubleshooting, you will not affect the resource adapter or the application that is hosting the endpoint.

1. Using the administrative console, navigate to the Message Endpoints panel for the application that is hosting the message endpoint.
  - a. Select the **Applications** → **Application Types** → **Websphere enterprise applications** → **application\_name**.
  - b. Select the **Runtime** panel.
  - c. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.
2. Optional: Temporarily disable a message endpoint from handling messages and troubleshoot the problem.
  - a. Deactivate the message endpoint by selecting the appropriate endpoint and clicking **Pause**.
  - b. When the message endpoint is inactive, diagnose and repair the underlying cause of the delivery failures.
  - c. Reactivate the message endpoint by selecting the appropriate endpoint and clicking **Resume**.

## Results

The behavior you will observe when you deactivate (pause) a message endpoint using the message endpoint MBean is dependent upon a variety of factors, including the resource adapter that manages the message endpoint, the configuration of the message endpoint and the application server topology. Some specific examples of interest are as follows:

- **MDB listening on a non-durable topic (dependent on configuration):** The behavior that is implied by the deactivation (pause) of a message endpoint is often dependent upon the function that it is fulfilling. For example, if you have configured a message-driven bean to listen on a non-durable topic on the service integration bus, deactivating the message endpoint is analogous to stopping the application and will cause the subscription to be closed. This means that any messages that are published during the time that the message endpoint is paused will not be received by the message-driven bean.
- **Clustered message-driven bean (dependent on topology):** In this scenario a message-driven bean application has been deployed to a cluster of servers. A given message endpoint MBean controls only the behavior of the MDB in one server from the cluster, so will cause only one server to stop processing

messages. Depending upon the messaging configuration and the specific resource adapter in use the messages that would have been consumed by the paused message endpoint may be consumed by the active message endpoints in the cluster, or they may remain unconsumed until the paused message endpoint is resumed.

- **Clustered message-driven bean, a non-clustered queue:** In this scenario, you have a cluster of servers with the same message-driven bean deployed to them. This is similar to the case, in which you have different message-driven beans with the same message selection criteria, except that in this case the message-driven beans are logically the same message-driven bean. Pausing the endpoint will cause only one of the servers to stop receiving messages, and the other message-driven beans will receive all the messages; none of the messages will be orphaned. To stop all of the endpoints, you must direct each server in the cluster to stop the local message endpoint.
- **Clustered message-driven bean, clustered queue:** In this scenario, each message-driven bean is pulling messages from a different partition of the queue. Messaging through WebSphere MQ and the Service Integration Bus have similar, but different, capabilities. If you are using WebSphere MQ, then pausing one endpoint will not allow the other instances of the message-driven bean to receive the messages. In the Service Integration Bus, messages from a paused endpoint will be redirected to the other message-driven beans.

### Related tasks

“Managing the message endpoint lifecycle using scripting” on page 1437

Use the Jython scripting language to manage your message endpoints with the wsadmin tool. Use this topic to query your configuration for message endpoint properties, and to deactivate or reactivate a message endpoint.

### Manage message endpoints

Use this panel to manage situations where messaging providers fail to deliver messages to their intended destinations. For example, a provider might fail to deliver messages to a message endpoint when its underlying message driven bean attempts to commit transactions against a database server that is not responding.

To view this administrative console panel:

1. Select the **Applications** → **Application Types** → **WebSphere enterprise applications** → *application\_name*.
2. Select the **Runtime** panel. You will only see the Runtime panel if you have an application installed that is hosting message-driven beans.
3. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.

#### **Name:**

Specifies the name of the message endpoint.

Click the name of the message endpoint to view the configuration binding for the underlying endpoint message-driven bean and Activation Specification.

#### **Running object scope:**

Specifies the server where the endpoint is running.

For more information on scope, see Administrative console scope settings.

#### **Status:**

Indicates whether the message endpoint is active or inactive.

Click **Pause** to deactivate a message endpoint and stop it from handling messages.

Click **Resume** to reactivate a message endpoint that is inactive.

## Configuring a JDBC provider and data source

For access to relational databases, applications use the JDBC drivers and data sources that you configure for the application server.

### Before you begin

Each vendor database requires different JDBC driver implementation classes for JDBC connectivity. A JDBC provider encapsulates those vendor-specific driver files. Through the data source that you associate with the JDBC provider, an application server obtains and manages the physical connections for transactions between applications and the database.

**Note:** If you are accessing a DB2 database, Data Studio pureQuery is an alternative to JDBC. For more information on pureQuery, see the topic "Task overview: Data Studio pureQuery" in the related links section.

Determine the version of data source that you need according to the API specification of your applications.

- *Data sources (WebSphere Application Server Version 4)* are for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification.
- Data sources of the latest standard version are for use with applications that implement the more advanced releases of these specifications.

**Note:** If you connect to DB2 for z/OS through the JDBC Universal JDBC Driver, follow the steps that are outlined in "Using the DB2 Universal JDBC Driver to access DB2 for z/OS" on page 1575. This article gives detailed instruction on installing the JDBC driver and related files, plus activating required JDBC properties.

1. Verify that all of the necessary JDBC driver files are installed on your node manager. Consult the article "Data source minimum required settings, by vendor" on page 1510 for that information. If you opt to configure a user-defined JDBC provider, check your database documentation for information about the driver files.

2. Create a JDBC provider.

From the administrative console, see [Creating a JDBC provider using the administrative console](#).

**OR**

Using the wsadmin scripting client, see ["Configuring a JDBC provider using scripting"](#) on page 1414.

**OR**

Using the Java Management Extensions (JMX) API, see [Creating a JDBC provider and data source using the Java Management Extensions API](#).

3. Create a data source.

From the administrative console, see [Creating a data source using the administrative console](#).

**OR**

Using the wsadmin scripting client, see ["Configuring new data sources using scripting"](#) on page 1415. (For V4 data sources, see ["Configuring new WAS40 data sources using scripting"](#) on page 1426.)

**OR**

Using the JMX API, see [Creating a JDBC provider and data source using the Java Management Extensions API](#).

**Note:** Different database vendors require different properties for implementations of their JDBC drivers. Set these properties on the WebSphere Application Server data source. Because Application Server contains templates for many vendor JDBC implementations, the administrative console surfaces the required properties and prompts you for them as you create

a data source. However, if you script your data access configurations, you must consult the article “Data source minimum required settings, by vendor” for the required properties and settings options.

4. **Optional: Configure custom properties.** Like the required properties, custom properties for specific vendor JDBC drivers must be set on the Application Server data source. Consult your database documentation for information about available custom properties. To configure a custom class to facilitate the handling of database properties that are not recognized natively by the Application Server, refer to “Developing a custom DataStoreHelper class” on page 1606  
You can also learn about optional data source properties in the Application Programming Guide and Reference for Java for your version of DB2 for z/OS if you use the DB2 Universal JDBC Driver provider.
5. **Bind resource references to the data source.** See the article Data source lookups for enterprise beans and Web modules .
6. **Test the connection (for non-container-managed persistence usage).** See the “Test connection service” on page 1608 article.

## Results

If you use the DB2 JDBC Universal Driver, you might experience data source failures that the application server JVM log does not document. Check the DB2 database log or the WebSphere Application Server JDBC trace log (if JDBC trace was active). You might find that a bad authentication credential is the cause of failure. Currently the DB2 JDBC Universal Driver does not identify or surface the errors that are produced by non-valid authentication credentials in a proper or consistent way.

Even if you receive information about a bad credential, check the database and JDBC trace logs. These logs provide more reliable, detailed error data on authentication failures.

**Note:** The JDBC trace log exists only if the JDBC trace service is active during server start up. Activate the service in the administrative console. For more information, see Enabling trace at server startup. Specify **WAS.database** as the trace group and select **com.ibm.ws.db2.logwriter** as the trace string.

## Data source minimum required settings, by vendor

These properties vary according to the database vendor requirements for Java Database Connectivity (JDBC) driver implementations. You must set the appropriate properties on every data source that you configure.

Use these tables for quick reference on the JDBC providers that represent your JDBC driver classes. Each table corresponds to a specific database vendor, product, and platform.

Following the tables are links to detailed requirements for creating data sources that correspond to each JDBC provider that the application server supports . The list includes information about connection properties that are required by the database and any optional properties that the JDBC driver supports. Use the administrative console or the wsadmin scripting tool to define these properties on your data sources.

Apache Derby		
JDBC provider	Transaction support	Version and other considerations
Derby JDBC Provider	One-phase	<ul style="list-style-type: none"> <li>Does not support Version 4 data sources</li> <li>Configurable only in nodes at version 6.0.2 and later</li> <li>Not for use in clustered environment: accessible from a single JVM only</li> </ul>
Derby JDBC Provider (XA)	One and two-phase	<ul style="list-style-type: none"> <li>Does not support Version 4 data sources</li> <li>Configurable only in nodes at version 6.0.2 and later</li> <li>Not for use in clustered environment: accessible from a single JVM only</li> </ul>
Derby JDBC Provider 40	One-phase	<ul style="list-style-type: none"> <li>Configurable only in nodes at version 7.0 and later</li> <li>Does not support Version 4 data sources</li> </ul>
Derby JDBC Provider 40 (XA)	One and two-phase	<ul style="list-style-type: none"> <li>Configurable only in nodes at version 7.0 and later</li> <li>Does not support Version 4 data sources</li> </ul>
Derby Network Server using Derby Client	One-phase	<ul style="list-style-type: none"> <li>Does not support Version 4.0 data sources.</li> <li>Configurable only in nodes at version 6.1 and later</li> <li><i>Can be used in clustered environment: a database instance can be accessed by multiple JVMs</i></li> <li>Only for use with Apache Derby databases that run on the same node as the application server</li> </ul>
Derby Network Server using Derby Client (XA)	One and two-phase	<ul style="list-style-type: none"> <li>Does not support Version 4 data sources</li> <li>Configurable only in nodes at version 6.1 and later</li> <li><i>Can be used in clustered environment: a database instance can be accessed by multiple JVMs</i></li> <li>Only for use with Apache Derby databases that run on the same node as the application server</li> </ul>

## Detailed requirements

The following list identifies required class files and connection properties per JDBC provider.

After you determine the JDBC provider that suits your application and environment, ensure that you acquire the corresponding JDBC driver at a release level supported by this version of the application server. Consult the IBM support website for supported hardware and software.

Use the following links to navigate to the requirements list. Each link corresponds to a specific database vendor, product, and platform.

- Apache Derby or Cloudscape 10.x
- DB2 on z/OS, connecting to the application server on z/OS
- DB2 UDB for iSeries®, connecting to the application server on z/OS
- Informix
- Microsoft SQL Server
- Oracle
- Sybase

### ***Data source minimum required settings for Apache Derby:***

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Apache Derby and Cloudscape data sources.

You can configure the following types of providers:

- Derby JDBC Provider
- Derby JDBC Provider (XA)
- Derby JDBC Provider 40
- Derby JDBC Provider 40 (XA)
- Derby Network Server using Derby Client
- Derby Network Server using Derby Client (XA)
- Derby Network Server using Derby Client 40
- Derby Network Server using Derby Client 40 (XA)
- **Derby JDBC Provider**

The Derby JDBC driver provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server. You cannot use any Version 4.0 data sources with this provider.

This provider:

- Is configurable only in nodes at version 6.0.2 and later
- Supports one phase data source with the following class:  
`org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource`
- Requires the JDBC driver file:  
  - derby.jar

The full path name is `${DERBY_JDBC_DRIVER_PATH}/derby.jar`. When you create a connection through the application server, the environment variables are set automatically.

- Requires the following `DataStoreHelper` class:  
`com.ibm.websphere.rsadapter.DerbyDataStoreHelper`

- Requires the following properties:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of `app_server_root/derby` or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

- **Derby JDBC Provider (XA)**

The Derby JDBC driver (XA) provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

This provider:

- Does not support use Version 4.0 data sources.
- Is configurable only in nodes at version 6.0.2 and later
- Supports the two-phase data source with the following class:

```
org.apache.derby.jdbc.EmbeddedXADataSource
```

- Requires JDBC driver file:

- derby.jar

The full path name is `${DERBY_JDBC_DRIVER_PATH}/derby.jar`. When you create a connection through the application server, the environment variables are set automatically.

- Requires the following `DataStoreHelper` class:  
`com.ibm.websphere.rsadapter.DerbyDataStoreHelper`

- Does not require a valid authentication alias.

- Requires the following properties:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of `app_server_root/derby` or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

- **Derby JDBC Provider 40**

The Derby JDBC Provider 40 provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

This provider:

- Is configurable only in nodes at version 7.0 and later.
- Does not support Version 4.0 data sources.
- Supports one phase data source with the following class:

```
org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40
```

- Requires the JDBC driver file:

- derby.jar

The full path name is `${DERBY_JDBC_DRIVER_PATH}/derby.jar`. When you create a connection through the application server, the environment variables are set automatically.

- Requires the following `DataStoreHelper` class:  
`com.ibm.websphere.rsadapter.DerbyDataStoreHelper`

- Requires the following properties:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of `app_server_root/derby` or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

- **Derby JDBC Provider 40 (XA)**

The Derby JDBC Provider 40 (XA) provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

This provider:

- Is configurable only in nodes at version 7.0 and later.
- Does not support Version 4.0 data sources.
- Supports one phase data source with the following class:

```
org.apache.derby.jdbc.EmbeddedXADataSource40
```

- Requires the JDBC driver file:

- `derby.jar`

The full path name is `${DERBY_JDBC_DRIVER_PATH}/derby.jar`. When you create a connection through the application server, the environment variables are set automatically.

- Requires the following `DataStoreHelper` class:  
`com.ibm.websphere.rsadapter.DerbyDataStoreHelper`

- Requires the following properties:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of `app_server_root/derby` or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

- **Derby Network Server using Derby Client**

Use this provider to access only Apache Derby databases that run on the same node as the application server.

This provider:

- Does not support Version 4.0 data sources.
- Is configurable only in nodes at version 6.1 and later
- Uses the following one phase data source for the Derby Network Server using Derby Client provider:

```
org.apache.derby.jdbc.ClientConnectionPoolDataSource
```

- Requires the following JDBC driver file:

- `derbyclient.jar`

- Requires `DataStoreHelper` class:

com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper

- Requires the following property:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app\_server\_root/derby* or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

`c:\temp\sampleDB;create=true`

- **Derby Network Server using Derby Client (XA)**

Use this provider to access only Apache Derby databases that run on the same node as the application server.

This provider:

- Does not support Version 4.0 data sources.
- Is configurable only in nodes at version 6.1 and later
- Uses the following XA data source for this Derby Network Server using Derby Client provider:

`org.apache.derby.jdbc.ClientXADataSource`

- Requires the following JDBC driver file:

- `derbyclient.jar`

- Requires the DataStoreHelper class:

`com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`

- Requires the following property:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app\_server\_root/derby* or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

`c:\temp\sampleDB;create=true`

- **Derby Network Server using Derby Client 40**

Use this provider to access only Apache Derby databases that run on the same node as the application server.

This provider:

- Is configurable only in nodes at version 7.0 and later
- Does not support Version 4.0 data sources.
- Uses the following one phase data source for the Derby Network Server using Derby Client provider:

`org.apache.derby.jdbc.ClientConnectionPoolDataSource40`

- Requires the following JDBC driver file:

- `derbyclient.jar`

- Requires DataStoreHelper class:

`com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`

- Requires the following property:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of

*app\_server\_root/derby* or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

- **Derby Network Server using Derby Client 40 (XA)**

Use this provider to access only Apache Derby databases that run on the same node as the application server.

This provider:

- Is configurable only in nodes at version 7.0 and later
- Does not support Version 4.0 data sources.
- Uses the following one phase data source for the Derby Network Server using Derby Client provider:  
`org.apache.derby.jdbc.ClientXADataSource40`
- Requires the following JDBC driver file:
  - `derbyclient.jar`
- Requires `DataStoreHelper` class:  
`com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`
- Requires the following property:

**databaseName**

The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app\_server\_root/derby* or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

If no database exists for the path name that you want to specify, append `;create=true` to the path name to create a database dynamically. For example:

```
c:\temp\sampleDB;create=true
```

### Related tasks

“Configuring a JDBC provider and data source” on page 1509

For access to relational databases, applications use the JDBC drivers and data sources that you configure for the application server.

“Configuring a JDBC provider using the administrative console” on page 1536

To create connections between an application and a relational database, the application server uses the driver implementation classes that are encapsulated by the JDBC provider.

“Configuring a data source using the administrative console” on page 1543

Application components use a data source to access connection instances to a relational database.

“Creating and configuring a JDBC provider and data source using the Java Management Extensions API” on page 1564

If your application requires access to a JDBC connection pool from a Java 2 Platform, Enterprise Edition (J2EE) 1.3 or 1.4, or Java Platform Enterprise Edition (Java EE) level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively.

***Data source minimum required settings for DB2 on z/OS, connecting to the application server on z/OS:***

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for a DB2 data source that is running on z/OS and connecting to an application server that is also running on z/OS.

You can configure the following types of providers:

- DB2 Using IBM JCC Driver
- DB2 Using IBM JCC Driver (XA)
- DB2 Universal JDBC Provider
- DB2 Universal JDBC Provider (XA)
- **DB2 Using IBM JCC Driver**

This provider is a one-phase commit JCC provider for DB2 that uses the IBM Data Server Driver for JDBC and SQLJ. The DB2 Using IBM JCC Driver is the next generation of the DB2 Universal JCC driver. Data sources you create under this provider support only 1-phase commit processing, unless you use the type 2 JDBC driver with the application server for z/OS. If you run the application server on z/OS with the type 2 driver, the driver uses RRS and supports 2-phase commit processing.

This provider:

- Is configurable in version 7.0 and later nodes
- Supports the following one-phase data source:  
`com.ibm.db2.jcc.DB2ConnectionPoolDataSource`
- Requires the following JDBC driver files:
  - `db2jcc4.jar` - After you install DB2, you can find this .jar file in the DB2 java directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must also set the `UNIVERSAL_JDBC_DRIVER_PATH` path variable to point to the `db2jcc4.jar` file.
  - `db2jcc_license_cu.jar` - This is the DB2 Universal JDBC driver license file that allows access to the DB2 Universal database. Use this .jar file or the next one to gain access to the database. This .jar file ships with the application server in a directory that is defined by the `${UNIVERSAL_JDBC_DRIVER_PATH}` environment variable.
  - `db2jcc_license_cisuz.jar` - This is the DB2 Universal JDBC driver license file that allows access to the following databases:
    - DB2 Universal
    - DB2 for iSeries
    - DB2 for z/OS
    - SQLDSThe `db2jcc_license_cisuz.jar` does not ship with the application server. Place this file in the same directory as the `db2jcc4.jar` file, so that the `UNIVERSAL_JDBC_DRIVER_PATH` points to both files.
- Uses the following class path:  
`${DB2_JCC_DRIVER_PATH}/db2jcc4.jar`  
`${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar`  
`${DB2_JCC_DRIVER_PATH}/db2jcc_license_cisuz.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`
- Requires a valid authentication alias.
- Requires properties:
  - **databaseName** - This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.

- **driverType** - The JDBC connectivity type of a data source. There are two permitted values: 2 and 4. If you want to use Universal JDBC Driver type 2, set this value to 2. If you want to use Universal JDBC Driver type 4, set this value to 4.
- **serverName** - The TCP/IP address or host name for the Distributed Relational Database Architecture™ (DRDA®) server. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.
- **portNumber** - The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.
- **useTransactionRedirect** Configure this property as a data source custom property if your backend uses the Database Partitioning Feature (DPF) of DB2 UDB Version 8.2, fix pack 10, and your partitioning key remains constant throughout a transaction. Activating the property affects how the DB2 Universal JDBC Driver directs each connection request that begins a transaction with DB2. The JDBC driver is triggered to send those connection requests to the DPF node that contains the target data of the first directable statement in the transaction, if such a statement exists. DB2 then directs the SQL statement to different partitions as needed; the transaction proceeds normally from the viewpoint of the application server.

You can use **useTransactionRedirect** for both **driverType 2** and **driverType 4** data sources. To configure the property, use either the wsadmin scripting tool or the administrative console page. Assign the property the value of true. For more information on using the scripting tool or the administrative console for this task, see either the Configuring new data source custom properties using scripting or Java EE resource provider or connection factory custom properties collection chapters in the *Administering applications and their environment* PDF book.

- **DB2 Using IBM JCC Driver (XA)**

The DB2 Using IBM JCC Driver (XA) is a two-phase commit JCC provider for DB2 that uses the IBM Data Server Driver for JDBC and SQLJ. The IBM Data Server Driver is the next generation of the DB2 Universal JCC driver. Data sources that you create under this provider support the use of XA to perform two-phase commit processing.

**Note:** Do not use the type 2 JDBC driver on the application server for z/OS.

This provider:

- Is configurable in version 7.0 and later nodes.
- Supports the following two-phase data source:
  - com.ibm.db2.jcc.DB2XADataSource
- Requires the following JDBC driver files:
  - db2jcc4.jar - This is the DB2 Universal JDBC Driver .jar file. After you install DB2, you can find this .jar file in the DB2 Java directory. For Type 4 JDBC driver support from a client machine where DB2 is not installed, copy this file to the local machine. If you install any fixes or upgrades to DB2, you must update this file as well. You must also specify the fully qualified path of db2jcc4.jar as the value of the *UNIVERSAL\_JDBC\_DRIVER\_PATH* environment variable.
  - db2jcc\_license\_cu.jar - This is the DB2 Universal JDBC Driver license file that allows access to the DB2 Universal database. Use this .jar file or the next one to gain access to the database. This .jar file ships with the application server in the *app\_server\_root/universalDriver/lib* directory.
  - db2jcc\_license\_cisuz.jar - This is the DB2 Universal JDBC Driver license file that allows access to the following databases:
    - DB2 Universal
    - DB2 for iSeries
    - DB2 for z/OS
    - SQLDS

You must use the right license .jar file to access a specific database backend.

- The native files required by the DB2 Universal JDBC Driver in the application server.

- Uses the following class path:

```

${DB2_JCC_DRIVER_PATH}/db2jcc4.jar
${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar
${DB2_JCC_DRIVER_PATH}/db2jcc_license_cisuz.jar
${DB2_JCC_DRIVER_NATIVEPATH}

```

- Requires the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
```

- Requires a valid authentication alias.

- Requires the following properties:

- **databaseName** - This is an actual database name if the **driverType** is set to **4**, or a locally cataloged database name if the **driverType** is set to **2**.
- **driverType** - The JDBC connectivity type of a data source. There are two permitted values: 2 and 4. If you want to use Universal JDBC Driver type 2 XA, set this value to 2. If you want to use Universal JDBC Driver type 4 XA (which requires DB2 8.1 Fix Pack 7 or higher), set this value to 4.
- **serverName** - The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **portNumber** - The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
- **useTransactionRedirect** Configure this property as a data source custom property if your backend uses the Database Partitioning Feature (DPF) of DB2 UDB Version 8.2, fix pack 10, and your partitioning key remains constant throughout a transaction. Activating the property affects how the DB2 Universal JDBC Driver directs each connection request that begins a transaction with DB2. The JDBC driver is triggered to send those connection requests to the DPF node that contains the target data of the first directable statement in the transaction, if such a statement exists. DB2 then directs the SQL statement to different partitions as needed; the transaction proceeds normally from the viewpoint of the application server.

You can use **useTransactionRedirect** for both **driverType 2** and **driverType 4** data sources. To configure the property, use either the wsadmin scripting tool or the administrative console page “Java EE resource provider or connection factory custom properties collection” on page 1560. Assign the property the value of true.

- **DB2 Universal JDBC Driver provider**

The DB2 Universal JDBC Driver is an architecture-neutral JDBC driver for distributed and local DB2 access. Because the DB2 Universal Driver architecture is independent of any particular JDBC driver connectivity or target platform, it allows both Java connectivity (Type 4) or Java Native Interface (JNI) based connectivity (Type 2) in a single driver instance to DB2. The DB2 Universal JDBC Driver provider supports both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases, as well as SQLJ use with CMP.

**Note:** To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for the application server for z/OS. Refer to “Using the DB2 Universal JDBC Driver to access DB2 for z/OS” on page 1575.

This provider:

- Supports the following data source:

```
com.ibm.db2.jcc.DB2ConnectionPoolDataSource
```

This data source can support two-phase transactions (for the application server on the z/OS platform only). If you set the DB2 Universal JDBC Driver for type 2 connectivity, the application server running on z/OS uses RRS to process transactions, including two-phase commit transactions. When used with driver type 4 connectivity, this data source implementation supports one-phase transactions only.

- Requires JDBC driver files:
  - db2jcc.jar - This is the DB2 Universal JDBC Driver .jar file, which is located in the DB2 installation directory. Specify the fully-qualified path of this .jar file for the value of your variable `DB2UNIVERSAL_JDBC_DRIVER_PATH`.
  - db2jcc\_license\_cisuz.jar - This DB2 Universal JDBC Driver license file is included with DB2. The installation program for DB2 places the license file in the same DB2 directory as db2jcc.jar. Therefore your variable `DB2UNIVERSAL_JDBC_DRIVER_PATH` ultimately points to both files.

**Note:** The driver file db2jcc\_license\_cu.jar ships with the application server in the `app_server_root/universalDriver/lib` directory. It is automatically set to the `UNIVERSAL_JDBC_DRIVER_PATH` variable. Although this driver file does not provide access to DB2 for z/OS, you can leave it as part of the variable definition.

- The native files of .so type are required by the DB2 Universal JDBC Driver in the application server for z/OS. Set the library path variable `DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH` to the directory that contains the native files. In cases that do not require native files, set the `DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH` to null.

- Uses the following class path:

```

${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar
${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar
${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cisuz.jar
${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}

```

- Requires the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper
```

- Requires a valid authentication alias if the `driverType` property (see properties below) is set to 4. If the `driverType` property is set to 2, you must specify a component-managed authentication alias to use the data source with res-auth APPLICATION.

In the case where `driverType 2` is specified and the data source is used with res-auth CONTAINER, you can specify a container-managed authentication alias; however, it is not required. If you do not specify a container-managed alias, the user identity associated with a connection created by the data source will be the user identity associated with the current thread at the time the connection is obtained.

- Requires the following properties:

- **databaseName** - This is an actual database name if the **driverType** is set to 4, or a locally cataloged database name if the **driverType** is set to 2.
- **driverType** - The JDBC connectivity type of a data source. There are two permitted values: 2 and 4. If you want to use Universal JDBC Driver type 2, set this value to 2. If you want to use Universal JDBC Driver type 4, set this value to 4.
- **serverName** - The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.
- **portNumber** - The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.

**Note:** DB2 supports additional connection properties for the DB2 Universal JDBC Driver; set them as custom properties on the data source. For information about these optional data source properties, consult the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

- **DB2 Universal JDBC Provider (XA)**

The XA DB2 Universal JDBC provider uses the DB2 Universal JDBC Driver to provide access to DB2 databases. The Universal JDBC Driver supports Java communication-based connectivity (driver Type 4). For XA transactions, driver type 2 connectivity is not supported by the DB2 Universal JDBC Driver on the application server for z/OS.

**Note:** To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for the application server for z/OS, or you must have the z/OS Application Connectivity to DB2 for z/OS feature installed and configured for the application server for z/OS. Refer to the topic “Using the DB2 Universal JDBC Driver to access DB2 for z/OS” on page 1575.

This provider:

- Allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. SQLJ use with CMP is also supported.
- Does not support the creation of Version 4.0 data sources.
- Supports the two phase data source:  
`com.ibm.db2.jcc.DB2XADataSource`
- Requires the following JDBC driver files:
  - `db2jcc.jar` - This is the DB2 Universal JDBC Driver .jar file, which is located in the DB2 installation directory. Specify the fully-qualified path of this .jar file for the value of your WebSphere variable `DB2UNIVERSAL_JDBC_DRIVER_PATH`. The application server uses this value to define the JDBC provider.
  - `db2jcc_license_cisuz.jar` - This DB2 Universal JDBC Driver license file is included with DB2. The installation program for DB2 places the license file in the same DB2 directory as `db2jcc.jar`. Therefore your variable `DB2UNIVERSAL_JDBC_DRIVER_PATH` ultimately points to both files.

**Note:** The driver file `db2jcc_license_cu.jar` ships with the application server in the `app_server_root/universalDriver/lib` directory. It is automatically set to the `UNIVERSAL_JDBC_DRIVER_PATH` variable. Although this driver file does not provide access to DB2 for z/OS, you can leave it as part of the variable definition.

- The native files of .so type are required by the DB2 Universal JDBC Driver in the application server for z/OS. Set the library path variable `DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH` to the directory that contains the native files. In cases that do not require native files, set the `DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH` to null.
- Uses the following class path:  
`${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar`  
`${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar`  
`${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cisuz.jar`  
`${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **databaseName** - This is a locally cataloged database name.
  - **driverType** - This is the JDBC connectivity type of a data source. If you are running a version of DB2 prior to DB2 V8.1 FP6, you are restricted to using only the type 2 driver.
  - **serverName** - The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.
  - **portNumber** - The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to **4**. This property is not required if your **driverType** is set to **2**.

**Note:** DB2 supports additional connection properties for the DB2 Universal JDBC Driver; set them as custom properties on the data source. For information about these optional data source properties, consult the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

To create connections between an application and a relational database, the application server uses the driver implementation classes that are encapsulated by the JDBC provider.

“Configuring a data source using the administrative console” on page 1543

Application components use a data source to access connection instances to a relational database.

“Creating and configuring a JDBC provider and data source using the Java Management Extensions API” on page 1564

If your application requires access to a JDBC connection pool from a Java 2 Platform, Enterprise Edition (J2EE) 1.3 or 1.4, or Java Platform Enterprise Edition (Java EE) level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively.

### **Data source minimum required settings for DB2 Universal Database for iSeries:**

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for a DB2 UDB data source.

What type of configuration do you have?

- “DB2 UDB for iSeries, connecting to the application server on z/OS”

### **DB2 UDB for iSeries, connecting to the application server on z/OS**

If you need to connect to DB2 UDB on iSeries to provide JDBC connectivity for an application run on the application server for z/OS, you can use the iSeries Toolbox driver for Java, the iSeries Toolbox XA-compliant driver for Java, or the DB2 JDBC Universal Driver XA.

You can configure the following types of providers:

- DB2 UDB for iSeries (Toolbox)
- DB2 UDB for iSeries (Toolbox XA)
- DB2 Universal JDBC Driver provider (XA)
- **DB2 UDB for iSeries (Toolbox)**

This JDBC driver, also known as iSeries Toolbox driver for Java, is provided in the DB2 for iSeries database server. Use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

This provider:

- Is for remote DB2 connections on iSeries.
- Supports the following one-phase data source:  
`com.ibm.as400.access.AS400JDBCConnectionPoolDataSource`
- Requires the following JDBC driver files:
  - jt400.jar
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`
- Requires an authentication alias.
- Requires the following properties:
  - **serverName** - The name of the server from which the data source obtains connections. Example:  
`myserver.mydomain.com`.

- **DB2 UDB for iSeries (Toolbox XA)**

This XA compliant JDBC driver, also known as iSeries Toolbox XA-compliant driver for Java, is provided in the DB2 for iSeries database server. Use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

This provider:

- Is for remote DB2 connections on iSeries.
- Supports the following two-phase data source:  
`com.ibm.as400.access.AS400JDBCXADataSource`
- Requires the following JDBC driver files:
  - `jt400.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`
- Requires an authentication alias.
- Requires properties:
  - **serverName** - The name of the server from which the data source obtains connections. Example:  
`myserver.mydomain.com`.

- **DB2 Universal JDBC Driver provider (XA)**

This provider is the XA DB2 Universal JDBC Driver provider that uses the DB2 Universal JDBC Driver to provide access to DB2 databases. The Universal JDBC Driver supports Java communication-based connectivity (driver type 4), which allows distributed access to DB2. If you are running the application server for z/OS and connecting to DB2 UDB for iSeries, you *cannot* use Java Native Interface (JNI) based connectivity (driver type 2) with this provider.

**Note:** To use this provider, you must have the DB2 Universal JDBC Driver for DB2 Version 7 or DB2 Version 8 installed and configured for the application server, or you must have the z/OS Application Connectivity to DB2 for z/OS feature installed and configured for the application server for z/OS. Refer to the topic “Using the DB2 Universal JDBC Driver to access DB2 for z/OS” on page 1575.

This provider:

- Allows applications to use both JDBC and Structured Query Language in Java (SQLJ) access to DB2 databases. SQLJ use with CMP is also supported.
- Does not support the creation of Version 4.0 data sources
- Supports the following two-phase data source:  
`com.ibm.db2.jcc.DB2XADataSource`
- Requires that you specify a name for the data source definition.
- Requires the following JDBC driver files:
  - `db2jcc.jar` - This is the DB2 Universal JDBC Driver jar file. After the DB2 installation, this jar file is located in DB2’s install directory. The fully-qualified path of this jar must be specified as the value of the `DB2UNIVERSAL_JDBC_DRIVER_PATH` environment variable:  
`${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc.jar`
  - `db2jcc_license_cu.jar` - This is the DB2 Universal JDBC Driver license file that allows access to DB2 Universal databases under Cloudscape and workstations. It is not used for the application server for z/OS, but is included to make the provider definition common between the application server for z/OS and other operating systems. The class path is:  
`${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar`
  - `db2jcc_license_cisuz.jar` - This is the DB2 Universal JDBC Driver license file that allows access to DB2 Universal databases under Cloudscape, workstations, and z/OS. After you install DB2, this jar file appears in the same DB2 directory as `db2jcc.jar`. Class path:  
`${DB2UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cisuz.jar`
  - The native files (.so type files) required by the DB2 Universal JDBC Driver in the application server for z/OS. Use the following library path:  
`${DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH}`

(In cases that do not require native files, set the `DB2UNIVERSAL_JDBC_DRIVER_NATIVEPATH` to null.)

- requires **DataStoreHelper** class:  
`com.ibm.websphere.rsadapter.DB2UniversalDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **databaseName** - This is a locally cataloged database name.
  - **driverType** - This is the JDBC connectivity type of a data source. Set this property to type 4 if you are running the application server for z/OS and connecting to DB2 UDB for iSeries.
  - **serverName** - The TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.
  - **portNumber** - The TCP/IP port number where the DRDA server resides. Provide a value for this property only if your **driverType** is set to 4. This property is not required if your **driverType** is set to 2.

### ***Data source minimum required settings for Informix:***

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Informix data sources.

You can configure the following types of providers:

- Informix Using IBM JCC Driver
- Informix Using IBM JCC Driver (XA)
- Informix Using IBM Universal JDBC Driver
- Informix Using IBM Universal JDBC Driver (XA)
- **Informix Using IBM JCC Driver**

The Informix Using IBM JCC Driver is a one-phase commit provider for Informix that uses the IBM Data Server Driver for JDBC and SQLJ. The IBM Data Server Driver is JDBC 4.0 compliant and is the next generation of the Universal JCC driver.

This provider:

- Is configurable in version 7.0 and later nodes.
- Supports the following one-phase data source:

`com.ibm.db2.jcc.DB2ConnectionPoolDataSource`

- Requires the following JDBC driver files and class path settings:
  - `${INFORMIX_JCC_DRIVER_PATH}/db2jcc4.jar`
  - `${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license_cu.jar`
- Requires the following DataStoreHelper class:
  - `com.ibm.websphere.rsadapter.InformixJccDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The TCP/IP address or host name for the DRDA server. The name of the Informix instance on the server.
  - **portNumber** - The TCP/IP port number where the DRDA server resides.
  - **databaseName** - The name of the database from which the data source obtains connections.
 Example: *Sample*.

- **Informix Using IBM JCC Driver (XA)**

The Informix Using IBM JCC Driver (XA) is a two-phase commit provider for Informix that uses the IBM Data Server Driver for JDBC and SQLJ. The IBM Data Server Driver is JDBC 4.0 compliant and is the next generation of the Universal JCC driver.

This provider:

- Is configurable in version 7.0 and later nodes.
  - Supports two phase data source:
    - `com.ibm.db2.jcc.DB2XADataSource`
  - Requires JDBC driver files:
    - `db2jcc4.jar`
    - `db2jcc_license_cu.jar`
    - `db2jcc_license_cisuz.jar`
- Note:** If you plan to use SQLJ for queries, this provider also requires driver file **ifxsq1j.jar**.
- Requires the following DataStoreHelper class:
    - `com.ibm.websphere.rsadapter.InformixJccDataStoreHelper`
  - Requires a valid authentication alias.
  - Requires the following properties:
    - **serverName** - The TCP/IP address or host name for the DRDA server. The name of the Informix instance on the server.
    - **portNumber** - The TCP/IP port number where the DRDA server resides.
    - **databaseName** - The name of the database from which the data source obtains connections.
 Example: *Sample*.

**Note:** You cannot use Informix XA data sources with ANSI databases if SQL statements are issued in local transactions instead of global transactions. This scenario might occur within the application code or within a component of Application Server such as scheduler. The following message might be logged if you are experiencing this problem:

```
java.sql.SQLException: Already in transaction.
 at com.informix.util.IfxErrMsg.getSQLException(IfxErrMsg.java:398)
 at com.informix.jdbc.IfXSqli.a(IfXSqli.java:3247)
 at com.informix.jdbc.IfXSqli.E(IfXSqli.java:3556)
 at com.informix.jdbc.IfXSqli.dispatchMsg(IfXSqli.java:2382)
 at com.informix.jdbcx.IfXASqli.receiveMessage(IfXASqli.java:120)
 at com.informix.jdbc.IfXSqli.X(IfXSqli.java:7926)
 at com.informix.jdbc.IfXSqli.a(IfXSqli.java:854)
 at com.informix.jdbc.IfXSqli.executeCommand(IfXSqli.java:749)
 at com.informix.jdbc.IfXResultSet.b(IfXResultSet.java:293)
 at com.informix.jdbc.IfXStatement.c(IfXStatement.java:1269)
```

```
at com.informix.jdbc.IfxStatement.b(IfxStatement.java:423)
at com.informix.jdbc.IfxStatement.executeUpdate(IfxStatement.java:277)
at com.informix.jdbc.IfxSqlConnect.setTransactionIsolation(IfxSqlConnect.java:2565)
```

To avoid this issue:

- Switch to a non-ANSI database.
- If the error is triggered by an application, update the application such that it always runs in a global transaction.

#### • Informix Using IBM Universal JDBC Driver

The Informix JDBC Driver is a Type 4 JDBC driver that is JDBC 3.0 compliant and provides access to the Informix database.

This provider:

- Supports the following one-phase data source:

```
com.ibm.db2.jcc.DB2ConnectionPoolDataSource
```

- Requires the following JDBC driver files:

```
db2jcc.jar
db2jcc_license_cu.jar
db2jcc_license_cisuz.jar
```

- Requires the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
```

- Requires a valid authentication alias.

- Requires the following properties:

- **serverName** - The TCP/IP address or host name for the DRDA server. The name of the Informix instance on the server.
- **portNumber** - The TCP/IP port number where the DRDA server resides.
- **databaseName** - The name of the database from which the data source obtains connections.  
Example: *Sample*.

#### • Informix Using IBM Universal JDBC Driver (XA)

The Informix JDBC Driver (XA) is a Type 4 JDBC driver that is JDBC 3.0 compliant and provides XA-compliant JDBC access to the Informix database.

This provider:

- Supports the following two-phase data source:

```
com.ibm.db2.jcc.DB2XADataSource
```

- Requires the following JDBC driver files:

```
db2jcc.jar
db2jcc_license_cu.jar
db2jcc_license_cisuz.jar
```

- Requires **DataStoreHelper** class:

```
com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
```

- Requires a valid authentication alias.

- Requires the following properties:

- **serverName** - The TCP/IP address or host name for the DRDA server. The name of the Informix instance on the server.
- **portNumber** - The TCP/IP port number where the DRDA server resides.
- **databaseName** - The name of the database from which the data source obtains connections.  
Example: *Sample*.

**Note:** You cannot use Informix XA data sources with ANSI databases if SQL statements are issued in local transactions instead of global transactions. This scenario might occur within the application

code or within a component of Application Server such as scheduler. The following message might be logged if you are experiencing this problem:

```
java.sql.SQLException: Already in transaction.
 at com.informix.util.IfxErrMsg.getSQLException(IfxErrMsg.java:398)
 at com.informix.jdbc.IfXSqli.a(IfXSqli.java:3247)
 at com.informix.jdbc.IfXSqli.E(IfXSqli.java:3556)
 at com.informix.jdbc.IfXSqli.dispatchMsg(IfXSqli.java:2382)
 at com.informix.jdbc.IfXASqli.receiveMessage(IfXASqli.java:120)
 at com.informix.jdbc.IfXSqli.X(IfXSqli.java:7926)
 at com.informix.jdbc.IfXSqli.a(IfXSqli.java:854)
 at com.informix.jdbc.IfXSqli.executeCommand(IfXSqli.java:749)
 at com.informix.jdbc.IfResultSet.b(IfResultSet.java:293)
 at com.informix.jdbc.IfStatement.c(IfStatement.java:1269)
 at com.informix.jdbc.IfStatement.b(IfStatement.java:423)
 at com.informix.jdbc.IfStatement.executeUpdate(IfStatement.java:277)
 at com.informix.jdbc.IfXSqliConnect.setTransactionIsolation(IfXSqliConnect.java:2565)
```

To avoid this issue:

- Switch to a non-ANSI database.
- If the error is triggered by an application, update the application such that it always runs in a global transaction.

### ***Data source minimum required settings for Microsoft SQL Server:***

These properties vary according to the database vendor requirements for Java Database Connectivity (JDBC) driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Microsoft SQL Server data sources.

**Note:** If you use only the features of Microsoft SQL Server that have no impact on JDBC transactions, you generally risk no exceptions by upgrading to a newer version.

The application server supports the SNAPSHOT and READ\_COMMITTED\_SNAPSHOT isolation levels in Microsoft SQL Server. This chart describes the SNAPSHOT and READ\_COMMITTED\_SNAPSHOT isolation levels for different types of providers:

JDBC provider	MS SQL Server feature	Configuration consideration
Microsoft SQL Server JDBC Driver	SNAPSHOT isolation level	Set the isolation level constant by invoking the <code>setTransactionIsolation</code> method: <ul style="list-style-type: none"> <li><code>conn.setTransactionIsolation (com.microsoft.sqlserver.jdbc.SQLServerConnection.TRANSACTION_SNAPSHOT)</code></li> <li><code>conn.setTransactionIsolation(<i>value_of_constant</i>)</code></li> </ul>
	READ_COMMITTED_SNAPSHOT isolation level	This isolation level is an implementation of the Read committed isolation level. The policy enforces optimistic locking for read operations with MS SQL Server 2005. <ol style="list-style-type: none"> <li>Configure the isolation level on the database</li> <li>Invoke the <code>setTransactionIsolation</code> method with the <code>conn.setTransactionIsolation (java.sql.Connection.TRANSACTION_READ_COMMITTED)</code> attribute.</li> </ol>
DataDirect ConnectJDBC type 4 driver for MS SQL Server	SNAPSHOT isolation level	This isolation level implements optimistic locking for transactions in which MS SQL Server 2005 serializes the data. <p>Configure the <code>ALLOW_SNAPSHOT_ISOLATION</code> setting on the database, and then set the isolation level in one of two ways:</p> <ul style="list-style-type: none"> <li>By isolation level constant. Invoke the <code>setTransactionIsolation</code> method with one of two attributes: <ul style="list-style-type: none"> <li><code>conn.setTransactionIsolation (com.ddtek.jdbc.extensions.ExtConstants.TRANSACTION_SNAPSHOT)</code></li> <li><code>conn.setTransactionIsolation(16)</code></li> </ul> </li> <li>By the custom data source property: <ul style="list-style-type: none"> <li>Set the data source custom property <code>snapshotSerializable</code> to <code>true</code>.</li> </ul> </li> </ul>
	READ_COMMITTED_SNAPSHOT isolation level	This isolation level is an implementation of the Read committed isolation level. The policy enforces optimistic locking for read operations with MS SQL Server 2005. <ol style="list-style-type: none"> <li>Configure the isolation level on the database</li> <li>Invoke the <code>setTransactionIsolation</code> method with the <code>conn.setTransactionIsolation (java.sql.Connection.TRANSACTION_READ_COMMITTED)</code> attribute.</li> </ol>

You can configure the following types of providers:

- Microsoft SQL Server JDBC Driver
- Microsoft SQL Server JDBC Driver (XA)
- DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server
- DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA)
- **Microsoft SQL Server JDBC Driver**

This provider:

- Supports the following data source:
  - `com.microsoft.sqlserver.jdbc.SQLServerConnectionPoolDataSource`
- Requires the following Java archive (JAR) files:
  - `sqljdbc.jar`
- Requires the following `DataStoreHelper` class:
  - `com.ibm.websphere.rsadapter.MicrosoftSQLServerDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - specifies the name of the server in which Microsoft SQL Server resides. Example: `myserver.mydomain.com`
  - **portNumber** - specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.
  - **databaseName** - specifies the name of the database from which the data source obtains connections. Example: `Sample`.

- **Microsoft SQL Server JDBC Driver (XA)**

This provider:

- Supports the following data source:

`com.microsoft.sqlserver.jdbc.SQLServerXADataSource`

- Requires the following Java archive (JAR) files:

- `sqljdbc.jar`

- Requires the following DataStoreHelper class:

`com.ibm.websphere.rsadapter.MicrosoftSQLServerDataStoreHelper`

- Requires the following properties:

- **serverName** - specifies the name of the server in which Microsoft SQL Server resides. Example: *myserver.mydomain.com*
  - **portNumber** - specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.
  - **databaseName** - specifies the name of the database from which the data source obtains connections. Example: *Sample*.

- **DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server**

DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server is a Type 4 JDBC driver that provides JDBC access to the Microsoft SQL Server database. Use this provider only with a Connect JDBC driver that is purchased from DataDirect Technologies.

The JDBC provider:

- Supports the following data source:

`com.ddtek.jdbcx.sqlserver.SQLServerDataSource`

- Requires the following JDBC driver files:

- `sqlserver.jar`

- Requires the following DataStoreHelper class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

- Requires a valid authentication alias.

- Requires the following properties:

- **serverName** - specifies the name of the server in which Microsoft SQL Server resides. Example: *myserver.mydomain.com*
  - **portNumber** - specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.
  - **databaseName** - specifies the name of the database from which the data source obtains connections. Example: *Sample*.

- **DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA)**

DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Microsoft SQL Server database. Use this provider only with a Connect JDBC driver that is purchased from DataDirect Technologies.

This provider:

- Supports the following data source:

`com.ddtek.jdbcx.sqlserver.SQLServerDataSource`

- Requires the following JDBC driver files:

- `sqlserver.jar`

- Requires the following DataStoreHelper class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

- Requires a valid authentication alias.

- Requires the following properties:

- **serverName** - specifies the name of the server in which Microsoft SQL Server resides. Example: *myserver.mydomain.com*
  - **portNumber** - specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.

- **databaseName** - specifies the name of the database from which the data source obtains connections. Example: *Sample*.

### **Data source minimum required settings for Oracle:**

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Oracle data sources.

You can configure the following types of providers:

- Oracle JDBC Driver
- Oracle JDBC Driver (XA)
- **Oracle JDBC Driver**

The Oracle JDBC Driver provides JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

This provider:

- Supports one-phase data source:  
`oracle.jdbc.pool.OracleConnectionPoolDataSource`
- Requires the following JDBC driver files:
  - `ojdbc6.jar`.

**Note:** Be aware of the following:

- Oracle does not support the use of `ojdbc14.jar` in an environment with the Java SE Development Kit Version 6 or later.
- In mixed node environments, the data source wizard in the administrative console allows you to choose a class path for `ojdbc6.jar` or `ojdbc14.jar`.
- For Oracle trace, use `ojdbcversion_g.jar`.
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper`

**Note:** You must use the `Oracle11gDataStoreHelper` with the `ojdbc6.jar` driver file, regardless of whether you use an Oracle 11g or Oracle 10g database server.

- Requires a valid authentication alias.
- Requires properties:

**URL** The URL that indicates the database from which the data source obtains connections. For example:

```
jdbc:oracle:thin:@myServer:1521:myDatabase
```

where *myServer* is the server name, *1521* is the port that the server uses for communication, and *myDatabase* is the database name.

- **Oracle JDBC Driver (XA)**

The Oracle JDBC Driver (XA) provides XA-compliant JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

This provider:

- Supports two-phase data source:  
`oracle.jdbc.xa.client.OracleXADataSource`
- Requires the following JDBC driver files:
  - `ojdbc6.jar`.

**Note:** Be aware of the following notes regarding the use of these driver files:

- Oracle does not support the use of `ojdbc14.jar` in an environment with the Java SE Development Kit Version 6 or later.
- In mixed node environments, the data source wizard in the administrative console allows you to choose a class path for `ojdbc6.jar` or `ojdbc14.jar`.
- For Oracle trace, use `ojdbcversion_g.jar`.

- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.Oracle11gDataSourceHelper`

**Note:** You must use the `Oracle11gDataSourceHelper` with the `ojdbc6.jar` driver file, regardless of whether you use an Oracle 11g or Oracle 10g database server.

- Requires a valid authentication alias.
- Requires properties:

**URL** Indicates the database from which the data source obtains connections. For example:  
`jdbc:oracle:thin:@myServer:1521:myDatabase`

where *myServer* is the server name, *1521* is the port that the server uses for communication, and *myDatabase* is the database name.

**Data source minimum required settings for Sybase:**

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Sybase data sources.

You can configure the following types of providers:

- Sybase JDBC 3 Driver
- Sybase JDBC 3 Driver (XA)
- Sybase JDBC 2 Driver
- Sybase JDBC 2 Driver (XA)
- **Sybase JDBC 3 Driver**

The Sybase JDBC 3 Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

This provider:

- Uses jConnect Version 6.05
- Supports one phase data source:  
`com.sybase.jdbc3.jdbc.SybConnectionPoolDataSource`
- Requires the following JDBC driver files:  
`jconn3.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*.
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  - **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: `java.lang.String`)

- **Sybase JDBC 3 Driver (XA)**

The Sybase JDBC 3 Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

This provider:

- Uses jConnect Version 6.05
- Supports two phase data source:  
`com.sybase.jdbc3.jdbc.SybXADataSource`
- Requires JDBC driver files:  
`jconn3.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.

- **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: `java.lang.String`)

- **Sybase JDBC 2 Driver**

The Sybase JDBC 2 Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

This provider:

- Uses jConnect Version 5.5
- Supports one phase data source:  
`com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource`
- Requires the following JDBC driver files:  
`jconn2.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*.
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  - **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: `java.lang.String`)

- **Sybase JDBC 2 Driver (XA)**

The Sybase JDBC 2 Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

This provider:

- Uses jConnect Version 5.5
- Supports two phase data source:  
`com.sybase.jdbc2.jdbc.SybXADataSource`
- Requires JDBC driver files:  
`jconn2.jar`
- Requires the following DataStoreHelper class:  
`com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  - **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: `java.lang.String`)

If your application requires access to a JDBC connection pool from a Java 2 Platform, Enterprise Edition (J2EE) 1.3 or 1.4, or Java Platform Enterprise Edition (Java EE) level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively.

## Configuring a JDBC provider using the administrative console

To create connections between an application and a relational database, the application server uses the driver implementation classes that are encapsulated by the JDBC provider.

### Before you begin

Each JDBC provider is essentially an object that represents vendor-specific JDBC driver classes to the application server, for establishing access to that particular vendor database. JDBC providers are prerequisites for data sources, which supply applications with the physical connections to a database. Consult the JDBC provider table to identify the appropriate JDBC provider for your database and application requirements.

**Note:** The application server no longer supports the DB2 for 390 and z/OS Legacy JDBC driver and the corresponding JDBC provider, the DB2 for zOS Local JDBC provider (RRS). Use the DB2 Using IBM JCC Driver or DB2 Universal JDBC Driver to connect to DB2 for z/OS.

### About this task

Configure at least one JDBC provider for each database server that you plan to use at a particular scope within your application server environment.

1. Open the administrative console.
2. Click **Resources** → **JDBC** → **JDBC Providers**.
3. Select the scope at which applications can use the JDBC provider. The scope that you select becomes the scope of any data source that you associate with this provider. You can choose a cell, node, cluster, or server. For more information on scope and how it can affect resources, see the information center topic on administrative scope settings.
4. Click **New**. This action causes the **Create a new JDBC Provider** wizard to launch.
5. Use the first drop-down list to select the database type of the JDBC provider that you need to create.

**Note:** Select **User-Defined** for your database type if you encounter either of the following scenarios:

- You do not see your database type.
- You cannot select the JDBC provider type that you need in the next step.

The user-defined selection triggers the wizard panel to display your provider type as a user-defined JDBC provider, and your implementation type as user-defined. Consult your database documentation for the JDBC driver class files, data source properties, and so on that are required for your user-defined provider. You must supply this information on the next two panels:

- database class path
  - database-specific properties
6. Select your JDBC provider type if it is displayed in the second drop-down list. Select **Show Deprecated** to trigger the display of both current and deprecated providers. If you cannot find your provider in this expanded list, then select **User-Defined** from the previous list of database types.
 

**Note:** The product issues a DSRA360 error message if you select the DB2 for z/OS Local JDBC Provider (RRS) provider. In Version 6.1 and later, the application server completely removes support for the DB2 for z/OS Local JDBC Provider (RRS) provider.
  7. From the third drop-down list, select the implementation type that is necessary for your application. If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Choose **XA Data Source**, however, if your application requires connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery.
 

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.
  8. Click **Next** to see the **Enter database class path information** wizard panel.
  9. In the Class path field, type the full path location of the database JDBC driver class files. Your class path information becomes the value of the WebSphere environment variable that is displayed on this panel, in the form of `#{DATABASE_JDBC_DRIVER_PATH}`. The application server uses the variable to define your JDBC provider; this practice eliminates the need to specify static JDBC class paths for individual applications. Remember that if you do not provide the full, correct JDBC driver class path for the variable, your data source ultimately fails. If the field already displays a fully qualified class path, you can accept that variable definition by completing the rest of this wizard panel and clicking **Next**.
 

**Note:** The application server supports multiple versions of the selected JDBC driver for the DataDirect ConnectJDBC type 4 driver for MS SQL Server. Each version of the JDBC driver has a unique class path. Select the appropriate version of the JDBC driver so the class path is populated correctly.
  10. Use the Native library path field to specify additional class files that your JDBC driver might require to function properly on your application server platform. Type the full directory path name of these class files.
  11. Click **Next** to see a summary of your JDBC provider settings.
  12. Click **Finish** if you are satisfied with the JDBC provider configuration. You now see the JDBC provider collection panel, which displays your new JDBC provider in a table along with other providers that are configured for the same scope.

## What to do next

The next step is to create a data source to associate with your JDBC provider. For detailed information, see the information center topic on configuring a data source using the administrative console.

### ***JDBC provider collection:***

Use this page to view JDBC providers. The JDBC provider object encapsulates the specific JDBC driver implementation class for the data sources that you define and associate with the provider.

To view this administrative console page, click **Resources > JDBC > JDBC providers** .

*Name:*

Specifies a text identifier for this provider.

For example, this field can be *DB2 JDBC Provider (XA)*.

**Data type** String

*Scope:*

Specifies the scope of the JDBC provider; if you use any scope other than the default of *Node*, the provider might not be available in other scope contexts. Data sources that are created with this JDBC provider inherit this scope.

*Description:*

Specifies a text string describing this provider.

**Data type** String

*JDBC provider settings:*

Use this page to modify the settings for a JDBC provider.

To view this administrative console page, click **Resources** → **JDBC** → **JDBC providers** → **JDBC\_provider**.

**Note:** If you use this page to modify the class path or native library path of an existing JDBC provider: After you apply and save the new settings, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

*Scope:*

Specifies the scope of the JDBC provider; data sources that are created with this JDBC provider inherit this scope.

*Name:*

Specifies the name of the resource provider.

**Data type** String

*Description:*

Specifies a text description for the resource provider.

**Data type** String

*Class path:*

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

For example:

- */usr/lpp/db2/db2710/classes/db2j2classes.zip* for z/OS.

Class path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Class paths contain variable (symbolic) names which you can substitute using a variable

map. Check the driver installation notes for the specific required JAR file names.

**Data type** String

*Native Library Path:*

Specifies a list of paths that forms the location for the resource provider native libraries.

Native path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names which you can substitute using a variable map.

**Data type** String

*Isolate this resource provider:*

Specifies that this resource provider will be loaded in its own class loader. This allows different versions or implementations of the same resource provider to be loaded in the same Java Virtual Machine. Give each version of the resource provider a unique class path that is appropriate for that version or implementation.

**Note:** Be aware of the following:

- You cannot isolate a resource provider if you specify a native library path. The Application Server will define a value for the native library path for some JDBC providers; this behavior is intended to help you configure your provider when a native library path is necessary. If you do not require the native library path, delete the value, and you will be able to select the option to isolate the resource provider.
- If you are running a mixed cell environment, the application server will remove any isolated JDBC providers from nodes that are running at versions earlier than 7.0 if the provider is scoped for a version 7.0 cell, and you have not migrated the provider from an older release. If you want to use isolated resources at the cell level, do not use the resources in nodes that are running at versions earlier than 7.0. Define a resource at the node level, or avoid using the resource in nodes that are earlier than version 7.0, because this will result in a "Naming not found" exception when the application server attempts to perform a lookup on an isolated resource at the cell level.

*Implementation class name:*

Specifies the Java class name of the JDBC driver implementation.

This class is available in the driver file mentioned in the class path description above.

For example, *com.ibm.db2.jcc.DB2XADataSource* for distributed and z/OS operating systems.

**Note:** If you modify the implementation class name of the JDBC provider after you have created the provider, you might disconnect the provider from the template used to create it. As a result, data sources created from this JDBC provider do not have an associated template; you must manually configure a working data source through setting custom properties.

**Data type** String

*JDBC provider summary:*

JDBC providers are prerequisites for data sources, which supply applications with the physical connections to a database.

Use these tables for quick reference on database-specific JDBC providers.

<b>Apache Derby</b>		
<b>JDBC provider</b>	<b>Transaction support</b>	<b>Version and other considerations</b>
Derby JDBC Provider	One-phase	<ul style="list-style-type: none"> <li>• Does not support Version 4 data sources</li> <li>• Configurable only in nodes at version 6.0.2 and later</li> <li>• Not for use in clustered environment: accessible from a single JVM only</li> </ul>

Sybase JDBC 3 Driver (XA)	One and two-phase	jConnect v6.05

Sybase		
JDBC provider	Transaction support	Version and other considerations
Sybase JDBC 2 Driver	One-phase	jConnect v5.5
Sybase JDBC 2 Driver (XA)	One and two-phase	jConnect v5.5

## Configuring a JDBC provider for a clustered environment

Use these steps to define a data source on multiple nodes that comprise a cluster.

### Before you begin

See Administrative console scope settings for more information about scope settings in general.

### About this task

The cluster scope has precedence over the node and cell scopes. Create a JDBC provider for a cluster if you want the associated data source to:

- Be available for all the members of this cluster to use
  - Override any resource factories that have the same JNDI name that is defined within the cell scope
1. Open the administrative console.
  2. Click **Resources > JDBC > JDBC Providers**.
  3. From the scope drop-down list, select the cluster for which you are creating the JDBC provider. (This scope becomes the scope of any data source that you associate with this provider.)
  4. Click **New**. This action causes the **Create a new JDBC Provider** wizard to launch.
  5. Complete the wizard, then click **Finish**. For details on using this wizard, see the article “Configuring a JDBC provider using the administrative console” on page 1536.
  6. Click **Environment > WebSphere Variables** in the administrative console.
  7. For each node in the cluster, select the symbolic variable used in the class path of your JDBC provider, and provide a value that is appropriate for the selected node. For example, if the class path of your JDBC provider uses the symbolic variable `#{DB2390_JDBC_DRIVER_PATH}`, you might supply the value `/usr/lpp/db2` on one node and `/usr/lpp/db2710` on another node, depending on where your DB2 390 installation is located.
  8. Click **DB2\_JDBC\_DRIVER\_PATH** (this already exists by default). Here provide the path (in the *value* field) where `db2java.zip` exists on the selected node.
  9. Click **Apply** and save the changes.

**Note:** This variable must be defined on each node within the cluster.

### What to do next

You are now ready to configure your data source. For guidance, refer to “Configuring a data source using the administrative console.”

## Configuring a data source using the administrative console

Application components use a data source to access connection instances to a relational database.

### Before you begin

The application server supports two different versions of data source. Determine the data source for your environment according to the enterprise bean and servlet specification levels that are the basis of your applications:

- *Data sources (WebSphere Application Server Version 4)* are for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification.
- Data sources of the latest standard version are for use with applications that implement the more advanced releases of these specifications.

## About this task

When you create a data source, you associate it with a JDBC provider that is configured for access to a specific vendor database. The application server requires both objects for your applications to make calls to that particular database and receive data from it. The data source provides connection management capabilities that physically make possible these exchanges between your applications and the database.

1. Open the administrative console.
2. Access the necessary console panel. Use one of the following paths:
  - Click **Resources** → **JDBC** → **Data sources**.
  - Click **Resources** → **JDBC** → **Data sources (WebSphere Application Server Version 4)**
  - Click **Resources** → **JDBC** → **JDBC providers** → *jdbc\_provider* → **Data sources**
  - Click **Resources** → **JDBC** → **JDBC providers** → *jdbc\_provider* → **Data sources (WebSphere Application Server Version 4)**.
3. Select the scope at which applications can use the data source. You can choose a cell, node, cluster, or server. For more information, see the topic on scope settings.

**Note:** From this point onward, the steps for creating WebSphere Application Server Version 4 data sources differ from the steps for creating data sources of the latest standard version. To configure a Version 4 data source:

- Click **New** to proceed to the console panel for defining required properties.
  - On this properties panel specify values for the fields that are grouped under the heading **Configuration**. The application server requires these properties to implement your JDBC driver classes.
  - Save your configuration by clicking **OK**. You are now finished with the primary data source configuration tasks.
  - Define other properties that your database vendor might require, or offer as options, for using the JDBC driver. The application server calls them custom properties, and requires that you set them on the data source. Begin by clicking the **Custom Properties** link that is now displayed on the administrative console panel. Consult your database documentation to learn about these required and optional properties.
- You can also learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS if you use the DB2 Universal JDBC Driver or DB2 Using IBM JCC Driver for the JDBC provider.
4. Click **New**. This action causes the **Create a data source** wizard to launch and display the **Enter basic data source information** panel. The first field is the scope field, which is read-only. This field displays your previous scope selection.
  5. Type a data source name in the **Data source name** field. This name identifies the data source for administrative purposes only.
  6. Type a Java Naming and Directory Interface (JNDI) name in the **JNDI name** field. The application server uses the JNDI name to bind resource references for an application to this data source. Follow these requirements when you specify JNDI names:
    - Do not assign duplicate JNDI names across different resource types, such as data sources versus J2C connection factories or JMS connection factories.
    - Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

For more information on JNDI, consult the topic on naming.

7. Click **Next** to see the **Select JDBC provider** panel . The **Select JDBC provider** panel is skipped if you do not have any JDBC providers that are configured at the current scope.
8. Select an existing JDBC provider, or create a new provider.
  - Select an existing JDBC provider.
    - a. Click **Select an existing JDBC provider**.
    - b. Select a JDBC driver from the drop-down list.
    - c. Click **Next**. You now see the panel entitled **Enter database specific properties for the data source**.
  - Create a new JDBC provider.
    - a. Click **Create new JDBC provider**.
    - b. Click **Next** to see the **Create JDBC provider** panel.
    - c. Use the first drop-down list to select the database type of the JDBC provider that you need to create.

**Note:** Select **User-Defined** for your database type if you encounter either of the following scenarios:

- You do not see your database type.
- You cannot select the JDBC provider type that you need in the next step.

The user-defined selection triggers the wizard panel to display your provider type as a User-defined JDBC provider, and your implementation type as User-defined. Consult your database documentation for the JDBC driver class files, data source properties, and so on that are required for your user-defined provider. You must supply this information on the next two wizard panels:

- database class path information
  - database-specific properties
- d. If the JDBC provider type is displayed in the second drop-down list, select your JDBC provider type. Select **Show Deprecated** to trigger the display of both current and deprecated providers. If you cannot find your provider in this expanded list, then select **User-Defined** from the previous list of database types.
  - e. From the third drop-down list, select the implementation type that is necessary for your application. If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Choose **XA Data Source**, however, if your application requires connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery.
 

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.
  - f. Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard panel Enter database class path information.
  - g. In the class path field, type the full path location of the database JDBC driver class files. Your class path information becomes the value of the WebSphere environment variable that is displayed on this panel, in the form of `${DATABASE_JDBC_DRIVER_PATH}`. The application server uses the variable to define your JDBC provider; this practice eliminates the need to specify static JDBC class paths for individual applications. Remember that if you do not provide the full, correct JDBC driver class path for the variable, your data source ultimately fails. If the field already displays a fully qualified class path, you can accept that variable definition by completing the rest of this wizard panel and clicking **Next**.
  - h. Use the **Native library path** field to specify additional class files that your JDBC driver might require to function properly on your application server platform. Type the full directory path name of these class files.

- i. Click **Next**. You now see the **Enter database specific properties for the data source** panel.
9. Complete all of the fields on the **Enter database specific properties for the data source** panel.
  - Click **Use this data source in container managed persistence (CMP)** if container managed persistence (CMP) enterprise beans must access this data source.
  - Any other property fields that are displayed on this wizard panel are specific to your database type. Consult the article “Data source minimum required settings, by vendor” on page 1510 for information on these property settings. The article addresses both current and deprecated JDBC providers that are pre-defined in the application server.

**Note:** This wizard panel does not display additional property fields for data sources that correspond with your user-defined JDBC providers. However, from the JDBC driver class files that you installed, The application server can generally extract the necessary data source property names. The application server defines them as data source custom properties, displays them on a custom properties console panel, and assigns them default values. Consult your database documentation about setting these properties and any other requirements for your user-defined data source. After you create the data source, navigate to the corresponding custom properties collection panel in the administrative console by clicking **Data sources** → **data\_source** → **Custom properties**. Review the property default values and modify them if necessary.

The application server can only extract vendor-specific properties from the driver class files if you install the files on the deployment manager node and configure their representative WebSphere variables correctly. Otherwise, the product displays an informational message (as opposed to an error message) that directs you to manually define the necessary properties as custom properties.

10. Optional: Configure the security aliases for the data source. You can select none for any of the authentication methods, or choose one of the following types:
  - **Component-managed authentication alias** - specifies an authentication alias to use when the component resource reference res-auth value is Application. To define a new alias, navigate to **Related Items** → **J2EE Connector Architecture (J2C) authentication data entries**. A component-managed alias represents a combination of ID and password that is specified in an application for data source authentication. Therefore, the alias that you set on the data source must be identical to the alias in the application code.
    - a. Use the drop-down list to select an existing component-managed authentication alias.
    - b. To create a new alias, click the links that are provided. This action closes the data source wizard and triggers the administrative console to display the J2C authentication data panel. Click **New** to define a new alias. Click **OK** to save your settings and view the new alias on the J2C authentication data panel. Restart the data source wizard by navigating back to the data source collection panel, selecting the appropriate scope, and clicking **New**.

For more information on Java 2 Connector (J2C) security, see the topic on managing Java 2 Connector Architecture authentication data entries.

- **Mapping-configuration alias** - will be used only in the absence of a login configuration on the component resource reference. The specification of a login configuration and the associated properties on the component resource reference is the preferred way to define the authentication strategy when the res-auth value is set to Container. If you specify the DefaultPrincipalMapping login configuration, the associated property will be a JAAS - J2C authentication data entry alias.
- **Container-managed authentication alias** - will be used only in the absence of a login configuration on the component resource reference. The specification of a login configuration and the associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is set to Container.

**Note:** If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the

servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

11. Click **Next** to view the **Summary** panel, and review any information for the data source. If any information is not correct, you can click **Previous** to go back and correct it.
12. Click **Finish** to save the configuration and exit the wizard. You now see the **Data sources** panel, which displays your new configuration in a table along with other data sources that are configured for the same scope.

## What to do next

You can override the default values for some data source properties. You can also configure additional properties that your database vendor might require or offers as options. Consult your database documentation about these settings.

If you use the DB2 Universal JDBC Driver provider or DB2 Using IBM JCC Driver, learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

The following topics in this information center inform you of how to use the administrative console to assign the property values:

- “Connection pool settings” on page 1476
- “Tuning connection pools”
- “WebSphere Application Server data source properties” on page 1554
- “Java EE resource provider or connection factory custom properties collection” on page 1560

### ***Tuning connection pools:***

Using connection pools helps to both alleviate connection management overhead and decrease development tasks for data access. Each time an application attempts to access a backend store (such as a database), it requires resources to create, maintain, and release a connection to that datastore. To mitigate the strain this process can place on overall application resources, the application server enables administrators to establish a pool of backend connections that applications can share on an application server. Connection pooling spreads the connection overhead across several user requests, thereby conserving application resources for future requests.

### **About this task**

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. Because users connect and disconnect frequently with applications on the Internet, the application requests for data access can surge to considerable volume. Consequently, the total overhead for a datastore can become high for Web-based applications quickly, and performance deteriorates. When connection pooling capabilities are used, however, Web applications can realize performance improvements of up to 20 times the normal results.

**Note:** Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

- **Prevent a connection deadlock.** Deadlock can occur if the application requires more than one concurrent connection per thread, and the database connection pool is not large enough for the number

of threads. Suppose each of the application threads requires two concurrent database connections and the number of threads is equal to the maximum connection pool size. Deadlock can occur when both of the following are true:

- Each thread has its first database connection, and all are in use.
- Each thread is waiting for a second database connection, and none would become available since all threads are blocked.

To prevent the deadlock in this case, increase the maximum connections value for the database connection pool by at least one. This will allow at least one of the waiting threads to obtain a second database connection and avoid a deadlock scenario.

For general prevention of connection deadlock, code your applications to use only one connection per thread. If you code the application to require *C* concurrent database connections per thread, the connection pool must support at least the following number of connections, where *T* is the maximum number of threads:

$$T * (C - 1) + 1$$

The connection pool settings are directly related to the number of connections that the database server is configured to support. If you increase the maximum number of connections in the pool and the corresponding settings in the database are not increased accordingly, the application might fail. The resulting SQL exception errors would be displayed in the following location(s):

- the SYSOUT of the servant

- **Disable connection pooling.**

- For relational resource adapters (RRAs), add the `disableWASConnectionPooling` custom property for your data sources.
  1. Click **JDBC > Data sources**.
  2. Click on the name of the data source that you want to configure.
  3. Click **Custom properties** under the **Additional Properties** heading.
  4. Click **New**.
  5. Complete the required fields with the following information:

Table 10. Custom property panel

Name	Value
<code>disableWASConnectionPooling</code>	<code>true</code>

- For other resource adapters, consult with the binding specifications for that resource adapter to configure your applications to disable connection pooling.

1. Programmatically disable connection pooling through the resource adapter.
2. The application server leverages the following code to detect the `javax.resource.NotSupportedException` exception and disable connection pooling:

```
_managedFactory.matchManagedConnections(s,subject,cri); // 169059 174269 }
catch(javax.resource.NotSupportedException e){
```

- **Enable deferred enlistment.** In the application server environment, deferred enlistment refers to the technique in which the application server waits until the connection is used before the connection is enlisted in the application's unit of work (UOW) scope.

Consider the following illustration of deferred enlistment:

- An application component that uses deferred enlistment calls the `getConnection` method from within a global transaction.
- The application component does not immediately use the connection.
- When the application issues the call for initial use of the connection, the transaction manager intercepts the call.
- The transaction manager enlists the XA resource for the connection and calls the `XAResource.start` method.

- The connection manager associated with the XA resource sends the call to the database.

Given the same scenario, but the application component does not use deferred enlistment, the component container immediately enlists the connection in the transaction. Thus the application server incurs, for no purpose, an additional load of all of the overhead associated with that transaction. For XA connections, this overhead includes the two phase commit (2PC) protocol to the resource manager.

Deferred enlistment offers better performance in the case where a connection is obtained, but not used, within the UOW scope. The technique saves the cost of transaction participation until the UOW in which participation must occur.

Check with your resource adapter provider if you need to know if the resource adapter provides this functionality. The application server relational resource adapter automatically supports deferred enlistment.

#### **Incorporating deferred enlistment in your code:**

The Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5 specification calls the deferred enlistment technique lazy transaction enlistment optimization. This support comes through a marker interface (`LazyEnlistableManagedConnection`) and a new method on the connection manager (`LazyEnlistableConnectionManager()`):

```
package javax.resource.spi; import javax.resource.ResourceException; import
javax.transaction.xa.Xid; interface LazyEnlistableConnectionManager { // application server void
lazyEnlist(ManagedConnection) throws ResourceException; } interface LazyEnlistableManagedConnection { // resource adapter }
```

#### **Disabling statement pooling:**

Disable statement pooling performing Data Definition Language (DDL) operations, which might not be compatible with statement pooling.

#### **About this task**

DDL operations, such as dropping and recreating tables, are not compatible with statement pooling when using the IBM Informix database. DDL operations invalidate the pooled statements or cause them to produce unexpected results.

Complete the following steps to use the administrative console to disable statement pooling. Statement pooling is disabled by specifying a value of zero for the statement cache size setting for your datasource.

1. From the administrative console, select **Resources** → **JDBC** → **Data sources** → **datasource\_name**.
2. Under Additional properties, click **WebSphere Application Server data source properties**.
3. Enter a value of zero (0) in the Statement cache size field.
4. Click **OK**, and then click **Save**.

#### **Data source collection:**

Use this page to view configured data sources, which are the resources that provide connections to your relational database.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **Data sources**
- **Resources** > **JDBC** > **JDBC providers** > *JDBC\_provider* > **Data sources**

**Note:** If you are using the Enterprise JavaBean (EJB) 1.0 specification and the Java Servlet 2.2 specification, you must use the **Data sources (WebSphere Application Server Version 4)** console page.

*Name:*

Specifies the display name of this data source.

Click a data source name to edit the data source configuration settings.

**Data type** String

*JNDI name:*

Specifies the Java Naming and Directory Interface (JNDI) name for this data source.

**Data type** String

*Scope:*

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

*Provider:*

Specifies the JDBC provider that encapsulates the appropriate classes.

*Description:*

Specifies a text description of the data source.

**Data type** String

*Category:*

Specifies a string that you can use to classify or group a data source.

**Data type** String

*Data source settings:*

Use this panel to edit the properties of a data source.

You can access this administrative console page in one of two ways:

- **Resources** → **JDBC** → **Data sources** → **data\_source**
- **Resources** → **JDBC** → **JDBC providers** → **JDBC\_provider** → **Data sources** → **data\_source**

**Note:** If your application uses an Enterprise JavaBean (EJB) 1.1 or a Java Servlet 2.2 module, use the **Data sources (WebSphere Application Server V4)** → **data\_source** console page.

*Test connection:*

Activates the test connection service for validating application connections to the data source.

Before you click **Test connection**, set your data source properties and click **Apply**.

*Scope:*

Specifies the scope of the JDBC provider that supports this data source. Only applications that are installed within this scope can use this data source.

*Provider:*

Specifies the JDBC provider that encapsulates the driver implementation classes to support this data source.

*Name:*

Specifies the display name for the data source.

Valid characters for this name include letters and numbers, but NOT most of the special characters. For example you can set this field to *Test Data Source*. But any name starting with a period (•) or containing special characters ( \ / , ; " \* ? < > | = + & % ' ` @ ) is not a valid name.

**Data type** String

*JNDI name:*

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of *markSection* generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

**Data type** String

*Use this data source in container-managed persistence (CMP):*

Specifies if this data source is used for container-managed persistence of enterprise beans.

This option triggers creation of a CMP connection factory, which corresponds to this data source, for the relational resource adapter.

**Data type** Boolean  
**Default** True (enabled)

*Description:*

Specifies a text description for the resource.

**Data type** String

*Category:*

Specifies a category string you can use to classify or group the resource.

**Data type** String

*Data store helper class name:*

Specifies the name of the `DataStoreHelper` implementation class that extends the capabilities of your selected JDBC driver implementation class to perform database-specific functions.

The application server provides a set of `DataStoreHelper` implementation classes for each of the JDBC provider drivers it supports. These implementation classes are in the package `com.ibm.websphere.rsadapter`. For example, if your JDBC provider is DB2, then your default `DataStoreHelper` class is `com.ibm.websphere.rsadapter.DB2DataStoreHelper`. The administrative console page you are viewing, however, might make multiple `DataStoreHelper` class names available to you in a drop-down list; be sure to select the one required by your database configuration. Otherwise, your application might not work correctly. If you want to use a `DataStoreHelper` other than those displayed in the drop-down list, select **Specify a user-defined DataStoreHelper**, and type a fully qualified class name. Refer to the information center for instructions on creating a custom `DataStoreHelper` class.

**Data type** Drop-down list or string (if **user-defined DataStoreHelper** is selected)

*Component-managed authentication alias:*

This alias is used for database authentication at run time.

The **Component-managed Authentication Alias** is only used when the application resource reference is using `res-auth = Application`.

If your database does not support `user ID` and `password`, then do not set the alias in the component-managed authentication alias or container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. This message is only a warning message; the data source is still created successfully.

If you do not set an alias (component-managed or otherwise), and your database requires the user ID and password to get a connection, then you receive an exception during run time.

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** Drop-down list

*Authentication alias for XA recovery:*

This field is used to specify the authentication alias that should be used during XA recovery processing. If this alias name is changed after a server failure, the subsequent XA recovery processing will use the original setting that was in effect before the failure.

If the resource adapter does not support XA transactions, then this field will not be displayed. The default value will come from the selected alias for application authentication (if specified).

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** Drop-down list

*Container-managed authentication alias:*

Specifies authentication data, which is a JAAS - J2C authentication data entry, for container-managed signon to the resource.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for J2EE Connector Architecture (J2C) authentication data entries.
2. Click **J2EE Connector Architecture (J2C) authentication data entries**.
3. Click **New**.
4. Define an alias.
5. Click **OK**. The console now displays an alias collection page. This page contains a table that lists all of your configured aliases. Before the table, this page also displays the name of your connection factory.
6. Click the name of your J2C connection factory. You now see the configuration page for the connection factory.
7. Select the new alias in the Container-managed authentication alias list.
8. Click **Apply**.

If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

**Data type** Drop-down list

*Mapping-configuration alias:*

Specifies the authentication alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

Click **Security** → **Global security**. In the **Authentication** section, click **Java Authentication and Authorization Service** → **Application logins**, and select an alias from the table.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the user ID and password. You can define and use other mapping configurations.

**Data type** Drop-down list

*Common and required data source properties:* These properties are specific to the data source that corresponds to your selected JDBC provider. They are either required by the data source, or are especially useful for the data source. You can find a complete list of the properties required for all supported JDBC providers in the information center.

*WebSphere Application Server data source properties:*

Use this page to set advanced data source properties in the application server. These properties activate and configure services that the application server applies to data sources to customize connections within an application server. These properties do not affect connections within the database.

To access this administrative console page complete one of the following paths:

- **Resources** → **JDBC** → **Data sources** → *data\_source* → **WebSphere Application Server data source properties**
- **Resources** → **JDBC** → **JDBC providers** → *JDBC\_provider* → **Data sources** → *data\_source* → **WebSphere Application Server data source properties**
- **Applications** → **Application Types** → **WebSphere enterprise applications** → *application\_name* → **Application scoped resources** → *data\_source* → **WebSphere Application Server data source properties**.

*Statement cache size:*

Specifies the number of statements that can be cached per connection. The application server caches a statement after you close that statement.

The WebSphere Application Server data source optimizes the processing of prepared statements and callable statements by caching those statements that are not used in an active connection. Both statement types help maximize the performance of transactions between your application and data store.

- A prepared statement is a precompiled SQL statement that is stored in a PreparedStatement object. The application server uses this object to run the SQL statement multiple times, as required by your application run time, with values that are determined by the run time.
- A callable statement is an SQL statement that contains a call to a stored procedure, which is a series of precompiled statements that perform a task and return a result. The statement is stored in the CallableStatement object. The application server uses this object to run a stored procedure multiple times, as required by your application run time, with values that are determined by the run time.

If the statement cache is not large enough, useful entries are discarded to make room for new entries. To determine the highest value for your cache size to avoid any cache discards, add the number of uniquely prepared statements and callable statements (as determined by the SQL string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. In general, configure a larger cache for applications with a greater number of statements.

If there is a particular statement that you do not want the application server to cache, configure the statement's poolability hint to false. The application server does not cache a statement if the poolability hint is set to false. The application specifies the statement poolability hints at run time.

In test applications, tuning the statement cache improves throughput from 10% to 20%. However, because of potential resource limitations, this might not always be possible.

**Data type** Integer

## Default

Default values depend on the database. Typically, this value is 10. For Informix versions 7.3, 9.2, 9.3, and 9.4, without the respective latest fixes, the default value must be 0. A default value of 0 means that there is no cache statement.

*Enable multithreaded access detection:* When you check this option, the application server detects the existence of access by multiple threads.

*Enable database reauthentication:* Indicates that the exact match on connections retrieved out of the application server's connection pool (the connection pool search criteria does not include a user name and password) cannot exist. Instead, the connection reauthentication is done in the `doConnectionSetupPerTransaction()` of the `DataStoreHelper` class. The application server does not provide a connection reauthentication implementation at run time. Therefore, when you check this box, you must extend the `DataStoreHelper` class to provide implementation of the `doConnectionSetupPerTransaction()` method where the reauthentication occurs. If you do not complete this process, the application server might return unusable connections. For more information, refer to the API documentation for the `com.ibm.websphere.rsadapter.DataStoreHelper#doConnectionSetupPerTransaction` method.

Connection reauthentication can help improve performance by reducing the overhead of opening and closing connections, particularly for applications that frequently request connections with different user names and passwords.

**Note:** You cannot enable database reauthentication if you select `TrustedConnectionMapping` for the mapping configuration alias.

*Enable JMS one-phase optimization support:* When you check this option, the application server allows Java messaging service (JMS) to get optimized connections from this data source. This property prevents Java database connectivity (JDBC) applications from sharing connections with container-managed persistence (CMP) applications.

*Manage cached handles:* Specifies whether the container tracks cached handles, which are connection handles that an application component holds active across transaction and method boundaries. You can use this property to debug connection problems, but tracking handles can cause large performance overhead during run time.

If the **Manage cached handles** property is selected in the administrative console, and you deselect it, the field will no longer be visible for resources that are at Version 7.0 of the application server. This field is only displayed if the `manageCachedHandles` property is set to `true` in the `resources.xml` file. To make the field available, change the value for the `manageCachedHandles` entry from `false` to `true` in the `resources.xml` file, or enter the following Jython command from the `wsadmin` tool:

```
AdminConfig.modify(myDataSourceVariable, '[[manageCachedHandles "true"]]')
```

**Note:** For any resources that are running at Version 6.x of the application server, the **Manage cached handles** property will always be visible. For example, if you have a node that is at Version 6.1, the entry in the `resources.xml` file will not affect how the field is displayed in the administrative console.

For an alternative method of debugging problems, use the multi-thread and cross-component diagnostic alerts to detect violations in the Java Connectivity Architecture (JCA) programming model. To enable these alerts, select those options from **Servers** → **Application servers** → *application\_server* → **Performance** → **Performance and Diagnostic Advisor Configuration** → **Performance and Diagnostic Advice configuration** panel. These alerts force the connection manager to manage cached handles, detect the connection conditions, and send alerts.

**Note:** For these alerts to be active you must also select **Enable Performance and Diagnostic Advisor Framework (Runtime Performance Advisor)** from the **Servers** → **Application servers** → **application\_server** → **Performance** → **Performance and Diagnostic Advisor Configuration** panel.

*Log missing transaction context:* Specifies whether the container issues an entry to the activity log when an application obtains a connection without a transaction context. These are exceptions to the Java Platform, Enterprise Edition (Java EE) programming model connection requirements.

*Non-transactional data source:* Specifies that the application server will not enlist the connections from this data source in global or local transactions. Applications must explicitly call `setAutoCommit(false)` on the connection if they want to start a local transaction on the connection, and they must commit or rollback the transaction that they started.

**Note:** Set this property to true in rare circumstances, but the Java Persistence API (JPA) requires both JTA and non-JTA data sources.

*Use WebSphere Application Server exception checking model:*

Specifies that the application server uses the error mapping facility that is defined in the data store helper to identify errors. The application server does not replace exceptions that are thrown by the JDBC driver with exceptions that are defined in the error map of the data store helper.

*Use WebSphere Application Server exception mapping model:*

Specifies that the application server uses the error mapping facility that is defined in the data store helper to identify errors, and the application server will replace the exceptions that are thrown by the JDBC driver with exceptions that are defined in the error map of the data store helper.

**Note:** This error detection model functions with JDBC Version 3.0 and earlier.

*Validate new connections:* Specifies whether the connection manager tests newly created connections to the database.

*Number of retries:* Specifies the number of times you want to retry making the initial connection to a database after the first pretest operation fails.

*Retry interval:* If you select **Validate new connections**, this option specifies the length of time, in seconds, that the application server waits before retrying to make a connection if the initial attempt fails.

*Validate existing pooled connections:* Specifies whether the connection manager tests the validity of pooled connections before returning them to applications.

*Retry interval:* If you select **Pretest existing pooled connections**, this option specifies the length of time, in seconds, to allot to the JDBC driver for validating a connection.

*Validation by JDBC driver:*

Specifies that the application server will use the JDBC driver to validate the connections. The JDBC provider must support JDBC 4.0 or greater to use this option.

*Timeout:* Specifies the timeout in seconds for testing connections (either new or pooled by the application server) to the database. If the timeout expires before validating then the connection is considered unusable. If retries are configured, the full value of the timeout applies to each retry. A value of 0 indicates the JDBC driver does not impose a timeout on validation attempts.

**Note:** This option is only available for JDBC drivers that are JDBC 4.0 compliant.

*Validation by SQL string (deprecated):*

Specifies an SQL statement that the application server sends to the database to test the connection. Use a query that is likely to have low impact on performance.

*Optimize for get/use/close/connection pattern with heterogenous pooling:*

Specifies that the application server will use the get/use/close/connection pattern. This allows connection pooling for the application server to share connections that are in the same transaction. This optimization pattern allows one connection to be shared during a transaction even when connections use different connection properties.

The heterogeneous pooling feature allows you to extend the data source definition so that you can specify different custom properties or allow applications to override non-core properties for the data source.

**Note:** This field is only available for DB2 data sources.

*Retry interval for client reroute:* Specifies the amount of time, in seconds, between retries for automatic client reroute.

**Note:** This field is only available for DB2 data sources.

*Maximum retries for client reroute:* Specifies the maximum number of connection retries that are attempted by the automatic client reroute function if the primary connection to the server fails. The property is only used when **Retry interval for client reroute** is set.

**Note:** This field is only available for DB2 data sources.

*Alternate server names:* Specifies the list of alternate server name or names for the DB2 server. If more than one alternate server name is specified, the names must be separated by commas. For example:  
host1,host2

**Note:** This field is only available for DB2 data sources.

*Alternate port numbers:* Specifies the list of alternate server port or ports for the DB2 server. If more than one alternate server port is specified, the ports must be separated by commas. For example:  
5000,50001

**Note:** This field is only available for DB2 data sources.

*Client reroute server list JNDI name:* Specifies the JNDI name that is used to bind the DB2 client reroute server list into the JNDI name space. The DB2 database server will use this name to look up the alternate server name list when the alternate server information is not already in memory. This option is not supported for type 2 data sources.

**Note:** This field is only available for DB2 data sources.

*Unbind client reroute list from JNDI:* Used with test connection only. When set to true, the Client reroute server list JNDI name will be unbound from the JNDI name space after a test connection is issued.

**Note:** This field is only available for DB2 data sources.

**Data source (WebSphere Application Server V4) collection:**

Use this page to view the settings of a WebSphere Application Server Version 4.0 data source.

These data sources use the WebSphere Application Server Version 4.0 Connection Manager architecture. All EJB 1.1 modules must use a WebSphere Application Server Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources > JDBC > Data sources (WebSphere Application Server V4)**
- **Resources > JDBC > JDBC providers > *JDBC\_provider* > Data sources (WebSphere Application Server V4)**

*Name:*

Specifies a text identifier of the data source.

**Data type** String

*JNDI Name:*

Specifies the Java Naming and Directory Interface (JNDI) name of the data source.

**Data type** String

*Scope:*

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

*Provider:*

Specifies the JDBC provider that encapsulates the appropriate classes.

*Description:*

Specifies a text description of the data source.

**Data type** String

*Category:*

Specifies a text string that you can use to classify or group the data source.

**Data type** String

*Data source (WebSphere Application Server Version 4) settings:*

Use this page to create a Version 4.0 style data source. This data source uses the WebSphere Application Server Version 4.0 connection manager architecture. All of your EJB1.x modules must use this data source.

You can access this administrative console page in one of two ways:

- **Resources > JDBC > Data sources (WebSphere Application Server V4) > *data\_source***
- **Resources > JDBC > JDBC providers > *JDBC\_provider* > Data sources (WebSphere Application Server V4) > *data\_source***

*Scope:*

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

*Provider:*

Specifies the JDBC provider that WebSphere Application Server uses for this data source.

The list shows all of the existing JDBC providers that are defined at the relevant scope. Select one from the list if you want to use an existing JDBC provider as Provider.

*Create new provider:*

Provides the option of configuring a new JDBC provider for the new data source.

**Create New Provider** is displayed only when you create, rather than edit, a data source.

Clicking **Create New Provider** causes the **Create a new JDBC provider** wizard to launch. Complete all of the wizard panels, then click **Finish**. The administrative console now displays the Data sources (WebSphere Application Server V4) configuration page again, where you see the new JDBC provider name in the Provider field.

*Name:*

Specifies the display name for the resource.

For example, you can set this field to *Test Data Source*.

**Data type** String

*JNDI name:*

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of *markSection* generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run the dump name space tool.

**Data type** String

*Description:*

Specifies a text description for the resource.

**Data type** String

*Category:*

Specifies a category string that you can use to classify or group the resource.

**Data type** String

*Database name:*

Specifies the name of the database that this data source accesses.

For example, you can call the database *SAMPLE*.

**Data type** String

*Default user ID:*

Specifies the user name to use for connecting to the database.

For example, you can use the ID *db2admin*.

**Data type** String

*Default password:*

Specifies the password used for connecting to the database.

For example, you can use the password *db2admin*.

**Data type** String

**Java EE resource provider or connection factory custom properties collection:**

Use this page to view the custom properties of a Java Platform, Enterprise Edition (Java EE) resource provider or connection factory.

You can configure custom property collections for numerous resource types. According to the resource type with which a collection is associated, your ability to add, delete, and modify individual properties and settings varies. Begin the configuration process by clicking on the *Required* field to sort those column values in descending order. All of the required (true) values are then sorted at the beginning of the page. Be sure to set all required properties.

**Note:** The following list displays three custom properties that are deprecated in WebSphere Application Server Version 6.10. The product now offers these properties as pre-configured options, which are the replacement properties in the following list. To avoid runtime error messages, permanently disable the original custom properties by deleting them from the table on this administrative console page.

- dbFailOverEnabled -- replaced by **Pretest new connection**
- validateNewConnection -- replaced by **Number of retries**
- connRetriesDuringDBFailover -- replaced by **Retry interval**

To set the replacement properties, click **Data sources** > *my\_data\_source* > **WebSphere Application Server data source properties**.

*Name:*

Specifies the property name.

You must ensure that the resource provider has the setting for this name.

**Data type** String

*Value:*

Specifies the property value.

**Data type** Variable; see “Custom property settings” for more information.

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

*Required:*

Specifies whether this property is required for the resource provider.

**Data type** Boolean or Check box

*Custom property settings:*

Use this page to specify the attributes of custom properties that might be required for resource providers and resource factories.

According to the resource type with which a property collection is associated, your ability to modify individual property settings varies. Therefore, consider the following descriptions as a general reference for custom property settings. (The administrative console page that you are using to configure your custom property may only allow you to modify a subset of the following settings.)

**Note:** The following list displays three custom properties that are deprecated in WebSphere Application Server Version 6.10. The product now offers these properties as pre-configured options, which are the replacement properties in the following list.

- dbFailOverEnabled -- replaced by **Pretest new connection**
- validateNewConnection -- replaced by **Number of retries**
- connRetriesDuringDBFailover -- replaced by **Retry interval**

Set the replacement properties on the WebSphere Application Server data source properties console page. Click **Data sources** > *my\_data\_source* > **WebSphere Application Server data source properties**.

*Required:*

Specifies properties that are required for this resource.

**Data type** Check box

*Name:*

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

**Data type** String

*Value:*

Specifies the value associated with this property in this property set.

**Data type** Determined by the **Type** setting, which you select from a drop-down list. If the type is `java.lang.String` then the value is of type String; if the type is `java.lang.Integer`, then the value is of type Integer; and so on.

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

*Type:*

Specifies the fully qualified Java data type of this property .

There are specific types that are valid:

- `java.lang.Boolean`
- `java.lang.String`
- `java.lang.Integer`
- `java.lang.Double`
- `java.lang.Byte`
- `java.lang.Short`
- `java.lang.Long`
- `java.lang.Float`

**Data type** Drop-down list

### ***Custom Properties (Version 4) collection:***

Use this page to view properties for a WebSphere Application Server Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources > JDBC > Data Sources (WebSphere Application Server V4) > *data\_source* > Custom Properties**
- **Resources > JDBC > JDBC Providers > *JDBC\_provider* > Data Sources (WebSphere Application Server V4) > *data\_source* > Custom Properties**

*Name:*

Specifies the name of the custom property

**Data type** String

*Value:*

Specifies the value of the custom property.

**Data type** Integer

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

*Required:*

Specifies properties that are required for this resource.

**Data type** String

*Custom property (Version 4) settings:*

Use this page to add properties for a WebSphere Application Server Version 4.0 data source.

To view this administrative console page, click **Resources > JDBC > JDBC Providers > JDBC\_provider > Data Sources (WebSphere Application Server V4) > data\_source > Custom Properties > custom\_property**.

*Required:*

Specifies properties that are required for this resource.

**Data type** Check box

*Name:*

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

**Data type** String

*Value:*

Specifies the value associated with this property in this property set.

**Data type** Integer

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

Type:

Specifies the fully qualified Java type of this property (java.lang.Integer, java.lang.Byte).

Data type String

## Creating and configuring a JDBC provider and data source using the Java Management Extensions API

If your application requires access to a JDBC connection pool from a Java 2 Platform, Enterprise Edition (J2EE) 1.3 or 1.4, or Java Platform Enterprise Edition (Java EE) level WebSphere Application Server component, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively.

### About this task

Alternatively, you can use the JMX API in combination with the WSadmin - scripting tool.

**Note:** Use the JMX API to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. You can create supported providers and associated data sources through the administrative console, or by using the WSadmin - scripting tool. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic “Data source minimum required settings, by vendor” on page 1510.

These steps outline the general procedure for using the JMX API to create a JDBC provider and data source, on WebSphere Application Server running on Windows platforms.

1. Put the appropriate JAR files in your classpath. You need thecom.ibm.ws.admin.client\_6.1.0.jar JAR file in your classpath.

The following command is an example for setting your classpath:

```
export CLASSPATH=$CLASSPATH:/WebSphere/V7R1M0/AppServer/runtime/com.ibm.ws.admin.client_6.1.0.jar
```

2. Look up the host and get an administration client handle.
3. Get a configuration service handle.
4. Update the resource.xml file using the configuration service as desired.
  - a. Add a JDBC provider.
  - b. Add the data source.
  - c. Add the connection factory. This step is necessary only for data sources that must support container-managed persistence.
5. Reload the resource.xml file to bind the newly created data source into the JNDI namespace. Perform this step if you want to use the newly created data source right away without restarting the application server.
  - a. Locate the DataSourceConfigHelper MBean using the name.
  - b. Put together the signature and parameters for the call.
  - c. Invoke the reload() call.
6. **Attention:** If you modify the class path or native library path of an existing JDBC provider, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

**Example: Using the Java Management Extensions API to create a JDBC driver and data source for a CMP bean:**

This code sample demonstrates how to configure a JDBC provider and data source, designate the data source for use with CMP beans, set an authorization alias for the data source, and reload the Mbean to make configuration changes.

```

/**
 * Creates a node-scoped resource.xml entry for a
 * DB2 for zOS Local JDBC Provider (RRS) data source
 * when WebSphere security is not enabled
 *
 * The data source created is for CMP use.
 *
 * To run this example, the following must be done:
 *
 * 1) Set the WAS_HOME environment variable to the location of
 * your WebSphere Application Server for z/OS Configuration
 * directory
 *
 * Example: export WAS_HOME=/install_root
 *
 * 2) Set the following environment variables:
 *
 * export WAS_LIB=$WAS_HOME/lib
 * export WAS_CLASSPATH=[DIRECTORY_CONTAINING_THIS_FILE]
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/admin.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/bootstrap.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/j2ee.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/jmxc.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/java/jre/lib/ext/mail.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.bootstrap_6.1.0.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.emf_2.1.0.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.runtime_6.1.0.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/org.eclipse.emf.common_2.2.1.v200609210005.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/org.eclipse.emf.ecore_2.2.1.v200609210005.jar
 * export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/runtime/admin.client_6.1.0.jar
 *
 *
 * 3) Execute the following commands:
 *
 * javac -classpath $WAS_CLASSPATH CreateDataSourceCMP.java
 * java -classpath $WAS_CLASSPATH CreateDataSourceCMP
 */
public class CreateDataSourceCMP {

 String dsName = "MyDataSourceCMP"; // the data source display name
 // this is also the JNDI name and connection factory name
 String dbName = "LOC1"; // database name
 String authDataAlias = "IBMUSER"; // an authentication data alias
}
```

```

String uid = "IBMUSER"; // user ID
String pw = "IBMUSER"; // password
String dbclasspath = "/db2beta/db2710/classes/db2j2classes.zip"; // path to the database driver
String dblibpath = "/db2beta/db2710/lib"; // path to the native library directory for the database

/**
 * Main method.
 */
public static void main(String[] args) {
 CreateDataSourceCMP cds = new CreateDataSourceCMP();
 try {
 cds.run(args);
 } catch (com.ibm.ws.exception.WsException ex) {

/**
 * Creates a node-scoped resource.xml entry for a
 * DB2 for zOS Local JDBC Provider (RRS) DataSource
 * when WebSphere security is not enabled
 *
 * To run this example, the following must be done:
 *

```

```

* 1) Set the WAS_HOME environment variable to the location of
* your WebSphere Application Server for z/OS Configuration
* directory
*
* Example: export WAS_HOME=install_root
*
* 2) Set the following environment variables:
*
* export WAS_LIB=$WAS_HOME/lib
* export WAS_CLASSPATH=[DIRECTORY_CONTAINING_THIS_FILE]
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/admin.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/bootstrap.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/j2ee.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_LIB/jmxc.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/java/jre/lib/ext/mail.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.bootstrap_6.1.0.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.emf_2.1.0.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/com.ibm.ws.runtime_6.1.0.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/org.eclipse.emf.common_2.2.1.v200609210005.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/plugins/org.eclipse.emf.ecore_2.2.1.v200609210005.jar
* export WAS_CLASSPATH=$WAS_CLASSPATH:$WAS_HOME/runtime/admin.client_6.1.0.jar
*
*
* 3) Run the following commands:
*
* javac -classpath $WAS_CLASSPATH CreateDataSourceBMP.java
* java -classpath $WAS_CLASSPATH CreateDataSourceBMP
*/
public class CreateDataSourceBMP {

 String dsName = "MyDataSourceBMP"; // Data source display name
 // this is also the JNDI name and connection factory name
 String dbName = "LOC1"; // database name
 String authDataAlias = "IBMUSER"; // an authentication data alias
 String uid = "IBMUSER"; // user ID
 String pw = "IBMUSER"; // password
 String dbclasspath = "/db2beta/db2710/classes/db2j2classes.zip"; // path to the database driver
 String dblibpath = "/db2beta/db2710/lib"; // path to the native library directory for the database

 /**

```

### **Example: Creating a JDBC provider and data source using Java Management Extensions API and the scripting tool:**

The following sample code is a JACL (WSadmin - scripting tool) script used to create a data source.

Use this script to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. See the topic *Creating configuration objects using the wsadmin tool* for instructions on how to use the `createUsingTemplate` command to establish these data sources. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic "Data source minimum required settings, by vendor" on page 1510.

This script sets up the following sample JDBC objects:

- Creates a data source `fvtds_1`
- Creates a 4.0 data source `fvtds_3`
- Creates a container-managed persistence (CMP) data source linked to `fvtds_1`

**Note:** If you later modify the class path or native library path of the JDBC provider associated with your data source, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

```
#AWE -- Set up XA DB2 data sources, both Version 4.0 and Connector architecture (JCA)-compliant data sources
```

```
#UPDATE THESE VALUES:
#The classpath that will be used by your database driver
set driverClassPath "c:/sqllib/java/db2java.zip"

## Using the DB2 Universal JDBC Driver to access DB2 for z/OS

The z/OS operating system requires that you configure the DB2 Universal JDBC Driver and your database to ensure interoperability. Within WebSphere Application Server, configure a JDBC provider object and a data source object to implement the driver capabilities for your applications.

### Before you begin

Use only the following versions of the DB2 Universal JDBC Driver to connect with DB2 on z/OS; consult DB2 service updates for available enhancements on the version that you choose.

- The DB2 Universal JDBC Driver in DB2 UDB for z/OS Version 8. This version supports both driver Types 2 and 4.
- The DB2 Universal JDBC Driver for DB2 UDB for OS/390 and z/OS Version 7, as documented in APAR PQ80841. This version supports both driver Types 2 and 4.
- The DB2 Universal JDBC Driver with the feature *z/OS Application Connectivity to DB2 for z/OS*, which provides Type 4 connectivity only. If you install this version of the driver, you must configure a DB2 Universal JDBC Driver provider (XA) to access remote DB2 databases.

**Note:** If you are replacing the DB2 for 390 and z/OS Legacy JDBC driver with the DB2 Universal JDBC Driver, you can migrate your existing JDBC provider settings. Consult the topic "Migrating from the JDBC/SQLJ Driver for OS/390 and z/OS to the DB2 Universal JDBC Driver" in the Information Management Software for z/OS Solutions Information Center, which is located at <http://publib.boulder.ibm.com/infocenter/dzichelp>.

1. Install the driver class files and any necessary native files in an available HFS directory. (Native files are class files that some versions of the DB2 Universal JDBC Driver require for running on the z/OS operating system.)

2. Configure the driver and database for interoperability

- a. Bind the required DB2 packages

As with any application that executes SQL statements in DB2 for z/OS, the Universal JDBC driver must first bind with DB2 the packages that represent the SQL statements to be executed.

The specific details of the bind utility and bind process are described by the README provided with the installed DB2 Universal JDBC Driver. Refer to this README for details on how to setup and perform the required binding.

Also note that the utility requires the server name (or IP address), the port number, and the database name (the database location on z/OS) for the target DB2. To get this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 system. This displays the IPADDR (IP address), the SQL DOMAIN (server name), the TCPPOINT number, and the LOCATION (database name/location) for you to use as input to the utility.

You must perform the bind process for each target DB2 that will be accessed using the DB2 Universal JDBC Driver.

- b. Set up to handle in-doubt transactions

You must perform this setup once for each target DB2 for z/OS Version 7 location that is accessed using the DB2 Universal JDBC Driver Type 4 XA support.

Because DB2 for z/OS Version 7 does not implement Java Platform, Enterprise Edition (Java EE) XA support, the Type 4 driver XA processing uses DB2 V7 two-phase commit protocol and a table in each location (database) to store a list of global transactions that are in doubt (finished but not committed).

This table must be set up at each DB2 V7 location that is accessed. To do this, use the In-Doubt Utility, which is included as part of the installed DB2 Universal JDBC Driver. Use this utility to create the SYSIBM.INDOUBT Table that stores information about In-Doubt Global Transactions. This utility also binds the package T4XAIndbtPkg, which contains the SQL statements to insert and delete from the SYSIBM.INDOUBT Table. The T4XAIndbtPkg package is written with SQLJ.

This installation process requires that the target DB2 subsystem be configured with DDF enabled for incoming TCP/IP connections.

- 1) To enable DDF on the target DB2, issue the DB2 **-START DDF** command on that system.
- 2) This utility requires the server name (or IP address) and the port number for the target DB2 V7. To obtain this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 V7 system. This displays the IPADDR (IP address), the SQL DOMAIN (server name), and the TCPSPORT number that can be used as input to the utility.

To find more detailed information about the In-Doubt utility, refer to the *DB2<sup>®</sup> Universal Database<sup>™</sup> for z/OS Version 7 Application Programming Guide and Reference for Java<sup>™</sup>* publication. (You can download it from the Library section of the DB2 Universal Database for z/OS Version 7 product information Web pages.) Within this publication, search for discussion about the utility under **DB2T4XAIndoubtUti1**, which is the official name of the In-Doubt utility.

**Note:** The previously described setup for in-doubt transactions is *not* a requirement for DB2 FOR z/OS Version 8 servers because DB2 FOR z/OS Version 8 natively supports XA commands over DRDA and manages the In-Doubt Global Transactions internally.

c. Define a db2.jcc.propertiesFile

A db2.jcc.propertiesFile for use by DB2 Universal JDBC Driver Type 2 processing under WebSphere Application Server for z/OS can be created and specified as input to the driver. This runtime properties file is for use in specifying various runtime options that the DB2 Universal JDBC Driver uses for Type 2 connectivity. These options are specified as properties in the form of parameter=value. Refer to the README file packaged with the installed DB2 Universal JDBC Driver for a detailed description of each of the properties.

This file is not required; however, if it is not provided, universal driver default processing is performed.

Of specific interest is the db2.jcc.ssid property. This property specifies the DB2 subsystem identifier (not location name), to be used by the DB2 Universal JDBC Driver Type 2 processing as the local subsystem name to which it should connect. If this property is not provided, the driver uses the subsystem identifier that it finds in the DSNHDECP load module. If the installation wants to use the DSNHDECP load module to specify the subsystem identifier, this load module must be included in a steplib dataset in the servant region PROCs associated with each server that will use the DB2 identified by the subsystem ID. Refer to the README file packaged with the universal driver for more information on using this load module. If that DSNHDECP load module does not accurately reflect the desired subsystem, or if multiple subsystems might be using a generic DSNHDECP, the db2.jcc.ssid property must be specified.

Although the db2.jcc.propertiesFile is not required, if you choose to define the file, you must specify the fully qualified-hfs-filename. To do this, specify the file as a JVM System property as follows:

- **db2.jcc.propertiesFile = <fully-qualified-hfs-filename>**

Because the driver-general properties are typically specific to a driver load (for example, server) rather than all servers using the JDBC provider, it is best to set this JVM property at the server level. To define the **db2.jcc.propertiesFile=** property to the server level using the WebSphere Application Server for z/OS Administrative Console:

- 1) Under the WebSphere Application Server for z/OS Administrative Console, go to **Servers > Application Servers**, then click the server to which you want to add the JVM property.
- 2) On the selected server page, expand **Java and Process Management** and click **Process Definition > Servant**.
- 3) On the Servant page, click **Additional Properties**, then click **Java Virtual Machine**.

- 4) On the Java Virtual Machine page, click **Additional Properties**, then click **Custom Properties**.
  - 5) On the Custom Properties page, scroll down and click **New** to configure a new JVM property for the selected server. The name of the property is **db2.jcc.propertiesFile**. The value of the property is the fully-qualified-hfs-filename that you created and initialized with the DB2 Universal JDBC Driver properties. These are the properties that you want the Type 2 driver to use for the selected server
  - 6) Click **Ok**.
  - 7) Click **Save** to save the new JVM property.
3. Define a JDBC provider for the DB2 Universal JDBC Driver. The JDBC provider object encapsulates the driver classes for implementation in WebSphere Application Server.
    - a. From the WebSphere Application Server for z/OS Administrative Console, click **Resources > JDBC > JDBC Providers**.
    - b. Select the *scope* at which applications can use the JDBC provider. (This scope becomes the scope of any data source that you associate with this provider.) You can choose a cell, node, cluster, or server. For more information, see Administrative console scope settings.
    - c. Click **New**. This action causes the **Create a new JDBC Provider** wizard to launch.
    - d. Use the first drop-down list to select DB2 for z/OS as your database type.
    - e. Select the DB2 Universal JDBC Driver provider as your JDBC provider type in the second drop-down list.
    - f. From the third drop-down list, select the implementation type that is necessary for your application.
 

If your application does not require that connections support two-phase commit transactions, and you plan to use type 4 connectivity, choose **Connection Pool Data Source**. If you use the connection pool data source with type 2 connectivity, however, Application Server on z/OS uses RRS to process *both* one-phase and two-phase transactions.

**Note:** Do not select **Connection Pool Data Source** if your installation has the z/OS Application Connectivity to DB2 for z/OS feature defined to WebSphere Application Server for z/OS. Only the XA implementation of the DB2 Universal JDBC Driver supports this feature.

Choose **XA Data Source** if you plan to use driver type 4, and your application requires connections that support two-phase commit transactions. Use only driverType 4 connectivity for the XA data source.

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.
    - g. Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard page Enter database class path information.
 

Typically you do not need to change the class path that already populates the field. (That class path is the value of the WebSphere environment variable that is displayed on this page, in the form of `#{DATABASE_JDBC_DRIVER_PATH}`.) Most likely you also do not need to change the native library path or the data source implementation class name.
    - h. Click **Next** to see a summary of your JDBC provider settings.
    - i. Click **Finish** if you are satisfied with the entire JDBC provider configuration. You now see the JDBC provider collection page, which displays your new JDBC provider in a table along with other providers that are configured for the same scope.
  4. Define a data source. WebSphere Application Server uses the data source object to obtain database connections and manage those connections.
    - a. From the WebSphere Application Server for z/OS Administrative Console, access the page for the data source version that your applications require. If you need support for two-phase transactions, use only a data source of the latest standard version. Version 4 data sources do not support connections that participate in two-phase transactions.
 

You can reach the appropriate page in one of two ways:

- Click **Resources > JDBC > Data sources**, or **Data sources (WebSphere Application Server Version 4)**.
  - Click **Resources > JDBC > JDBC providers > JDBC\_provider > Data sources**, or **Data sources (WebSphere Application Server Version 4)**.
- b. Select the *scope* at which applications can use the data source. You can choose a cell, node, cluster, or server. For more information, see the Administrative console scope settings article.

**Note:** From this point onward, the steps for creating Data sources (WebSphere Application Server Version 4) differ from the steps for creating data sources of the latest standard version. To configure a Version 4 data source:

- Click **New** to proceed to the console page for defining required properties.
  - On this properties page specify values for the fields that are grouped under the heading **Configuration**. Application Server requires these properties to implement your JDBC driver classes; consult “Data source minimum required settings, by vendor” on page 1510 to learn about acceptable values.
  - Save your configuration by clicking **OK**. You are now finished with the primary data source configuration tasks.
  - Optional: Define additional properties that are supported by the DB2 Universal JDBC provider. Application Server calls them *custom properties*, and requires that you set them on the data source as well. Begin by clicking the Custom Properties link that is now displayed on the administrative console page. You can learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.
- c. Click **New**. This action causes the **Create a data source** wizard to launch and display the Enter basic data source information page. The first field is the scope field, which is read-only. This field displays your previous scope selection.
- d. Type a data source name in the Data source name field. This name identifies the data source for administrative purposes only.
- e. Type a Java Naming and Directory Interface (JNDI) name in the JNDI name field. WebSphere Application Server uses the JNDI name to bind application resource references to this data source. For more information on JNDI, consult the “Naming” on page 2160 article.
- f. Configure a component-managed alias to secure your data source if you plan to implement driverType 4 connectivity with the DB2 Universal JDBC Driver. If you plan to use driverType 2 connectivity, you do not have to set an alias. In this case the connection manager uses a default authentication alias, which is the user identity of a thread when that thread delivers a getConnection request.

A component-managed alias consists of an ID and password that are specified in an application for data source authentication. Therefore, the alias that you set on the data source must be identical to the alias in the application code. For more information on Java 2 Connector (J2C) security, see the Managing Java 2 Connector Architecture authentication data entries article.

To set a component-managed alias, either select an existing alias or create a new one.

- Use the drop-down list to select an existing component-managed authentication alias.
  - To create a new alias, click the **create a new one** link. This action closes the data source wizard and triggers the administrative console to display the J2C authentication data collection page. Click **New** to define a new alias. Click **OK** to save your settings and view the new alias on the J2C authentication data collection page. Restart the data source wizard by navigating back to the data source collection page, selecting the appropriate scope, and clicking **New**.
- g. Click **Next** to see the wizard page Select JDBC provider.
- h. Either select an existing JDBC provider, or create a new provider.

**To select an existing JDBC provider:**

- 1) Click **Select an existing JDBC provider**.

- 2) Select a JDBC driver from the drop-down list.
- 3) Click **Next**. You now see the page entitled Enter database specific properties for the data source.

**To create a new JDBC provider:**

- 1) Click **Create new JDBC provider**.
- 2) Click **Next** to see the Create JDBC provider page.
- 3) Use the first drop-down list to select DB2 for z/OS as your database type.
- 4) Select the DB2 Universal JDBC Driver provider as your JDBC provider type in the second drop-down list.
- 5) From the third drop-down list, select the implementation type that is necessary for your application.

If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Both driverType 2 and driverType 4 connectivity implementations of the DB2 Universal JDBC Driver support connection pool data sources.

**Note:** Do not select this provider if your installation has the z/OS Application Connectivity to DB2 for z/OS feature defined to WebSphere Application Server for z/OS. Only the XA implementation of the DB2 Universal JDBC Driver supports this feature.

Choose **XA Data Source** if your application requires connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery. Use only driverType 4 connectivity for the XA implementation.

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.

- 6) Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard page Enter database class path information.  
Typically you do not need to change the class path that already populates the field. (That class path is the value of the WebSphere environment variable that is displayed on this page, in the form of `#{DATABASE_JDBC_DRIVER_PATH}`.) Most likely you also do not need to change the native library path or the data source implementation class name.
- 7) Click **Next**. You now see the page entitled Enter database specific properties for the data source.
  - i. Click **Use this data source in container managed persistence (CMP)** if container managed persistence (CMP) enterprise beans must access this data source.
  - j. Specify all of the remaining properties, as they are required for implementation of the DB2 Universal JDBC Driver. These properties include:
    - Database name, which is the location name of the target database used when establishing connections with this data source
    - driverType, which is the JDBC connectivity type used by the data source
    - Server name, which is the TCP/IP address or host name for the Distributed Relational Database Architecture (DRDA) server.  
This property is required only if driverType is set to 4. This property is not used if driverType is set to 2.
    - Port number, which is the TCP/IP port number where the DRDA server resides.  
Provide a value for this property only if driverType is set to 4. Do not set this property if driverType is set to 2.
  - k. Click **Finish** to save the configuration and exit the wizard. You now see the Data source collection page, which displays your new configuration in a table along with other data sources that are configured for the same scope.

## What to do next

You can override the default values for some data source properties. Click your new data source link in the table to view the general configuration page for required data source properties. You can also define additional properties that are supported by the DB2 Universal JDBC Driver. Application Server requires that you set them as custom properties on the data source. Learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

## Extend DB2 data source definitions at the application level

Extend data source definitions, which consist of non-core or custom properties, for DB2 data sources to add a greater level of application flexibility when you are using the DB2 Universal JDBC driver or DB2 Using IBM JCC driver. Use this feature to configure a DB2 data source in the application server with a core set of data source properties, and defer to individual applications to define any custom or non-core properties, like `currentSchema` or `clientApplicationInformation`, that you want to be application specific. You can also use these extended definitions to override any non-core or custom properties that are already defined for the data source. In addition, this feature can reduce the number of physical connections that the application server uses by employing one connection pool between resources that connect to the same data source.

## Before you begin

You must be using a DB2 data source, and the data source must be configured in the application server with one of the following JDBC providers:

- DB2 Universal JDBC driver (Version 3.1 or higher)
- DB2 Using IBM JCC driver (Version 3.1 or higher)

## About this task

Associate non-core properties with different resource references for a data source, and configure your applications to take advantage of these resource references to extend or override any non-core properties for the data source. You can choose to define new non-core or custom properties, or override any non-core properties that are already defined for the data source.

Also, applications can share the same connection pool in the application server, even though each application might have its own unique set of data source properties. There might be only one data source that is defined in the application server, and therefore only one connection pool, but to individual applications it would appear that there is more than one data source that is defined. This can result in:

- Reduction in memory consumption by the application server. Data source definitions will correspond to one connection pool, so there are fewer objects in memory when compared with a data source definition that corresponds to its own connection pool.
- Reduction in the number of open connections to the data source, which can reduce the memory consumption by the data source. The application server can reduce the number of idle connections by providing one connection pool that corresponds to multiple data sources, providing a more efficient use of connections.
- Avoidance of two-phase commit (XA) transactions in certain DB2 scenarios, when your applications use the `get/use/close` connection pattern. The application server can share connections between different resource references that have same set of core properties, even if they have different non-core properties, within the same transaction. This behavior can avoid two-phase commit processing if the connection sharing leads the application server to use one and only one physical connection.

1. Update the data source definitions for an application that is already installed.
  - a. Navigate to the panel to manage the resource references for the application.
    - For applications that do not use container-managed persistence, click **Applications** → **WebSphere enterprise applications** → *application\_name* → **Resource references**.

- For applications that use container-managed persistence, click **Applications** → **WebSphere enterprise applications** → *application\_name* → **Provide default data source mapping for modules containing 2.x entity beans**. You cannot add extended properties for individual CMP beans.
- You can to configure two resource reference files on the same data source. This allows you to extend the custom properties on the data source to include two different schema names (currentSQLId on z/OS or currentSchema name in the custom properties) that can be used to exploit the capabilities of the application server. See “Configure two resource reference files on the same data source” on page 1582 for more information.

**Note:** For pureQuery, if this is an XA data source you must define a new custom property on the data source where *property\_name* = downgradeHoldCursorsUnderXa and boolean value = true.

- Navigate to the panel for extended data source properties. Click **Extended properties...** in the **Target Resource JNDI Name** column. If the data source does not support extended data source properties, you will receive an error when you try to apply these changes.
  - Add a data source definition that is specific to that target resource. Click **New**, and complete the required fields. You cannot modify the following data source properties, which must be the same for all applications that use this data source:
    - accountingInterval
    - dataSourceName
    - databaseName
    - kerberosServerPrincipal
    - loginTimeout
    - logWriter
    - password
    - pkList
    - planName
    - portNumber
    - readOnly
    - securityMechanism
    - serverName
    - user
  - Optional: Configure two res-refs and the isolation level in the ibm-ejb-jar-ext.xml
- Optional: To avoid two-phase commit transactions, employ the get/use/close connection pattern. The get/use/close pattern is when an application gets a connection from a data source or connection factory and completes the current work within a single method, and the application does not call another method until that work is complete.
    - Ensure that your applications use the get/use/close connection pattern.
    - Enable the application server to verify use of the get/use/close connection pattern in applications, which will lead to the avoidance of two-phase commit processing if the sharing leads to one and only one physical connection being used.
      - Click **Resources** → **JDBC** → **Data sources** → *data\_source* → **WebSphere Application Server data source properties**
      - Select **Optimize for get/use/close connection pattern with heterogenous pooling**. You will receive error messages if you select this option and your applications do not use the get/use/close connection pattern.

## Related concepts

“Data sources” on page 1395

Installed applications use a *data source* to obtain connections to a relational database. A data source is analogous to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity to other types of enterprise information systems (EIS).

“JDBC providers” on page 1394

Installed applications use JDBC providers to interact with relational databases.

## Related tasks

“Using the DB2 Universal JDBC Driver to access DB2 for z/OS” on page 1575

The z/OS operating system requires that you configure the DB2 Universal JDBC Driver and your database to ensure interoperability. Within WebSphere Application Server, configure a JDBC provider object and a data source object to implement the driver capabilities for your applications.

## Related reference

“WebSphere Application Server data source properties” on page 1554

Use this page to set advanced data source properties in the application server. These properties activate and configure services that the application server applies to data sources to customize connections within an application server. These properties do not affect connections within the database.

### ***Extended data source properties:***

Use this page to set the extended data source properties for a DB2 database. You can use these properties to allow an application to extend the custom properties for a data source or override any non-core properties that already exist for that data source.

To access this administrative console page:

- For applications that do not use container-managed persistence click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application\_name* → **Resource references**
- For applications that use container-managed persistence click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application\_name* → **Provide default data source mapping for modules containing 2.x entity beans.**

For data sources that use the DB2 Universal JDBC driver or DB2 Using IBM JCC Driver, click **Extended properties...** in the **Target Resource JNDI Name** column.

*Name:* Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used.

Do not start your property names with *was*, because this prefix is reserved for properties that are predefined in the application server.

**Data type** String

*Value:*

Specifies the property value.

**Data type** Variable

### ***Configure two resource reference files on the same data source:***

You can configure two resource reference files on the same data source. This allows you to extend the custom properties for the data source to be extended to include two different schema names (currentSQLId on z/OS or currentSchema name in the custom properties) that can be used to exploit the capabilities of the application server.

### About this task

When an EntityManager is created, the application server obtains a connection to the database. When you are using a pessimistic transaction, the EntityManager will retain that connection until the EntityManager is closed. When there are two EntityManagers that extend the data source definitions, the openjpa.jdbc.TransactionIsolation property might cause a problem with the transaction. This property can be found in the persistence.xml file in the following entry:

```
property name="openjpa.jdbc.TransactionIsolation" value="read-committed"
```

In order to satisfy this request, Java Persistence API (JPA) will obtain a connection and immediately call setTransactionIsolation(READ\_COMMITTED). When you have two EntityManagers share a single physical connection to the database, the first EntityManager creates a connection to the database and involves that connection in a transaction. When the second EntityManager creates a connection, it is not able to change the isolation level.

You can avoid this problem by creating two resource reference files in the same data source. You can create the resource references with Rational Application Developer or by editing the XML files. You will need to make changes to the ejb-jar.xml, ibm-ejb-jar-bnd.xml, ibm-ejb-jar-ext.xml, persistence.xml files.

**Note:** For pureQuery, if this is an XA data source you must define a new custom property on the data source where *property\_name* = downgradeHoldCursorsUnderXa and boolean value = true.

See the following sections for information on how to accomplish this:

- Configure two resource reference files on the same data source using Rational Application Developer.
- Configure two resource reference files on the same data source by editing the XML files.
- Configure two resource reference files on the same data source using Rational Application Developer.
  1. Edit the ejb-jar.xml file
    - a. Create the deployment descriptor if it doesn't already exist:
      - 1) Go to the context menu of the Enterprise Java beans (EJB) project and select **Java EE** → **Generate Deployment Descriptor Stub**.
    - b. Edit the deployment descriptor:
      - 1) Go to the project's META-INF directory and select the ejb-jar.xml file.
    - c. Add the enterprise bean's element to the deployment descriptor if it doesn't already exist:
      - 1) In the left hand pane, select **EJB Project node**. Click **Add**.
      - 2) In the dialog, select **Enterprise Beans**. Click **OK**.
    - d. Add the session bean to the deployment descriptor if it's not already there:
      - 1) In the left pane, select **Enterprise Beans**. Click **Add**.
      - 2) Select **Session Bean**. Click **OK**.
      - 3) Enter the name of the session bean in the dialog. Click **OK**.
      - 4) In the right-side pane, enter the EJB Class, the business local, and the business remote interfaces.
    - e. Add the resource reference elements to the session bean:
      - 1) Select the session bean in the left pane and click **Add**.
      - 2) Select **Resource Reference**. Click **OK**.
      - 3) In the **Add Resource Reference** dialog, enter the name, type, authentication and sharing scope fields. Click **OK**.

- 4) Repeat for the second resource reference.
- f. Save the editor
2. Edit the `ibm-ejb-jar-bnd.xml` file
  - a. Create the WebSphere EJB bindings descriptor if it doesn't already exist
    - 1) Go to the context menu of the Enterprise JavaBeans (EJB) project and select **Java EE** → **Generate WebSphere Bindings Deployment Descriptor**.
  - b. Edit the bindings descriptor:
    - 1) In the project's META-INF directory, select the `ibm-ejb-jar-bnd.xml` file.
  - c. Add a binding element for the session bean to the bindings descriptor:
    - 1) In the left pane, select **EJB Jar Bindings** node and click **Add**.
    - 2) In the dialog, select **Session** and click **OK**.
    - 3) In the right pane, enter the name of the session bean.
  - d. Add the bindings for the resource references to the session bean:
    - 1) In the left pane, select the session bean and click **Add**.
    - 2) In the dialog, select **Resource Reference** and click **OK**.
    - 3) In the left pane, select the resource reference.
    - 4) In the right pane, enter the name and binding name for the reference
    - 5) Repeat for the second resource reference.
  - e. Save the editor
3. Edit the `ibm-ejb-jar-ext.xml` file.
  - a. Create the WebSphere EJB extensions descriptor if it doesn't already exist:
    - 1) Go to the context menu of the Enterprise JavaBeans (EJB) project and select **Java EE** → **Generate WebSphere Extensions Deployment Descriptor**.
  - b. Edit the extensions descriptor:
    - 1) In the project's META-INF directory, select the `ibm-ejb-jar-ext.xml` file.
  - c. Add an extensions element for the session bean to the extensions descriptor:
    - 1) In the left pane, select the **EJB Jar Extensions** node and click **Add**.
    - 2) In the dialog, select **Session** and click **OK**.
    - 3) In the right pane, enter the name of the session bean.
  - d. Define the isolation level for the resource references:
    - 1) In the left pane, select the session bean and click **Add**.
    - 2) In the dialog, select **Resource Reference** and click **OK**.
    - 3) In the left pane, select the resource reference.
    - 4) In the right pane, enter the name and the isolation level.
    - 5) Repeat for the second resource reference.
  - e. Save the editor
4. Edit the `persistence.xml` file.
  - a. Add JPA support to the EJB project, which will create the `persistence.xml` file:
    - 1) From the project's context menu, select **Properties**.
    - 2) In the left pane, select the **Project Facets** node.
    - 3) In the right pane, check the box beside **Java Persistence**.
    - 4) Click **OK**.
  - b. Edit the `persistence.xml` file:
    - 1) In the project's META-INF directory, select the `persistence.xml` file

- c. The created persistence.xml file already contains a persistence unit definition. Edit this persistence.xml file
    - 1) In the left pane, select the **Persistence Unit** node. Set the name, JTA data source and exclude the unlisted classes fields.
  - d. Create a new persistence unit definition in the file:
    - 1) In the left pane, select the **Persistence** node and click **Add** .
    - 2) In the dialog, select **Persistence Unit** and click **OK**.
    - 3) In the left pan, select the **Persistence Unit** node. Set the name, JTA data source and exclude the unlisted classes fields.
  - e. Add classes to the persistence unit:
    - 1) In the left pane, select the persistence unit node and click **Add** .
    - 2) In the dialog, select **Class** and click **OK**.
    - 3) In the right pane, enter the name of the class.
    - 4) Repeat for each class.
  - f. Add properties to the persistence unit
    - 1) If there is not already a **Properties** element in the file, select the persistence unit node in the left pane and click **Add**.
    - 2) In the dialog, select **Properties** and click **OK**.
    - 3) In the left pane, select the **Properties** node and click **Add**.
    - 4) In the dialog, select **Property** and click **OK**.
    - 5) In the right pane, enter the name and value for the property
    - 6) Repeat the previous three steps to add the additional properties.
  - g. Save the editor
- Configure two resource reference files on the same data source by editing the XML files.

#### 1. Edit the ejb-jar.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" metadata-complete="false" version="3.0" xmlns="http://java.sun.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd">
 <enterprise-beans>
 <session>
 <ejb-name>NewOrderSessionFacadeBean</ejb-name>
 <business-local>newordersession.ejb3.NewOrderSessionFacade</business-local>
 <business-remote>newordersession.ejb3.NewOrderSessionFacadeRemote</business-remote>
 <ejb-class>newordersession.ejb3.NewOrderSessionFacadeBean</ejb-class>
 <session-type>Stateless</session-type>
 </session>
 <resource-ref>
 <description></description>
 <res-ref-name>jdbc/ERWWDDataSourceV5</res-ref-name>
 <res-type>javax.sql.DataSource</res-type>
 <res-auth>Container</res-auth>
 <res-sharing-scope>Shareable</res-sharing-scope>
 </resource-ref>
 <resource-ref>
 <description></description>
 <res-ref-name>jdbc/ERWWDDataSourceV5_HP</res-ref-name>
 <res-type>javax.sql.DataSource</res-type>
 <res-auth>Container</res-auth>
 <res-sharing-scope>Shareable</res-sharing-scope>
 </resource-ref>
 </enterprise-beans>
</ejb-jar>
```

#### 2. Edit the ibm-ejb-jar-bnd.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd"
version="1.0">
 <session name="NewOrderSessionFacadeBean" simple-binding-name="ejb/session/NewOrderSessionFacadeBean">
 <resource-ref name="jdbc/ERWWDDataSourceV5" binding-name="jdbc/ERWWDDataSourceV5"></resource-ref>
 <resource-ref name="jdbc/ERWWDDataSourceV5_HP" binding-name="jdbc/ERWWDDataSourceV5"></resource-ref>
 </session>
</ejb-jar-bnd>
```

### 3. Edit the ibm-ejb-jar-ext.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-ext xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-ext_1_0.xsd"
 version="1.0" metadata-complete="true">
 <session name="NewOrderSessionFacadeBean">
 <resource-ref name="jdbc/ERWWDDataSourceV5"
 isolation-level="TRANSACTION_READ_COMMITTED" />
 <resource-ref name="jdbc/ERWWDDataSourceV5_HP"
 isolation-level="TRANSACTION_READ_COMMITTED" />
 </session>
</ejb-jar-ext>
```

### 4. Edit the persistence.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 version="1.0" xsi:schemaLocation="
 http://java.sun.com/xml/ns/persistence http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd">
 <persistence-unit name="NewOrderSessionEJB3">
 <jta-data-source>java:comp/env/jdbc/ERWWDDataSourceV5</jta-data-source>
 <class>warehousejb3.WarehouseJPA</class>
 <class>districtejb3.DistrictJPA</class>
 <class>customerejb3.CustomerJPA</class>
 <class>stockejb3.StockJPA</class>
 <class>orderejb3.OrderJPA</class>
 <class>orderlineejb3.OrderlineJPA</class>
 <class>neworderejb3.NewOrderJPA</class>
 <exclude-unlisted-classes>true</exclude-unlisted-classes>
 <properties>
 <property name="openjpa.LockManager" value="pessimistic"/>
 <property name="openjpa.ReadLockLevel" value="read"/>
 <property name="openjpa.WriteLockLevel" value="write"/>
 <property name="openjpa.LockTimeout" value="30000"/>
 <property name="openjpa.FetchBatchSize" value="1" />
 <property name="openjpa.jdbc.TransactionIsolation" value="read-committed" />
 <property name="openjpa.Log" value="none"/>
 </properties>
 </persistence-unit>
 <persistence-unit name="ItemEJB3">
 <jta-data-source>java:comp/env/jdbc/ERWWDDataSourceV5_HP</jta-data-source>
 <class>itemejb3.ItemJPA</class>
 <exclude-unlisted-classes>true</exclude-unlisted-classes>
 <properties>
 <property name="openjpa.LockManager" value="pessimistic"/>
 <property name="openjpa.ReadLockLevel" value="read"/>
 <property name="openjpa.WriteLockLevel" value="write"/>
 <property name="openjpa.LockTimeout" value="30000"/>
 <property name="openjpa.FetchBatchSize" value="1" />
 <property name="openjpa.jdbc.TransactionIsolation" value="read-committed" />
 <property name="openjpa.Log" value="none"/>
 </properties>
 </persistence-unit>
</persistence>
```

## Related tasks

“Extend DB2 data source definitions at the application level” on page 1580

Extend data source definitions, which consist of non-core or custom properties, for DB2 data sources to add a greater level of application flexibility when you are using the DB2 Universal JDBC driver or DB2 Using IBM JCC driver. Use this feature to configure a DB2 data source in the application server with a core set of data source properties, and defer to individual applications to define any custom or non-core properties, like `currentSchema` or `clientApplicationInformation`, that you want to be application specific. You can also use these extended definitions to override any non-core or custom properties that are already defined for the data source. In addition, this feature can reduce the number of physical connections that the application server uses by employing one connection pool between resources that connect to the same data source.

## Enabling trusted context for DB2 databases

Enable trusted context in your applications to improve how the application server interacts with DB2 database servers. Use trusted connections to preserve the identity records of clients that are connecting to a DB2 database through your applications; trusted connections can provide a more secure environment by granting access based on the identity of those users.

## Before you begin

Ensure that the following prerequisites are met before enabling trusted connections:

- You are using a database server that is running DB2 Version 9.5 or later for AIX, HP-UX, Linux, Solaris, or Windows operating systems or DB2 Version 9.1 or later for z/OS. See the list of list of supported software for the application server for more support information.
- You do not need to be connected to the database to configure trusted context in the application server.
- Trusted context is enabled for the DB2 database.
- Global security is enabled. Read about [Setting up and enabling security](#) for more information on configuring security.

## About this task

**Note:** With trusted connections you can:

- Access the DB2 database with the caller identity, obviating the need to create a new connection for every user.
- Preserve the identity of the end-user when the application server is interacting with the database.
- Strengthen database security by avoiding granting all of the privileges to a single user.
- Improve performance, as compared to the existing model of using the `resetConnection()` method to take advantage of identity propagation.

**Note:** Non-trusted connections cannot be used as trusted connections. If the connection pool contains only non-trusted connections and a request comes in for a trusted connection, a new request will be sent to the database for the trusted connection.

Enable trusted context for your applications.

- Enable trusted context when you are installing a new application.
  1. Perform a typical installation for the application until you reach **Step 7: Map resource references to resources** in the installation wizard.
  2. In **Step 7: Map resource references to resources**, select **Use trusted connections (one-to-one mapping)** in the **Specify authentication method** section.
  3. Select an authentication alias from the list that matches an alias that is already defined in the DB2 data source. If you do not have an alias defined that is suitable, continue with the installation, and enable trusted context after the application is installed.

**Note:** You can specify a default user (UNAUTHENTICATED) to be used if no client identity is available, but that default ID (UNAUTHENTICATED) must also exist in the DB2 database. If the `com.ibm.mapping.unauthenticatedUser` is set to null or an empty string, then the application server will use the default user (UNAUTHENTICATED). Read about setting the `com.ibm.mapping.unauthenticatedUser` property for more information on this property.
  4. Select a data source from the table that has trusted context enabled.
  5. Click **Apply**.
  6. Edit the properties of the custom login configuration. Read “Setting the security properties for trusted connections” on page 1589.
  7. Finish the installation wizard.
- Enable trusted context on an application that is already installed.

**Note:** Remove the `propagateClientIdentityUsingTrustedContext` custom property for the DB2 data source, if it is present. If the `propagateClientIdentityUsingTrustedContext` is enabled, the application server will issue the following warning at run time:

```
IDENTITY_PROPAGATION_PROP_WARNING=DSRA7029W: The propagateClientIdentityUsingTrustedContext custom property for the Datasource is no longer used, value will be ignored.
```

The application server will determine at run time if the request is using trusted context, and the application server will enable trusted context based on that information. Therefore, the same data source in the application server can be used for both trusted and non-trusted access.

1. Click **Websphere enterprise applications** > *application\_name*.
2. Click **Resource references** from the **Resources** heading.
3. Select **Use trusted connections (one-to-one mapping)** in the **Specify authentication method** section.
4. Select an authentication alias from the list that matches an alias that is already defined in the DB2 data source. If you do not have an alias defined that is suitable, define a new alias.
  - a. Click **JDBC** > **Data sources** > *data\_source\_name*.
  - b. Click **JAAS - J2C authentication data** from the **Related Items** heading.
  - c. Click **New**.
  - d. Define the properties for the alias in **General properties**.
  - e. Click **OK**.

**Note:** You can specify a default user (UNAUTHENTICATED) to be used if no client identity is available, but that default ID (UNAUTHENTICATED) must also exist in the DB2 database. If the `com.ibm.mapping.unauthenticatedUser` is set to null or an empty string, then the application server will use the default user (UNAUTHENTICATED). Read about setting the `com.ibm.mapping.unauthenticatedUser` property for more information on this property.

5. Select a data source from the table that has trusted context enabled.
6. Click **Apply**.
7. Edit the properties of the custom login configuration. Read “Setting the security properties for trusted connections” on page 1589.

## What to do next

Be aware of the following error conditions that can occur if trusted context is not configured properly:

- The application server will issue a warning if you use the `TrustedConnectionMapping` login configuration and the database server does not support trusted context. The application server will then return a normal, non-trusted connection. If you are using a DB2 database for the database server, and it doesn't support trusted connections, then the DB2 database server will throw an exception.
- The application server will throw the following exception if you use the `TrustedConnectionMapping` login configuration and `ThreadIdentity` is specified:

IDENTITY\_PROPAGATION\_CONFLICT2\_ERROR=DSRA7028E: You cannot use the `TrustedConnectionMapping` login configuration when the `ThreadIdentity` property is enabled.

- The application server will throw the following exception if you use the `TrustedConnectionMapping` login configuration and reauthentication is specified:

IDENTITY\_PROPAGATION\_CONFLICT1\_ERROR=DSRA7025E: The reauthentication custom property for the `Datasource` cannot be enabled when you are using the `TrustedConnectionMapping` login configuration.

“Data sources” on page 1395

Installed applications use a *data source* to obtain connections to a relational database. A data source is analogous to the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection factory, which provides connectivity to other types of enterprise information systems (EIS).

“JDBC providers” on page 1394

Installed applications use JDBC providers to interact with relational databases.

## Related tasks

Using thread identity support

The thread identity function allows you to assign a thread identifier as an owner of a connection when you first obtain the connection. This function only applies to Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) resource adapters and Relational Resource Adapter (RRA) wrapped Java Database Connectivity (JDBC) providers that support the use of thread identity for connection ownership.

“Using the DB2 Universal JDBC Driver to access DB2 for z/OS” on page 1575

The z/OS operating system requires that you configure the DB2 Universal JDBC Driver and your database to ensure interoperability. Within WebSphere Application Server, configure a JDBC provider object and a data source object to implement the driver capabilities for your applications.

## ***Setting the security properties for trusted connections:***

Trusted connections are a solution that can pass the requesting user identity to DB2 and also take full advantage of the connection pooling. Utilizing the DB2 trusted context object, the trusted connection is used to separate the identity used to establish the connection from the identity that accessed the DB2 server services. The connection is established by a user whose credentials are authorized by the DB2 server to open the connection and trusted by the DB2 server to assert the identity of the requesting users when accessing the DB2 server from the application.

## Before you begin

To use the trusted connection functionality, you must be running at database server with DB2 Version 9.5 or later for AIX, HP-UX, Linux, Solaris, or Windows operating systems or DB2 Version 9.1 or later for z/OS. Trusted connections can be used if the application server is installed on iSeries systems, as long as a supported version of DB2 is installed on a platform other than iSeries systems, and the DB2 universal driver is used. See the list of list of supported software for the application server for more support information. An existing J2EE connector (J2C) data alias must exist for passing user credentials to the DB2 server when establishing a connection, meaning container authorization must be used.

Read about “Enabling trusted context for DB2 databases” on page 1586 for steps to configure the application server to use trusted connections.

## About this task

Trusted connections support client identity propagation while taking advantage of connection pooling to reduce the performance penalty of closing and reopening connections with a different identity. When you select **Use trusted connection (one-to-one mapping)** for the connection mapping, five custom properties are created. Review these properties to ensure that the default values of these properties correspond with your intended settings.

1. Click **Enterprise applications** → *application\_name* → **Resource references** → **Resources** panel in the administrative console.
2. Select the correct enterprise bean, and click **Mapping Properties** to view the properties that are set by default when you configured the trusted connection.
3. Confirm that the default values assigned to these properties are correct for your environment.

Table 11. Security Properties

Property	Default Value	Information
com.ibm.mapping.authDataAlias	none	The value that is assigned for this property is the value that you selected from the menu list.
com.ibm.mapping.propagateSecAttrs	false	A false value for this property specifies that the security attributes are not propagated. You can change this value to true to add the RunAs subject as an opaque token in the IdentityPrincipal object.
com.ibm.mapping.targetRealmName	null	If this value is not specified or null, the security run time process will use the current user realm name. This process assumes that the Enterprise Information System (EIS) is using the current user realm. In this context, a realm is a logical representation of the user repository. If the application server and DB2 server are using different user repositories, the value of this property should be set to the realm name of the DB2 server. This enables a principal or credential mapping to be set at the target EIS.
com.ibm.mapping.unauthenticatedUser	UNAUTHENTICATED	This property is a user identity that is used by the EIS to indicate a user identity that is unauthenticated. This is defined at <code>com.ibm.ISecurityUtilityImpl.SecConstants.java</code> <pre>public final static String UnauthenticatedString = "UNAUTHENTICATED"</pre>
com.ibm.mapping.useCallerIdentityproperty	false	A false value for this property specifies the Run As identity is asserted in the IdentityPrincipal object. Change the value of this property to true if you want to assert the caller identity in the IdentityPrincipal object instead of the Run As identity.

4. Click **OK** to confirm all the current values.
5. Click **OK** and **Save** on the Resource references panel to save your changes to the master configuration.

## Results

After the completion of these steps and a restart of the application server, trusted connections will be used with the chosen mapping properties to connect with the DB2 database server.

### **Trusted connections with DB2:**

Trusted connections allow for the application server to use DB2 Trusted Context objects to establish connections with a user whose credentials are trusted by the DB2 server to open the connection. By establishing a Trusted Context, this user is then trusted to assert other user identities on the DB2 server without the expense of reauthentication. This also enhances the security of your DB2 database by eliminating the need to assign all privileges to a single user. Implementing trusted connections results in client identity propagation while leveraging connection pooling to eliminate the performance penalty of closing and reopening connections with a different identity.

**Note:** To use the trusted connection functionality you must be using DB2 Version 9.5 or later for AIX, HP-UX, Linux, Solaris, or Windows operating systems or DB2 Version 9.1 or later for z/OS. You can use trusted connections if version 7.0 is installed on an iSeries system as long as a supported version of DB2 is installed on a platform other than an iSeries system and the DB2 universal driver is being used. See the list of list of supported software for the application server for more support information.

To reduce the significant expense of establishing new connections, the connection manager maintains a connection pool in which each connection is tracked by the credential originally used to open the connection. When an application needs a connection, the connection manager uses the credential object to match a free connection from the connection pool. If no free connection is available and the maximum

number of connections has not been reached, the connection pool manager opens a new connection using that credential object. This connection mapping is the default connection mapping used by the application server and is known as a many-to-one credential mapping because the connection is opened using the credential object in the subject, which is usually not the same as the RunAs identity. This simple mapping supports easy connection pooling, but the caller identity is never propagated to database server.

To propagate the caller identity to the database server, you can plug in a Java Authentication and Authorization Service (JAAS) login module. Using this method, you would map the application server user credential to the user credential suitable for the database server security realm. This approach maintains the caller identity, but does not use connection pooling.

Trusted connections are used instead of the default mapping or a JAAS mapping to connect to the data source. Trusted connections support client identity propagation and can also use connection pooling to reduce the performance penalty of closing and reopening connections with a different identity. Trusted connections use the DB2 trusted context object.

The DB2 trusted context is an object that the database administrator defines and that contains a system authorization ID and a set of trust attributes. The trust attributes identify characteristics of a connection that are required for the connection to be considered trusted. The relationship between a database connection and a trusted context is established when the connection to the DB2 server is created. After a trusted context is defined, and an initial trusted connection to the DB2 database server is made, the application server can use that database connection from a different user without a full reauthentication. This is because an authentication token is required with the user identity. The database authenticates the user and then verifies the user authorization to access the database before allowing any database requests to be processed on behalf of that user.

**Note:** For a z/OS server, the user identity must be the Resource Access Control Facility (RACF®) ID.

Using the trusted connection provides the needed plug-in points to support adding your own secure implementation of the DB2 trusted context. Trusted connections separate the identity used to establish the connection from the identity that accesses the back-end server services. The connection is established by a user whose credentials are trusted by the DB2 server to open the connection. The same user is also then trusted to assert the identity of the other users. This assertion also helps strengthen database security by eliminating the need to grant all privileges to a single user.

When the application requests a connection to the database, the connection manager can find any idle trusted connection and assert the user identity to the backend server. All the operations performed on the backend server are from the asserted user identity. The use of an identity mapping may still be needed if the back-end server uses a different user repository than that of the application server.

A new mapping configuration called `TrustedConnectionMapping` implements trusted connections. The `TrustedConnectionMapping` configuration maps the RunAs subject to a resource subject that contains the following elements:

- A resource principal object that this resource subject represents
- A `PasswordCredential` object in the private credential set
- An `IdentityPrincipal` object in the principal set

The principal object represents the RunAs identity. The `PasswordCredential` object contains a user ID and password to be used by the resource adapter to establish the trusted connection. The `IdentityPrincipal` object by default contains the RunAs identity, but can be changed to use the identity of the caller. The `IdentityPrincipal` object also contains an original user identity that represents the user who sent the request initially, an optional realm name that indicates the set of registries where the user identity is defined and an optional security token, which is a serialized security context of the user.

***Enabling trusted context with authentication:***

Enable trusted context in your applications to improve how the application server interacts with DB2 database servers. Use trusted connections to preserve the identity records of clients that are connecting to a DB2 database through your applications; trusted connections can provide a more secure environment by granting access based on the identity of those users. DB2 provides an option for trusted connections in which a password is required when switching the user identity. You can configure the application server to use trusted connections with authentication, and plug-in your own code to take advantage of trusted context with authentication.

## Before you begin

Refer to the topic on enabling trusted context for DB2 databases to ensure that trusted connections are properly configured for the application server.

## About this task

If the WITH AUTHENTICATION option is specified when the trusted context is created, the database requires that you provide an authentication token with the end user's identity. The database authenticates the end user and verifies the end user's authorization to access the database before the database allows any requests to be processed.

The end user's identity must be the RACF ID.

1. Set useTrustedContextWithAuthentication custom property to true for the DB2 data source.
  - a. Click **JDBC** → **Data sources**.
  - b. Click the name of the data source that you want to configure.
  - c. Click **Custom properties** from the **Additional Properties** heading.
  - d. Click **New**.
  - e. Complete the required fields. Use the following information:

Table 12. Custom property panel

Name	Value
useTrustedContextWithAuthentication	true

If the useTrustedContextWithAuthentication custom property is not set to true, the application server will provide an implementation of reusing DB2 trusted connections without authentication at run time. In this case you are not required to provide anything to use the trusted context feature.

2. Use the login configuration for TrustedConnectionMapping, as described in the topic on enabling trusted context for DB2 databases.
3. Extend the DataStoreHelper class, and provide the implementation for the getPasswordForUseWithTrustedContextWithAuthentication method as described in the topic on developing a custom DataStoreHelper class. At run time, the application server will call this method to return the password that the application server is required to use to switch the trusted context identity when you have enabled trusted context with authentication. The password that is returned by this method will be sent to the database when the application server switches trusted context identities, and the password will not be stored by the application server.

This application server only calls this method if the following is true:

- You set the useTrustedContextWithAuthentication data source custom property to true.
- You use the TrustedConnectionMapping login configuration.

The following is an example of the getPasswordForUseWithTrustedContextWithAuthentication method:

```
public String getPasswordForUseWithTrustedContextWithAuthentication(String identityname, String realm)
 throws SQLException
{
 return customersOwnUtility().getPassword(identityname) // customers use their own
 // implementation to get the password
}

```

**Note:** You cannot enable the `useTrustedContextWithAuthentication` custom property for the data source without overwriting the `getPasswordForUseWithTrustedContextWithAuthentication` method in the `DataStoreHelper` class to get the password for switching the identity for trusted connections. If you do not provide implementation for the `getPasswordForUseWithTrustedContextWithAuthentication` method, the application server will throw an exception with the following message at run time:

```
TRUSTED_WITH_AUTHENTICATION_IMPLEMENTATION_ERROR=DSRA7033E: You cannot enable the
useTrustedContextWithAuthentication custom property for the data source without
overwriting the getPasswordForUseWithTrustedContextWithAuthentication DataStoreHelper.
TRUSTED_WITH_AUTHENTICATION_IMPLEMENTATION_ERROR.explanation=The
useTrustedContextWithAuthentication custom property is enabled, but the implementation
code for the DataStoreHelper method that will return the password that the application
server will use to switch the identity is not provided.
TRUSTED_WITH_AUTHENTICATION_IMPLEMENTATION_ERROR.useraction=Overwrite the
getPasswordForUseWithTrustedContextWithAuthentication DataStoreHelper method and
provide the implementation code that will return the password, or set the
useTrustedContextWithAuthentication custom property for the data source to false.
```

## Configuring the application server and DB2 to authenticate with Kerberos

Configure the application server to use Kerberos as the authentication mechanism for the application server that connects to a DB2 database server. The Kerberos authentication mechanism enables interoperability between other applications that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.

## About this task

In order to take advantage of Kerberos authentication with resources in the application server, you need to configure both DB2 and the application server to use Kerberos as the authentication mechanism. Read about Kerberos (KRB5) authentication mechanism support for security for a better understanding of how to set up Kerberos as the authentication mechanism in this version of the application server.

1. Configure Kerberos as the authentication mechanism for the application server.
  - a. Configure the application server to use an LDAP user registry. See the topic on configuring Lightweight Directory Access Protocol user registries for more information.

- b. Configure Kerberos as the authentication mechanism. See the topic on configuring Kerberos as the authentication mechanism using the administrative console.
  - c. Enable global security. See the topic on enabling security for more information.
2. Configure resource adapters for the application server to use Kerberos authentication.
- a. Create a JDBC Provider for DB2, and use it to create a data source. For more information on this task, refer to the topic on configuring a JDBC provider and data source.
  - b. Configure the data source to connect to the desired DB2 server and data table.
  - c. Configure the appropriate security settings for the data source.
    - 1) Set the authentication alias for XA recovery to **(none)**
    - 2) Set the component-managed authentication alias to **(none)**
    - 3) Set the mapping-configuration alias to **KerberosMapping**.

**Note:** If the Kerberos credential connection fails, the resource adapter can be configured to try a second connection authentication using Default Principle Mapping. To configure this fallback, select an alias from the Container-managed authentication alias list. To disable this fallback, select **(none)** from the Container-managed authentication alias list.

- 4) Configure the custom properties for the data source. In the **Additional Properties** → **Custom properties** panel for the data source, set the following properties to use Kerberos as the primary authentication method on a data source:

Name	Value
KerberosServerPrincipal	<i>domain_name</i>  For example, domain.rchland.ibm.com
SecurityMechanism	11

3. Configure the settings for DB2 to use Kerberos authentication. For more information on how to configure DB2, see the link to the DB2 product family site in the IBM Suggests section.
- a. Configure the databases and tables that you will use for tests and general operation.
  - b. Start a db2 command prompt.
  - c. From the DB2 command prompt, set the authentication mechanism for DB2.
    - 1) To set the mechanism, enter the following:
 

```
db2 update dbm cfg using authentication <mechanism>
```

<mechanism> can be Kerberos or Server. Therefore, to configure Kerberos authentication, enter:

```
db2 update dbm cfg using authentication Kerberos
```
    - 2) To validate that the authentication is set:
      - a) Retrieve the configuration by entering the following command:
 

```
db2 get db2 cfg
```
      - b) Scroll through the properties until you find the <Authentication> entry. Validate that this entry is set to the mechanism that you specified.
  - d. Configure the DB2 service. Start the db2 service that corresponds to your DB2 instance with a Kerberos user account that is not mapped to a SPN. This must be the same user account that you used when you configured LDAP security in the application server. To start a service with a defined user on Windows operating systems, for example:
    - 1) Open the Windows Services control panel. Click **Control Panel** → **Administrative Tools** → **Services**.
    - 2) Find the service that controls the DB2 installation.

- 3) Right-click the service, and choose **Properties** from the list.
  - 4) In the new window, select the **Log On** tab.
  - 5) Select the **This account** radio button.
  - 6) Enter the user name and password for Kerberos User 2.
  - 7) Apply the changes, and click **OK**.
  - 8) Stop and start the DB2 service. If the user name and password is correct, then the service should start.
- e. Configure java security.
- 1) Create a jaas.conf file, and put it in the appropriate directory. On Windows operating systems, for example, you can put this file in c:\winnt
  - 2) Complete the jaas.conf file with the following:
 

```
JaasClient {
 com.ibm.security.auth.module.Krb5LoginModule required
 debug=false useDefaultCcache=false;
};
```
  - 3) Locate the java directory structure that DB2 uses. Modify the java.security file, which is located in the java/jre/lib/security directory, to point to the jaas.conf file. For example:
 

```
login.config.url.1=file:c:/temp/jaas.conf
```
- f. Verify that you can retrieve a ticket granting ticket (TGT). The DB2 machine requires a TGT from the Kerberos server. To manually attempt to retrieve a TGT, enter the following command at a prompt:
- ```
java DEBUG=TRUE com.ibm.security.krb5.internal.tools.Kinit -f -p
```
- DB2 should now be fully configured with Kerberos.

Related concepts

Kerberos (KRB5) authentication mechanism support for security

The Kerberos authentication mechanism enables interoperability with other applications (such as .NET, DB2 and others) that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.

Related tasks

Configuring Lightweight Directory Access Protocol user registries

To access a user registry using the Lightweight Directory Access Protocol (LDAP), you must know a valid user name (ID) and password, the server host and port of the registry server, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the user registry that is searchable. You can use any user ID that has the administrative role to log in.

Configuring Kerberos as the authentication mechanism using the administrative console

You can use the administrative console to configure Kerberos as the authentication mechanism for the application server. When you have entered and applied the required information to the configuration, the Kerberos service principal name is formed as *<service name>/<fully qualified hostname>@KerberosRealm*, and is used to verify incoming Kerberos token requests.

Enabling security

By enabling security, you protect your server from unauthorized users and are then able to provide application isolation and requirements for authenticating application users.

“Configuring a JDBC provider and data source” on page 1509

For access to relational databases, applications use the JDBC drivers and data sources that you configure for the application server.

Related reference

“WebSphere Application Server data source properties” on page 1554

Use this page to set advanced data source properties in the application server. These properties activate and configure services that the application server applies to data sources to customize connections within an application server. These properties do not affect connections within the database.

Configuring Oracle Real Application Cluster (RAC) with the application server

Oracle Real Application Cluster (RAC) is a “share-everything” database architecture in which two or more Oracle RAC nodes are clustered together and share the same storage. The RAC nodes are connected together with a high-speed interconnect that enables fast communication between the Oracle nodes. The nodes can exchange various categories of data block ownership information during startup, lock information, exchange transaction information and data, and so on.

About this task

Note: Using the Oracle JDBC driver, you can configure failover support, load balancing, or both, in an Oracle RAC environment.

Oracle Real Application Clusters (RAC) is an option of an Oracle database that brings together two or more computers to form a clustered database that behaves as a single system. In a RAC database, Oracle processes that are running in separate nodes access the same data from a shared disk storage. First introduced in Oracle Version 9i, RAC provides both high availability and flexible scalability.

A typical Oracle RAC cluster consists of the following:

- **Cluster nodes** – 2 to *n* nodes or hosts, running the Oracle database server.
- **Network Interconnect** – a private network used for cluster communications and cache fusion. This is typically used for transferring database blocks between node instances.
- **Shared Storage** – used to hold the database system and data files. The shared storage is accessed by the cluster nodes.
- **Production network** – used by clients and application servers to access the database.

The following figure depicts a typical configuration for Oracle RAC:

Here are two of the many features that Oracle RAC provides:

- *Oracle Notification Service (ONS)* allows for Oracle RAC to communicate the status for the nodes, which are typically UP and DOWN events, to the Oracle JDBC driver and the driver's connection cache. To take advantage of ONS, you must configure the application server to use Oracle's connection caching instead of the application server's connection pooling feature. Read "Configuring Oracle connection caching in the application server" on page 1600 for more information on this process.
- *Distributed Transaction Processing (DTP)* is a feature that was introduced in Oracle 10gR2. When this feature is enabled, Oracle will ensure that all in-flight prepared transactions that belong to a DTP service for failed RAC instances are pushed to disk. Then, Oracle will restart the DTP service on any of the RAC instances that are still operational.

For more information on Oracle RAC and how it works with the application server, refer to *Building a high availability database environment using WebSphere middleware: Part 3: Handling two-phase commit in WebSphere Application Server using Oracle RAC* on the developerWorks web site.

- "Configuring a simple RAC configuration in an application server cluster."
- "Configuring Oracle connection caching in the application server" on page 1600.
- "Configuring two-phase commit distributed transactions with Oracle RAC" on page 1602.

Related reference

[Building a high availability database environment using WebSphere middleware: Part 3: Handling two-phase commit in WebSphere Application Server using Oracle RAC](#)

Configuring a simple RAC configuration in an application server cluster:

Oracle Real Application Cluster (RAC) is a "share-everything" database architecture that can provide high availability and load balancing. A typical configuration for an Oracle RAC contains two or more Oracle RAC nodes that are clustered together and share the same storage.

About this task

This figure depicts a typical RAC physical topology in a cluster environment for the application server, and both the failover and load balancing are enabled:

In the figure above, the application server cluster consists of two members: cluster-member1 and cluster-member2. The Oracle RAC physical configuration contains two nodes: rac-node1 and rac-node2. The RAC nodes can be located in the same physical machine with the cluster members, or they could be placed in entirely different machines. The actual placement does not impact the fundamental qualities of the services provided by RAC. To achieve both high availability and load-balancing, you can specify the Oracle data source URL for both cluster members in the application server with the required properties.

1. Navigate to the Oracle data source. Click **Resources** → **JDBC** → **Data sources** → **oracle_data_source**.
If you don't already have an Oracle data source, create a new data source by clicking **New** and completing the wizard. For the URL, substitute the properties in the next step.
2. Set the URL for the Oracle database with the required configuration parameters.

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(
  ADDRESS=(PROTOCOL=TCP)(HOST= rac-node1)(PORT=1521))
  ADDRESS=(PROTOCOL=TCP)(HOST= rac-node2)(PORT=1521))
  (FAILOVER=on)(LOAD_BALANCE=on)
  (CONNECT_DATA=(SERVER=DEDICATED)
  (SERVICE_NAME=<service_name>)))
```

Note: Be aware of these configuration options:

- If you are not using Oracle services, then *service_name* will be the database name in the example. If you are using Oracle services, then *service_name* will be the name of the services.
- The example has FAILOVER and LOAD_BALANCE turned on. To turn one or both of these features off, change on to off in the above example.

3. Click **Apply** or **OK**.

Related tasks

“Configuring Oracle connection caching in the application server”

You can elect to configure an Oracle data source to use Oracle’s connection caching feature instead of using the application server’s connection pooling. Connection caching for Oracle databases is similar to connection pooling in the application server.

“Configuring two-phase commit distributed transactions with Oracle RAC” on page 1602

Real Application Cluster (RAC) configurations for Oracle 10g have an inherent issue with the transaction manager when Oracle attempts to recover two-phase commit distributed transactions that span over multiple Oracle RAC nodes. A problem can occur when one node fails, and Oracle opens up the other surviving nodes for business before the Oracle RAC completes the necessary recovery action for the node that has failed. The application server’s ability to maintain transaction affinity provides you the ability to circumvent this issue.

“Configuring Oracle Real Application Cluster (RAC) with the application server” on page 1597

Oracle Real Application Cluster (RAC) is a “share-everything” database architecture in which two or more Oracle RAC nodes are clustered together and share the same storage. The RAC nodes are connected together with a high-speed interconnect that enables fast communication between the Oracle nodes. The nodes can exchange various categories of data block ownership information during startup, lock information, exchange transaction information and data, and so on.

Configuring Oracle connection caching in the application server:

You can elect to configure an Oracle data source to use Oracle’s connection caching feature instead of using the application server’s connection pooling. Connection caching for Oracle databases is similar to connection pooling in the application server.

About this task

Currently, Oracle only supports connection caching with data sources that use the `oracle.jdbc.pool.OracleDataSource` implementation class, instead of the `oracle.jdbc.pool.OracleConnectionPoolDataSource` or `oracle.jdbc.xa.client.OracleXADataSource` classes. By default, the Oracle JDBC providers in the application server are configured to use the `oracle.jdbc.pool.OracleConnectionPoolDataSource` for non-XA data sources, or `oracle.jdbc.xa.client.OracleXADataSource` for XA data sources. To enable Oracle connection caching, you must configure and use a new JDBC provider in the application server that implements the `oracle.jdbc.pool.OracleDataSource` class.

Note: Oracle connection caching does not support XA.

1. Create a data source and user-defined JDBC provider.
 - a. Click **Resources** → **JDBC** → **Data sources**
 - b. Select a server from the **Scope** drop-down list.

- c. Click **New**.
 - d. Enter the name and JNDI name for the data source. Click **Next**.
 - e. Create a new JDBC provider. Select **Create new JDBC provider**, and click **Next**.
 - f. Define the required properties for the JDBC provider. Use the following configuration settings:
 - **Database type:** User-defined
 - **Implementation class name:** oracle.jdbc.pool.OracleDataSource
 Click **Next**.
 - g. Enter the class path for ojdbc6.jar, and click **Next**.
 - h. For **Data store helper class name**, enter com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper. Click **Next**.
 - i. Define the security aliases for this data source, and click **Next**.
 - j. Finish the wizard.
 - k. Save the configuration changes.
2. Configure the data source that you created.
 - a. Click the name of the data source. You will be taken to the configuration panel.
 - b. Select **Custom properties**, and create or modify the properties for this data source. Enter or update the following custom properties:

| Name | Value |
|--|---|
| disableWASConnectionPooling | true |
| connectionCachingEnabled | true |
| connectionCacheName | <i>your_cache_name</i> |
| removeExistingOracleConnectionPoolIfExists | true
Note: The removeExistingOracleConnectionPoolIfExists property must be set to true so the application server will remove any existing Oracle connection pools with an identical name. Otherwise, the Oracle data source will fail the getConnection method if the pool name that is created has a name that is identical to an existing pool.

For example, if you run a test connection, the test connection process will create an Oracle connection pool that will prevent the application server from working properly at run time. |
| URL | <i>Oracle_URL</i> |

Note: The order in which the custom properties are set is important. This could be an issue, as the application server passes the properties as a collection and the order is not guaranteed. If you encounter this issue, contact Oracle and reference Oracle bug #6638862.

3. Click **Apply** or **OK**.
4. Save the changes to the application server's configuration.
5. Restart the application server.

Results

Be aware that Oracle will not display a message if the pool creation fails, and a normal connection will be returned instead. You can confirm that the connection pool is created by running your application, and try to issue a test connection. If the Oracle connection pool was created successfully, the test connection will fail with an exception that the Oracle pool name is already used. Therefore, you must create the data source and JDBC provider at the server scope.

“Configuring Oracle Real Application Cluster (RAC) with the application server” on page 1597
Oracle Real Application Cluster (RAC) is a “share-everything” database architecture in which two or more Oracle RAC nodes are clustered together and share the same storage. The RAC nodes are connected together with a high-speed interconnect that enables fast communication between the Oracle nodes. The nodes can exchange various categories of data block ownership information during startup, lock information, exchange transaction information and data, and so on.

“Configuring two-phase commit distributed transactions with Oracle RAC”

Real Application Cluster (RAC) configurations for Oracle 10g have an inherent issue with the transaction manager when Oracle attempts to recover two-phase commit distributed transactions that span over multiple Oracle RAC nodes. A problem can occur when one node fails, and Oracle opens up the other surviving nodes for business before the Oracle RAC completes the necessary recovery action for the node that has failed. The application server’s ability to maintain transaction affinity provides you the ability to circumvent this issue.

Configuring two-phase commit distributed transactions with Oracle RAC:

Real Application Cluster (RAC) configurations for Oracle 10g have an inherent issue with the transaction manager when Oracle attempts to recover two-phase commit distributed transactions that span over multiple Oracle RAC nodes. A problem can occur when one node fails, and Oracle opens up the other surviving nodes for business before the Oracle RAC completes the necessary recovery action for the node that has failed. The application server’s ability to maintain transaction affinity provides you the ability to circumvent this issue.

About this task

Errors can occur when the recovery process attempts to commit or rollback a transaction branch through a RAC node that was previously active but later failed. The transaction manager would receive the following exception:

```
ORA- 24756: transaction does not exist
```

If this error is encountered, the Oracle database administrator might need to manually resolve the in-doubt transaction by forcing a rollback or commit process. If you do not desire a manual intervention, however, you might want to configure an automatic and transparent strategy for transaction recovery.

If the in-doubt transaction is not resolved, any subsequent transactions will receive the following exception:

```
ORA-01591 lock held by in-doubt distributed transaction
```

The result is that portions of the database will not be usable.

The key to a transparent recovery strategy is to eliminate the possibility of a global transaction spanning more than one transaction branch over multiple RAC nodes. A transaction branch corresponds to a database connection that is enlisted in a global transaction. If all connections in a global two-phase commit transaction originate from the same node, transaction recovery problems should not arise. Configure an Oracle RAC with the application server to prevent errors with two-phase transactions.

The application server maintains transaction affinity for incoming connections, and you can take advantage of this feature to configure automatic recovery for Oracle RAC with two-phase commit transactions. If you implement this configuration, all connections from a given application server will be received from the same Oracle node, and the connections will finish on that same node. This configuration will avoid situations in which transactions span multiple nodes, and you should not experience a recovery problem if one or more Oracle nodes go down.

- You can elect to manually resolve the in-doubt transaction.

1. Get the orphaned transaction ID. Issue the following command:

```
sql > select state, local_tran_ID, Global_tran_Id from dba_2pc_pending where state = "prepared"
```

2. Roll back all of the transaction IDs that are in the prepared phase.

```
sql > rollback force '';
```

- Configure an automatic strategy for transaction recovery.

1. Create an Oracle service that has only one primary node. Creating the service with one primary node will ensure that load balancing is disabled. You can also specify one or more alternate nodes with the `-a` parameter. Run this command to create the service:

```
srvctl add service -d <database_name> -s <service_name> -r <primary_nodes> -a <alternate_nodes>
```

2. Enable Distributed Transaction Processing (DTP) on the Oracle service. DTP was first introduced in Oracle 10gR2. Each DTP service is a singleton service that is available on only one Oracle RAC instance. Run this command:

```
execute dbms_service.modify_service (service_name => '<service_name>' , dtp => true);
```

3. Configure each cluster member in the application server to use the Oracle DTP service.

Results

If you configured an automatic recovery strategy, the DTP service will start automatically on the preferred instance. However, if the database is restarted, the DTP service will not start automatically. You can start the DTP service using this command:

```
srvctl start service -d -s
```

If a RAC node stops working, Oracle will not failover the DTP service until the Oracle RAC cleanup and recovery is complete. Even if the Oracle nodes come back up, the Oracle DTP service will not return to the freshly restarted RAC node. Instead, you will have to manually move the service to the restarted RAC node.

When you configure DTP on the Oracle service, you have transferred load balancing from the Oracle JDBC provider to the application server. The workload will be distributed by the application server instead of Oracle, which is why you created services that do not implement load balancing and only use one primary node. This configuration prevents situations in which transaction processes span multiple RAC nodes and alleviates recovery problems that can arise when one or more RAC nodes fail.

The RAC nodes are connected together with a high-speed interconnect that enables fast communication between the Oracle nodes. The nodes can exchange various categories of data block ownership information during startup, lock information, exchange transaction information and data, and so on.

Configuring client reroute for applications that use DB2 databases

The client reroute feature enables you to configure your client applications for a DB2 universal database to recover from a communication loss, and the applications can continue to work with minimal interruption. Rerouting is central to the support of continuous operations, but rerouting is only possible when there is an alternate location that is identified to the client connection.

Before you begin

This task assumes the following:

- You have a DB2 data source defined in the application server.
- The DB2 data source to which your application connects is running one of the following:

- DB2 for z/OS Version 9.1 or later
- DB2 Version 9.5 or later of DB2 for Linux, HP-UX, Solaris, or Windows.
- You have implemented the DB2 database with a redundant setup or the ability to fail the DB2 server to a standby node.

About this task

Note: Client reroute for DB2 allows you to provide an alternate server location, in case the connection to the database server fails. If you decide to use client reroute with the persistence option, the alternate server information will persist across Java Virtual Machines (JVMs). In the event of an application server crash, the alternate server information will not be lost when the application server is restored and attempts to connect to the database.

Without any configuration on the client side, a JDBC driver for DB2 supports the client reroute capability, if it is enabled, when the driver makes an initial connection to the DB2 server. When the JDBC driver connects to a DB2 server that has an alternate server configured, the primary server sends information about the alternate server to the JDBC driver. If the connection to the primary server fails, the JDBC driver is able to reroute connections to the alternate server. If the client process crashes, however, the alternate server information is lost, and the client will need to connect to the primary server again. If the client cannot make an initial connection to the primary server, the client will have no knowledge of the alternate server and cannot reroute.

You can configure a DB2 data source in the application server with the **Alternate server name** and **Alternate port number** fields, or with the `clientRerouteAlternateServerName` and `clientRerouteAlternatePortNumber` data source custom properties, to support client reroute even on the initial connection attempt. If the JDBC driver is not able to connect to the primary DB2 server, the information that is necessary for a client reroute is already present, and the JDBC driver can reroute the connection to an alternate server.

Additionally, if you have configured a DB2 data source as a Type 4 JDBC driver, you can use the **Client reroute server list JNDI name** field, or the `clientRerouteServerListJNDIName` data source custom property, to enable persistence of the client reroute state. Typically, when a connection is rerouted and the JDBC driver has connected to the alternate DB2 server, the alternate server sends information about its own alternate server to the JDBC driver. The JDBC driver will then have the information that is required to reroute the connection again if the alternate DB2 server is not available. Effectively, the server that was originally the alternate server is now the primary server, and a new alternate server has been established. If you enable persistence for client reroute, this new state can be remembered. If the application server crashes and is restarted, the JDBC driver can connect to the DB2 server that was considered the primary server at the time of the crash. Without the persistence feature, the JDBC driver would have to start from the original server configuration and attempt to connect to the server that was originally considered the primary server.

You can use the automatic client rerouting feature within the following DB2 configurable environments:

- Enterprise Server Edition (ESE) with the data partitioning feature (DPF)
 - Data Propagator (DPROPR)-style replication
 - High availability cluster multiprocessor (HACMP™)
 - High availability disaster recovery (HADR).
1. In the administrative console, click **Resources** → **JDBC** → **Data sources** → *data_source*.
 2. Click **WebSphere Application Server data source properties**.
 3. In the **DB2 automatic client reroute options** section, fill in the fields to enable client rerouting. Complete the following fields:

Alternate server names

Specifies the list of alternate server name or names for the DB2 server. If more than one alternate server name is specified, the names must be separated by commas. For example:

```
host1,host2
```

Alternate port numbers

Specifies the list of alternate server port or ports for the DB2 server. If more than one alternate server port is specified, the ports must be separated by commas. For example:

```
5000,50001
```

Note: Ensure that an equal number of entries must be specified for both alternate ports and hosts. Otherwise, a warning is displayed and client reroute is not enabled.

4. Optional: Enable client reroute with the persistence option.
 - a. Complete the field for **Client reroute server list JNDI name**. The field specifies the JNDI name that is used to bind the DB2 client reroute server list into the JNDI name space. The DB2 database server will use this name to look up the alternate server name list when the alternate server information is not already in memory.

Note: Be aware of the following:

- This option is not supported for Type 2 data sources. If you use a DB2 data source that is configured as a Type 2 JDBC driver, the JDBC driver uses a catalog to persist the client reroute information. If this property is configured with a Type 2 driver, the application server will issue a warning.
- Use different JNDI names among different data sources. Otherwise, when you delete a data source, and the JNDI entry is removed from the name space, the other data sources that share the JNDI entry will be affected.

5. Configure the retry count and interval for the client reroute function. Complete these two fields:

Retry interval for client reroute

Specifies the amount of time, in seconds, between retries for automatic client reroute.

Maximum retries for client reroute

Specifies the maximum number of connection retries that are attempted by the automatic client reroute function if the primary connection to the server fails. The property is only used when **Retry interval for client reroute** is set.

6. Click **OK**.
7. Restart the application server.

What to do next

If you later want to remove the client reroute information that is bound in JNDI, you can do so by deleting the data source. You can also use the unbind feature with the test connection service to delete the JNDI binding for the client reroute function from the application server's JNDI name space without deleting the data source.

To delete the JNDI binding for client reroute:

1. Select **Unbind client reroute list from JNDI**.
2. Click **OK**.
3. Save the configuration.
4. Click **Test connection** for the data source.
5. Deselect **Unbind client reroute list from JNDI**.
6. Click **OK**.
7. Save the configuration.

Related tasks

“Configuring a JDBC provider and data source” on page 1509

For access to relational databases, applications use the JDBC drivers and data sources that you configure for the application server.

Developing a custom DataStoreHelper class

Apply the WebSphere extension, `GenericDataStoreHelper` class, to create your own data store helper for data sources that the application server does not support. With this helper class, your JDBC configuration can use database-specific functions during transactions.

Before you begin

If you are using a configuration with a data source that is not supported by the application server, you might want to create a custom data store helper. This helper will allow you to leverage the database to perform functions during a transaction that would not otherwise be available. You will need to create a user-defined `DataStoreHelper` class, and there is information for creating a new exception handler to catch any exceptions that might be created with the use of your custom data handler.

1. Create a class that extends the `com.ibm.websphere.rsadapter.GenericDataStoreHelper.java` class or any of the existing data store helpers. Use the following code as an example; this type of data source is based on a user-defined JDBC provider:

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
 * Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
 * The implementation for each method is provided only as an example. More detail is probably
 * required for any custom DataStoreHelper that is created for use by a real application.
 * In this example, we will override the doStatementCleanup(),getIsolationLevel(), and set userDefined
 * exception map.
 */
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{
    public ExampleDataStoreHelper(java.util.Properties props)
    {
        super(props);

        // Update the DataStoreHelperMetaData values for this helper.
        getMetaData().setGetTypeMapSupport(false);

        // Update the exception mappings for this helper.
        java.util.Map xMap = new java.util.HashMap();

        // Add an Error Code mapping to StaleConnectionException.
        xMap.put(new Integer(2310), StaleConnectionException.class);
        // Add an Error Code mapping to DuplicateKeyException.
        xMap.put(new Integer(1062), DuplicateKeyException.class);
        // Add a SQL State mapping to the user-defined ColumnNotFoundException
        xMap.put("S0022", ColumnNotFoundException.class);
        // Undo an inherited StaleConnection SQL State mapping.
        xMap.put("S1000", Void.class);

        setUserDefinedMap(xMap);

        // If you are extending a helper class, it is
        // normally not necessary to issue 'getMetaData().setHelperType(...)'
        // because your custom helper will inherit the helper type from its
        // parent class.
    }

    public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
    {
        // Clean up the statement so it may be cached and reused.

        stmt.setCursorName("");
        stmt.setEscapeProcessing(true);
        stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
        stmt.setMaxFieldSize(0);
        stmt.setMaxRows(0);
    }
}
```

```

        stmt.setQueryTimeout(0);
    }

    public int getIsolationLevel(AccessIntent intent) throws ResourceException
    {
        // Determine an isolation level based on the AccessIntent.

        // set WebSphere default isolation level to TRANSACTION_SERIALIZABLE.
        if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

        return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
            java.sql.Connection.TRANSACTION_READ_COMMITTED :
            java.sql.Connection.TRANSACTION_REPEATABLE_READ;
    }

    public int getLockType(AccessIntent intent) {
        if ( intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC ) {
            if ( intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ) {
                return WSInteractionSpec.LOCKTYPE_SELECT;
            }
            else {
                return WSInteractionSpec.LOCKTYPE_SELECT_FOR_UPDATE;
            }
        }
        return WSInteractionSpec.LOCKTYPE_SELECT;
    }
}

```

2. Optional: Create your own exception handler class. Use the following code as a guide:

```

package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import com.ibm.websphere.ce.cm.PortableSQLException;

/**
 * Example PortableSQLException subclass, which demonstrates how to create a user-defined
 * exception for exception mapping.
 */
public class ColumnNotFoundException extends PortableSQLException
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}

```

3. Compile the newly created DataStoreHelper class or classes. You will need the following JAR files in your classpath to compile them:

- *app_server_root*/dev/JavaEE/j2ee.jar
- *app_server_root*/dev/was_public.jar

Note: was_public.jar contains classes from *app_server_root*/lib/rsahelpers.jar that are needed to compile a custom DataStoreHelper class.

- *app_server_root*/plugins/com.ibm.ws.runtime.jar
- If you are using a development environment, such as Eclipse, you need to set the above JAR files in your classpath to be able to compile. Then, create a JAR file of the project after you have finished editing your files (see the help documentation for your development environment for specific instructions).
- If you do not have development environment, and you are using the javac compiler:
 - a. Create your .java file that extends the GenericDataStoreHelper or any other data store helper, as shown in Step 1.
 - b. Change to your home directory after you are done editing your file or files in the command line utility.
 - c. Set the classpath using this command:
 - d. Compile your class or classes. For example, on Windows operating systems enter the following command (this will compile all the .java files in the directory that you specify):

```
C:\javac your_directory\*.java
```
 - e. From the Java directory, create a JAR file of all the compiled class files in your directory. For example, enter the following command on Windows operating systems (change *myFile* to the name you want for your JAR file):

```
C:\Java> jar cf myFile.jar *.class
```

For more information on using the javac compiler go to the website for the Java compiler at Sun Microsystems.

4. Place your compiled JAR files in a directory, and update the class path for the JDBC provider to include that location. For example, if your JAR file is c:\myFile.jar, then make sure to modify the JDBC class path to include c:\myFile.jar.
 - a. Click **Resources** → **JDBC** → **JDBC Providers** > **JDBC_provider**.
 - b. In the **Class path** field, add the location of the JAR files that you compiled. For example, press ENTER in the field and add a new line:
c:\myFile.jar
5. Configure the application server to use your new custom DataStoreHelper class.
 - a. From the administrative console select **Resources** > **JDBC** > **Data Sources**.
 - b. Select the data source that you want to configure with your custom DataStoreHelper class.
 - c. In the section labeled **Data store helper class name**, select **Specify a user-defined data store helper**.
 - d. Enter the class name for the data store helper that you created.
 - e. Apply your changes and select **OK**.

Verifying a connection

Many connection problems can be easily fixed by verifying some configuration parameters. There are some steps that you must complete to enable a successful connection.

About this task

If your connection is still not successful after completing these steps and reviewing the applicable information, check the SYSOUT for the servant for warning or exception messages.

1. Create the authentication data alias.
2. Create the JDBC provider.
3. Create a data source.
4. Save the data source.
5. If you created a new authentication alias, restart the server for which you need to verify connectivity.
6. Test the connection

You can test your connection from the data source collection view or the data source details view. Access either view in the administrative console, and then select a connection from the list. Click the **Test Connection** button on the connection.

Test connection service

WebSphere Application Server provides a test connection service for validating data source configurations. The testConnection operation instantiates the data source configuration, gets a connection, and then immediately closes the connection.

If the definition of your data source includes a WebSphere variable, you need to determine how your scope settings for both the variable and data source can affect the test connection results. Your next step is to choose which of the three ways you want to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program.

Verifying your scope settings

Associating WebSphere variables with your data source configurations can elicit test connection results that are incongruent with the run-time behavior of your application. In some cases, a test connection operation fails, but the physical data source functions normally during application runtime. The cause of

the potential conflict is the difference between how your application server handles the scope settings of WebSphere variables at runtime, and how it handles those same scope settings for a test connection operation. Understanding the difference helps you create successful data source configurations.

At runtime, WebSphere Application Server invokes a physical data source by resolving the appropriate variable at a level where one of the following criteria exists:

- The scope of the variable can contain the data source configuration; that is, the variable has the larger scope.
- The variable and the data source have identical scopes.

Application Server meets these conditions by attempting to resolve the variable at each level of the scope spectrum. That is, the product tries to resolve the variable in the server scope, then the cluster scope, then the node scope, and lastly the cell scope.

However, Application Server tests connections at one scope only; it performs the test operation in the JVM of the same scope as that of the data source configuration. The product attempts to resolve the driver class path variable at that scope only.

Table 13. Correlation of data source scope with the test connection JVM

| Data source scope | JVM where the test connection operation occurs |
|-------------------|---|
| Cell | Deployment manager process |
| Node | Node agent process (of the relevant node) |
| Cluster | Node agent for each node that contains a cluster member |
| Server | Server; if the server is unavailable, the test connection operation is retried in the node agent for the node that contains the application server. |

If the scope of the WebSphere variable is smaller than that of the data source, the test connection operation fails. The following table shows the scenarios that produce this failure, as well as those that produce success.

Table 14. Test connection results for different data source and WebSphere variable combinations

| Data source scope | Cell level variables | Node level variables | Server level variables |
|-------------------|----------------------|----------------------|------------------------|
| Cell level | Ok | Fail | Fail |
| Node level | Ok | Ok | Fail |
| Server level | Ok | Ok | Ok |

Contrary to expectations, these test connection failures generally do not translate into run-time failures. Ensure that the location of your JDBC driver files is accessible to every client that must use the data source, and configure your WebSphere variable with the full path of that location.

Test connection success, but run-time failure

However, one of the scope combinations listed in Table 2 can produce the reverse scenario: the test connection operation succeeds, but the data source fails at runtime. This anomaly occurs in the case of a cell-scoped data source that uses a cell-scoped WebSphere variable. The connection test is successful because the operation takes place in the deployment manager process (as indicated in Table 1), where Application Server can resolve the cell-scoped variable. That data source can fail at runtime because the cell-scoped variable might be overridden with a null value.

When you create a node, Application Server creates environment variables for all supported JDBC drivers at the node scope, and initializes each variable with an empty string. Because an application server attempts to resolve variables from the low end of the scope spectrum to the high end, the node scope

variable overrides the cell scope variable at runtime. The server reads the empty string and accepts it as the JDBC driver class path. The null class path elicits a `ClassNotFoundException` exception when the server attempts to use the data source.

Using either one of the Application Server administrative options, you can prevent the empty string from becoming the final value for the driver class path variable.

- **Using the WebSphere Application Server administrative console:** The data source wizard program copies the value of the cell-scoped variable (which you specify in the JDBC provider creation wizard) to the node-scoped variable of the same name. The wizard program performs this copy operation only if the node-scoped variable has the empty string value; thus the program does not change a valid class path that you specified earlier.

To ensure that the data source works with the node-scoped variable at runtime, follow these steps:

1. Install the JDBC driver files on the deployment manager node, as well as every node where the data source must function.
2. Use the driver file path on the deployment manager to define the WebSphere variable for a JDBC provider at the cell scope.
3. Ensure that the data source is associated with the deployment manager JDBC provider, and has the same cell scope.

Note: Ensure success by installing the driver files in locations with identical full-path names on all nodes, including the deployment manager node. Otherwise, the same scenario of test connection success, but run-time failure, is likely to reoccur.

- **Using the wsadmin scripting tool:** To make the data source work for both the test connection operation and runtime, create the same driver class path configurations at the cell scope and at all relevant node scopes. Follow these steps:
 1. Install the JDBC driver files on the deployment manager node; use that path name to define the driver class path variable for a JDBC provider at the cell scope.
 2. Ensure that the data source is associated with the deployment manager JDBC provider, and has the same cell scope.
 3. On each node where the data source must function, install the JDBC driver files and use the path to define the WebSphere variable for a JDBC provider at the node scope. Each of these providers must have the same configuration.

Note: Ensure success by installing the driver files in locations with identical full-path names on all nodes, including the deployment manager node. Otherwise, the same scenario of test connection success, but run-time failure, is likely to reoccur.

Use cell scope resources only if all nodes that need access to the data source, including the deployment manager node, run on the same platform and have the JDBC drivers installed in the same location. Otherwise, use the node scope as the largest scope setting for your data sources.

Bypassing variable lookups

You can bypass the environment variable lookups by changing the class path entries for the JDBC provider to hard-coded values. However, this strategy succeeds only if you configure the class path identically on all nodes where the data source must function.

Activating the test connection service

There are three ways to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program. Each process invokes the same methods on the same MBean.

Administrative console

WebSphere Application Server allows you to test a connection from the administrative console by simply pushing a button: the *Data source collection*, *Data source settings*, *Version 4 data source collection*, and *Version 4 data source settings* pages all have **Test Connection** buttons. After you define and save a data source, you can click this button to ensure that the parameters in the data source definition are correct. On the collection page, you can select several data sources and test them all at once. Note that there are certain conditions that must be met first. For more information, see *Testing a connection with the administrative console*.

Note: The following exception occurs when you click Test Connection to connect a Sybase data source from the administrative console.

```
Test connection failed for data source isagent on server server1 at node
svtaix24Node01 with the following exception: java.lang.Exception:
java.sql.SQLException: JZ006: Caught IOException: java.net.ConnectException: A
remote host refused an attempted connect operation.DSRA0010E: SQL State = JZ006,
Error Code = 0
```

This exception occurs when the Sybase data source port number is not matched to the port configured in Sybase server. The default port number is 5000. Check the port number of your Sybase server in the interfaces file under `/<sybase install directory>`.

WsAdmin tool

The wsadmin tool provides a scripting interface to a full range of WebSphere Application Server administration activities. Because the Test Connection functionality is implemented as a method on an MBean, and wsadmin can invoke MBean methods, wsadmin can be utilized to test connections to data sources. You have two options for testing a data source connection through wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. For information, see *Testing a connection using wsadmin*.

You can also test a connection by invoking the MBean operation. Use *Example: Testing data source connection using wsadmin* as a guide for this technique.

Java stand-alone program

Finally, you can test a connection by executing the testConnection() method on the DataSourceCfgHelper MBean. This method allows you to pass the configuration ID of the configured data source. The Java program connects to a running Java Management Extensions (JMX) server to access the MBean. In a Network Deployment installation of Application Server, you connect to the JMX server running in the deployment manager, usually running on port 8879.

The return value from this invocation is either 0, a positive number, or an exception. 0 indicates that the operation completed successfully, with no warnings. A positive number indicates that the operation completed successfully, with the number of warnings. An exception indicates that the test of the connection failed.

You can find an example of this code in *Example: Test a connection using testConnection(ConfigID)*.

Testing a connection with the administrative console

After you have defined and saved a data source, you can click the **Test Connection** button to ensure that the parameters in the data source definition are correct.

Before you begin

About this task

You can select multiple data sources on the data source collection page and test them as a group. Be sure that the following conditions are met before using the Test Connection button:

- If you are testing a connection using a WebSphere Application Server Version 4.0 type of data source, ensure that the *user* and *password* information is set.
- Designate variables appropriately.

If you used a WebSphere environment entry for the class path or other fields, such as `${DB2390_JDBC_DRIVER_PATH}/classes/db2j2classes.zip`, make sure that you assign it a value in the *WebSphere Variables* page.

- Verify that the environment variables exist in the scope of the test. For example, if the node scoped data source you defined uses `${DB2_JDBC_DRIVER_PATH}`, check that there exists a node level definition for `DB2_JDBC_DRIVER_PATH = c:\sqllib\java` (or your system dependent value).
- Restart the deployment manager and node agents after you define or edit WebSphere variables.
- Restart the deployment manager and node agents after you create or edit an authentication alias for the data source.
- Ensure that the deployment manager and node agent are up and running.
- You can now test a connection to the data source. On the data source collection page in the administrative console, select the data source and click **Test Connection**.

A Test Connection operation can have three different outcomes, each resulting in a different message being displayed in the messages panel of the page on which you press the Test Connection button.

1. The test can complete successfully, meaning that a connection is successfully obtained to the database using the configured data source parameters. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful.
2. The test can complete successfully with warnings. This means that while a connection is successfully obtained to the database, warnings were issued. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful with warning(s). View the JVM Logs for more details.

The **View the JVM Logs** text is a hyperlink that takes you to the JVM Logs console screen for the process.

3. The test can fail. A connection to the database with the configured parameters is not obtained. The resulting message states: Test Connection failed for data source *DataSourceName* on process *ProcessName* at node *NodeName* with the following exception: *ExceptionText*. View the JVM Logs for more details.

Again, the text for **View the JVM Logs** is a hyperlink to the appropriate logs screen.

Testing a connection using wsadmin

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object.

Before you begin

About this task

The testConnection operation takes a data source *configuration ID* as an argument.

Note: This invocation cannot accept user IDs and passwords that must be defined in the database itself. This invocation can only be used for databases that do not require a user ID and password to make a connection (such as DB2 on a Windows machine), or for data sources that have a component-managed or container-managed authentication alias set on the data source object.

1. Invoke the `getid()` method for your data source.
2. Set the value of the *configuration id* to a variable.

```
set myds [$AdminConfig getid /JDBCProvider:mydriver/DataSource:mydatasrc/]
```

where `/JDBCProvider:mydriver/DataSource:mydatasrc/` is the data source you want to test. After you have the configuration ID of the data source, you can test the connection to the database.

3. Test the connection to the database.

```
$AdminControl testConnection $myds
```

Example: Testing a connection using `testConnection(ConfigID)`:

The following sample code creates a data source instance and an associated connection instance, and tests them to ensure database connectivity.

This program uses JMX to connect to a running server and invoke the `testConnection` method on the `DataSourceCfgHelper` MBean. The acronym *ND* in a comment line indicates that the following code applies to WebSphere Application Server Network Deployment. The word *Base* in a comment line indicates that the following code applies to WebSphere Application Server.

```
/**
 * Description
 * Resource adapter test program to make sure that the MBean interfaces work.
 * Following interfaces are tested
 *
 * --- testConnection()
 *
 * We need following to run
 * C:\src>java -Djava.ext.dirs=C:\WebSphere\AppServer\lib;C:\WebSphere\AppServer\java\jre\lib\ext testDSGUI
 * must include jre for log.jar and mail.jar, else get class not found exception
 *
 */

```

Configuring data access for the Application Client

Configuring data access for the Application Client involves specifying the resource reference and associated database information required for data access. This specification is done as part of the assembly and deployment steps for the Application Client.

About this task

There are two tools needed to configure data sources used by J2EE application clients:

- An assembly tool for defining the resource reference in the deployment descriptor; and
- The Application Client Resource Configuration Tool (ACRCT) for defining the connection to the database in the client deployment environment.

Data access from an application client uses the JDBC driver connection functions directly from the client side. It does not take advantage of the additional pooling support available in the WebSphere Application Server run time. Configuring data access for an application client does not require configuration of a JDBC provider and data source on the WebSphere Application Server server machine.

If you want to take advantage of the pooling and additional database functions provided by the product, it is recommended that your client application utilize an enterprise bean running on the server side to perform data access.

Defining an application client resource reference using an assembly tool

1. Assemble your application client module as described in *Assembling application clients*.
2. Create a new resource reference:
 - a. In a Project Explorer view, right-click your application client module and click **Open With > Deployment Descriptor Editor**.
 - b. On the **References** tab, click **Add > Resource reference > Next**.
 - c. On the Resource Reference page, enter the **Name** of this resource reference. The Application Client for WebSphere Application Server run time uses this name for two purposes: to bind the object into the *java:comp/env* portion of the JNDI namespace, and to find client specific configuration information. If the code for the Application Client performs a lookup for *java:comp/env/jdbc/myDB*, the name of the resource reference should be *jdbc/myDB*.
 - d. For **Type**, select *javax.sql.DataSource* for JDBC connections.
 - e. For **Authentication**, select *Application* if your client application intends to provide authentication information. If the Application Client run time provides the authentication information (as configured by the Application Client Resource Configuration tool), select *Container*.
 - f. Ignore the **Sharing scope** setting; it is unused in an application client resource reference. All Application Client resources are not shared.
 - g. Click **Finish**.
 - h. Close the deployment descriptor and save your changes.

Results

The JNDI name field appears under **WebSphere Bindings** after you add the reference.

Client configuration with the ACRCT

About this task

There are two client resources for you to configure in the Application Client Resource Configuration Tool (ACRCT) to enable data access from an application client: a data source provider and a data source.

Note: The following objects, which can be bound into the server name space, are not supported on the client:

- Java 2 Connector (J2C) objects
- Connection manager objects

The Application Client does not provide client database drivers. If your client application uses a database directly, rather than using an enterprise bean, you must provide the database drivers on the client machine. This action can involve contacting your database vendor to acquire client database driver code and licenses.

Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on the application server. Enterprise beans can also take advantage of the additional database functions provided by the run time.

1. Configure a new data source provider as described in Configuring new data source providers. This provider describes the JDBC database implementation for your client application.
2. Enter the following information on the **General** tab:
 - a. A **name** for this data source provider.
 - b. Optional: A **description**.
 - c. The **classpath** to the data source provider implementation classes or JAR files. This is optional if the implementation classes or JAR files are already in the class path configuration of the client.
 - d. The name of the **implementation class**. For example, for DB2 this value is *COM.ibm.db2.jdbc.DB2DataSource*. Remember this class must implement the *javax.sql.DataSource* class. The ACRCT does not verify this class and you receive an error when you run your client application if the class does not implement *javax.sql.DataSource*.

Use the **Custom** tab to configure non-standard properties of the data source provider. This panel enables you to enter property-value pairs. During run time the *implementation class name* is created and any custom properties added on this panel are set on the newly created data source object using reflection. Any properties configured on this panel must have an appropriate set method on the data source class. For example, assume there is a property called *use2Phase* and its value should be 1. On the custom panel you enter the value *use2Phase* into the **name** column and the value *1* into the **value** column. The Application Client run time then uses reflection to find a property on the data source class called, typically *setUse2Phase* and call that method passing the value of 1. See your database product documentation for valid properties on your data source implementation.

3. Click **OK**.
4. Configure a new data source as described in Configuring new data sources for application clients. This describes the client properties of the database your client application uses.
5. Enter the following information on the **General** tab:
 - a. A **Name**. This field is required and identifies a name for the Application Client Resource Configuration Tool to use. This name is **not** used by your client application program.
 - b. Optional: A **description**.
 - c. The **JNDI name**. This field is required and must match the value entered in the **Name** field on the Add Resource Reference page of the assembly tool. In the example above, set this value to *jdbc/myDB*.
 - d. Optional: The **Database Name**.

- e. Optional: Your *userid* in the **User** field.
- f. Optional: Your *password* in the **Password** field. This password does not display.
- g. Your password again to confirm in the **Re-Enter password** field. Note: The **User** and **Password** fields are used only when the **Authentication** field on the Add Resource Reference page of the assembly tool is set to *Container*.

Resource references

Use this page to designate how the resource references of application modules map to the actual resources that are configured for the application.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application_name* → **Resource references**.

- If your application uses any of the following resource types, you can set or reset their mapping configurations:
 - Default messaging JMS queues destinations
 - Default messaging JMS topic destinations
 - Data source
 - Generic JMS connection factory
 - Mail session
 - J2C connection factory
 - JMS queue connection factory for the JMS provider of WebSphere MQ
 - JMS queue destination for WebSphere MQ
 - JMS topic connection factory for WebSphere MQ
 - JMS topic destination for WebSphere MQ
 - Unified JMS connection factory for WebSphere MQ
 - URL configuration
- The page is comprised of sections that correspond to each applicable resource type. Each section heading is the class name for the resource. If your application contains only one applicable resource type, you see only one section.
- Each section contains a table. Each table row depicts a resource reference within a specific module of your application.
- The rows contain the JNDI names of resource mapping targets for your references *only* if you bound them together during application assembly. You can modify those bindings on this administrative console page.
- To set your mappings:
 1. Select a row. Be aware that if you check multiple rows on this page, the resource mapping target that you select in step 2 applies to all of those references.
 2. Click **Browse** to select a resource from the new page that is displayed, the Available Resources page. The Available Resources page shows all resources that are available mapping targets for your application references.
 3. Click **Apply**. The console displays the Resource references page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
 4. Repeat the previous steps as necessary.
 5. Click **OK**. You now return to the general configuration page for your enterprise application.
- **For data sources and connection factories:** Sections for these resource types contain an additional set of steps for modifying your security settings. Use the last column in the displayed table to view the authorization type for each resource configuration per application module. You can modify the corresponding authentication method only if the authorization type is container. Container-managed

authorization indicates that the product performs signon to the resource rather than the enterprise bean code. The reconfiguring process differs slightly for each authentication method option:

- If you select **None**:
 1. Determine which resource configurations to designate with no authentication method.
 2. Select the appropriate table rows.
 3. Select **None** from the list of authentication method options that precede the table.
 4. Click **Apply**.
- If you select **Default**:
 1. Determine which resources to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. You must apply this option to each resource individually if you want to designate different authentication data aliases. See the "J2EE connector security" Information center topic for more information on the default mapping configuration.
 2. Select the appropriate table rows.
 3. Select **Use default method** from the list of authentication method options that precede the table.
 4. Select an authentication data entry or alias from the list.
 5. Click **Apply**.
- If you select **Use trusted connections (one-to-one mapping)**:
 1. You must have a data source server that is running DB2 Version 9.1 for z/OS, and the data source must have trusted context enabled.
 2. Select an authentication alias from the list that matches an alias that is already defined in the DB2 data source. If you do not have an alias defined that is suitable, you need to define a new alias.
 3. Select a data source from the table that has trusted context enabled.
 4. Click **Apply**.
 5. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.
- If you select **Custom login configuration**:
 1. Determine which resources to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the "J2EE connector security" Information center topic for more information on custom JAAS login configurations.
 2. Select the appropriate table row.
 3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
 4. Select an application login configuration from the list.
 5. Click **Apply**.
 6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select

Select the check boxes of the rows that you want to edit.

Module

The name of a module in the application.

EJB

The name of an enterprise bean that is contained by the module.

URI

Specifies location of the module relative to the root of the application EAR file.

Resource Reference

The name of a resource reference that is used in the enterprise bean, if applicable, and is declared in the deployment descriptor of the application module.

Target Resource JNDI name

The Java Naming and Directory Interface (JNDI) name of the resource that is the mapping target of the resource reference.

Data type String

Login configuration

This column applies to data sources and connection factories only and refers to the authorization type and the authentication method for securing the resource.

Mapping-configuration alias

This panel allows you to select a mapping configuration alias for the resource that you are configuring. This panel is only available when security domains are defined. Security domains allow you to isolate mapping configuration aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them. For example, a cell-scoped security domain will be hidden from the tree if all servers and clusters in the tree have defined their own security domain. If you are looking for an alias that is not visible in the tree, it is because the alias cannot be used by any servers that have visibility to this resource. In this case, you must define the alias at the global scope or in a different security domain that is visible to this resource.

To view this administrative console panel:

1. You must have a security domain defined in the application server.
2. Click one of the following paths in the administrative console:
 - **Resources** → **JDBC** → **Data sources** → **data_source**. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
 - **Resources** → **JDBC** → **JDBC Providers** → **jdbbc_provider** → **Data sources** → **data_source**. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
 - **Resources** → **Resource Adapters** → **J2C connection factories** → **j2c_connection_factory**. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.

Note: Be careful when selecting an alias, because it is possible to select an alias that is only accessible by a subset of the servers that will use the resource. If you select a global alias, you are guaranteed that an alias by that name will be accessible to all users of the resource. If the alias has been overridden in a security domain, however, that alias will be used instead of the global one. The tree view includes icons to help you select the proper alias:

-  The alias is accessible by all servers that can access this resource.
-  There is at least one server that cannot access the alias. Check the tree view to see if this is OK for the application that will be using this resource.
-  The alias is defined in multiple places.

Select a J2C authentication alias

This panel allows you to select a J2C authentication alias for the resource that you are configuring. This panel is only available when security domains are defined. Security domains allow you to isolate J2C

authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them. For example, a cell-scoped security domain will be hidden from the tree if all servers and clusters in the tree have defined their own security domain. If you are looking for an alias that is not visible in the tree, it is because the alias cannot be used by any servers that have visibility to this resource. In this case, you must define the alias at the global scope or in a different security domain that is visible to this resource.

To view this administrative console panel:

1. You must have a security domain defined in the application server.
2. Click one of the following paths in the administrative console:
 - **Resources** → **JDBC** → **Data sources** → *data_source*. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
 - **Resources** → **JDBC** → **JDBC providers** → *jdbc_provider* → **Data sources** → *data_source*. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
 - **Resources** → **Resource Adapters** → **J2C connection factories** → *j2c_connection_factory*. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
 - **Resources** → **Resource Adapters** → **J2C activation specifications** → *j2c_activation_specification*. Click **Browse...** in the security section for **Authentication Alias**.
 - **Resources** → **JMS** → **Connection factories** → *connection_factory*. Click **Browse...** in the security section for **Authentication Alias**.
 - **Resources** → **JMS** → **JMS providers** → *jms_provider* → **[Additional properties] Connection factories** → *connection_factory*. Click **Browse...** in the security section for **Authentication Alias**.

Note: Be careful when selecting an alias, because it is possible to select an alias that is only accessible by a subset of the servers that will use the resource. If you select a global alias, you are guaranteed that an alias by that name will be accessible to all users of the resource. If the alias has been overridden in a security domain, however, that alias will be used instead of the global one. The tree view includes icons to help you select the proper alias:

-  The alias is accessible by all servers that can access this resource.
-  There is at least one server that cannot access the alias. Check the tree view to see if this is OK for the application that will be using this resource.
-  The alias is defined in multiple places.

Considerations for isolated resource providers

There are some design considerations that you should be aware of when working with resource providers that you have specified to be isolated in their own class loaders.

Be aware of the following issues that you need to address if you isolate a resource provider in its own class loader:

- **Client container**

The client container does not manage the class path of resource providers, so resource providers that are isolated will not be supported in the client container.
- **Multiple resource provider versions per application**

If an application refers to resources from multiple versions or implementations of the same resource provider, then all of the resource providers that are referenced must be isolated.
- **References to isolated resource provider classes**

If a module directly refers to classes that are loaded by an isolated resource provider, which means the module has import statements of resource provider classes, the following restrictions are in place:

- The module can only refer to resources from one version or implementation of an isolated resource provider. This is an inherent class loading restriction, because a module class loader can only refer to one version of a class.
- The module cannot perform direct JNDI lookup without the use of Java EE resource reference meta-data. This restriction is required, because without resource reference metadata the application server has no mechanism to link the class loader of the module to the class loader of the isolated resource provider.

The relational resource adapter does not generally allow direct access to resource provider classes, so these restrictions will typically only affect modules that implement the `com.ibm.websphere.rsadapter.WSCallHelper` class. For mail providers, these restrictions will most likely be in place, because the `javax.mail` API relies heavily on classes rather than interfaces. Therefore, the implementation details are necessarily part of the API.

Passing client information to a database

Using a WebSphere Application Server API or trace function, you can pass unique client information on every connection that originates from the same data source.

About this task

Some databases, such as DB2, support a data source custom property that triggers your database servers to extract client information from WebSphere Application Server connections. (Consult the database documentation to see whether your product supports this capability and which property the product requires.) Be aware, however, that these properties introduce a very limited functionality in Application Server. Consequently, an application server connection manager incurs the following risky behaviors, which can result in the transfer of wrong client information to the database.

- The connection manager cannot change client information on the data source, or the connections obtained from that data source, dynamically.
- The connection manager must set the same client information on all connections that are obtained from that data source. For example, if you set `ApplicationName` as part of the data source `clientInformation` property, all connections from that data source have the same application name.

Application Server offers two methods of passing client information that provide the necessary connection management flexibility. Using either method, you can set client information on some connections and not others, as well as set different client information on different database connections from the same data source.

- Use the IBM proprietary `setClientInformation(Properties)` API. The API is defined on the `WSCConnection` class, which is part of the `plugins_root/com.ibm.ws.runtime_6.1.0.jar` file.
 1. Cast the connection objects in your applications to `com.ibm.websphere.rsadapter.WSCConnection` before calling the API.
 2. Optionally, set a properties object for adding new client information on a connection if and when new information is introduced by the backend database:

```
public void setClientInformation (Properties props)throws SQLException;
```
- You can also activate the function implicitly (that is, within Application Server) by using the `WAS.clientinfo` trace string. Enable this trace dynamically, from the administrative console, just as you activate any other trace. For more information about passing client information implicitly, see “Implicitly set client information” on page 1623.

Results

Example

See “Example: Setting client information with the `setClientInformation(Properties)` API.”

Example: Setting client information with the `setClientInformation(Properties)` API

With this API, set WebSphere Application Server client information on connections to pass that information to your database.

The following example code calls `setClientInformation(Properties)` on the `com.ibm.websphere.rsadapter.WSConnection` object.

```
import com.ibm.websphere.rsadapter.WSConnection;
.....
try {
    InitialContext ctx = new InitialContext();
    //Perform a naming service lookup to get the DataSource object.
    DataSource ds = (javax.sql.DataSource)ctx.lookup("java:comp/jdbc/myDS");
} catch (Exception e) {System.out.println("got an exception during lookup: " + e);}

WSConnection conn = (WSConnection) ds.getConnection();
Properties props = new properties();
props.setProperty(WSConnection.CLIENT_ID, "user123");
props.setProperty(WSConnection.CLIENT_LOCATION, "127.0.0.1");
props.setProperty(WSConnection.CLIENT_ACCOUNTING_INFO, "accounting");
props.setProperty(WSConnection.CLIENT_APPLICATION_NAME, "appname");
props.setProperty(WSConnection.CLIENT_OTHER_INFO, "cool stuff");
conn.setClientInformation(props);
conn.close()
```

Parameters

props contains the client information to be passed. Possible values are:

- `WSConnection.CLIENT_ACCOUNTING_INFO`
- `WSConnection.CLIENT_LOCATION`
- `WSConnection.CLIENT_ID`
- `WSConnection.CLIENT_APPLICATION_NAME`
- `WSConnection.CLIENT_OTHER_INFO`
- `WSConnection.OTHER_CLIENT_TYPE`

Refer to the `WSConnection` documentation for more details on which client information is passed to the backend database. To reset the client information, call the method with a null parameter.

Exceptions

This API creates an SQL exception if the database issues an exception when setting the data.

Passing client info to a db `cdat_clientinfo`

Implicitly set client information

If you track client information in your database, you can choose one of two ways to pass WebSphere Application Server client data on database connections.

You can choose to *explicitly* pass the information on connections by calling an IBM proprietary API, `setClientInformation(Properties)`, on the `com.ibm.websphere.rsadapter.WSConnection` object within your application code. The `com.ibm.websphere.rsadapter.WSConnection` object is located in the `plugins_root/com.ibm.ws.runtime_6.1.0.jar` file. In some cases, however, you might want WebSphere

Application Server to handle the passing of client information to database connections. This method of setting the client information is referred to as *implicit*. You might choose the implicit method because:

- You want to keep your application free of proprietary APIs, or
- Your application uses container-managed persistence (CMP), in which case you cannot use the proprietary API to set client information on database connections.

The WebSphere Application Server trace facility provides the capability for setting client information implicitly. You can designate one of two special trace groups to enable or disable client information passing: “WAS.clientinfo trace” or “WAS.clientinfopluslogging trace” on page 1625.

Possible run-time scenarios

- Connection sharing

In the case of connection sharing, WebSphere Application Server sets the client information on the first acquired connection handle only. If connection sharing is enabled and two or more `getConnection` methods are called (resulting in two handles on the same connection), only the first `getConnection` call causes the client information to pass to the backend database. This scenario does not apply to the explicit process of passing client information; in such cases every `setClientInformation` method is relayed to the database regardless of connection sharing.

- Implicit/explicit co-existence

When you use both the explicit and implicit procedures for relaying client information, some combination of the explicitly set data and implicitly set data is combined, but the explicit setting usually takes precedence. For example, if the application sets the client accounting information to “myAccountingInfo”, the final accountingInfo string that is passed to the backend database looks something like the following sample code:

```
000325_WSRdbManagedConnectionImpl@1234_myAccountingInfo:
```

where 000325 is the thread id and `WSRdbManagedConnectionImpl@1234` is the WebSphere connection instance.

- Client information reset

When you configure Application Server to pass client information, it does reset client information when a connection is returned to the pool, but *only* if the `WAS.clientinfo` and `WAS.clientinfopluslogging` trace mechanisms are disabled (that is, `WAS.clientinfo=all=disabled:WAS.clientinfopluslogging=all=disabled`).

In the explicit case, however, the reset operation is done only when the application issues `setClientInformation(null)` on the `WConnection` connection.

WAS.clientinfo trace

By default, the implicit mechanism is disabled. You can turn on this mechanism dynamically, without stopping and starting your application server, or statically by setting the WebSphere Application Server trace group `WAS.clientinfo=all=enabled`.

The information implicitly collected and set on the database connection consists of the thread ID, user name, user location, and application name.

Note: User name and user location can only be implicitly collected and set on the database connection if you enable Java 2 security.

thread ID

An eight-character hexadecimal value that identifies the Java thread that controls the processing of the application request within WebSphere Application Server. This ID is displayed in the trace header.

user name

The name of the user that initiates the application request. This option is collected and passed to

the backend database (when supported) only if Java 2 security is enabled. Information here is collected by calling the `WSSecurityHelper.getFirstCaller` method.

user location

The name of the location of the user, in the form of `cell:node:server`. This option is collected and passed to the backend database, when appropriate, only when Java 2 security is enabled. Information here is collected by calling the `WSSecurityHelper.getFirstServer` method.

application name

The name of the application running. This value is the output of the `getApplication` method from the Java `EName` object. This value is collected regardless of the Global Security setting.

WAS.clientinfopluslogging trace

When debugging database problems, such as deadlocks, there is a set of information that is needed to help with the debugging effort. This information is typically obtained by enabling a WebSphere Relational Resource Adapter (RRA) trace, and an Enterprise JavaBean (EJB) container trace. However, there are some cases where timing is an issue when reproducing a given problem. Having too much tracing information can alter the behavior of the application, such as change the timing, and the problem might no longer occur.

Because of this situation, a new trace group is provided where only a minimum set of information is collected. This trace group is `WAS.clientinfopluslogging`. This function sets the client information implicitly on the connection, just like the `WAS.clientinfo` trace, as well as logs and traces important application activities. Those activities are:

- SQL Strings that are run (such as, `select userId from tabl1 where id=? for update`).
- Start, commit, and rollback of transactions.
- EJB calls (such as, `Create`, `Remove`, `findByPrimaryKey`, and so on).

Setting client information traces with the administrative console

Use one of two WebSphere Application Server trace groups to pass client information to a database.

About this task

The `WAS.clientinfo` and `WAS.clientinfopluslogging` traces pass client data on every connection that originates from the same data source.

1. Open the administrative console.
2. Select **Troubleshooting**.
3. Select **Log and Trace**.
4. Select the server you want to use.
5. Select **Change log detail levels**.
6. Select the **Configuration** or **Run time** tab.
7. In the **Trace Specification** entry field, type `WAS.clientinfopluslogging=all`. This starts the `WAS.clientinfopluslogging` trace, which passes the client information to the backend data store (if your database supports receiving client information in this manner) and logs important client activities. Type `WAS.clientinfo=all` to pass client information to the backend without tracing of client activities. To deactivate either trace, simply type the trace group name followed by `=off` (without spacing between characters).

About Apache Derby

Use Apache Derby as a test and development database only. Apache Derby must run at a minimal version of v10.3 or Cloudscape v10.1x. The Apache Derby package that is bundled with the application server is backed by full IBM Quality Assurance (QA).

Unlike versions 5.1.60x and earlier, Apache Derby is a pure Java database server. The Apache Derby code base, which the open source community calls Derby, is a product of the Apache Software Foundation (ASF) open source relational database project. Apache Derby includes the Derby base code without any modification to the underlying source code. You can investigate more incompatibilities about Derby code at the Apache Derby web site.

Note: Earlier versions of Apache Derby cannot conduct two phase-commit transactions over the Network Server framework, but later versions of the Derby Client JDBC driver provides Apache Derby with support for XA transactions. Only the Network Server framework provides support for multiple Java virtual machines (JVMs), such as application servers, to access Apache Derby.

Apache Derby is equipped with the following .bat/sh tools:

- sysinfo: displays database version information
- ij: manipulates the database instances

Note: Use ij as an alternative for the Cloudscape cview tool, which does not exist in Derby. When you run the ij tool, surround the dbname by double quotation marks (" ") if it includes the full path name; for example:

```
ij> connect "c:\temp;create=true"
```

This is ' " " ' without spaces.

- dblook: dumps DDL information
- networkServerControl: controls the networkServer process (can be used for functions such as ping and trace)
- startNetworkServer: starts the networkServer process
- stopNetworkServer: stops the networkServer process

Verifying the Cloudscape automatic migration

Version 7.0 of the application server requires Cloudscape or Apache Derby to run at a minimal version of v10.1.x. During the application server upgrade to version 7.0, the migration tool automatically upgrades the database instances that are accessed through the embedded framework by some internal components, such as the UDDI registry. The tool also attempts to upgrade Cloudscape or Derby instances that your applications access through the embedded framework. You must verify the migration results for these backend databases.

Before you begin

Do not use Apache Derby or Cloudscape as a production database. Use it for development and test purposes only.

The migration tool attempts to upgrade Cloudscape database instances that are accessed through the embedded framework only. You must manually upgrade Cloudscape instances that transact with application servers on the Network Server framework. See the "Upgrading Cloudscape manually" on page 1629 topic. This requirement eliminates the risk of corrupting third party applications that use the Network Server framework to access the same database instances as WebSphere Application Server.

Other applications can access Apache Derby or Cloudscape on Network Server because the framework provides the database with a foundation of connectivity software; the embedded framework does not. Derby Network Server or Cloudscape Network Server can transact with multiple Java Virtual Machines (JVM) or application servers concurrently, whereas Cloudscape or Derby on the embedded framework works with only a single JVM. Clustered or coexistence implementations of Application Server require Network Server. For more information, consult the IBM Cloudscape Information Center. Find the link in the following IBM Suggests section.

About this task

For database instances that your applications access through the embedded framework, the automatic migration can succeed completely, fail completely, or succeed with warnings. A migration that produces warning messages does create an Apache Derby or Cloudscape database with your data, but does not migrate all of your configured logic and other settings, such as:

- keys
- checks
- views
- triggers
- aliases
- stored procedures

To distinguish between a partially and a completely successful migration, you must verify the auto-migration results by checking both the general post-upgrade log and the individual database logs. Performing these tasks gives you vital diagnostic data to troubleshoot the partially migrated databases as well as those that fail auto-migration completely. Ultimately, you migrate these databases through a manual process.

1. Open the post-upgrade log of each new profile for the application server. The path name of the log is *app_server_root/profiles/profileName/logs/WASPostUpgrade.timestamp.log*.
2. Examine the post-upgrade log for database error messages. These exceptions indicate database migration failures. The following lines are an example of post-upgrade log content, in which the database error code is DSRA7600E. The migration tool references all database exceptions with the prefix DSRA.

```
MIGR0344I: Processing configuration file /opt/WebSphere51/AppServer/cloudscape
/db2j.properties.
```

```
MIGR0344I: Processing configuration file /opt/WebSphere51/AppServer/config/cells
/migr06/applications/MyBankApp.ear/deployments/MyBankApp/deployment.xml.
```

```
DSRA7600E: Cloudscape migration of database instance /opt/WebSphere61/Express
/profiles/default/databases/_opt_WebSphere51_AppServer_bin_DefaultDB failed,
reason: java.sql.SQLException: Failure creating target db
```

```
MIGR0430W: Cloudscape Database /fvt/temp/51BaseXExpress/PostUpgrade50BaseFVTTTest9
/testRun/pre/websphere_backup/bin/DefaultDB failed to migrate <new database name>
```

Note: Call IBM WebSphere Application Server Support if you see a migration failure message for a Cloudscape instance that is accessed by a WebSphere internal component (that is, a component that helps comprise WebSphere Application Server rather than one of your applications).

3. Open the individual database migration log that corresponds with each of your backend Cloudscape databases. These logs have the same timestamp as that of the general post-upgrade log. The logs display more detail about errors that are listed in the general post-upgrade log, as well as expose errors that are not documented by the general log.

The path name of each database log is *app_server_root/profiles/profileName/logs/myFulldbName_migrationLogtimestamp.log*.

4. Examine each database migration log for errors. For a completely successful migration, the log displays a message that is similar to the following text:

```
MIGR0429I: Cloudscape Database F:\temp\51BaseXExpress\PostUpgrade50BaseFVTTTest2\testRun
\pre\websphere_backup\bin\DefaultDB was successfully migrated. See log C:\WebSphere61
\Express\profiles\default\logs\DefaultDB_migrationLogSun-Dec-18-13.31.40-CST-2005.log
```

Otherwise, the log displays error messages in the format of the following example:

```
connecting to source db <jdbc:db2j:/fvt/temp/51BaseXExpress/PostUpgrade50BaseFVTest9
/testRun/pre/websphere_backup/bin/DefaultDB>
```

```
connecting to source db <jdbc:db2j:/fvt/temp/51BaseXExpress/PostUpgrade50BaseFVTest9
/testRun/pre/websphere_backup/bin/DefaultDB> took 0.26 seconds
```

```
creating target db <jdbc:derby:/opt/WebSphere61/Express/profiles/default/databases
/_opt_WebSphere51_AppServer_bin_DefaultDB>
```

ERROR: An error occurred during migration. See debug.log for more details.

```
shutting down databases
```

```
shutting down databases took 0.055 seconds
```

- For more data about a migration error, consult the debug log that corresponds with the database migration log. The WebSphere Application Server migration utility triggers a *debug migration trace* by default; this trace function generates the database debug logs. The full path name of a debug log is `app_server_root/profiles/profileName/logs/myFulldbName_migrationDebugtimestamp.log`.

The following lines are a sample of debug text. The lines display detailed exception data for the error that is referenced in the previous sample of database migration log data.

```
java.sql.SQLException: Database_opt_WebSphere51_AppServer_bin_DefaultDB already exists. Aborting migration
at com.ibm.db2j.tools.migration.MigrateFrom51Impl.go(Unknown Source)
at com.ibm.db2j.tools.migration.MigrateFrom51Impl.doMigrate(Unknown Source)
at com.ibm.db2j.tools.MigrateFrom51.doMigrate(Unknown Source)
at com.ibm.ws.adapter.migration.CloudscapeMigrationUtility.migr
```

Results

- The migration utility for the application server changes your Apache Derby or Cloudscape JDBC configurations whether or not it successfully migrates the database instances that are accessed by your applications. The tool changes the class paths for the Derby or Cloudscape JDBC provider, data source implementation classes, and data source helper classes. The following table depicts these changes:

Table 15. New class information

| Class type | Old value | New value |
|---|--|--|
| JDBC provider class path | <code>\${CLOUDSCAPE_JDBC_DRIVER_PATH}/db2j.jar</code> | <code>\${DERBY_JDBC_DRIVER_PATH}/derby.jar</code> <ul style="list-style-type: none"> Where <code>DERBY_JDBC_DRIVER_PATH</code> is the WebSphere environment variable that defines your Cloudscape JDBC provider Where <code>derby.jar</code> is the base name of the JDBC driver class file (In your environment, reference the JDBC driver class file by the full path name.) |
| Data source implementation class: Connection pool | <code>com.ibm.db2j.jdbc.DB2jConnectionPool DataSource</code> | <code>org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource</code> |
| Data source implementation class: XA | <code>com.ibm.db2j.jdbc.DB2jXADataSource</code> | <code>org.apache.derby.jdbc.EmbeddedXADataSource</code> |
| Data source helper class | <code>com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper</code> | <code>com.ibm.websphere.rsadapter.DerbyDataStoreHelper</code> |

Additionally, the `db2j.properties` file changes:

- The name `app_server_root/cloudscape/dbj.properties` changes to `app_server_root/derby/derby.properties`
- Within the file, property names change from `db2j.drda.*` to `derby.drda.*`
- A partial or a completely successful database migration changes the location and name of the database according to the following example:
 - Old database name:** `c:\temp\mydb`
 - New database name:** The new name includes a hash code that combines the entire path name of the old database and the migration time stamp. The new name also includes the old database name and time stamp exactly. For example:
`app_server_root/profiles/profile_name/databases/my_database_hashCode_timestamp`

Note: For both partial and failed migrations, the log messages contain the exact old and new database path names that you must use to run the manual migration. Note these new path names precisely.

What to do next

If you experience a partial migration, attempt to troubleshoot the Cloudscape or Derby database only if you have expert knowledge of these database types. Otherwise, delete the new database. Perform the manual migration procedure on the original database, just as you do for each database that completely fails auto-migration. Consult “Upgrading Cloudscape manually” for instructions.

For successfully migrated Derby or Cloudscape instances, be aware that new cell-scoped data sources can only be used by nodes that run version 6.0.2 or later of the application server. Earlier versions of the product do not support the new versions of Derby or Cloudscape. When applications on nodes that are earlier than version 6.0.2 try to access a Cloudscape or Derby data source, the application server will issue exceptions at run time.

After a successful database migration, reboot the database and compress tables to improve performance. See the Apache Derby documentation for instructions.

Upgrading Cloudscape manually

During the upgrade of your application server, the migration tool attempts to upgrade instances of Cloudscape that are accessed through the embedded framework only. The automatic upgrade excludes Cloudscape instances that transact with applications through the Network Server framework. This exclusion eliminates the risk of corrupting third party applications that access the same database instances as the application server. You must manually upgrade database instances that are accessed through the Network Server framework. Do the same for databases that fail the automatic migration.

Before you begin

Do not use Apache Derby Version 10.1.x or Cloudscape v10.1.x as a production database. Use them for development and test purposes only.

For instances of Cloudscape that are accessed through the embedded framework, determine which instances completely failed the automatic upgrade process and which ones were only partially upgraded. The topic on verifying the Cloudscape automatic migration documents how to uncover database errors and diagnostic data from various migration logs. The log messages contain the exact old and new database path names that you must use to run the manual migration. Note these new path names precisely.

To minimize the risk of migration errors for databases that were only partially upgraded during the automatic migration process, delete the new database. Troubleshoot the original database according to the log diagnostic data, then perform manual migration on the original database.

About this task

The following section consists of steps to migrate Cloudscape instances that are accessed through both the embedded framework as well as the Network Server framework. Steps that apply only to the Cloudscape Network Server framework are marked accordingly. As a migration best practice, ensure that your user ID has one of the following authorities:

- Administrator of the application server that accesses the Cloudscape instance
- A umask that can access the database instance

Otherwise, you might see runtime errors about the database instance being read-only.

1. **Network Server framework only:** Ensure that every client of the Cloudscape database can support Cloudscape v10.1.x or Apache Derby. Application server clients of the database must run versions 6.02.x or later of the application server.

In the case of mixed-node cells, remember that only nodes of Version 6.02 or later of the application server can use data sources that you create post-migration for access to Cloudscape 10.1.x or Apache Derby. Earlier versions of the product do not support Cloudscape 10.1x or Apache Derby. When applications on nodes that are earlier than v6.02 try to access a cell-scoped Cloudscape 10.1.x or Apache Derby data source, the application server will issue exceptions at run time.

2. **Network Server framework only:** Take the database offline. No clients can access it during the migration process.
3. Examine a sample Cloudscape migration script that the application server provides, either `db2jmmigrate.bat` or `db2jmmigrate.sh`. The path of both scripts is `app_server_root\derby\bin\embedded`. You can modify the script according to the requirements of your environment. Consult the Cloudscape migration document for information about options that you can use with the script. For example, you can use the following option to specify the DDL file for the new database:

```
-DB2j.migrate.ddlFile=filename
```

4. To generate database debug logs when you run the migration script, ensure that the debug migration trace is active. By default, this trace function is enabled. Reactivate the debug trace if it is disabled.
 - a. To set the trace options in the administrative console, click **Troubleshooting > Logging and Tracing** in the console navigation tree.
 - b. Select the application server name.
 - c. Click **Change Log Level Details**.
 - d. Optional: If **All Components** has been enabled, you might want to turn it off, and then enable specific components.
 - e. Optional: Select a component or group name. For more information see the topic on log level settings. If the selected server is not running, you will not be able to see individual component in graphic mode.
 - f. Enter a trace string in the trace string box. In this case, enter one of the following:
 - all traces*=all
 - com.ibm.ws.migration.WASUpgrade=allFor more information on tracing read the topic on working with trace.
 - g. Select **Apply**, then **OK**.

5. Specify your old database name and the full post-migration path of the new database name when you run the script. For example: `E:\WebSphere\AppServer\derby\bin\embedded>db2jmmigrate.bat myOldDB myNewDB` The logs from the automatic migration provide the exact path names to specify for both the old database and the target database. You must use this target database name to specify the new database, because your migrated Cloudscape data sources (updated by the WebSphere Application Server migration utilities) now point to the target database name. The following sample text demonstrates how log messages display target database names:

```
DSRA7600E: Cloudscape migration of database instance C:\temp\migration2\profiles\AppSrv01\
installedApps\ghongellNode01Cell\DynamicQuery.ear\EmployerFinderDB to new database instance
C:\WebSphere\AppServer\profiles\AppSrv01\databases\C__WAS602_AppServer_profiles_AppSrv01_
installedApps_ghongellNode01Cell_DynamicQuery.ear_EmployerFinderDB failed,
reason: java.sql.SQLException: Failure creating target db
```

For instances of Cloudscape that are accessed through the Network Server framework, input any name that you want for the new database. Remember to modify your existing data sources to point to the new database name.

6. When the migration process ends, examine the database migration log to verify the results. The path name of each database migration log is `app_server_root/logs/derby/myFulldbName_migrationLog.log`.

For a successful migration, the database migration log displays a message that is similar to the following text:

```
Check E:\WebSphere\AppServer\derby\my01dDB_migrationLog.log for progress
Migration Completed Successfully
E:\WebSphere\AppServer\derby\bin\embedded>
```

Otherwise, the log displays error messages in the format of the following example:

```
Check E:\WebSphere\AppServer\derby\my01dDB_migrationLog.log for progress
ERROR: An error occurred during migration. See debug.log for more details.
ERROR XMG02: Failure creating target db
java.sql.SQLException: Failure creating target db
    at com.ibm.db2j.tools.migration.MigrationState.getCurrSQLException(Unknown Source)
    at com.ibm.db2j.tools.migration.MigrateFrom51Impl.handleException(Unknown Source)
    at com.ibm.db2j.tools.migration.MigrateFrom51Impl.go(Unknown Source)
    at com.ibm.db2j.tools.migration.MigrateFrom51Impl.main(Unknown Source)
    at com.ibm.db2j.tools.MigrateFrom51.main(Unknown Source)
```

...

7. For more data about a migration error, consult the debug log that corresponds with the database migration log. The full path name of a debug log file is *app_server_root/logs/derby/myFulldbName_migrationDebug.log*.

The following lines are a sample of debug text.

```
sourceDBURL=jdbc:db2j:E:\WebSphere\my01dDB
newDBURL=jdbc:derby:e:\tempo\myNewDB
ddlOnly=false
connecting to source db <jdbc:db2j:E:\WebSphere\my01dDB>
connecting to source db <jdbc:db2j:E:\WebSphere\my01dDB> took 0.611 seconds
creating target db <jdbc:derby:e:\tempo\myNewDB>
creating target db <jdbc:derby:e:\tempo\myNewDB> took 6.589 seconds
initializing source db data structures
initializing source db data structures took 0.151 seconds
recording DDL to create db <E:\WebSphere\my01dDB>
recording DDL to create db <E:\WebSphere\my01dDB> took 5.808 seconds
```

Results

As indicated in the previous steps, the database migration log displays either a Migration Completed Successfully message, or a message containing migration failure exceptions.

What to do next

- For databases that fail migration, troubleshoot according to the logged error data. Then rerun the migration script.
- To access successfully upgraded databases through the embedded framework, modify your data sources to point to the new database names.
- To access successfully upgraded databases through the Network Server framework, you can use either the DB2 Universal JDBC driver or the Derby Client JDBC driver.
 - If you want your existing JDBC configurations to continue to use the DB2 Universal JDBC driver, modify your data sources to point to the new database names.
 - If you want to use the Derby Client JDBC driver, which can support XA data sources, modify your JDBC providers to use the new Derby Client JDBC driver class and the new data source implementation classes. Then reconfigure every existing data source to use the correct Derby data source helper class, and to point to the new database name.

Consult the article in the information center on vendor-specific data sources minimum required settings for all of the new class names.

Database performance tuning

Database performance tuning can dramatically affect the throughput of your application. For example, if your application requires high concurrency (multiple, simultaneous interactions with backend data), an improperly tuned database can result in a bottleneck. Database access threads accumulate in a backlog when the database is not configured to accept a sufficient number of incoming requests.

Because WebSphere Application Server supports the integration of many different database products, each one with unique tuning configurations, consult your database vendor documentation for comprehensive tuning information. This information center provides introductory material on for your convenience:

- “DB2 tuning tips for z/OS” on page 1635

DB2 tuning parameters

DB2 has many parameters that you can configure to optimize database performance. For complete DB2 tuning information, refer to the *DB2 UDB Administration Guide: Performance* document.

DB2 logging:

DB2 has corresponding log files for each database that provides services to administrators, including viewing database access and the number of connections. For systems with multiple hard disk drives, you can gain large performance improvements by setting the log files for each database on a different hard drive from the database files.

- **How to view or set:** At a DB2 command prompt, issue the command: `db2 update db cfg for [database_name] using newlogpath [fully_qualified_path]`.
- **Default value:** Logs reside on the same disk as the database.
- **Recommended value:** Use a separate high-speed drive, preferably performance enhanced through a redundant array of independent disk (RAID) configuration.

DB2 configuration advisor:

Located in the DB2 Control Center, this advisor calculates and displays recommended values for the DB2 buffer pool size, the database, and the database manager configuration parameters, with the option of applying these values. See more information about the advisor in the online help facility within the Control Center.

Number of connections to DB2 - MaxAppls and MaxAgents:

When configuring the data source settings for the databases, confirm the DB2 MaxAppls setting is greater than the maximum number of connections for the data source. If you are planning to establish clones, set the MaxAppls value as the maximum number of connections multiplied by the number of clones. The same relationship applies to the session manager number of connections. The MaxAppls setting must be equal to or greater than the number of connections. If you are using the same database for session and data sources, set the MaxAppls value as the sum of the number of connection settings for the session manager and the data sources.

For example, $\text{MaxAppls} = (\text{number of connections set for the data source} + \text{number of connections in the session manager}) \times \text{number of clones}$.

After calculating the MaxAppls settings for the WebSphere Application Server database and each of the application databases, verify that the MaxAgents setting for DB2 is equal to or greater than the sum of all of the MaxAppls values. For example, $\text{MaxAgents} = \text{sum of MaxAppls for all databases}$.

DB2 buffpage:

Improves database system performance. Buffpage is a database configuration parameter. A buffer pool is a memory storage area where database pages containing table rows or index entries are temporarily read and changed. Data is accessed much faster from memory than from disk.

- **How to view or set:** To view the current value of buffpage for database *x*, issue the DB2 command `get db cfg for x` and look for the value **BUFFPAGE**. To set **BUFFPAGE** to a value of *n*, issue the DB2 command `update db cfg for x using BUFFPAGE n` and set **NPAGES** to -1 as follows:

```
db2 <-- go to DB2 command mode, otherwise the following "select" does not work as is
      connect to x <-- (where x is the particular DB2 database name)
      select * from syscat.bufferpools
          (and note the name of the default, perhaps: IBMDEFAULTBP)
          (if NPAGES is already -1, there is no need to issue following command)
      alter bufferpool IBMDEFAULTBP size -1
      (re-issue the above "select" and NPAGES now equals -1)
```

You can collect a snapshot of the database while the application is running and calculate the buffer pool hit ratio as follows:

1. Collect the snapshot:
 - a. Issue the **update monitor switches using bufferpool on** command.
 - b. Make sure that bufferpool monitoring is on by issuing the **get monitor switches** command.
 - c. Clear the monitor counters with the **reset monitor all** command.
 2. Run the application.
 3. Issue the **get snapshot for all databases** command before all applications disconnect from the database, otherwise statistics are lost.
 4. Issue the **update monitor switches using bufferpool off** command.
 5. Calculate the hit ratio by looking at the following database snapshot statistics:
 - Buffer pool data logical reads
 - Buffer pool data physical reads
 - Buffer pool index logical reads
 - Buffer pool index physical reads
- **Default value:** 250
 - **Recommended value:** Continue increasing the value until the snapshot shows a satisfactory hit rate.

The buffer pool hit ratio indicates the percentage of time that the database manager did not need to load a page from disk to service a page request. That is, the page is already in the buffer pool. The greater the buffer pool hit ratio, the lower the frequency of disk input and output. Calculate the buffer pool hit ratio as follows:

- $P = \text{buffer pool data physical reads} + \text{buffer pool index physical reads}$
- $L = \text{buffer pool data logical reads} + \text{buffer pool index logical reads}$
- $\text{Hit ratio} = (1 - (P/L)) * 100\%$

DB2 query optimization level:

Sets the amount of work and resources that DB2 puts into optimizing the access plan. When a database query runs in DB2, various methods are used to calculate the most efficient access plan. The range is from 0 to 9. An optimization level of 9 causes DB2 to devote a lot of time and all of its available statistics to optimizing the access plan.

- **How to view or set:** The optimization level is set on individual databases and can be set with either the command line or with the DB2 Control Center. Static SQL statements use the optimization level that is specified on the **prep** and **bind** commands. If the optimization level is not specified, DB2 uses the default optimization as specified by the `dft_queryopt` setting. Dynamic SQL statements use the optimization class that is specified by the current query optimization special register, which is set using the SQL Set statement. For example, the following statement sets the optimization class to 1:

```
Set current query optimization = 1
```

If the current query optimization register is not set, dynamic statements are bound using the default query optimization class.

- **Default value:** 5

- **Recommended value:** Set the optimization level for the needs of the application. Use high levels only when there are very complicated queries.

DB2 reorgchk:

Obtains the current statistics for data and rebinding. Use this parameter because SQL statement performance can deteriorate after many updates, deletes or inserts.

- **How to view or set:** Use the DB2 **reorgchk update statistics on table all** command to perform the **runstats** operation on all user and system tables for the database to which you are currently connected. Rebind packages using the **bind** command. If statistics are available, issue the **db2 -v "select tname, nleaf, nlevels, stats_time from sysibm.sysindexes"** command on DB2 CLP. If no statistic updates exist, nleaf and nlevels are -1, and stats_time has an empty entry (for example: "-"). If the runstats command was previously run, the real-time stamp from completion of the runstats operation also displays under stats_time. If you think the time shown for the previous runstats operation is too old, run the runstats command again.
- **Default value:** None
- **Recommended value:** None

DB2 locktimeout:

Specifies the number of seconds that an application waits to obtain a lock. Setting this property helps avoid global deadlocks for applications.

- **How to view or set:** To view the current value of the lock timeout property for database xxxxxx, issue the DB2 **get db cfg for xxxxxx** command and look for the value, LOCKTIMEOUT. To set LOCKTIMEOUT to a value of *n*, issue the DB2 **update db cfg for xxxxxx** command using **LOCKTIMEOUT n**, where xxxxxx is the name of the application database and *n* is a value between 0 and 30 000 inclusive.
- **Default value:** -1, meaning lock timeout detection is turned off. In this situation, an application waits for a lock if one is not available at the time of the request, until either of the following events occurs:
 - The lock is granted
 - A deadlock occurs
- **Recommended value:** If your database access pattern tends toward a majority of writes, set this value so that it gives you early warning when a timeout occurs. A setting of 30 seconds suits this purpose. If your pattern tends toward a majority of reads, either accept the default lock timeout value, or set the property to a value greater than 30 seconds.

DB2 maxlocks:

Specifies the percentage of the lock list that is reached when the database manager performs escalation, from row to table, for the locks held by the application. Although the escalation process does not take much time, locking entire tables versus individual rows decreases concurrency, and potentially decreases overall database performance for subsequent attempts to access the affected tables.

- **How to view or set:** To view the current value of the maxlocks property for database xxxxxx, issue the DB2 **get db cfg for xxxxxx** command and look for the MAXLOCKS value. To set MAXLOCKS to a value of *n*, issue the DB2 **update db cfg for xxxxxx** command using **MAXLOCKS n**, where xxxxxx is the name of the application database and *n* is a value between 1 and 100 inclusive.
- **Default value:** Refer to the current database information for property default values per operating system.
- **Recommended value:** If lock escalations are causing performance concerns, you might need to increase the value of this parameter or the locklist parameter, which is described in the following paragraph. You can use the database system monitor to determine if lock escalations are occurring.

DB2 locklist:

Specifies the amount of storage that is allocated to the lock list.

- **How to view or set:** To view the current value of the locklist property for database xxxxxx, issue the DB2 **get db cfg for xxxxxx** command and look for the LOCKLIST value . To set LOCKLIST to a value of *n*, issue the DB2 **update db cfg for xxxxxx** command using **LOCKLIST n**, where xxxxxx is the name of the application database and *n* is a value between 4 and 60 000 inclusive.
- **Default value:** Refer to the current database information for property default values per operating system.
- **Recommended value:** If lock escalations are causing performance concerns, you might need to increase the value of this parameter or the maxlocks parameter, which is described in the previous paragraph. You can use the database system monitor to determine if lock escalations are occurring. Refer to the *DB2 Administration Guide: Performance* document for more details.

DB2 tuning tips for z/OS

Performance tuning for DB2 is usually critical to the overall performance of a WebSphere Application Server application. DB2 is often the preferred datastore for Enterprise JavaBeans (EJBs). Listed here are some basic guidelines for DB2 tuning as well as some guidelines for tuning DB2 for WebSphere Application Server. For more complete information on DB2 tuning, refer to the DB2 Universal Database for OS/390 and z/OS Administration Guide Document Number SC26-9931-03. The DB2 books can be accessed at the following Internet location:<http://www.ibm.com/servers/eserver/zseries/zos/>.

Benefits of Structured Query Language in Java (SQLJ)

If you use the DB2 Universal JDBC driver provider, you can implement SQLJ as the query language for both BMP and CMP beans. SQLJ incurs less transaction overhead than the default query language for JDBC transactions, which is dynamic SQL. SQLJ is static and uses pre-prepared plans. Thus SQLJ generally improves application performance. For DB2 for z/OS database administrators, SQLJ is often easy to adopt because the security model and the statement repeatability features are similar to those of static SQL. SQLJ does require extra steps that are features of newer versions of WebSphere Studio Application Developer and Rational Application Developer..

See the *Administering applications and their environment* PDF for more information.

General DB2 tuning tips:

This discussion relates only to DB2 for z/OS JDBC Driver which is referred to as the DB2 for z/OS Legacy JDBC Driver.

- First, ensure that your DB2 logs are large enough, are allocated on the fastest volumes you have, and make sure they have optimal CI sizes.
- Next, ensure that you have tuned your bufferpools so that the most often-read data is in memory as much as possible. Use ESTOR and hyperpools.
- You may want to consider pre-formatting tables that are going to be heavily used. This avoids formatting at runtime.

DB2 for WebSphere tuning tips:

- Ensuring DB2 Tracing Under the DB2 for z/OS Universal Driver is Turned Off.
 - If the `db2.jcc.propertiesFile` jvm property has been defined to specify a DB2 jcc properties file to the WebSphere Application Server for z/OS, ensure that the following trace statements in the file are commented out if they are specified:

```
# jcc.override.traceFile=<file name>
# jcc.override.traceFile=<file name>
```
 - If any of the DB2 Universal JDBC Driver datasources your applications are using are defined with a nonzero `traceLevel` custom property, use the WebSphere Application Server for z/OS Administrative console to set the `traceLevel` to zero.
- We recommend that you ensure indexes are defined on all your object primary keys. Failure to do so will result in costly tablespace scans.

- Ensure that, once your tables are sufficiently populated, you do a re-org to compact the tables. Running RUNSTATS will ensure that the DB2 catalog statistics about table and column sizes and accesses are most current so that the best access patterns are chosen by the optimizer.
- You will have to define more connections called threads in DB2. WebSphere Application Server uses a lot of threads. Sometimes this is the source of throughput bottlenecks since the server will wait at the create thread until one is available.
- Make sure you are current with JDBC maintenance. Many performance improvements have been made to JDBC. To determine the JDBC maintenance level, enter the following from the shell:

```
java com.ibm.db2.jcc.DB2Jcc -version
```

If this returns a class not found, either you are at a level of the driver that is older and doesn't support this command or you have not issued the command properly.

- We recommend that you enable dynamic statement caching in DB2. To do this, modify your ZPARMS to say CACHEDYN(YES) MAXKEEPD(16K). Depending on the application, this can make a very significant improvement in DB2 performance. Specifically, it can help JDBC and LDAP query.
- Increase DB2 checkpoint interval settings to a large value. To do this, modify your ZPARMS to include CHKFREQ=xxxxx, where xxxxx is set at a high value when doing benchmarks. On production systems there are other valid reasons to keep checkpoint frequencies lower, however.

Example: This example identifies zparm values discussed in this article.

```

WebSphere Application Server tuning tips for use with DB2:

WebSphere Application Server uses JDBC prepared statement caching as a performance enhancing feature. If you are using this feature together with DB2 for z/OS, be aware of the potential impact on the number of DB2 JDBC cursor objects available.

Prepared statement caching effects on DB2 for OS/390 JDBC cursor objects

When you obtain a *ResultSet* object by running a *PreparedStatement* object, a DB2 JDBC cursor object is bound to it until the corresponding DB2 prepared statement is closed. This happens when the DB2 *Connection* object is released from the WebSphere Application Server connection pool. From an application perspective, the result set, prepared statement, and connection are each closed in turn. However, the underlying DB2 *Connection* is pooled by the WebSphere Application Server, the underlying

DB2 *PreparedStatement* is cached by the application server, and each underlying DB2 JDBC cursor object associated with each *ResultSet* created on this *PreparedStatement* object is not yet freed.

Each *PreparedStatement* object in the cache can have one or more result sets associated with it. If a result set is opened and not closed, even though you close the connection, that result set is still associated with the prepared statement in the cache. Each of the result sets has a unique JDBC cursor attached to it. This cursor is kept by the statement and is not released until the prepared statement is cleared from the WebSphere Application Server cache.

If there are more of the cached statements than there are cursors, eventually the execution of a *PreparedStatement* object results in the following exception:

```
java.sql.SQLException: DB2SQLJDBCProfile Error: No more JDBC Cursors without hold
```

Some WebSphere Application Server tuning suggestions to help avoid this problem are:

1. Decrease the *statement cache size* setting on the DB2 for OS/390 data source definition. Setting this value to zero (0) eliminates statement caching, but causes a noticeable performance impact.
2. Decrease the *minConnections* connection pool setting on the DB2 for OS/390 data source definition.
3. Decrease the *Aged Timeout* connection pool setting on the DB2 for OS/390 data source definition. However, it is **NOT** recommended that you set this to zero (0), as this disables the Aged Timeout function.

Data access tuning parameters

For better application performance, you can tune some data access resources through the WebSphere Application Server administrative console.

Tune these properties of data sources and connection pools to optimize the performance of transactions between your application and datastore. See the *Administering applications and their environment* PDF for more information.

Data source tuning

To view the administrative console page where you configure the following properties, click **Resources > JDBC Providers > JDBC_provider > Data sources > data_source > WebSphere Application Server connection properties**.

Enable JMS one phase optimization support

If your application does not use JMS messaging, **do not** select this option. Activating this support enables the Java Message Service (JMS) to get optimized connections from the data source. Activating this support also *prevents* JDBC applications from obtaining connections from the data source. For further explanation of JMS one phase support, refer to the article entitled "Sharing connections to benefit from one phase commit optimization" in this information center.

Statement cache size

Specifies the number of statements that can be cached per connection.

The WebSphere Application Server data source optimizes the processing of *prepared statements* and *callable statements* by caching those statements that are not being used in an active connection. Both statement types help reduce overhead for transactions with backend data.

- A prepared statement is a precompiled SQL statement that is stored in a *PreparedStatement* object. Application Server uses this object to run the SQL statement multiple times, as required by your application run time, with values that are determined by the run time.
- A callable statement is an SQL statement that contains a call to a stored procedure, which is a series of precompiled statements that perform a task and return a result. The statement is stored in the *CallableStatement* object. Application Server uses this object to run a stored procedure multiple times, as required by your application run time, with values that are determined by the run time.

In general, the more statements your application has, the larger the cache should be. **Be aware**, however, that specifying a larger statement cache size than needed wastes application memory and *does not* improve performance.

Determine the value for your cache size by adding the number of uniquely prepared statements and callable statements (as determined by the SQL string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible statements that can be cached on a given connection over the life of the server. See the *Administering applications and their environment* PDF for more information.

Default: For most databases the default is 10. Zero means there is no cache statement.

Connection pool tuning

To view the administrative console page where you configure the following properties, click **Resources > JDBC Providers > JDBC_provider > Data sources > data_source > Connection pool settings**.

Maximum connections

Specifies the maximum number of physical connections that can be created in this pool. These are the physical connections to the backend datastore. When this number is reached, no new physical connections are created; requestors must wait until a physical connection that is currently in use is returned to the pool.

For optimal performance, set the value for the connection pool lower than the value for the Web container threadpool size. Lower settings, such as 10 to 30 connections, might perform better than higher settings, such as 100. See the *Administering applications and their environment* PDF for more information.

Default: 10

Minimum connections

Specifies the minimum number of physical connections to maintain. Until this number is exceeded, the pool maintenance thread does not discard physical connections.

If you set this property for a higher number of connections than your application ultimately uses at run time, you do not waste application resources. WebSphere Application Server does not create additional connections to achieve your minimum setting. Of course, if your application requires more connections than the value you set for this property, application performance diminishes as connection requests wait for fulfillment. See the *Administering applications and their environment* PDF for more information.

Default: 1

Managing resources through JCA lifecycle management operations

You can manage the run-time status of your data source and connection factory resources to perform some data access administrative tasks without restarting the application server. This topic outlines the process for managing those resources through the administrative console.

Before you begin

When you manage the run-time status of connection factories or data sources, you are applying Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) lifecycle management operations to the MBeans that are associated with these resources. The management operations are PAUSE and RESUME. Pausing an MBean halts outbound communication to the backend, such as a database. This action affects all applications that use the corresponding connection factory or data source on the same server.

About this task

With these management operations, you can perform some administrative tasks dynamically, without restarting your application server:

- Respond to a security threat, and prevent new connection requests from reaching the backend
 - Perform maintenance on the backend
 - Apply configuration changes to non-required properties of the connection factory or data source, such as turning JDBC trace on or off, or modifying preferences for collecting client information
1. Navigate to the administrative console page that corresponds to the resource type that you want to manage.
 - For connection factories, use either of the following paths:
 - **Resources > Resource Adapters > J2C connection factories**
 - **Resources > Resource Adapters > Resource Adapters > *resource_adapter* > J2C connection factories**
 - For data sources, use either of the following paths:
 - **Resources > JDBC > Data sources**
 - **Resources > JDBC > JDBC providers > *JDBC_provider* > Data sources**
 2. Select the connection factory or data source configurations that you want to manage, and click **Manage state**. The administrative console now displays the JCA lifecycle management page, which contains a table that depicts the full scope configuration of your previous selection.

The table is comprised of three columns:

 - **JNDI name:** The Java Naming and Directory Interface (JNDI) name of the connection factory or data source configuration.
 - **Running object scope:** The server that is running the connection factory or data source MBean.
 - **Status:** The status of the connection factory or data source MBean.
 3. Select the rows that represent each invocation of the resource, per running server, that you want to manage. Be aware that when you click your management operation, WebSphere Application Server applies it to every resource object in your selection.

Note: If the MBean status of a row has a value of NOT_ACCESSED, you cannot apply JCA lifecycle management operations to that MBean. The NOT_ACCESSED state indicates that the MBean exists on the specified server, but no applications performed a JNDI namespace lookup on the corresponding connection factory or data source.

4. Click **Pause** or **Resume**. The status column of the table changes to reflect the new state of the MBean.

JCA lifecycle management

Use this page to perform JCA lifecycle management operations on data source and connection factory MBeans. With these management operations, you can control the runtime status of the corresponding data source and connection factory resources.

You can view this administrative console page in different locations, depending on whether you want to manage data sources or J2C connection factories. For example:

- For connection factories: Click **Resources** → **Resource adapters** → **J2C connection factories**. Select the connection factory configurations that you want to manage, and click **Manage state**.
- For data sources, click **Resources** → **JDBC** → **Data sources**. Select the data source configurations that you want to manage, and click **Manage state**.

Guidelines for using this administrative console page:

- The table displays a list of MBeans that correspond to the data sources or connection factories in your selection from the previous console page. These MBeans are compatible with Version 6.0.2 and later of the application server.
- You can only perform JCA lifecycle management actions on MBeans that are in the active state. In this context, an MBean is considered active when an application performs a Java Naming and Directory Interface (JNDI) name space lookup on the corresponding data source or connection factory resource.
- Pausing an MBean halts outbound communication to the backend, such as a database. This action affects all applications that use the resource on the selected server.

Pause:

Specifies to pause the MBean that is selected. Pausing an MBean halts outbound communication to the back end resource, and this action will affect all applications that use the resource on the selected server.

Resume:

Specifies to resume the MBean that is selected. Resuming an MBean will enable outbound communication to the back end resource, and this action will affect all applications that use the resource on the selected server.

Purge:

Specifies to purge the contents of the connection pool for the data source or connection factory that is specified. Purging the pool will not affect ongoing transactions.

Name (JNDI name):

The name of the connection factory or data source configuration, followed by the Java Naming and Directory Interface (JNDI) name in parenthesis.

Running object scope:

The server that is running the connection factory or data source MBean.

Status:

The state of the connection factory or data source MBean.

Possible values:

| State | Indications |
|--------|--|
| ACTIVE | <ul style="list-style-type: none"> • The resource that corresponds with the MBean is ready to provide an application with connections to a backend. • An application performed a JNDI namespace lookup on this resource. <p>You can apply the JCA lifecycle management operation of PAUSE to an MBean in this state.</p> |

| State | Indications |
|--------------|--|
| PAUSED | <ul style="list-style-type: none"> All outbound communication to the backend through the corresponding resource is stopped, as a result of a JCA lifecycle management operation that was applied previously to the MBean. An application performed a JNDI namespace lookup on the resource. <p>You can apply the JCA lifecycle management operation of RESUME to an MBean in this state.</p> |
| NOT_ACCESSED | <ul style="list-style-type: none"> The MBean exists on the specified server, but no applications performed a JNDI name space lookup on the corresponding connection factory or data source. <p>You cannot apply JCA lifecycle management operations to an MBean in this state.</p> |

Data access problems

WebSphere Application Server diagnostic tools provide services to help troubleshoot database connection problems. Additionally, the IBM Web site provides flexible searching capabilities for finding documented solutions to database-specific connection problems.

The following steps help you quickly isolate connectivity problems.

- Browse the log files of the application server for clues.
See Setting up the error log.
- Browse the Helper Class property of the data source to verify that it is correct and that it is on the WebSphere Application Server class path. Mysterious errors or behavior might result from a missing or misnamed Helper Class name. If WebSphere Application Server cannot load the specified class, it uses a default helper class that might not function correctly with your database manager.
- Verify that the Java Naming and Directory Interface (JNDI) name of the data source matches the name used by the client attempting to access it. If error messages indicate that the problem might be naming-related, such as referring to the **name server** or **naming service**, or including error IDs beginning with **NMSV**, look at the Naming related problems and Troubleshooting the naming service component topics.
- Enable tracing for the resource adapter using the trace specification, RRA=all=enabled. Follow the instructions for dumping and browsing the trace output, to narrow the origin of the problem.

For a comprehensive list of database-specific troubleshooting tips, see the WebSphere Application Server product support page. (Find the link at the end of this article.) In the Search Support field, type a database vendor name among your search terms. Select **Solve a problem**, then click **Search**.

Remember that you can always find Support references in the Troubleshooting help from IBM article of this information center.

Currently this information center provides a limited number of troubleshooting tips for the following databases:

- Oracle
- DB2
- SQL Server
- Apache Derby
- Sybase
- General data access problems

General data access problems

- An exception "IllegalConnectionUseException" occurs
- WTRN0062E: An illegal attempt to enlist multiple one phase capable resources has occurred.
- ConnectionWaitTimeoutException.
- com.ibm.websphere.ce.cm.StaleConnectionException: [IBM][CLI Driver] SQL1013N The database alias name or database name "NULL" could not be found. SQLSTATE=42705
- java.sql.SQLException: java.lang.UnsatisfiedLinkError:
- "J2CA0030E: Method enlist caught java.lang.IllegalStateException" wrapped in error "WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred" when attempting to execute a transaction.
- java.lang.UnsatisfiedLinkError:xaConnect exception when attempting a database operation
- "J2CA0114W: No container-managed authentication alias found for connection factory or datasource *datasource*" when attempting a database operation
- An error is thrown if you use the ws_ant command to perform the database customization for Structured Query Language in Java on HP platforms
- Container-managed persistence (CMP) cannot successfully obtain the database access function as defined.

IllegalConnectionUseException

This error can occur because a connection obtained from a WAS40DataSource is being used on more than one thread. This usage violates the J2EE 1.3 programming model, and an exception generates when it is detected on the server. This problem occurs for users accessing a data source through servlets or bean-managed persistence (BMP) enterprise beans.

To confirm this problem, examine the code for connection sharing. Code can inadvertently cause sharing by not following the programming model recommendations, for example by storing a connection in an instance variable in a servlet, which can cause use of the connection on multiple threads at the same time.

WTRN0062E: An illegal attempt to enlist multiple one phase capable resources has occurred

This error can occur because:

- An attempt was made to share a single-phase connection, when each **getConnection** method has different connection properties; such as the AccessIntent. This attempt causes a non-shareable connection to be created.
- An attempt was made to have more than one unshareable connection participate in a global transaction, when the data source is not an XA resource.
- An attempt was made to have a one-phase resource participate in a global transaction while an XA resource or another one-phase resource already participated in this global transaction.
 - Within the scope of a global transaction you try to get a connection more than once and at least one of the resource-refs you use specifies that the connection is unshareable, and the data source is not configured to support two-phase commit transactions. It does not support an XAResource. If you do not use a resource-ref, you default to unshareable connections.
 - Within the scope of a global transaction you try to get a connection more than once and at least one of the resource-refs you use specifies that the connection is shareable and the data source is not configured to support two-phase commit transactions. That is, it does not support an XAResource. In addition, even though you specify that connections are shareable, each getConnection request is made with different connection properties (such as IsolationLevel or AccessIntent). In this case, the connections are not shareable, and multiple connections are handed back.
 - Multiple components (servlets, session beans, BMP entity beans, or CMP entity beans) are accessed within a global transaction. All use the same data source, all specify shareable connections on their resource-refs, and you expect them to all share the same connection. If the properties are different, you get multiple connections. AccessIntent settings on CMP beans change their properties. To share a connection, the AccessIntent setting must be the same. For more information about CMP beans sharing a connection with non-CMP components, see the *Data access application programming*

interface support and Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans topics in the `DataAccess` section of the information center.

To correct this error:

- Check what your client code passes in with its `getConnection` requests, to ensure they are consistent with each other.
- Check the connection sharing scope from the resource binding, using an assembly tool.
 - If you are running an unshareable connection scope, verify that your data source is an XA data source.
 - If you are running a shareable connection scope, verify that all connection properties, including `AccessIntent`, are sharable.
- Check the JDBC provider implementation class from the Manage JDBC resource panel of the administrative console to ensure that it is a class that supports XA-type transactions.

ConnectionWaitTimeoutException accessing a data source or resource adapter

If your application receives exceptions like a `com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException` or `com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException` when attempting to access a WebSphere Application Server data source or JCA-compliant resource adapter, respectively, some possible causes are:

- The maximum number of connections for a given pool is set too low. The demand for concurrent use of connections is greater than the configured maximum value for the connection pool. One indication that this situation is the problem is that you receive these exceptions regularly, but your CPU utilization is not high. This exception indicates that there are too few connections available to keep the threads in the server busy.
- Connection Wait Time is set too low. Current demand for connections is high enough such that sometimes there is not an available connection for short periods of time. If your connection wait timeout value is too low, you might timeout shortly before a user returns a connection back to the pool. Adjusting the connection wait time can give you some relief. One indication of this problem is that you use close to the maximum number of connections for an extended period and receiving this error regularly.
- You are not closing some connections or you are returning connections back to the pool at a very slow rate. This situation can happen when using unshareable connections, when you forget to close them, or you close them long after you are finished using them, keeping the connection from returning to the pool for reuse. The pool soon becomes empty and all applications get `ConnectionWaitTimeoutExceptions`. One indication of this problem is you run out of connections in the connection pool and you receive this error on most requests.
- You are driving more load than the server or backend system have resources to handle. In this case you must determine which resources you need more of and upgrade configurations or hardware to address the need. One indication of this problem is that the application or database server CPU is nearly 100% busy.

To correct these problems, either:

- Modify an application to use fewer connections
- Properly close the connections.
- Change the pool settings of `MaxConnections` or `ConnectionWaitTimeout`.
- Adjust resources and their configurations.

`com.ibm.websphere.ce.cm.StaleConnectionException: [IBM][CLI Driver] SQL1013N The database alias name or database name "NULL" could not be found. SQLSTATE=42705`

This error occurs when a data source is defined but the `databaseName` attribute and the corresponding value are not added to the custom properties panel.

To add the **databaseName** property:

1. Click **Resources>Manage JDBC Providers** link in the administrative console.
2. Select the JDBC provider that supports the problem data source.
3. Select **Data Sources** and then select the problem data source.
4. Under **Additional properties** click **Custom Properties**.
5. Select the **databaseName** property, or add one if it does not exist, and enter the actual database name as the value.
6. Click **Apply** or **OK**, and then click **Save** from the action bar.
7. Access the data source again.

java.sql.SQLException: java.lang.UnsatisfiedLinkError:

This error indicates that the directory containing the binary libraries which support a database are not included in the LIBPATH environment variable for the environment in which the WebSphere Application Server starts.

The path containing the DBM vendor libraries vary by dbm. One way to find them is by scanning for the missing library specified in the error message. Then you can correct the LIBPATH variable to include the missing directory, either in the `.profile` of the account from which WebSphere Application Server is executed, or by adding a statement in a `.sh` file which then executes the `startServer` program.

Configure the java LIBPATH (`java.library.path`) property with the `domain_region_libpath` environment variable, like `control_region_libpath`, `server_region_libpath`, `adjunct_region_libpath`. See the topic on changing the values of variables referenced in BBOM00011 messages for instructions on how to set the region libpath variables.

"J2CA0030E: Method enlist caught java.lang.IllegalStateException" wrapped in error "WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred" when attempting to execute a transaction.

This error can occur when last participant support is missing or disabled. Last participant support allows a one-phase capable resource and a two-phase capable resource to enlist within the same transaction.

Last participant support is only available if the following are true:

- WebSphere Application Server Programming Model Extensions (PME) is installed. PME is included in the Application Server Integration Server product.
- The Additional Integration Server Extensions option is enabled when PME is installed. If you perform a typical installation, this function is enabled by default. If you perform a custom installation, you have the option to disable this function, which disables last participant support.
- The application enlisting the one-phase resource is deployed with the **Accept heuristic hazard** option enabled. This deployment is done with an assembly tool.

java.lang.UnsatisfiedLinkError:xaConnect exception when attempting a database operation

This problem has two main causes:

- The most common cause is that the jdbc driver which supports connectivity to the database is missing, or is not the correct version, or that native libraries which support the driver are on the system's path.
 - To resolve this problem on a Windows platform, verify that the JDBC driver jar file is on the system PATH environment variable:
 - If you are using DB2, verify that at least the DB2 client product has been installed on the WebSphere host

- On DB2 version 7.2 or earlier, the file where the client product is installed on the WebSphere Application Server is db2java.zip. Verify that the usejdbc2.bat program has been executed after the database install and after any upgrade to the database product.
- On DB2 version 8.1 or later, use the DB2 Universal JDBC Provider Driver when defining a JDBC provider in WebSphere Application Server. The driver file is db2jcc.jar. If you use the type 2 (default) option, verify that at least the DB2 client product is installed on the WebSphere Application Server host. If you specify the type 4 option, the DB2 client does not need to be installed, but the file db2jcc.jar still must be present.

When specifying the location of the driver file, it is recommended that you specify the path and file name of the target DB2 installation, rather than simply copying the file to a local directory, if possible. Otherwise, you may be exposed to problems if the target DB2 installation is upgraded and the driver used by WebSphere Application Server is not.

- On operating systems such as AIX or Linux, ensure that any native libraries required to support the database client of your database product are specified in the LD_LIBRARY_PATH environment variable in the profile of the account under which WebSphere Application Server executes.

If you are using DB2 The native library is libdb2jdbc.so. The best way to ensure that this library is accessed correctly by WebSphere is to call the db2profile script supplied with DB2 from the .profile script of the account (such as "root") under which WebSphere runs.

- If you are using DB2 version 7.2 or earlier, ensure that the usejdbc2.script provided with DB2 is called from the profile of the account under which WebSphere Application server is launched.
- If you are using DB2 version 8.1 or later, see the previous instructions for the Windows operating system.

- If the database manager is DB2, you may have chosen the option to create a 64-bit instance. Sometimes a 64-bit configuration is not supported. If this has happened, remove the database instance and create a new one with the default 32-bit setting.

If you are using the Universal JDBC T2 driver, WebSphere Application Server does support interaction with a DB2 UDB 64-bit server, but it must be through a DB2 UDB 32-bit client. The WebSphere Application Server environment (CLASSPATH and so on) must use the 32-bit client code to ensure correct function.

With a Universal JDBC T4 driver, you do not need the 32-bit DB2 client. You need only configure the CLASSPATH to include db2jcc.jar and its license files in the WebSphere Application Server environment.

Note: For general help in configuring JDBC drivers and data sources in WebSphere Application Server, see the topic Accessing data from applications.

"J2CA0114W: No container-managed authentication alias found for connection factory or datasource *datasource*" when attempting a database operation

This error might occur in the SystemOut.log file when you run an application to access a data source after creating the data source using JACL script.

The error message occurs because the JACL script did not set container-managed authentication alias for CMP connection factory. The JACL is missing the following line:

```
$AdminConfig create MappingModule $cmpConnectorFactory "{mappingConfigAlias
DefaultPrincipalMapping} {authDataAlias $authDataAlias}
```

To correct this problem, add the missing line to the JACL script and run the script again. See "Example: Creating a JDBC provider and data source using Java Management Extensions API and the scripting tool" on page 1572 for a sample JACL script.

An error is thrown if you use the `ws_ant` command to perform the database customization for Structured Query Language in Java on HP platforms

If you use the `ws_ant` command to perform the database customization for Structured Query Language in Java (SQLJ) on HP platforms, you can receive an error similar to the following:

```
[java] [ibm][db2][jcc][sqlj]
[java] [ibm][db2][jcc][sqlj] Begin Customization
[java] [ibm][db2][jcc][sqlj] encoding not supported!!
```

The cause of this error might be that your databases were created using the HP default character set. The Java Common Client (JCC) driver depends on the software development kit (SDK) to perform the codepage conversions. The SDK shipped with this product, however, does not support the HP default codepage.

You need to set your `LANG` to the ISO locale before creating the databases. It should be similar to the following:

```
export LANG=en_US.iso88591
```

Refer to the IBM support site for Information Management software to access the latest technotes for DB2.

Container-managed persistence (CMP) cannot successfully obtain the database access function as defined.

When WebSphere Application Server is caching certain generated code that is accessed in the database on the connection factory, and if any changes in the Java archive (JAR) file require regeneration of the database access, the changes are not effective until you stop and restart the server.

Examples of when this failure might occur include:

- Adding an enterprise bean custom finder method; a `NullPointerException` exception is created.
- Updating an enterprise bean custom finder method; the new SQL statement does not run.
- Changing schema mapping; the new SQL statement does not run.

In summary, if you add or update an enterprise bean that contains a custom finder method, you must stop and then restart the server.

Data access problems - Oracle data source

This article provides troubleshooting tips for accessing Oracle data sources.

What kind of error do you see when you try to access your Oracle-based data source?

- "An invalid Oracle URL is specified" on page 1648
- "'DSRA0080E: An exception was received by the data store adapter. See original exception message: ORA-00600' when connecting to or using an Oracle data source" on page 1648
- "'DSRA8100E: Unable to get a {0} from the DataSource. Explanation: See the linkedException for more information.'" on page 1648
- "'Error while trying to retrieve text for error' error when connecting to an Oracle data source" on page 1648
- "'java.lang.UnsatisfiedLinkError:' connecting to an Oracle data source" on page 1649
- "'java.lang.NullPointerException referencing 8i classes, or ' internal error: oracle.jdbc.oci8. OCIEnv'" connecting to an Oracle data source" on page 1649
- "'WSVR0016W: Classpath entry for the Oracle JDBC Thin Driver has an invalid variable" on page 1650
- "'Transaction recovery failure (for XA data sources)" on page 1650

An invalid Oracle URL is specified

This error might be caused by an incorrectly specified URL on the URL property of the target data source.

Examine the URL property for the data source object in the administrative console. For the 8i OCI driver, verify that **oci8** is used in the URL. For the 9i OCI driver, you can use either **oci8** or **oci**.

Examples of Oracle URLs:

- For the thin driver: jdbc:oracle:thin:@hostname.rchland.ibm.com:1521:IBM
- For the thick (OCI) driver: jdbc:oracle:oci8:@tnsname1

"DSRA0080E: An exception was received by the data store adapter. See original exception message: ORA-00600" when connecting to or using an Oracle data source

A possible reason for this exception is that the version of the Oracle JDBC driver being used is older than the Oracle database. It is possible that more than one version of the Oracle JDBC driver is configured on the WebSphere Application Server.

Examine the version of the JDBC driver. Sometimes you can determine the version by looking at the class path to determine what directory the driver is in.

If you cannot determine the version this way, use the following program to determine the version. Before running the program, set the class path to the location of your JDBC driver files.

```
import java.sql.*;
import oracle.jdbc.driver.*;
class JDBCVersion
{
    public static void main (String args[])
    throws SQLException
    {
        // Load the Oracle JDBC driver
        DriverManager.registerDriver(new oracle.jdbc.driver.OracleDriver());
        // Get a connection to a database
        Connection conn = DriverManager.getConnection
        ("jdbc:oracle:thin:@appaloosa:1521:app1","sys","change_on_install");
        // Create Oracle DatabaseMetaData object
        DatabaseMetaData meta = conn.getMetaData();
        // gets driver info:
        System.out.println("JDBC driver version is " + meta.getDriverVersion());
    }
}
```

If the driver and the database are at different versions, replace the JDBC driver with the correct version. If multiple drivers are configured, remove any that occur at the incorrect level.

DSRA8100E: Unable to get a {0} from the DataSource. Explanation: See the linkedException for more information.

When using an oracle thin driver, Oracle creates a "java.sql.SQLException: invalid arguments in call" error if no user name or password is specified when getting a connection. If you see this error while running WebSphere Application Server, the alias is not set.

To remove the exception, define the alias on the data source.

"Error while trying to retrieve text for error" error when connecting to an Oracle data source

The most likely cause of this error is that the Oracle 8i OCI driver is being used with an ORACLE_HOME property that is either not set or is set incorrectly.

To correct the error, examine the user profile that WebSphere Application Server is running under to verify that the \$ORACLE_HOME environment variable is set correctly.

"**java.lang.UnsatisfiedLinkError:**" connecting to an Oracle data source

The environment variable LIBPATH might not be set or is set incorrectly, if your data source creates an **UnsatisfiedLinkError** error, and the full exception indicates that the problem is related to an Oracle module, as in the following examples.

Example of invalid an LIBPATH for the 8i driver:

```
Exception in thread "main" java.lang.UnsatisfiedLinkError:
/usr/WebSphere/AppServer/java/jre/bin/libocijdbc8.so:
load ENOENT on shared library(s)
/usr/WebSphere/AppServer/java/jre/bin/libocijdbc8.so libclntsh.a
```

Example of an invalid LIBPATH for the 9i driver:

```
Exception in thread "main" java.lang.UnsatisfiedLinkError:
no ocijdbc9 (libocijdbc9.a or .so) in java.library.path
at java.lang.ClassLoader.loadLibrary(ClassLoader.java:Compiled Code))
at java.lang.Runtime.loadLibrary0(Runtime.java:780)
```

To correct the problem:

1. Examine the user profile under which the WebSphere Application Server is running to verify that the LIBPATH environment variable includes Oracle libraries. Scan for the libocijdbc8.so file to find the right directory.
2. Configure the java LIBPATH (java.library.path) property with the *domain_region_libpath* environment variable, like *control_region_libpath*, *server_region_libpath*, *adjunct_region_libpath*. See the topic on changing the values of variables referenced in BBOM00011 messages for instructions on how to set the region libpath variables.

java.lang.NullPointerException referencing 8i classes, or " internal error: oracle.jdbc.oci8.OCIEnv" connecting to an Oracle data source

The problem might be that the 9i OCI driver is being used on an AIX 32-bit machine, the LIBPATH is set correctly, but the ORACLE_HOME environment variable is not set or is set incorrectly. You can encounter an exception similar to either of the following when your application attempts to connect to an Oracle data source:

Exception example for the java.lang.NullPointerException:

```
Exception in thread "main" java.lang.NullPointerException
at oracle.jdbc.oci8.OCIDBAccess.check_error(OCIDBAccess.java:1743)
at oracle.jdbc.oci8.OCIEnv.getEnvHandle(OCIEnv.java:69)
at oracle.jdbc.oci8.OCIDBAccess.logon(OCIDBAccess.java:452)
at oracle.jdbc.driver.OracleConnection.<init>(OracleConnection.java:287)
```

Exception example for the java.sql.SQLException:

```
Exception in thread "main" java.sql.SQLException:
internal error: oracle.jdbc.oci8. OCIEnv@568b1d21
at oracle.jdbc.dbaccess.DBError.throwSQLException(DBError.java:184)
at oracle.jdbc.dbaccess.DBError.throwSQLException(DBError.java:226)
at oracle.jdbc.oci8.OCIEnv.getEnvHandle(OCIEnv.java:79)
```

To correct the problem, examine the user profile that WebSphere Application Server is running under to verify that it has the \$ORACLE_HOME environment variable set correctly, and that the \$LIBPATH includes \$ORACLE_HOME/lib.

WSVR0016W: Classpath entry for the Oracle JDBC Thin Driver has an invalid variable

This error occurs when there is no environment variable defined for the property, ORACLE_JDBC_DRIVER_PATH.

Verify this problem in the administrative console. Go to **Environment > Manage WebSphere Variables** to verify whether the variable ORACLE_JDBC_DRIVER_PATH is defined.

To correct the problem, click **New** and define the variable. For example, name : **ORACLE_JDBC_DRIVER_PATH** , value : **c:\oracle\jdbc\lib**. Use a value that names the directory in your operating system that contains the ojdbc6.jar file (or the ojdbc14_g.jar file to enable Oracle trace).

Transaction recovery failure (for XA data sources)

Problem

When WebSphere Application Server attempts to recover Oracle database transactions, the transaction service issues the following exception:

```
WTRN0037W: The transaction service encountered an error on an xa_recover operation.
The resource was com.ibm.ws.rsadapter.spi.WSRdbXaResourceImpl@1114a62.
The error code was XAER_RMERR. The exception stack trace follows:
javax.transaction.xa.XAException
at oracle.jdbc.xa.OracleXAResource.recover(OracleXAResource.java:726)
at com.ibm.ws.rsadapter.spi.WSRdbXaResourceImpl.recover(WSRdbXaResourceImpl.java:954)
at com.ibm.ws.Transaction.JTA.XARminst.recover(XARminst.java:137)
at com.ibm.ws.Transaction.JTA.XARecoveryData.recover(XARecoveryData.java:609)
at com.ibm.ws.Transaction.JTA.PartnerLogTable.recover(PartnerLogTable.java:511)
at com.ibm.ws.Transaction.JTA.RecoveryManager.resync(RecoveryManager.java:1784)
at com.ibm.ws.Transaction.JTA.RecoveryManager.run(RecoveryManager.java:2241)
```

Cause

Oracle requires services such as the WebSphere Application Server transaction service to have special permissions for performing transaction recoveries.

Solution

As user **SYS**, run the following commands on your Oracle server:

```
grant select on pending_trans$ to public;
grant select on dba_2pc_pending to public;
grant select on dba_pending_transactions to public;
grant execute on dbms_system to <user>;
```

User is a user ID in the application server that is authorized to perform transaction recovery for the XA data source. If you have not authorized any user IDs to perform transaction recovery, the application server will use the login alias for the data source as the user ID.

This problem is mentioned under Oracle bug: 3979190. Running the preceding commands solves the problem.

Data access problems - DB2 database

This article provides troubleshooting tips for accessing DB2 databases.

What kind of problem are you having accessing your DB2 database?

- “SQL0567N “DB2ADMIN ” is not a valid authorization ID. SQLSTATE=42602” on page 1651
- “SQL0805N Package package-name was not found” on page 1651
- “SQL0805N Package “NULLID.SQLLC300” was not found. SQLSTATE=51002” on page 1652

- “SQL30082N Attempt to establish connection failed with security reason "17" ("UNSUPPORTED FUNCTION") SQLSTATE=08001” on page 1652
- “SQLException, with ErrorCode -99,999 and SQLState 58004, with Java “StateConnectionException: COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver] CLI0119E Unexpected system failure. SQLSTATE=58004”, when using WAS40-type data source” on page 1652
- “Error message java.lang.reflect.InvocationTargetException: com.ibm.ws.exception.WsException: DSRA0023E: The DataSource implementation class “COM.ibm.db2.jdbc.DB2XADataSource” could not be found. when trying to access a DB2 database” on page 1653
- “CLI0119E System error. SQLSTATE=58004 - DSRA8100 : Unable to get a XAconnection or DSRA0011E: Exception: COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver] CLI0119E Unexpected system failure. SQLSTATE=5800” on page 1653
- “COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver][DB2/NT] SQL0911N The current transaction has been rolled back because of a deadlock or timeout. Reason code "2". SQLSTATE=40001” on page 1653
- ““COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource” could not be found for data source ([data-source-name])” on page 1654
- “Error 10500 (E_Fatal) returns when an attempt is made to either publish or inquire on an entity exceeding 255 characters in one of its fields.” on page 1655
- “ java.sql.SQLException: Failure in loading T2 native library db2jcct2 DSRA0010E: SQL State = null, Error Code = -99,999 ” on page 1655
- Lock contention exception occurs in database when data source implementation type is XA
- “DSRA8050W: Unable to find the DataStoreHelper class specified” exception occurs when trying to use a DB2 Universal Datasource in a mixed release cell.” on page 1656
- “Receive “SYSTEM’ is not a valid authorization ID” message when trying to access DB2 on a Windows machine where WebSphere Application Server is also installed.” on page 1656
- “XAException: XAER_NOTA on XA prepare call in DB2 Universal JDBC Driver type 4 after one phase transaction rollback” on page 1657
- “java.rmi.MarshalException logged for application client due to incompatibility of JDBC driver file versions” on page 1657
- “Database failure triggers problematic -99999 exception for applications that use DB2 Universal Driver type 4” on page 1658
- “Cannot access DB2 on Linux when using the DB2 Universal JDBC Driver” on page 1658
- “Data access problems - DB2 database” on page 1650
- “Illegal conversion occurs on any VARCHAR FOR BIT DATA column in a container-managed persistent bean” on page 1659

SQL0567N “DB2ADMIN ” is not a valid authorization ID. SQLSTATE=42602

If you encounter this error when attempting to access a DB2 Universal Database (UDB):

1. Verify that your user name and password in the data source properties page in the administrative console are correct.
2. Ensure that the user ID and password do not contain blank characters before, in between, or after.

SQL0805N Package *package-name* was not found

Possible reasons for these exceptions:

- If the package name is NULLID.SQLLC300, see SQL0805N Package “NULLID.SQLLC300” was not found. SQLSTATE=51002. for the reason.
- You are attempting to use an XA-enabled JDBC driver on a DB2 database that is not XA-ready.

To correct the problem on a DB2 Universal Database (UDB), run this one-time procedure, using the db2cmd interface while connected to the database in question:

1. **DB2 bind @db2ubind.lst blocking all grant public**
2. **DB2 bind @db2cli.lst blocking all grant public**

The db2ubind.lst and db2cli.lst files are in the bnd directory of your DB2 installation root. Run the commands from that directory.

SQL0805N Package "NULLID.SQLLLC300" was not found. SQLSTATE=51002

This error can occur because:

- The underlying database was dropped and recreated.
- DB2 was upgraded and its packages are not rebound correctly.

To resolve this problem, rebind the DB2 packages by running the db2cli.lst script found in the bnd directory. For example: db2>@db2cli.lst.

SQL30082N Attempt to establish connection failed with security reason "17" ("UNSUPPORTED FUNCTION") SQLSTATE=08001

This error can occur when the security mechanism specified by the client is not valid for this server. Some typical examples:

- The client sent a new password value to a server that does not support the change password function.
- The client sent SERVER_ENCRYPT authentication information to a server that does not support password encryption.
- The client sent a userid, but no password, to a server that does not support authentication by userid only.
- The client has not specified an authentication type, and the server has not responded with a supported type. This can include the server returning multiple types from which the client is unable to choose.

To resolve this problem, ensure that your client and server use the same security mechanism. For example, if this is an error on your data source, verify that you have assigned a user id and password or authentication alias.

SQLException, with ErrorCode -99,999 and SQLState 58004, with Java "StaleConnectionException: COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver] CLI0119E Unexpected system failure. SQLSTATE=58004", when using WAS40-type data source

An unexpected system failure usually occurs when running in XA mode (two-phase commit). Among the many possible causes are:

- An invalid username or password was provided.
- The database name is incorrect.
- Some DB2 packages are corrupted.

To determine whether you have a user name or password problem, look in the db2diag.log file to view the actual error message and SQL code. A message like the following example, with an SQLCODE of -1403, indicates an invalid user ID or password:

```
2002-07-26-14.19.32.762905 Instance:db2inst1 Node:000
PID:9086(java) Appid:*LOCAL.db2inst1.020726191932
XA DTP Support sqlxa_open Probe:101
DIA4701E Database "POLICY2" could not be opened
for distributed transaction processing.
String Title: XA Interface SQLCA PID:9086 Node:000
SQLCODE = -1403
```

To resolve these problems:

1. Correct your user name and password. If you specify your password on the GUI for the data source, ensure that the user name and password you specify on the bean are correct. The user name and password you specify on the bean overwrite whatever you specify when creating the data source.
2. Use the correct database name.
3. Rebind the packages (in the bnd directory) as follows:

```
db2connect to dbname
c:\SQLLIB\bnd>DB2 bind @db2ubind.lst blocking all grant public
c:\SQLLIB\bnd>DB2 bind @db2cli.lst blocking all grant public
```

4. Ensure that the `\WebSphere\AppServer\properties\wsj2cdpm.properties` file has the right user ID and password.

**Error message `java.lang.reflect.InvocationTargetException`:
`com.ibm.ws.exception.WsException: DSRA0023E: The DataSource implementation class
"COM.ibm.db2.jdbc.DB2XADataSource" could not be found. when trying to access a DB2
database`**

One possible reason for this exception is that a user is attempting to use a JDBC 2.0 DataSource, but DB2 is not JDBC 2.0-enabled. This situation frequently happens with new installations of DB2 because DB2 provides separate drivers for JDBC 1.X and 2.0, with the same physical file name. By default, the JDBC 1.X driver is on the class path.

To confirm this problem:

- On Windows systems, look for the `inuse` file in the `java12` directory in your DB2 installation root. If the file missing, you are using the JDBC 1.x driver.
- On operating systems such as AIX or Linux, check the class path for your data source. If the class path does not point to the `db2java.zip` file in the `java12` directory, you are using the JDBC 1.x driver.

To correct this problem:

- On Windows systems, stop DB2. Run the `usejdbc2.bat` file from the `java12` directory in your DB2 installation root. Run this file from a command line to verify that it completes successfully.
- On operating systems such as AIX or Linux, change the class path for your data source to point to the `db2java.zip` file in the `java12` directory of your DB2 installation root.

**CLI0119E System error. SQLSTATE=58004 - DSRA8100 : Unable to get a XAconnection or
DSRA0011E: Exception: COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver] CLI0119E
Unexpected system failure. SQLSTATE=5800**

If you encounter this error when attempting to access a DB2 Universal Database (UDB) data source:

1. On the data source properties page in the administrative console, verify that the correct database name is specified on the data source.
2. On the custom properties page, check your user name and password custom properties. Verify that they are correct.
3. Ensure the user ID and password do not contain any blank characters, before, in between, or after.
4. Check that the `WAS.policy` file exists for the application, for example, `D:\WebSphere\AppServer\installedApps\markSection.ear\META-INF\was.policy`.
5. View the entire exception listing for an underlying SQL error, and look it up using the DBM vendor message reference.

If you encounter this error while running DB2 on Red Hat Linux, the **max queues system wide** parameter is too low to support DB2 while it acquires the necessary resources to complete the transaction. When this problem exists, the exceptions `J2CA0046E` and `DSRA0010E` can precede the exception `DSRA8100E`.

To correct this problem, edit the `/proc/sys/kernal/msgmni` file to increase the value of the **max queues system wide** parameter to a value greater than 128.

**COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver][DB2/NT] SQL0911N The current
transaction has been rolled back because of a deadlock or timeout. Reason code "2".
SQLSTATE=40001**

This problem is probably an application-caused DB2 deadlock, particularly if you see an error similar to the following when accessing a DB2 data source:

ERROR CODE: -911
COM.ibm.db2.jdbc.DB2Exception: [IBM][CLI Driver][DB2/NT] SQL0911N
The current transaction has been rolled back because of a deadlock or timeout.
Reason code "2". SQLSTATE=40001

To diagnose the problem:

1. Execute these DB2 commands:
 - a. db2 update monitor switches using LOCK ON
 - b. db2 get snapshot for LOCKS on dbName >

The *directory_name\lock_snapshot.log* now has the DB2 lock information.

2. Turn off the lock monitor by running: db2 update monitor switches using LOCK OFF

To verify that you have a deadlock:

1. Look for an application handle that has a lock-wait status, and then look for the ID of the agent holding lock to verify the ID of the agent.
2. Go to that handle to verify it has a lock-wait status, and the ID of the agent holding the lock for it. If it is the same agent ID as the previous one, then you know that you have a circular lock (deadlock).

To resolve the problem:

1. Examine your application and use a less restrictive isolation level if no concurrency access is needed.
2. Use caution when changing the **accessIntent** value to move to a lower isolation level. This change can result in data integrity problems.
3. For DB2/UDB Version 7.2 and earlier releases, you can set the DB2_RR_TO_RS flag from the DB2 command line window to eliminate unnecessary deadlocks, such as when the accessIntent defined on the bean method is too restrictive, for example, PessimisticUpdate. The DB@_RR_TO_RS setting has two impacts:
 - If RR is your chosen isolation level, it is effectively downgraded to RS.
 - If you choose another isolation level, and the DB2_RR_TO_RS setting is on, a scan skips over rows that are deleted but not committed, even though the row might qualify for the scan. The skipping behavior affects the RR, Read Stability (RS), and Cursor Stability (CS) isolation levels.

For example, consider the scenario where transaction A deletes the row with column1=10 and transaction B does a scan where column1>8 and column1<12. With DB2_RR_TO_RS off, transaction B waits for transaction A to commit or rollback. If transaction A rolls back, the row with column1=10 is included in the result set of the transaction B query. With DB2_RR_TO_RS on, transaction B does not wait for transaction A to commit or rollback. Transaction B immediately receives query results that do not include the deleted row. Setting DB2_RR_TO_RS effectively changes locking behavior, thus avoiding deadlocks.

"COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource" could not be found for data source ([data-source-name])"

This error is denoted by message DSRA8040I: Failed to connect to the DataSource.

This error usually occurs when the class path of the DB2 JDBC driver is set correctly to `${DB2_JDBC_DRIVER_PATH}/db2java.zip` but the environment variable `DB2_JDBC_DRIVER_PATH` is not set.

This error can also occur if you are using DB2 Version 7.1 or 7.2 and you have not yet run *usejdbc2*. This might be the problem if your path is correct but you still receive this error.

To confirm this problem:

1. Go to the **Manage WebSphere Variables** panel.
2. Select **Environment** to verify that there is no entry for the variable `DB2_JDBC_DRIVER_PATH`.

To correct this problem: Add the variable DB2_JDBC_DRIVER_PATH with **value** equal to the directory path containing the db2java.zip file.

Error 10500 (E_Fatal) returns when an attempt is made to either publish or inquire on an entity exceeding 255 characters in one of its fields.

This error usually occurs when you make an attempt to either publish or inquire on an entity exceeding 255 characters in one of its fields. This is less obvious when using non-English characters, as the real limit is reached before 255 visual characters are displayed.

To correct this problem: Accept this as a limitation in using DB2 Version 7 on z/OS. Do not exceed the 255 character limit.

java.sql.SQLException: Failure in loading T2 native library db2jct2 DSRA0010E: SQL State = null, Error Code = -99,999

The *Failure in loading* message indicates one of two things:

- Usually this happens when the machine was not rebooted after installing DB2. Reboot the machine getting the error and try it again.
- The DB2 context is not getting set up correctly for the user running WebSphere Application Server. Source the db2profile file on the machine, and ensure that the environment contains pointers to the DB2 native libraries.

Lock contention exception occurs in database when data source implementation type is XA

Note: Because a lock contention exception can be caused by many factors, consider the following explanation and recommended response as a strategy for eliminating the possible reasons for your lock contention problem.

| | |
|--------------------|---|
| Symptom | A lock contention exception occurs in a DB2 database that your application accesses through a data source of implementation type XA. |
| Problem | Your application is trying to access database records that are locked by an XA transaction that is in ended (e) state, but cannot be prepared by the transaction manager. |
| Description | An XA transaction to DB2 that ends, but cannot be prepared, is in ended (e) state. Because it is <i>not</i> considered to be <i>in doubt</i> , the transaction manager cannot recover this transaction. DB2 does not return it in the list of in doubt transactions.

DB2 also does not roll the transaction back immediately; it waits until all connections to the database are released. During this period of inaction, the transaction continues to hold locks on the database. If your application server does not disconnect all connections from the database to allow rollback, the ended transaction persists in locking the same database records. If your application attempts to access these locked records, a lock contention exception occurs in DB2. |

Recommended response

DB2 Version 8.2 is shipped with a sample application that connects to a defined DB2 server and uses the available DB2 APIs to obtain a list of these particular ended transactions. The application offers a configuration setting that enables you to designate an amount of time after which the application rolls these transactions back. Locate the sample application in the `sql1lib/samples/db2xamon.c` directory of DB2 Version 8.2 and run it.

"DSRA8050W: Unable to find the DataStoreHelper class specified" exception occurs when trying to use a DB2 Universal Datasource in a mixed release cell.

This error usually occurs when you are using WebSphere Application Server Version 6.0 or above in conjunction with a previous version and attempt to create a DB2 Universal Datasource on the previous version.

This can happen because the DB2 Universal Datasource was not available on Version 5 and previous versions, but the Version 6 administrative console allows you to build one.

To correct this problem: create the datasource on Version 6.0 or later.

Receive "'SYSTEM' is not a valid authorization ID" message when trying to access DB2 on a Windows machine where WebSphere Application Server is also installed.

| | |
|-------------|--|
| Symptom | <p>For a WebSphere Application Server on Windows installation that uses DB2 as the backend, you see the following exception in the JVM log:</p> <pre>java.sql.SQLException: [IBM][CLI Driver] SQL0567N "SYSTEM" is not a valid authorization ID. SQLSTATE=42602 DSRA0010E: SQL State = 42602, Error Code = -567 at COM.ibm.db2.jdbc.app.SQLExceptionGenerator.throw_SQLException (Unknown Source) at COM.ibm.db2.jdbc.app.SQLExceptionGenerator.check_return_code (Unknown Source) at COM.ibm.db2.jdbc.app.DB2Connection.connect(Unknown Source) at COM.ibm.db2.jdbc.app.DB2Connection.<init>(Unknown Source) at COM.ibm.db2.jdbc.app.DB2ReusableConnection.<init>(Unknown Source) at COM.ibm.db2.jdbc.DB2PooledConnection.getConnection(Unknown Source) at com.ibm.ws.rsadapter.spi.WSRdbDataSource.getConnection (WSRdbDataSource.java:1035) at com.ibm.ws.rsadapter.spi.WSManagedConnectionFactoryImpl createManagedConnection(WSManagedConnectionFactoryImpl.java:937) at com.ibm.ejs.j2c.poolmanager.FreePool createManagedConnectionWithMCWrapper(FreePool.java:1502)</pre> |
| Problem | <p>This exception occurs for configurations in which WebSphere Application Server is a client to the DB2 server. The underlying problem is an authorization conflict between WebSphere Application Server on Windows and DB2 that arises when an application attempts to connect to DB2 without providing a user ID and a password.</p> |
| Description | <p>When a DB2 client and the DB2 database run on the same machine, DB2 allows the client to connect without a user ID and password. The connection is made under the credentials of the user that owns the client process: in this case, the application server JVM. However, if WebSphere Application Server runs as a Windows service, and the "Log on as" option is set to "Local System Account", the application server JVM is categorized as a subcomponent of a special Windows user called SYSTEM. This user is not allowed to connect to DB2, resulting in the previously shown exception.</p> |

| | |
|----------------------|---|
| Recommended response | <p>You have two options:</p> <ul style="list-style-type: none"> • Modify the WebSphere Application Server service to use a Log on as option of This account, and provide an account with permission to connect to DB2. Or • Configure your application server to provide credentials on the DB2 connection by using container-managed or component-managed authentication. |
|----------------------|---|

XAException: XAER_NOTA on XA prepare call in DB2 Universal JDBC Driver type 4 after one phase transaction rollback

Symptom

For applications that use the DB2 Universal JDBC Driver type 4 XA available with DB2 v8.2, a connection might fail and trigger an XAER_NOTA XAException error. The following code block is an example of this exception:

```
J2CA0027E: An exception occurred while invoking prepare
on an XA Resource Adapter from dataSource jdbc/SDOSVT,
within transaction ID {XidImpl: formatId(57415344),
grid_length(36), bqual_length(54),
data(000000ff5191398200000001000000296cac5c42fe3c6838631cbaafc8b5a9253b846544
000000ff5191398200000001000000296cac5c42fe3c6838631cbaafc8b5a9253b84654400000000
1000000000000000000000000000002)}:
javax.transaction.xa.XAException: XAER_NOTA
at com.ibm.db2.jcc.a.xb.a(xb.java:1682)
at com.ibm.db2.jcc.a.xb.a(xb.java:841)
at com.ibm.db2.jcc.a.xb.prepare(xb.java:812)
at com.ibm.ws.rsadapter.spi.WSRdbXAResourceImpl.prepare
(WSRdbXAResourceImpl.java:837)
...
```

Problem

If a DB2 Universal JDBC Driver type 4 XA connection is used in a single-phase transaction, such as a local transaction with autocommit set to false, and that single-phase transaction is rolled back, the next use of the connection in a two-phase transaction fails on the prepare call.

A problem in the DB2 Universal JDBC Driver type 4 XA support causes the XA prepare call to fail. This problem does not occur if the single-phase transaction is committed, and it does not occur when using the DB2 Universal JDBC Driver in type 2 mode.

Solution

Upgrade to DB2 Version 8.2 Fix Pack 1, which is equivalent to Version 8.1 Fix Pack 8. The Universal JDBC Driver XA that is available with these releases solves the previously described issue for type 4 mode.

java.rmi.MarshalException logged for application client due to incompatibility of JDBC driver file versions

Symptom

For an application that includes a application client, the following error message is displayed in the client log file of the application server:

```
java.rmi.MarshalException: CORBA MARSHAL
0x4942f89a No; nested exception is:
org.omg.CORBA.MARSHAL: Unable to read value from
underlying bridge : Mismatched serialization
UIDs : Source (Rep.
```

```
IDRMI:com.ibm.db2.jcc.c.SqlException:63EEE52211DCD763:82CE0C0DA2B0A000)
= 82CE0C0DA2B0A000 whereas Target (Rep. ID
RMI:com.ibm.db2.jcc.c.SqlException:63EEE52211DCD763:91C6171BC645E41B)
= 91C6171BC645E41B vmcid: 0x4942f000 minor code:
2202 completed: No
```

Problem

The db2jcc.jar files on the application client machine and on your application server are from versions of DB2 that are not compatible with each other, or are not compatible with the version of DB2 that functions as the datastore.

Solution

Check the db2jcc.jar files on the application client machine, your application server, and your DB2 server. On the client machine and the application server, install files of the same version that is compatible with the DB2 server.

Database failure triggers problematic -99999 exception for applications that use DB2 Universal Driver type 4

Symptom

If you use the DB2 Universal Driver type 4 for access to DB2 or Cloudscape Network Server, and your database fails, the database server issues a generic -99999 exception in response to every JDBC getConnection request. This exception, which is exemplified in the following code excerpt, can cause unexpected behavior in your applications.

```
java.sql.SQLException: IO Exception opening socket to
server bs8.rchland.ibm.com on port 1527.
The DB2 Server may be down.DSRA0010E: SQL State = null,
Error Code = -99,999DSRA0010E: SQL State = null,
Error Code = -99,999
at com.ibm.db2.jcc.b.a.<init>(a.java:125)
at com.ibm.db2.jcc.b.b.a(b.java:1011)
at com.ibm.db2.jcc.c.l.<init>(l.java:197)
at com.ibm.db2.jcc.b.b.<init>(b.java:258)
at com.ibm.db2.jcc.DB2PooledConnection.
<init>(DB2PooledConnection.java:44)
at com.ibm.db2.jcc.DB2ConnectionPoolDataSource.getPooledConnectionX
(DB2ConnectionPoolDataSource.java:80)
at com.ibm.db2.jcc.DB2ConnectionPoolDataSource.getPooledConnection
(DB2ConnectionPoolDataSource.java:45)
at com.ibm.ws.rsadapter.DSConfigurationHelper$1.run
(DSConfigurationHelper.java:945)
```

Problem

When running in type 4 mode, some versions of the DB2 Universal Driver trigger a generic exception for database failure rather than a specific error code that WebSphere Application Server can map to a stale connection exception. This problem occurs with versions of the driver that are associated with DB2 8.1 Fix Pack 6 or Fix Pack 7, and DB2 8.2.

Solution

Upgrade to DB2 Version 8.2 Fix Pack 1, equivalent to Version 8.1 Fix Pack 8, which provides a valid error code in the previously described scenario. WebSphere Application Server maps this error code to a StaleConnectionException, as expected.

Cannot access DB2 on Linux when using the DB2 Universal JDBC Driver

Symptom

In the WebSphere Application Server on Linux environment, applications that use the DB2 Universal JDBC Driver to access DB2 on Linux might not connect with the database. The database server can issue the following exceptions to the application server error log:

- `java.security.AccessControlException: Access denied (java.lang.RuntimePermission accessClassInPackage.sun.io)`
- *If you run 64-bit Linux:*
`com.ibm.db2.jcc.b.SqlException: Failure in loading T2 native library db2jcc2`

Problem

The process for configuring DB2 on Linux to work with the Universal JDBC Driver is not complete.

Solution

- Verify that the setup requirements for the Java™ SDK 1.4.2 for the Linux platform are complete.
- Configure your development environment for building Java applications on Linux with DB2 JDBC support. See the application development topics for DB2 for more information.
- If you run DB2 on the Linux/IA64 platform and are using DB2 v8.1 Fix Pack 7A, perform the additional step that is described in the technote on DB2 UDB Version 8 FixPak 7a for Linux on IA64 reporting a missing `libdb.so.3` library. This step is necessary only for Fix Pack 7A. This step is not necessary for DB2 v8.1 Fix Pack 7 or earlier versions of DB2; this step is not necessary for DB2 v8.1 Fix Pack 8 or later versions of DB2.

Illegal conversion occurs on any VARCHAR FOR BIT DATA column in a container-managed persistent bean

When enterprise beans with container-managed persistent (CMP) types that have any VARCHAR FOR BIT DATA columns defined on a DB2 table are deployed in the DB2 universal JDBC type 4 driver to persist the data, an `SQLException` of illegal conversion is thrown at run time. This exception only occurs when you use the DB2 universal JDBC type 4 driver and with the `deferPrepares` property being set to `true`. When the `deferPrepares` property is set to `true`, the DB2 universal JDBC type 4 driver uses the standard JDBC data mapping.

Currently, the generated deployed code does not follow the standard JDBC specification mapping. The failure at execution time is because of a problem in the tool that prepared the enterprise beans for execution.

To avoid receiving this exception, choose one of the following options:

- Set the `deferPrepares` property to `false` in the data source configuration.
- Do not use the DB2 universal JDBC type 4 driver if your table has any VARCHAR FOR BIT DATA or LONG VARCHAR FOR BIT DATA columns. Refer to DB2 V8.1 readme for more details.

Data access problems - Microsoft SQL Server data source

This article provides troubleshooting tips for accessing Microsoft SQL Server data sources.

What kind of problem are you having accessing your Microsoft SQL Server database?

- “ERROR CODE: 20001 and SQL STATE: HY000 accessing SQLServer database” on page 1660
- “Application fails with message stating “Cannot find stored procedure...” accessing a Microsoft SQL Server database” on page 1660
- “ERROR CODE: SQL5042 when you run a Java application” on page 1660

ERROR CODE: 20001 and SQL STATE: HY000 accessing SQLServer database

The problem might be that the distributed transaction coordinator service is not started. Look for an error similar to the following example when attempting to access a Microsoft SQL Server database:

```
ERROR CODE: 20001
SQL STATE: HY000
java.sql.SQLException: [Microsoft][SQLServer JDBC Driver]
[SQLServer]xa_open (0) returns -3
at com.microsoft.jdbc.base.BaseExceptions.createException(Unknown Source) ...
at com.microsoft.jdbcx.sqlserver.SQLServerDataSource.getXAConnection
(Unknown Source) ...
```

To confirm this problem:

1. Go to the Windows **Control Panel** and click **Services**(or click **Control Panel > Administrative Tools > Services**)
2. Verify whether the service **Distributed Transaction Coordinator** or **DTC** is started.
3. If not, start the Distributed Transaction Coordinator service.

Application fails with message stating "Cannot find stored procedure..." accessing a Microsoft SQL Server database

This error can occur because the stored procedures for the Java Transaction API (JTA) feature are not installed on the Microsoft SQL Server.

To resolve the problem, repeat the installation for the stored procedures for the JTA feature, according to the DataDirect Connect for JDBC driver installation guide.

ERROR CODE: SQL5042 when you run a Java application

This error can occur when you configure your application to run in the following manner:

1. You use a type 2 (application) driver running on the gateway to the OS 390
2. Your application is an XA application.

OS 390 does not use XA, but uses SPM. To resolve the problem:

1. Check your dbm cfg to see that the SPM is not started on the gateway.
2. Assign a port and set the *db2comm* variable to **TCPIP**.
3. Update the dbm cfg value *SPM_NAME* to use your machine name.
4. Start the SPM on the gateway.

Data access problems - Apache Derby database

This article provides troubleshooting tips for accessing Apache Derby databases.

What kind of problem are you having accessing your Apache Derby database?

- "Unexpected IOException wrapped in SQLException, accessing Apache Derby database" on page 1661
- "The "select for update" operation causes table lock and deadlock when accessing Apache Derby" on page 1661
- "ERROR XSDB6: Another instance of Apache Derby may have already booted the database "database"" on page 1661
- "Error "The version of the IBM Universal JDBC driver in use is not licensed for connectivity to Apache Derby databases"" on page 1661
- "Running an application causes a runtime exception which produces an unreadable message." on page 1662

Tip: Apache Derby errorCodes (2000, 3000, 4000) indicate levels of severity, not specific error conditions. In diagnosing Apache Derby problems, pay attention to the given sqlState value.

Unexpected IOException wrapped in SQLException, accessing Apache Derby database

This problem can occur because Apache Derby databases use a large number of files. Some operating systems, such as the Solaris Operating Environment, limit the number of files an application can open at one time. If the default is a low number, such as 64, you can get this exception.

If your operating system lets you configure the number of file descriptors, you can correct the problem by setting the number to a high value, such as 1024.

The "select for update" operation causes table lock and deadlock when accessing Apache Derby

If a select for update operation on one row locks the entire table, which creates a deadlock condition, there might be undefined indexes on that table. The lack of an index on the columns you use in the where clause can cause Apache Derby to create a table lock rather than a row level lock.

To resolve this problem, create an index on the affected table.

ERROR XSDB6: Another instance of Apache Derby may have already booted the database "database"

This problem occurs because Apache Derby embedded framework only allows one Java virtual machine (JVM) to access the database instance at a time.

To resolve this problem:

1. Verify that you do not have other JDBC client programs, such as **ij** or **cvview** running on that database instance, when WebSphere Application Server is running.
2. Verify that you do not use the same instance of the database for more than one data source or use the networkServer framework, which doesn't have this limitation.
3. If there are no connections to Apache Derby, delete the db.lck lock file. This file can be found in the directory where the Apache Derby database is mounted, under the schema directory. For example, if the database is mounted at /myDerbyDB, issue the command: `rm /myDerbyDB/schemaName/db.lck`

Error "The version of the IBM Universal JDBC driver in use is not licensed for connectivity to Apache Derby databases"

Error "The version of the IBM Universal JDBC driver in use is not licensed for connectivity to Apache Derby databases"

At the client runtime, an error similar to the following occurs:

```
The version of the IBM Universal JDBC driver in use is not
licensed for connectivity to Apache Derby databases. To connect
to this DB2 server, please obtain a licensed copy of the IBM DB2
Universal Driver for JDBC and SQLJ. An appropriate license file
db2jcc_license_*.jar for this target platform must be installed to
the application classpath. Connectivity to Apache Derby databases is
enabled by any of the following license files:
{ db2jcc_license_c.jar, b2jcc_license_cu.jar, db2jcc_license_cisuz.jar }
```

The problem occurs because an incorrect JDBC driver jar file name is specified in the class path for JDBC provider. For example, the jar file name may have an extra '_', as follows:

```
/${UNIVERSAL_JDBC_DRIVER_PATH}/db2jcc_license__cu.jar
```

To resolve the problem:

1. Correct the UNIVERSAL_JDBC_DRIVER_PATH jar file name in the JACL script
2. Restart the cluster.
3. Rerun the client.

Running an application causes a runtime exception which produces an unreadable message.

At client runtime, you may receive a message similar to the following: Caused by:
com.ibm.db2.jcc.a.SqlException: DB2 SQL error: SQLCODE: -1, SQLSTATE: 42X05, SQLERRMC:
ANNUITYHOLDER20^T42X05

The problem occurs because the property *retrieveMessagesFromServerOnGetMessage*, which is required by WebSphere Application Server, has not been set.

To resolve the problem, on the administrative console

1. Click **Resources -> JDBC Providers**
2. Click on a Apache Derby provider
3. Scroll down and click on **Data Sources**
4. Select your data source (or add a new one)
5. Scroll down and select **Custom Properties**
6. If the property *retrieveMessagesFromServerOnGetMessage* already exists, set its value to true. If the property does not exist, select **New** and add the property *retrieveMessagesFromServerOnGetMessage* with a value **true**
7. Rerun the client

The SystemOut.log will now generate readable messages so that you can resolve the underlying problem.

Data access problems - Sybase data source

This article provides troubleshooting tips for accessing Sybase data sources.

What kind of problem are you having accessing your Sybase database?

- "Sybase Error 7713: Stored Procedure can only be executed in unchained transaction mode" error.
- "JZ0XS: The server does not support XA-style transactions. Please verify that the transaction feature is enabled and licensed on this server."
- A container managed persistence (CMP) enterprise bean is causing exceptions.
- "Sybase JDBC data source fails with "Incorrect URL format" exception in IPv6 environment" on page 1663
- "Executing the DatabaseMetaData.getBestRowIdentifier() method in an XA transaction causes errors" on page 1664
- "Sybase requirements for using the escapes and DatabaseMetaData methods" on page 1664
- "Database deadlocks and XA_PROTO errors occur when using Sybase" on page 1665
- "Executing a stored procedure containing a SELECT INTO command causes exception" on page 1665
- "Error is incorrectly reported about IMAGE to VARBINARY conversion" on page 1665
- "JDBC 1.0 standard methods are not implemented and generate a SQL exception when used" on page 1666
- "Sybase transaction manager fails after trying to alleviate a deadlock error" on page 1666
- "Starting an XA transaction when the autoCommit value of the connection is false causes error" on page 1666
- "Sybase does not throw an exception when an incorrect database name is specified" on page 1666

"Sybase Error 7713: Stored Procedure can only be executed in unchained transaction mode" error

This error occurs when either:

- The JDBC attempts to put the connection in **autocommit(true)** mode.
- A stored procedure is not created in a compatible mode.

To fix the **autocommit(true)** mode problem, let the application change the connection to chained mode using the **Connection.setAutoCommit(false)** mode, or use a **set chained on** language command.

To resolve the stored procedure problem, use the `sp_procxmode procedure_name "anymode"` command.

"JZ0XS: The server does not support XA-style transactions. Please verify that the transaction feature is enabled and licensed on this server."

This error occurs when XA-style transactions are attempted on a server that does not have Distributed Transaction Management (DTM) installed.

To resolve this problem, use the instructions in the Sybase Manual titled: *Using Adaptive Server Distributed Transaction Management Features* to enable Distributed Transaction Management (DTM). The main steps in this procedure are:

1. Install the DTM option.
2. Check the `license.dat` file to verify that the DTM option is installed.
3. Restart the license manager.
4. Enable DTM in ISQL.
5. Restart the ASE service.

A container managed persistence (CMP) enterprise bean is causing exceptions

This error is caused by improper use of reserved words. Reserved words cannot be used as column names.

To correct this problem: Rename the variable to remove the reserved word. You can find a list of reserved words in the *Sybase Adaptive Server Enterprise Reference Manual; Volume 1: Building Blocks*, Chapter 4. This manual is available online at: <http://manuals.sybase.com/onlinebooks/group-as/asg1250e/refman>.

Sybase JDBC data source fails with "Incorrect URL format" exception in IPv6 environment

Problem

If you configure a Sybase JDBC data source through the administrative console and attempt to use it in an IPv6 environment, you can experience the following exception:

```
java.sql.SQLException: JZ0NE: Incorrect URL format
```

Cause

The Sybase JDBC drivers that are listed as selections for JDBC provider type in the administrative console do not support IPv6. The administrative console does not contain a pre-formatted template for the Sybase jConnect JDBC driver v6.0 EBF12884, which is the version required to connect to the database in an IPv6 environment.

However, you can still use the administrative console to define the Sybase jConnect JDBC driver v6.0 EBF12884.

Solution

Complete the following steps to define the Sybase jConnect JDBC driver v6.0 EBF12884:

1. In the administrative console, go to **Resources > JDBC Providers** and click **New**.
2. Select **User-defined** for the database type. This selection triggers the console to set your provider type to User-defined JDBC provider and implementation type to User-defined.
3. Click **Next** to go to the JDBC provider general configuration page.
4. In the Class path field, replace the default JAR file name with `jconn3.jar`.
5. For Implementation class name:
 - For a data source implementation that supports only one phase transactions, input

com.sybase.jdbc3.jdbc.SybConnectionPoolDataSource

- For an implementation that supports two phase transactions, input

com.sybase.jdbc3.jdbc.SybXADataSource

6. Click **Apply**. Then click the Data sources link.
7. Click **New** to define the general properties of your data source.
8. Click **Apply** after defining the general data source properties. Then click the Custom properties link.
9. Define the following properties as custom properties. To set these properties, click **New**. Input the property name and a valid value for each one.
 - databaseName
 - serverName
 - portNumber

Executing the DatabaseMetaData.getBestRowIdentifier() method in an XA transaction causes errors

Executing the DatabaseMetaData.getBestRowIdentifier() method while in an XA transaction causes the following errors:

SQL Exception: The 'CREATE TABLE' command is not allowed within a multi-statement transaction in the 'tempdb' database. Calling DatabaseMetaData.getBestRowIdentifier()

Currently, this method fails when using Sybase. This problem occurs with other methods as well, including:

- getBestRowIdentifier();
- getVersionColumns();
- getTablePrivileges();
- getProcedureColumns();
- getPrimaryKeys();
- getIndexInfo();
- getImportedKeys();
- getExportedKeys();
- getCrossReference();
- getColumns();
- getColumnPrivileges();

Case 10880427 has been opened with Sybase to resolve this problem.

Sybase requirements for using the escapes and DatabaseMetaData methods

To use the escapes and DatabaseMetaData methods, you must install stored procedures on the Adaptive Server Enterprise or Adaptive Server Anywhere database where you want to use these methods. These stored procedures are also required by some of the connection methods.

To check for the presence of LOCATE ():

1. Open a Sybase **isql** command prompt.
2. Type the command **use master**.
3. Type the command **go**.
4. Type the SQL command and select * from jdbc_function_escapes.
5. Type the command **go**.

The following appears:

| escape_name | map_string |
|-------------|------------|
| abs | abs(%1) |
| acos | acos(%1) |
| asin | asin(%1) |

JDBC 1.0 standard methods are not implemented and generate a SQL exception when used

The following JDBC 1.0 standard methods are not implemented and generate a SQL exception when used:

- `ResultSetMetaData.getSchemaName()`
- `ResultSetMetaData.getTableName()` (implemented only for text and image datatypes)
- `ResultSetMetaData.getCatalogName()`

Sybase transaction manager fails after trying to alleviate a deadlock error

If an application encounters a deadlock, Sybase detects the deadlock and throws an exception. Because of this detection, the transaction manager calls an `xa_end` with a `TMFAIL` in it.

The call succeeds, but causes another Sybase exception, `XAERR_PROTO`. This exception only appears in the error log and does not cause any functional problems. All applications should continue to run, therefore no workaround is necessary.

Case 10869169 has been opened with Sybase to resolve this problem.

Starting an XA transaction when the `autoCommit` value of the connection is `false` causes error

The exception thrown is `javax.transaction.xa.XAException` with stack trace similar to the following:

```
at com.sybase.jdbc2.jdbc.SybXAResource.sendRPC(SybXAResource.java:711)
at com.sybase.jdbc2.jdbc.SybXAResource.sendRPC(SybXAResource.java:602)
at com.sybase.jdbc2.jdbc.SybXAResource.start(SybXAResource.java:312)
```

This problem affects you when you do both local and global transactions. If, in a local transaction, the `autoCommit` default value is set to `false`, and a global or XA transaction starts (either a user transaction started by you, or a container transaction started by a container), the exception occurs.

This problem is a Sybase bug as the `start()` method can fail unexpectedly, regardless of the value of `autoCommit`. Currently, there is no workaround for this problem, therefore it is not recommended that you mix local and global transactions. Case 10880792 has been opened to resolve this problem.

Sybase does not throw an exception when an incorrect database name is specified

Verify that your database name is correctly entered on the data source properties.

Most databases (DB2, Oracle, Informix, MS SQL Server and Cloudscape) throw an exception when the database specified does not exist. But Sybase does not throw an exception when an incorrect database name is specified. Sybase generates an SQL warning and then connects to the default database. If you misspell the requested database name, Sybase connects you to the master or the default database where the table you requested is not found.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes). If you do not find your problem listed there, contact IBM Support.

JDBC trace configuration

If your application displays JDBC-related exception messages, activate the JDBC trace service. The resulting log text can help you identify the problem.

Trace strings for JDBC data sources

Turn on tracing for most database JDBC implementations through the administrative console; see the article [Tracing and logging configuration](#) for instructions.

This method activates JDBC trace for all applications that run in the server you specify. Identify your database type by selecting the trace group `WAS.database` and typing one of the following trace strings in the console:

- **`com.ibm.ws.database.logwriter`** Trace string for databases that use the `GenericDataStoreHelper`. You can also use this trace string for unsupported databases.
- **`com.ibm.ws.db2.logwriter`** Trace string for DB2 databases.
- **`com.ibm.ws.oracle.logwriter`** Trace string for Oracle databases.
- **`com.ibm.ws.derby.logwriter`** Trace string for Derby databases.
- **`com.ibm.ws.informix.logwriter`** Trace string for Informix databases.
- **`com.ibm.ws.sqlserver.logwriter`** Trace string for Microsoft SQL Server databases.
- **`com.ibm.ws.sybase.logwriter`** Trace string for Sybase databases.

A few JDBC drivers require that you set trace differently, at the data source level. These drivers include:

- Microsoft SQL Server JDBC driver
- DataDirect Connect for JDBC driver for MS SQL Server

Configuring trace for these drivers through the `WAS.database` group results in corrupt trace information. The application server sets trace for the group at the server level, causing the trace service to begin only after your application establishes an initial connection. Because that first connection does not carry trace information, re-use of it is never tracked. Consequently the application cannot accurately match trace information to connection use.

Set trace for the previously mentioned JDBC drivers through data source custom properties. For example, use the `spyAttributes` custom property to enable JDBC trace for the DataDirect Connect for JDBC driver. Consult your driver documentation for details on the custom property that enables trace for your JDBC implementation.

Additional resources

If the JDBC tracing service cannot help you isolate and fix your problem, consult the IBM Support web site for WebSphere Application Server. Use the site search function to find current information on known problems and their resolutions. Locating the right troubleshooting tip can save time that you might otherwise spend on opening and tracking a PMR.

Configuring the connection validation timeout

You can configure a timeout for connection validation by the Java Database Connectivity (JDBC) driver through a data source custom property in the data source configuration panels.

About this task

You can choose between validating connections with the JDBC driver or by having the application server run a SQL query. Select one or both of the following connection pretest attributes:

- Validate new connections
- Validate existing pooled connections

By default, connection validation is disabled. When you save the configuration for the data source, the administrative console supplies only the option that is selected. The administrative console will select validation by timeout or validation by a query, but if validation is not enabled then the application server will select neither option.

1. Open the administrative console.

2. Go to the **WebSphere Application Server Data Source properties** panel for the data source.
 - a. Select **Resources** → **JDBC** → **Data Sources** → *data_source*
 - b. Select **WebSphere Application Server Data Source properties**.
3. Go to the **Connection Validation Properties** section.
4. Select the type of connections that the application server will validate.
 - Select **Validate new connections**. This option specifies that the connection manager tests newly created connections to the database.
 - Select **Validate existing pooled connections**. This options specifies that the connection manager tests the validity of pooled connections before returning them to applications.
 - You can also select both options

Note: You must make a selection here. If you do not select one or both of these options, you will not be able to select **Validation by JDBC Driver**. The **Validation by JDBC Driver** timeout feature is only available for JDBC providers that comply with the JDBC 4.0 specification.
5. Click **Validation by JDBC Driver**. The application server issues a warning if **Validation by JDBC driver** is configured and the JDBC driver does not implement JDBC 4.0, or if the `Connection.isValid` method raises an error.

Note: Connection validation by SQL query is deprecated. Use validation by JDBC Driver instead.
6. Enter the timeout value in the input box. The timeout value is in seconds.

Note: If retries are configured, meaning the retry interval is not set to 0, for **Validate new connections** or **Validate existing pooled connections**, then the full value of the timeout applies to each retry. For each retry, the application server waits for the retry interval. Then the JDBC driver uses the full value of the timeout to validate the connection
7. Save the data source configuration.

What to do next

If you are modifying an existing data source, restart your server for this change to go into effect. If this is a new data source, restarting the server is not necessary.

Deploying data access applications

Frequently, deploying data access applications involves more than installing your WAR or EAR file onto a server. Deployment can include tasks for configuring your application to use the data access resources of the server and overall run-time environment.

Before you begin

You can only deploy application code that is assembled into the appropriate modules. The topic *Assembling data access applications* provides guidelines for this process.

About this task

Perform the following steps if your application requires access to a relational database (RDB). If your application requires access to a different type of enterprise information system (EIS), such as an object-oriented database or the Customer Information Control System (CICS), consult the topics “Resource adapters” on page 1389 and *Accessing data using Java EE Connector Architecture connectors*.

1. If your RDB configuration does not already exist:
 - a. Create a database to hold the data.
 - b. Create tables required by your application.

If your application uses CMP entity beans to access the data

You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see *Recreating database tables from the exported table data definition language*.

If your application uses BMP entity beans, or does not use entity beans

You must use your database server interfaces to create the tables.

You can also use the EJB to RDB Mapping wizard of an assembly tool to create your database tables for either type of entity bean. Select the top-down mapping option in the wizard. Keep in mind, however, that this option does not give you direct control in naming the RDB elements or choosing column types. Additionally, because the top-down process is automatic, it might not provide mappings to reflect the precise relationships that you intend.

If you use Rational Application Developer, consult the information center about the mapping wizard. To learn about all of your assembly tool options, consult the *Assembly tools* article in this information center.

- c. Check “Data source minimum required settings, by vendor” on page 1510 to see any database vendor requirements for connecting to an application server.
2. If necessary, map your entity beans to the database tables through the meet-in-the-middle mapping option of an assembly tool. This step is necessary only if you did not create your database schema through the top-down mapping option, did not generate your mapping relationships through bottom-up mapping, or did not generate mappings during the application assembly process. For information on the top-down mapping option refer to the information center for Rational Application Developer.
3. Install your application onto the application server. Consult *Installing enterprise application files*. When you install the application, you can alter data access settings that were made during application assembly, or set them for the first time if they were omitted from the assembly process. These settings include resource bindings and resource authentication aliases, which are addressed in the following substeps:
 - a. Bind application resource references to the data sources, or other resource objects, that provide database connectivity. For details on the concept of binding, see the *Data source lookups for enterprise beans and Web modules* topic.

Note: After deployment, you can use the WebSphere Application Server administrative console to alter resource bindings. Click **Applications** → **Application Types** → **Webphere enterprise applications** → **application_name**, and select the link to the appropriate mapping page. For example, if you want to alter the binding of an EJB module resource, you might click **Map data sources for all 2.x CMP beans** . For a Web module resource, click **Resource references**.

- b. Define authentication alias data for resources that must be authenticated with the backend through *container-managed* authorization. In this security configuration, WebSphere Application Server performs EIS signon for data source or connection factory connections. Consult the “J2EE connector security” on page 1503 topic for detailed reference on resource authentication.
4. Start the deployed application files using the administrative console , the `wsadmin startApplication` command, or your own Java program.
5. Save the changes to your administrative configuration.
6. Test the application. For example, point a Web browser at the URL for a deployed application and examine the performance of the application.

What to do next

If the application does not perform as desired, update the application, then save and test it again.

Available resources

Use this page to select configured resources that you want to bind to the resource references of the enterprise beans or web modules in your application.

To view this administrative console page:

1. Click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application_name*.
2. Click the link for any of these resource configuration pages:
 - **Resource references**
 - **Map data sources for all 2.x CMP beans**
 - **Provide default data source mapping for modules containing 2.x entity beans**
3. Locate the table row of the EJB or web module that you want to map to a different resource.
4. Within the row, locate the JNDI name of the resource that is currently bound to the EJB or web module.
5. Click **Browse**.
You now see **Available resources**.

Each table row corresponds to a resource that you can bind to your enterprise bean or web module.

Select

Select the resource that you want to bind to the resource reference of your module.

JNDI name

The Java Naming and Directory Interface (JNDI) name of the resource that you want to bind to the resource reference of your module.

Data type String

Scope

The scope of the resource. Note that this administrative console page displays only resources that are configured for a scope at which your application operates.

Description

The text description of the resource.

Map data sources for all 1.x CMP beans

Use this page to designate how the container-managed persistence (CMP) 1.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application_name* → **Map data sources for all 1.x CMP beans**.

Guidelines for using this administrative console page:

- The table depicts the 1.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly or installation. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:
 1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.
 2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.
 3. Click **Apply**. The console displays the 1.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.

4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
 - To specify data source security settings:
 1. Select one or more rows in the table.
 2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
 3. Click **Apply** that immediately follows the user name and password input fields.
 - Repeat all of the previous steps as necessary.
 - Click **OK** to save your settings.

Select

Select the check boxes of the rows that you want to edit.

EJB

The name of an enterprise bean in the application.

EJB Module

The name of the module that contains the enterprise bean.

URI

Specifies location of the module relative to the root of the application EAR file.

JNDI name

The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

Data type String

User name

The user name and password that comprise the authentication alias for securing the data source.

Map default data sources for modules containing 1.x entity beans

Use this page to set the default data source mapping for EJB modules that contain 1.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 1.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → *application_name* → **Map default data sources for modules containing 1.x entity beans**.

Guidelines for using this administrative console page:

- The page displays a table that depicts the EJB modules in your application that contain 1.x CMP beans.
- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
 1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.

2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
3. Click **Apply**. The console displays the 1.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
 - To specify security settings for the default data source:
 1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.
 2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
 3. Click **Apply** that immediately follows the user name and password input fields.
 - Repeat all of the previous steps as necessary.
 - Click **OK** to save your work.

Select

Select the check boxes of the rows that you want to edit.

EJB Module

The name of the module that contains the 1.x enterprise beans.

URI

Specifies location of the module relative to the root of the application EAR file.

JNDI name

The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type String

User name

The user name and password that comprise the authentication alias for securing the data source.

Map data sources for all 2.x CMP beans settings

Use this page to map container-managed persistence (CMP) 2.x beans of an application to data sources that are available to the application.

To view this administrative console page, click **Applications** → **Application Types** → **Websphere enterprise applications** → *application_name* → **Map data sources for all 2.x CMP beans**.

Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI names

Specify the Java Naming and Directory Interface (JNDI) name for multiple EJB modules. Select one or more EJB modules from the table, and select a JNDI name from this list to configure the EJB modules with that JNDI name.

Data type Drop-down list

Set Authorization Type

Specify the authorization type for securing the data source. Select one or more EJB modules from the table to set the authorization type.

Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon.

Modify Resource Authentication Method

Specify the authorization type and the authentication method for securing the data source. Select one or more EJB modules from the table to modify the resource authentication method.

You can choose between the following authentication methods:

- **None:**
 1. Determine which data source configurations to designate with no authentication method.
 2. Select the appropriate table rows.
 3. Select **None** from the list of authentication method options that precede the table.
 4. Click **Apply**.
- **Use default method (many-to-one mapping):**
 1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
 2. Select the appropriate table rows.
 3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
 4. Select an authentication data entry or alias from the list.
 5. Click **Apply**.
- **Use Kerberos authentication:** Specifies to use the Kerberos authentication method.
 1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
 2. Select the appropriate table row.
 3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
 4. Select an application login configuration from the list.
 5. Click **Apply**.
 6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Use trusted connections (one-to-one mapping):**
 1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
 2. Select the appropriate table row.
 3. Ensure that the database to which the modules will connect is configured for trusted connections.
 4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
 5. Select an application login configuration from the list.
 6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration:**

1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
2. Select the appropriate table row.
3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
4. Select an application login configuration from the list.
5. Click **Apply**.
6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select

Select the check boxes of the rows that you want to edit.

EJB

The name of an enterprise bean in the application.

EJB Module

The name of the module that contains the enterprise bean.

URI

Specifies location of the module relative to the root of the application EAR file.

Target resource JNDI name

Specifies the resource to which the CMP bean is bound.

Resource authorization

Specifies the current setting for the resource authorization type.

Modify this setting with **Set authorization type**.

Map data sources for all 2.x CMP beans

Use this page to set the default data source mapping for EJB modules that contain 2.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 2.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console panel, click **Applications** → **Application Types** → **Websphere enterprise applications** → *application_name* → **Map data sources for all 2.x CMP beans** .

This panel displays a table that depicts the EJB modules in your application that contain 2.x CMP beans. Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI Names

Specifies the JNDI name to bind to one or more modules. Select one or more modules, click **Set Multiple JNDI Names**, and select the JNDI name for the resource to which you would like to bind the module.

Set Authorization Type

Specifies the authorization type that you to use for the modules. Select one or more modules, click **Set Authorization Type**, and select the authorization type.

You can choose:

- Per application - indicates that the enterprise bean code performs signon.
- Container - indicates that the application server performs signon to the data source.

Modify Resource Authentication Method

Specifies the resource authentication method for the modules that you have configured with container-managed authorization. Select one or more modules, click **Modify Resource Authentication Method**, and select the authentication method.

You can choose between the following authentication methods:

- **None:**
 1. Determine which data source configurations to designate with no authentication method.
 2. Select the appropriate table rows.
 3. Select **None** from the list of authentication method options that precede the table.
 4. Click **Apply**.
- **Use default method (many-to-one mapping):**
 1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
 2. Select the appropriate table rows.
 3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
 4. Select an authentication data entry or alias from the list.
 5. Click **Apply**.
- **Use Kerberos authentication:** Specifies to use the Kerberos authentication method.
 1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
 2. Select the appropriate table row.
 3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
 4. Select an application login configuration from the list.
 5. Click **Apply**.
 6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Use trusted connections (one-to-one mapping):**
 1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
 2. Select the appropriate table row.
 3. Ensure that the database to which the modules will connect is configured for trusted connections.
 4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
 5. Select an application login configuration from the list.
 6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration:**

1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
2. Select the appropriate table row.
3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
4. Select an application login configuration from the list.
5. Click **Apply**.
6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select

Select the check boxes of the rows you want to edit.

EJB Module

Specifies the name of the module that contains the 2.x enterprise beans.

URI

Specifies location of the module relative to the root of the application EAR file.

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type

String

Resource authorization

Specifies the authorization type and the authentication method for securing the data source.

Extended Datasource Properties

When selected, you will be directed to a panel on which you can specify extended properties that the module can use for the DB2 data source.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

Chapter 8. Messaging resources

Managing messaging with the default messaging provider

This topic is the entry point into a set of topics about enabling WebSphere Application Server applications to use messaging resources provided by the default messaging provider.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider as described in this topic. To integrate WebSphere Application Server messaging into a predominantly WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third party messaging provider. To choose the provider that is best suited to your needs, see [Choosing a messaging provider](#).

About this task

The default messaging provider is installed and runs as part of WebSphere Application Server, and is based on service integration technologies.

The default messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces). This enables applications to use common interfaces for both point-to-point and publish/subscribe messaging. This also enables both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, this approach is recommended for new applications. The domain-specific interfaces are supported for backwards compatibility for applications developed to use domain-specific queue interfaces, as described in section 1.5 of the JMS 1.1 specification.

You can use the WebSphere Application Server administrative console to configure JMS resources for applications, and can manage messages and subscriptions associated with JMS destinations.

WebSphere Application Server Version 5.1 Java EE applications can use messaging resources of the default messaging provider in WebSphere Application Server Version 7.0. This JMS interoperation from WebSphere Application Server Version 5.1 to later versions is enabled and managed by a WebSphere MQ client link created on the WebSphere Application Server Version 7.0 node. This JMS interoperation is only intended as an aid to the migration from the embedded messaging in WebSphere Application Server Version 5.1 to the default messaging provider in WebSphere Application Server Version 7.0.

Note: Java EE applications running under WebSphere Application Server Version 7.0 can use messaging resources of Version 5 embedded messaging without any need for a WebSphere MQ client link.

For more information about using the default messaging provider of WebSphere Application Server, see the following topics:

- [Learning about the default messaging provider](#)
- [“Configuring resources for the default messaging provider”](#) on page 1678
- [“Interoperating with a WebSphere MQ network”](#) on page 1707
- [Migrating from WebSphere Application Server Version 5 embedded messaging](#)
- [“Managing WebSphere Application Server Version 5.1 JMS use of messaging resources in later versions of the product”](#) on page 1741
- [“Configuring the messaging engine selection process for JMS applications”](#) on page 1751
- [“Managing messages and subscriptions for JMS destinations”](#) on page 1753
- [“Using JMS from standalone clients to interoperate with service integration resources”](#) on page 1754
- [“Using JMS from a third party application server”](#) on page 1761

Configuring resources for the default messaging provider

Use the following tasks to configure JMS connection factories, activation specifications, and destinations for the default messaging provider.

About this task

Use these tasks to configure administrative JMS resources provided by the default messaging provider.

These administrative JMS resources are in addition to any temporary JMS destinations created by applications.

- “Listing JMS resources for the default messaging provider”
- Configuring a JMS connection factory.
- Configuring a JMS queue connection factory.
- Configuring a JMS topic connection factory.
- Configuring a JMS queue destination.
- Configuring a JMS topic destination.
- “Configuring a JMS activation specification for the default messaging provider” on page 1686

Configuring resources for the default messaging provider by using the wsadmin tool

You can use these commands to manage JMS resources for the default messaging provider.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

1. Open a wsadmin command session in local mode For example:

```
wsadmin -conntype none
```
2. Type the command as indicated in the related reference topics.

Listing JMS resources for the default messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for the default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Connection factory (unified)
- Queue connection factory
- Topic connection factory
- Queue
- Topic
- Activation specification

When you use the Administrative Console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation.** This lets you view all providers (or just those for a specified scope if required), then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider owns it. Any navigation that starts with **Resources** → **JMS** → **JMS providers** is provider-centric.
- **Resource-centric navigation.** This lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider owns it (you

can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** → **JMS** → *resource_type*, where *resource_type* is one of the resource types listed above is resource-centric.

You can use either of these navigation pathways to locate resources of any type.

- Optional: To use provider-centric navigation, for example to navigate to a specified connection factory, use the administrative console to complete the following steps:
 1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**. This opens the providers collection which lists all currently configured providers across all scopes (you can modify the scope if required).
 2. From the providers collection, select the required provider. This opens the configuration tab for that provider. The configuration tab contains a set of links to all the resources owned by that provider.
 3. From the configuration tab, click the link for a resource type, for example the connection factories link. This opens the connection factories collection which lists all the connection factories for that provider.
 4. From the connection factories collection, select the required connection factory.
- Optional: To use resource-centric navigation, for example to navigate to a specified connection factory, use the administrative console to complete the following steps:
 1. In the navigation pane, click **Resources** → **JMS** → **Connection factories**. This opens the connection factories collection which lists all the connection factories across all providers.
 2. From the connection factories collection, select the required connection factory.

Results

You can now view and work with the resource's properties.

Configuring JMS resources for point-to-point messaging

Configure connection factories, queues and service integration bus destinations for point-to-point messaging.

About this task

For an application to use point-to-point messaging with JMS queues, you need to configure the following JMS resources. These JMS resources depend on the corresponding configuration of service integration resources, including a service integration bus and a queue. For more information about defining these resources, see the related tasks.

- Configure a connection factory.

Use the connection factory type that matches the JMS level and domain pattern in which an application is developed. For example, use a domain-independent JMS connection factory for a JMS application developed to use JMS 1.1 domain-independent interfaces, and use a JMS queue connection factory for a JMS application developed to use domain-specific queue interfaces.
- Configure a queue.

A *JMS queue* is an administrative object that encapsulates the name of a queue destination on a service integration bus. Applications find the JMS queue by looking up its name in the JNDI namespace.
- Configure a queue destination.

For each JMS queue, define a bus destination of type queue on the appropriate service integration bus.

Configuring JMS resources for publish/subscribe messaging

Use this task to configure a JMS resources for publish/subscribe messaging.

About this task

For an application to use publish/subscribe messaging with JMS topics, you need to configure the following JMS resources. These JMS resources depend on the corresponding configuration of service integration resources, including a service integration bus and topicspace. For more information about defining these resources, see the related tasks.

- A JMS connection factory

You should use the connection factory type that matches the JMS level and domain pattern in which an application is developed. For example, use a domain-independent JMS connection factory for a JMS application developed to use JMS 1.1 domain-independent interfaces, and use a JMS topic connection factory for a JMS application developed to use domain-specific topic interfaces.

If durable subscriptions are to be used by the application, then you need to set the durable subscription properties on the connection factory.

- A JMS topic

A *JMS topic* is an administrative object that encapsulates the name of a topic and a topic space on a service integration bus. Applications can obtain the JMS topic by looking its name up in the JNDI namespace.

- Service integration resources For each JMS topic, you need to define a bus destination as a topic space on a service integration bus, and assign the JMS topic to a topic name within that topic space.

Configuring a unified JMS connection factory for the default messaging provider

Use this task to configure a unified JMS connection factory for applications that use the JMS 1.1 domain-independent (unified) interfaces.

About this task

A unified¹ JMS connection factory can be used for both point-to-point and publish/subscribe JMS messaging. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.

To configure a JMS connection factory for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new connection factory if you have not already created the connection factory that you want to configure.

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure a unified connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Connection factories**. This displays any existing connection factories in the content pane.
5. If the connection factory is for use by client applications, display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.

Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

Name Type the name by which the connection factory is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the connection factory into the name space.

1. The term “unified” refers to the support of both queues and topics by the same connection factory. This is similar to the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

Bus name

Select the name of the service integration bus to which the connection factory is to create connections. This service integration bus hosts the destinations that the JMS queues and topics represent.

6. Review the other properties for the JMS connection factory, to check that the defaults are suitable. If needed, change the values according to your needs.

If the connection factory is for use by client applications running outside of an application server, you need to specify suitable provider endpoints. For more information about configuring provider endpoints, see “Configuring a connection to a non-default bootstrap server” on page 1693.

By default connections created using the connection factory in the server containers (for example, from an enterprise bean) are pooled using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.

7. Click **OK**.
8. Save your changes to the master configuration.

Administrative properties for JMS connections to a bus:

This topic describes properties that you can configure to enable workload management of connections to a service integration bus for JMS applications.

The same properties can also be used to control the client connection topology. For example, connection options can be specified such that client applications only connect to a set of client serving messaging engines and never to the set of destination serving messaging engines in a bus.

The properties for connecting JMS applications to a bus are for administrator interest; the JMS applications are unconcerned with connections to the bus, beyond using a JMS connection factory or JMS activation specification (for message-driven beans).

The general aim of connecting to a bus is to connect to a suitable messaging engine that provides the message point for a JMS destination that the application wants to use. Applications running inside an application server can locate a suitable messaging engine and connect directly to the selected messaging engine. Client applications running outside of an application server cannot locate a suitable messaging engine themselves, these clients must use a bootstrap server to locate a suitable messaging engine on behalf of the client application.

When an application connects to the bus, the bus chooses a suitable messaging engine based on administrative properties of the JMS connection factory or activation specification that the application uses. For maximum connection flexibility, you can leave most properties to default, the only required connection property is the name of the bus that the application is to connect to.

The bus uses the following general process to choose a suitable messaging engine, based on the value you select for the Connection proximity property. If you understand this process, you can better configure the properties that control how the bus chooses messaging engines.

- If a **Target group** is specified then the process checks the nearest messaging engine that supports the required **Remote transport chain** and is a member of the target group in the bus. If the messaging engine is within the specified **Connection proximity** it is chosen as a suitable messaging engine for the application to connect to.
- If a **Target group** is not specified then the process checks the nearest messaging engine that supports the required **Remote transport chain** in the bus. A messaging engine in the same server is nearer than

a messaging engine in the same host, which is nearer than a messaging engine in another host. If the messaging engine is within the specified **Connection proximity** it is chosen as a suitable messaging engine for the application to connect to.

- If the selected messaging engine is not within the specified **Connection proximity**, then the **Target significance** is used. If the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available. If the **Target significance** is set to Preferred then the target group is ignored and the nearest messaging engine that supports the required **Remote transport chain** is used. If no messaging engine is found then the connection request is rejected with no suitable messaging engine being available.

The following rules are used to test the connection proximity for a selected messaging engine:

- If the Connection proximity value is Bus, then the selected messaging engine is used.
- If the Connection proximity value is Cluster, then the selected messaging engine is used if it is in the same cluster as the application (or the bootstrap server). Otherwise, one of the following options is chosen.
 - If the selected messaging engine is not in the same cluster as the application (or the bootstrap server), and the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available.
 - If the **Target significance** is set to Preferred then the nearest messaging engine - in the same cluster - that supports the required **Remote transport chain** is used
 - If no suitable messaging engine is found, then the connection request is rejected.
- If the Connection proximity value is Host, and the selected messaging engine is in the same host as the application (or bootstrap server), then the selected messaging engine is used. Otherwise, one of the following options is chosen.
 - If the selected messaging engine is not in the same host as the application (or the bootstrap server), and the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available.
 - If the **Target significance** is set to Preferred then the nearest messaging engine - in the same host - that supports the required **Remote transport chain** is used
 - If no suitable messaging engine is found, then the connection request is rejected.
- If the Connection proximity value is Server, and the selected messaging engine is in the same server as the application (or bootstrap server), then the selected messaging engine is used. Otherwise, one of the following options is chosen.
 - If the selected messaging engine is not in the same server as the application (or is in the bootstrap server), and the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available.
 - If the **Target significance** is set to Preferred then the nearest messaging engine - in the same server - that supports the required **Remote transport chain** is used
 - If no suitable messaging engine is found, then the connection request is rejected.

When a connection is made to a messaging engine in the same server as the application, the connection is made directly through memory, so the **Remote transport chain** is ignored.

Configuring a JMS queue connection factory for the default messaging provider

Use this task to configure a JMS queue connection factory for point-to-point messaging with the default messaging provider. This is intended more for backwards compatibility, as described in section 1.5 of the JMS 1.1 specification.

About this task

To configure a JMS queue connection factory for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new queue connection factory.

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure a queue connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Queue connection factories**. This displays any existing JMS queue connection factories for the default messaging provider in the content pane.
5. Display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.

Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

Name Type the name by which the connection factory is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the connection factory into the name space.

Bus name

Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics represent.

6. Review the other JMS queue connection factory [Settings], to check that the defaults are suitable. If needed, change the values according to your needs.

If the connection factory is for use by client applications running outside of an application server, you need to specify suitable provider endpoints. For more information about configuring provider endpoints, see “Configuring a connection to a non-default bootstrap server” on page 1693.

By default connections created using the connection factory in the server containers (for example, from an enterprise bean) are pooled using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.

7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a JMS topic connection factory for the default messaging provider

Use this task to configure a JMS topic connection factory for publish/subscribe messaging with the default messaging provider. This is intended more for backwards compatibility, as described in section 1.5 of the JMS 1.1 specification.

About this task

You need to configure JMS connection factories when deploying JMS applications that use publish/subscribe messaging.

To configure a JMS topic connection factory for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new topic connection factory.

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.

4. In the content pane, under the Additional properties heading, click **Topic connection factories**. This displays any existing JMS topic connection factories for the default messaging provider in the content pane.
5. Optional: Display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.
Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

Name Type the name by which the connection factory is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the connection factory into the name space.

Bus name

Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics represent.

6. Review the other properties for the connection factory, to check that the defaults are suitable. If needed, change the values according to your needs.
If the connection factory is for use by client applications running outside of an application server, you need to specify suitable provider endpoints. For more information about configuring provider endpoints, see “Configuring a connection to a non-default bootstrap server” on page 1693.
By default connections created using the connection factory in the server containers (for example, from an enterprise bean) are pooled using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a JMS queue for the default messaging provider

Use this task to configure a JMS queue for point-to-point messaging with the default messaging provider.

Before you begin

This task configures a JMS queue to use a queue destination on a service integration bus. The queue destination is the virtual location on the bus where messages are stored and processed for the JMS queue. If you have not created the required destination, use the task described in Configuring a destination for JMS queues.

About this task

To configure a JMS queue for the default messaging provider, use the administrative console to complete the following steps.

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure a queue.
3. Optional: Change the **Scope** check box to set the level at which the JMS queue is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Queues**. This displays any existing JMS queues for the default messaging provider in the content pane.
5. Display the properties of the JMS queue. If you want to display an existing JMS queue, click one of the names listed.

Alternatively, if you want to create a new JMS queue, click **New**, then specify the following required properties:

Name Type the name by which the queue is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the queue into the name space.

Queue name

Select the name of the queue on a service integration bus that this JMS queue is to use.

6. Specify properties for the JMS queue, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a JMS topic for the default messaging provider

Use this task to configure a JMS topic for publish/subscribe messaging with the default messaging provider.

Before you begin

This task configures a JMS topic to use a topic space destination on a service integration bus. The topic space (a hierarchical collection of topics) is the virtual location on the bus where messages are stored and processed for the JMS topic. If you have not created the required destination, use the task described in *Configuring a destination for publish/subscribe messaging*.

About this task

To configure a JMS topic for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new JMS topic.

1. Display the default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure a topic.
3. Optional: Change the **Scope** check box to set the level at which the topic is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Topics**. This displays any existing JMS topics for the default messaging provider in the content pane.
5. Display the properties of the JMS topic. If you want to display an existing JMS topic, click one of the names listed.

Alternatively, if you want to create a new JMS topic, click **New**, then specify the following required properties:

Name Type the name by which the topic is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the topic into the name space.

Topic name

Type the name of the topic (as a qualifier in the topic space) that this JMS topic is to use.

Topic space

Type the name of the topic space that this JMS topic is to use.

6. Specify properties for the JMS topic, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a JMS activation specification for the default messaging provider

A JMS activation specification is a configurable resource that enables a message-driven bean to communicate with the default messaging provider.

About this task

You create a JMS activation specification if you want to use a message-driven bean to communicate with the default messaging provider through Java EE Connector Architecture (JCA) 1.5. JCA provides Java connectivity between application servers such as WebSphere Application Server, and enterprise information systems. It provides a standardized way of integrating JMS providers with Java EE application servers, and provides a framework for exchanging data with enterprise systems, where data is transferred in the form of messages.

One or more message-driven beans can share a single JMS activation specification.

For WebSphere Application Server Version 5.1, the interface between message-driven beans and their destinations was the listener port. Although you cannot use listener ports with the default messaging provider in Version 7.0, you can continue to use listener ports with external JMS providers such as the WebSphere MQ messaging provider.

Listener ports can be manually started and stopped. When the listener port is stopped, the message-driven bean associated with it can no longer process messages. Furthermore, if a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. Because a JMS activation specification is a group of messaging configuration properties not a component, it cannot be manually started and stopped. For this reason, to prevent a message-driven bean from processing messages you must complete the following tasks:

- Stop the application that contains the message-driven bean.
- Stop the messaging engine.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using Java EE 1.4 and EJB 2.1 with the default message provider in WebSphere Application Server Version 7.0 or Version 6.x, you must use activation specifications. A connector message-driven bean uses JCA to access its resources, so the connector must be configured with an activation specification. This is for new bean development, and does not affect the conversion of message-driven beans from EJB 2.0 to EJB 2.1.
- If you are using Java EE 1.4 and EJB 2.1 with a third-party JMS provider in WebSphere Application Server Version 7.0 or Version 6.x, the decision depends on whether your JMS provider API is implemented with JCA. In Java EE 1.4, the JMS 1.1 API can be implemented with the JCA 1.5 API. If so, your message-driven bean is a JMS message-driven bean that is implemented as a connector message-driven bean, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for Java EE 1.3, and you must configure this EJB 2.1 message-driven bean in the same way as you would configure an EJB 2.0 message-driven bean, which in WebSphere Application Server is to use a listener port.
- If you are using Java EE 1.3 and EJB 2.0 with WebSphere Application Server Version 5.1, you must use listener ports. The message-driven beans are JMS message-driven beans that implement `MessageListener`, and there is no Java EE Connector Architecture (JCA) support. WebSphere Application Server Version 5.1 uses listener ports to associate message-driven bean classes with their JMS destinations.

All the activation specification configuration properties apart from **Name**, **JNDI name**, **Destination JNDI name**, and **Authentication alias** are overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 message-driven bean. For an EJB 2.0 message-driven bean, the **Destination type**, **Subscription durability**, **Acknowledge mode** and **Message**

selector properties are overridden by the corresponding elements in the deployment descriptor. For either type of bean the **Destination JNDI name** property can be overridden by a value specified in the message-driven bean bindings.

To configure a JMS activation specification for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for creating a new JMS activation specification.

1. Display the default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure an activation specification.
3. Optional: Change the **Scope** check box to the scope level at which the activation specification is to be visible to applications, according to your needs.
4. In the content pane, under the Additional properties heading, click **Activation specifications**. This lists any existing JMS activation specifications for the default messaging provider in the content pane.
5. Display the properties of the JMS activation specification. If you want to display an existing activation specification, click one of the names listed.

Alternatively, if you want to create a new activation specification, click **New**, then specify the following required properties:

Name Type the name by which the activation specification is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the activation specification into the JNDI name space.

Destination type

Whether the message-driven bean uses a queue or topic destination.

Destination JNDI name

Type the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI name space.

Select the type of destination on the Destination type property.

Bus name

The name of the bus to connect to.

Specify the name of the service integration bus to which connections are made. This must be the name of the bus on which the bus destination identified by the Destination JNDI name property is defined.

You can either select an existing bus or type the name of another bus. If you type the name of a bus that does not exist, you must create and configure that bus before the activation specification can be used.

6. Specify properties for the JMS activation specification, according to your needs.
7. Optional: Specify the JMS activation specification connection properties that influence how the default messaging provider chooses the messaging engine to which your message-driven bean application connects. By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received. For information about why and how to do this, see How JMS applications connect to a messaging engine on a bus.
8. Click **OK**.
9. Save your changes to the master configuration.

Deleting JMS resources for the default messaging provider

Use this task with the WebSphere Application Server administrative console to delete JMS resources.

About this task

To delete JMS resources, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to delete resources.
3. In the content pane, under the Additional properties heading, select the link for the type of JMS resource:
 - Connection factory
 - Queue connection factory
 - Topic connection factory
 - Queue
 - Topic
 - Activation specification

This displays a list of the selected JMS resource type in the content pane.

4. Select the check box next to the JMS resource that you want to delete.
5. Click **Delete**
6. Save your changes to the master configuration.

Configuring JMS connection factory properties for durable subscriptions

Use this task to configure durable subscription properties of JMS connection factories for use by enterprise beans with the default messaging provider.

About this task

To enable applications to create durable subscriptions to JMS topics with the default messaging provider, you can set a number of properties on JMS connection factories.

If applications use message-driven beans to create durable subscriptions, you should set the properties on the JMS activation specification used by the message-driven beans, as described in [Configuring JMS activation specifications for durable subscriptions](#), instead of using the task described in this topic.

This topic describes the setting of properties on a unified JMS connection factory. You can also set the same properties on a JMS topic connection factory instead.

To configure the durable subscription properties to a topic for use by enterprise beans with the default messaging provider, use the administrative console to complete the following steps:

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure connection factory properties.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Connection factories**. This displays any existing JMS connection factories for the default messaging provider in the content pane.
5. Click the name of the connection factory you want to configure. This displays the properties for the connection factory in the content pane.
6. Specify the following properties for the connection factory:

Client identifier

This is the JMS client identifier that applications need to identify durable topic subscriptions created on all connections using this connection factory. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

Durable subscription home

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.

This identifies the messaging engine where durable subscriptions are localized on the service integration bus. Administrators can manage the runtime state of durable subscriptions through publication points for that messaging engine.

7. Click **OK**.
8. Save your changes to the master configuration.

What to do next

When applications have created durable subscriptions, you can use the administrative console to manage the runtime state of those subscriptions, as described in “Administering durable subscriptions” on page 1324.

The JMS connection factory has some other advanced properties that you can configure to change the behavior for durable subscriptions. You should not normally need to change these properties from their defaults.

Read ahead

This controls read ahead optimization during message delivery. This defines whether or not the provider can stream messages to durable subscribers ahead of their requests (to provide a performance enhancement).

Share durable subscriptions

This controls whether or not durable subscriptions can be accessed simultaneously by several subscribers.

If you want to control read ahead optimization during message delivery for individual topics, you can set the Read ahead property on the topics.

Configuring JMS activation specification properties for durable subscriptions

Use this task to configure durable subscription properties of JMS activation specifications for use by message-driven beans with the default messaging provider.

About this task

To enable a message-driven bean (MDB) application to create durable subscriptions on JMS topics with the default messaging provider, you set a number of properties on the JMS activation specification used by the application.

If applications use message-driven beans to create durable subscriptions, you should set the properties on the JMS activation specification used by the message-driven beans, as described in this topic. Otherwise, for enterprise beans to create durable subscriptions, you should set the properties on the JMS connection factory as described in “Configuring JMS connection factory properties for durable subscriptions” on page 1688.

To configure the durable subscription properties to a topic for use by message-driven beans with the default messaging provider, use the administrative console to complete the following steps

1. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Select the default provider for which you want to configure activation specification properties.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.

4. In the content pane, under the Additional properties heading, click **Activation specifications**. This displays any existing JMS activation specifications for the default messaging provider in the content pane.
5. Click the name of the activation specification you want to configure. This displays the properties for the activation specification in the content pane.
6. Specify the following properties for the activation specification:

Client identifier

This is the JMS client identifier that applications need to identify durable topic subscriptions created on all connections using this activation specification. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

Durable subscription home

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

This identifies the messaging engine where durable subscriptions are localized on the service integration bus. Administrators can manage the runtime state of durable subscriptions through publication points for that messaging engine.

Subscription durability

To be able to create durable subscriptions, set this property to Durable.

Subscription name

The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

7. Specify the properties for the activation specification, according to your needs.
8. Click **OK**.
9. Save your changes to the master configuration.

What to do next

When applications have created durable subscriptions, you can use the administrative console to manage the runtime state of those subscriptions, as described in “Administering durable subscriptions” on page 1324.

Enabling a provider to stream messages to cloned durable subscriptions

Use this task to enable a provider to stream messages to consumers ahead of their message requests. This is most often used by publish/subscribe consumers to provide a performance enhancement.

About this task

To indicate that a provider must stream messages to consumers, you can set the Read ahead property to Enabled. This property can be set on a connection factory to specify the behavior for all connections created using that connection factory. The property can also be set on JMS topics, to enable different behavior when sending messages to different JMS topics from the same connection.

You are recommended to leave this property set to Default, which enables the messaging provider to decide whether or not it should stream messages to consumers. The messaging provider makes this

decision based on the environment in which the durable subscriber is running. You should only set this property to enable message streaming if you are sure that a durable subscription is used by only one consumer at a time.

- In a non-cloned environment, the default setting enables messaging streaming for durable subscribers.
- For cloned durable subscribers (that is, a durable subscriber that is part of an application cloned in a server cluster), the default setting prevents message streaming and the messages on the subscription are shared among the clones. If you are moving from a non-cloned environment, to cloned durable subscribers, you may see a drop in performance. If you are sure that a durable subscription is still used by only one consumer at a time, you can enable message streaming as described in this topic.

Messages that are streamed to the consumer but are not consumed before the consumer disconnects are unlocked when the consumer closes. Only then do those messages become available for consumption by other consumers.

To force the messaging provider to stream messages to cloned durable subscriptions, use the administrative console to complete the following steps to change the connection factory:

1. Display the JMS connection factory; for example, as described in “Configuring a unified JMS connection factory for the default messaging provider” on page 1680. All clones of a durable subscriber use the same JMS connection factory.
2. Set the Read ahead property to Enabled.
3. Click **OK**.
4. Save your changes to the master configuration.

Enabling CMP entity beans and messaging engine data stores to share database connections

Use this task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

About this task

To enable CMP entity beans to share the database connections used by the data store of a messaging engine, complete the following steps.

1. Configure the data store to use a data source that is not XA-capable. For more information about configuring a data store, see “Configuring a JDBC data source for a messaging engine” on page 1285.
2. Select the Share data source with CMP option.

This option is provided on the JMS connection factory or JMS activation specification used to connect to the service integration bus that hosts the bus destination that is used to store and process messages for the CMP bean.

For example, to select the option on a unified JMS connection factory, complete the following steps:

- a. Display the default messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
- b. Select the default provider for which you want to configure a unified connection factory.
- c. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
- d. In the content pane, under Additional Properties, click **Connection factories**
- e. Optional: To create a new unified JMS connection factory, click **New**.

Specify the following properties for the connection factory:

Name Type the name by which the connection factory is known for administrative purposes.

JNDI name

Type the JNDI name that is used to bind the connection factory into the name space.

Bus name

Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics are assigned to.

- f. Optional: To change the properties of an existing connection factory, click one of the connection factories displayed. This displays the properties for the connection factory in the content pane.
- g. Select the check box for the Share data source with CMP field
- h. Click **OK**.
- i. Save your changes to the master configuration.

The JMS connection factory can only be used to connect to a “local” messaging engine that is in the application server on which the CMP beans are deployed.

3. Deploy the CMP beans onto the application server that contains the messaging engine, and specify the same data source as used by the messaging engine. You can use the administrative consoles to complete the following steps:
 - a. Optional: To determine the data source used by the messaging engine, click **Servers** → **Server Types** → **WebSphere application servers** → *server_name* → **[Server messaging] Messaging engines** → *engine_name* → **[Additional Properties] Message store** The **Data source name** field displays the name of the data source; by default:
`jdbc/com.ibm.ws.sib/engine_name`
 - b. Click **Applications** → **New Application** → **New Enterprise Application**.
 - c. On the first Preparing for application install page, specify the full path name of the source application file (.ear file otherwise known as an EAR file), then click **Next**
 - d. On the second Preparing for application install page, complete the following steps:
 - 1) Select the check box for the Generate Default Bindings property. Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source user name password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
 - 2) Under Connection Factory Bindings, click the check box for the **Default connection factory bindings**: property, then type the JNDI name for the data source and optionally select a **Resource authorization** value.
 - 3) Click **Next**
4. If your application uses EJB modules that contain Container Managed Persistence (CMP) beans that are based on the EJB 1.x specification, for Step: Provide default data source mapping for modules containing 1.x entity beans, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
5. If your application has CMP beans that are based on the EJB 1.x specification, for Step: Map data sources for all 1.x CMP, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, then a validation error displays after you click **Finish** (step 13) and the installation is cancelled.
6. Complete other panels as needed.
7. On the Summary panel, verify the cell, node, and server onto which the application modules will install:
 - a. Beside Cell/Node/Server, click the **Click here** link.
 - b. Verify the settings on the Map modules to servers page displayed. Ensure that the application server that is specified contains the messaging engine and its data store.

- c. Specify the Web servers as targets that will serve as routers for requests to this application. This information is used to generate the plug-in configuration file (plugin-cfg.xml) for each Web server.
- d. Click **Finish**.

Results

For more information about installing applications, see [Installing application files with the console](#).

Configuring a connection to a non-default bootstrap server

A bootstrap server is an application server running in the same cell, specifically the same core group, as the service integration bus.

About this task

Connection to a non-default bootstrap server is provided by a JMS connection factory or a JMS activation specification. The connection allows applications to use a bootstrap server with a non-default endpoint address. The provider endpoint syntax example described here is also relevant to bootstrap endpoint configuration in other tasks, for example when configuring a service integration bus link.

To use JMS destinations of the default messaging provider, an application or MDB connects to a messaging engine on the target service integration bus where the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Applications running in a server that is part of the same cell as the service integration bus can normally connect to a messaging engine on that bus without requiring the configuration of provider endpoints. If the cell has been split using two core groups, each defined with its own policies, client applications that are running in a client container and client applications running outside the WebSphere Application Server environment cannot automatically locate the required service integration bus so it is necessary to configure one or more provider endpoints, unless a core group bridge has been configured between the core groups in the same cell. Similarly, an application running on a server in one cell cannot connect to a bus in another cell without the configuration of provider endpoints, unless a core group bridge has been established between the two cells.

In the scenarios where provider endpoints are required, the clients or the servers in another bus must complete a bootstrap process through a bootstrap server. The bootstrap server does not have to be a member of the service integration bus, and it does not have to contain any messaging engines. For the application to locate the required bootstrap server, the provider endpoint property of the JMS connection factory or JMS activation specification used by the client application must be configured. When the bootstrap server receives the client request, it selects a messaging engine that matches the criteria specified by the connection factory or activation specification, for example the target transport chain, target group, connection proximity. It returns the location information for this messaging engine to the client, and the client transparently creates a new connection to the target messaging engine if necessary.

Figure 17. Connection to a messaging engine - Applications running outside an application server. This figure shows a client application running outside an application server. To connect to a messaging engine, the application connects first to a bootstrap server. The bootstrap server selects a messaging engine then tells the client application to connect to that messaging engine.

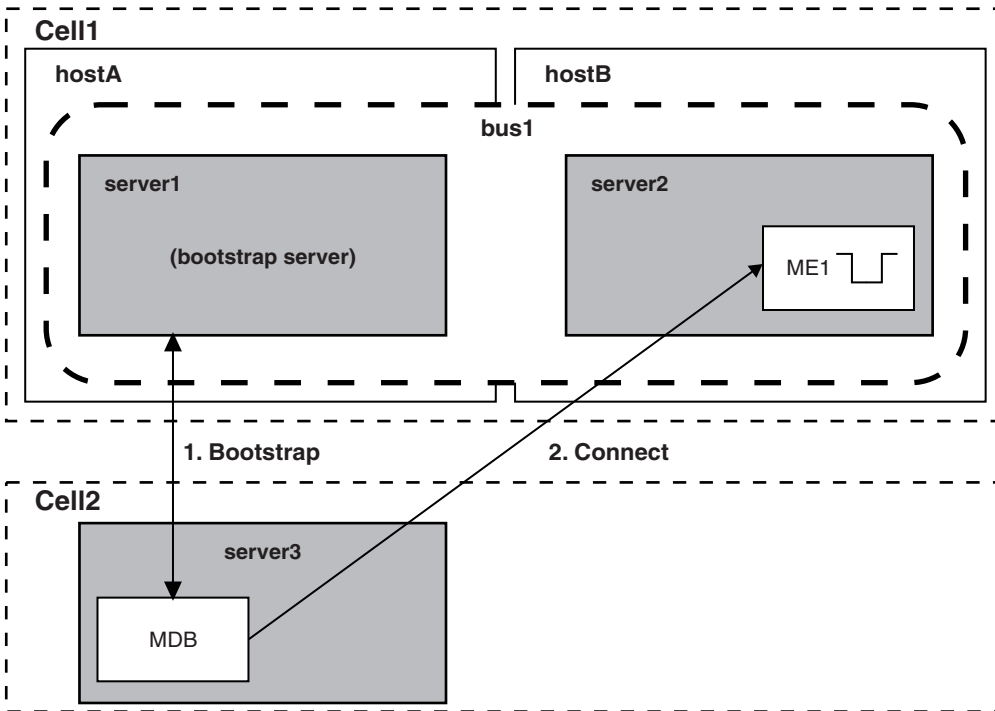

Figure 18. Connection to a messaging engine - MDB application connecting to a destination in a different cell. This figure shows an MDB running in an application server that is in a different cell to the bus that the MDB needs to be connected to in order to receive messages. To connect to a messaging engine, the MDB connects first to a bootstrap server. The bootstrap server selects a messaging engine then tells the MDB to connect to that messaging engine.

A bootstrap server listens on an endpoint that is defined by the combination of:

- the host name of the host on which the bootstrap server is running
- a specific port which is either `SIB_END_POINT` or, if security is enable, `SIB_ENDPOINT_SECURE_ADDRESS`
- a bootstrap transport chain

The properties of a JMS connection factory or activation specification used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine. If a provider endpoint is not specified, a default value is inserted depending on whether or not a password has been supplied. If the application does not supply a password, a default endpoint address of `localhost:7276:BootstrapBasicMessaging` is used. That is, by default, applications try to use a bootstrap server on the same host as the client, and using port 7276 and the predefined bootstrap transport chain called `BootstrapBasicMessaging`. If the application does supply a password, the default secure port of 7286 and transport chain of `BootstrapSecureMessaging` is provided to prevent transmission of an unencrypted password to the server.

If you want an application to use a bootstrap server with a different endpoint address, you need to specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories or JMS activation specifications that the client application or MDB uses. You can specify one or more endpoint addresses of bootstrap servers using a comma separated list.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only need to specify a short list of bootstrap servers on each connection factory.

This task is based on an application that uses a unified JMS connection factory. You can use the same task to configure a JMS queue connection factory or JMS topic connection factory, but during the task would need to select the appropriate type of connection factory instead of **JMS connection factory**. You can also use this task to configure a JMS activation specification instead of a JMS connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values using colons as separators. The syntax is as follows:

```
[ [host_name] [ ":" [ port_number] [ ":" chain_name] ] ]
```

Specifying `host_name : chain_name` instead of `host_name : : chain_name` (with two colons) is incorrect. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

For an application to use a bootstrap server with a non-default endpoint address, complete the following steps:

1. Identify the endpoint address of the application server that you want to use as the bootstrap server. The endpoint address has the form `host_name:port_number:chain_name` where:

host_name

is the name of the host on which the server runs. It can be an IP address. In the case of an IPv6 address, put square braces ([]) around *host_name*. The default is localhost.

port_number

where specified, is one of the following addresses of the messaging engine hosting the remote end of the link:

- SIB_ENDPOINT_ADDRESS if security is not enabled
- For secure connections, SIB_ENDPOINT_SECURE_ADDRESS if security is enabled.

This value is mandatory. The default is 7276 if the application has not specified a password, or 7286 if a password has been specified.

To find either of these values by using the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** → *server_name* → **[Communications] Ports**.

chain_name

is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging if a password has not been provided, or BootstrapSecureMessaging if a password has been provided.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging

This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging

This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers** → **Server Types** → **WebSphere application servers** → *server_name* → **[Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP using HTTP wrappers.

BootstrapTunneledSecureMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers** → **Server Types** → **WebSphere application servers** → *server_name* → **[Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP using HTTP wrappers.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. You should be able to specify the endpoint address for each bootstrap server; for example: for a server assigned non-secure port 7278, on host boothost1, and using the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
```

or

```
boothost1:7278
```

and for a server assigned secure port 7289, on host boothost2, and using the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

2. Optional: Configure the endpoint address of the bootstrap server on the Provider endpoint property of the connection factory.

If the client application uses a JMS connection factory in the client container, use the Client Resource Configuration tool (ACRCT):

- a. Start the tool and open the EAR file for which you want to configure the JMS connection factory. The EAR file contents are displayed in a tree view.
- b. From the tree, select the JAR file in which you want to configure the JMS connection factory.
- c. Expand the JAR file to view its contents.
- d. Expand **Messaging Providers > Default Provider > Connection Factories**.
- e. Display the general properties of the connection factory:
 - If you want to use an existing JMS connection factory, click the name of the connection factory.
 - If you want to create a new JMS connection factory, click **New**.For more information about configuring a JMS connection factory in the JMS provider configuration for your application client, see *Configuring new JMS providers with the Application Client Resource Configuration Tool*.
- f. On the General tab, ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses; for example:

```
boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging
```

- g. Click **OK**.
- h. To save your changes, click **File > Save**.

If the client application uses a JMS connection factory on the server, use the WebSphere Application Server administrative console:

- a. Start the WebSphere Application Server administrative console.
- b. To display the default messaging provider, click **Resources** → **JMS** → **JMS providers**.
- c. Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
- d. In the content pane click **Default messaging provider**. This displays a table of properties for the default messaging provider, including links to the types of JMS resources that it provides.
- e. In the content pane, under Additional Properties, click **Connection factories**. This displays any existing connection factories in the content pane.
- f. Display the general properties of the connection factory:
 - If you want to use an existing JMS connection factory, click the name of the connection factory.
 - If you want to create a new JMS connection factory, click **New**.For more information about configuring a JMS connection factory, see “Configuring a unified JMS connection factory for the default messaging provider” on page 1680.

- g. Ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses; for example:
`boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging`
 - h. Click **OK**.
 - i. Save your changes to the master configuration.
3. Optional: Follow this step to configure the endpoint address of the bootstrap server on the Provider endpoint property of the activation specification.
- If the client application uses a JMS activation specification on the server, use the WebSphere Application Server administrative console:
- a. Start the WebSphere Application Server administrative console.
 - b. To display the default messaging provider, click **Resources** → **JMS** → **JMS providers**.
 - c. Select the default provider for which you want to configure an activation specification.
 - d. Optional: Change the **Scope** check box to the scope level at which the activation specification to be visible to applications, according to your needs.
 - e. In the content pane, under the Additional Properties heading, click **Activation specifications**. This lists any existing JMS activation specifications for the default messaging provider in the content pane.
 - f. Display the properties of the JMS activation specification:
 - If you want to use an existing JMS activation specification, click one of the names listed.
 - If you want to create a new JMS activation specification, click **New**.

For more information about configuring a JMS activation specification, see “Configuring a JMS activation specification for the default messaging provider” on page 1686.
 - g. Ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses; for example:
`boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging`
 - h. Click **OK**.
 - i. Save your changes to the master configuration.

Configuring MDB throttling on the default messaging provider

Use this task to configure the throttling of messages for message-driven beans that you have deployed as JCA 1.5 resources on the default messaging provider.

About this task

Use this task if you want to throttle messages for a message-driven bean deployed as a J2EE Connector Architecture (JCA) 1.5 resource on the default messaging JMS provider.

The default messaging provider (the service integration bus JMS Resource Adapter) uses a special type of message throttling. You should use the throttling support described in this topic instead of the JCA 1.5 throttling of messages described in Throttling of inbound message flow for JCA 1.5 message-driven beans. You can leave the message-driven bean pools to the default size of 500.

The default messaging provider enables the throttling of message delivery to a message-driven bean through a configuration option on the JMS activation specification used to deploy the bean. This configuration option is labelled **Maximum concurrent endpoints** and can be found on the JMS activation specification panels in the administrative console.

- The maximum number of instances of each message-driven bean is controlled by the Maximum concurrent endpoint setting in the activation specification used to deploy the message-driven bean. This maximum concurrency limit helps prevent a temporary build up of messages from starting an excessive number of MDB instances. By default, the maximum number of concurrent MDB instances is set to 10.

The Maximum concurrent endpoints field limits the number of endpoints (instances of a given message-driven bean) that process messages concurrently. If the maximum has been reached, new messages are not accepted from the messaging engine for delivery until an endpoint finishes its current processing.

If the available message count (queue depth) associated with a message-driven bean is frequently high, and if your server can handle more concurrent work, you can benefit from increasing the maximum concurrency setting.

If you set the maximum concurrency for a message-driven bean, be sure that you specify a value smaller than the maximum number of endpoint instances that can be created by the adapter that the message-driven bean is bound to. If necessary, increase the endpoint instance limit.

- An activation specification also has a **Maximum batch size** that refers to how many messages can be allocated to an endpoint in one batch for serial delivery. So, for example, if you have set the Maximum concurrent endpoints property to 10 and the Maximum batch Size property to 3, then there can be up to 10 endpoints each processing up to 3 messages giving a total of 30 messages allocated to that message-driven bean. If there are multiple message-driven beans deployed against a single activation specification then these maximum values apply to each message-driven bean individually.
- Take care to ensure that you always set the Maximum concurrent endpoints property is always less than the JCA pool size.

Note: You might want to tune the throttling of your message-driven beans, which is especially important on z/OS. Workload arriving on the destination the message-driven bean is consuming from might use up more server resource and therefore obstruct other activities. An example of this is when restarting MDB applications you find a backlog of messages. The number of messages can be throttled so that the message-driven bean can process them in the most efficient manner.

To configure the message throttling support of the default messaging provider (the service integration bus JMS Resource Adapter), use the administrative console to complete the following steps.

- Tune the maximum number of instances of a message-driven bean.

The maximum concurrency is set in the activation specification used to deploy the message-driven bean.

1. Click **Resources** → **Resource Adapters** → **J2C activation specifications** → **activation_specification_name** → → **[Additional Properties] J2C activation specification custom properties**.
2. View the maxConcurrency custom property. The default value is 10. For high throughput primitive MDB tests, 40 was found to be an optimal value.
3. Optional: To change the maxConcurrency setting, click the value field. This displays a panel for you to type a new value. In the Value field, type the new value then click **OK**. Save your changes to the master configuration.

- Tune the maximum batch size for a message-driven bean.

By default, only a single message is delivered to a message-driven bean instance at one time. You can improve performance by batching messages to the message-driven bean. Each message-driven bean instance then receives a number (between 1 and the batch size) of messages at a time. A change in the maximum concurrency is likely to be beneficial if the available message count (queue depth) associated with the message-driven bean is frequently high. For more information about the available message count, see View the Available Message Count on a destination. The maximum batch size is set in the activation specification used to deploy the message-driven bean.

1. Click **Resources** → **Resource Adapters** → **J2C activation specifications** → **activation_specification_name** → → **[Additional Properties] J2C activation specification custom properties**.
2. View the maxBatchSize custom property. The default value is 1. For high throughput primitive MDB tests, 5 was found to be optimal value (providing a 20 per cent gain over batch size 1).

3. Optional: To change the `maxBatchSize` setting, click the value field. This displays a panel for you to type a new value. In the Value field, type the new value then click **OK**. Save your changes to the master configuration..

Protecting a message-driven bean from system resource problems

This task describes how to configure the system so that, in the event of a dependent external system resource problem, the enterprise application is stopped before messages are moved to an exception destination unnecessarily. This configuration also allows occasional problems with messages to be handled without blocking the enterprise application.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources. To complete this task an exception destination must be configured for the messaging engine, and you need the following information:

- The enterprise application that contains the MDB
- The dependent external system resources
- An acceptable value for the **Sequential failed message threshold**, that is, the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- An acceptable value for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages may be delivered during this period, unless the **Sequential failed message threshold** and the maximum concurrency is set to 1.
- An acceptable value for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

When an MDB fails to process a message, the message is rolled back and made available to the MDB again. Typically, the messaging system is configured in one of the following ways:

1. Failed messages are retried a finite number of times, and if they continue to fail are moved to an exception destination allowing subsequent messages to be processed.
2. Failed messages are retried indefinitely until the problem is rectified.

Configuration (1) protects the MDB against an occasional problem message that prevents subsequent messages from being processed. However if there is a prolonged problem with a resource that the MDB's enterprise application is dependent on, for example a database, all messages that are sent to the destination may be moved to the exception destination.

Configuration (2) blocks the delivery of messages until the original failing message problem is resolved. This configuration prevents messages being moved to an exception destination unnecessarily, but it also blocks subsequent messages as soon as a single problem message fails to be processed.

An MDB's activation specification can be configured to stop an MDB endpoint automatically when it detects a number of failures with sequential messages, which indicates a problem with a dependent resource. When the problem is resolved, the MDB endpoint is restarted manually. This configuration tolerates occasional message failures, allowing individual problem messages to be moved to the exception destination without blocking the entire MDB.

Follow these steps to protect an enterprise application from dependent external system resource failures.

1. Navigate to the deployed enterprise application that contains the MDB.

2. From the MDB, navigate to its JMS activation specification, **Resources** → **JMS** → **Activation specifications** → *activation_specification_name*.
3. Enter a value for the **Sequential failed message threshold**.
4. Save the configuration and navigate to the destination to which the MDB is listening, **Service integration** → **Buses** → *bus_name* → [**Destination resources**] **Destinations** → *queue_name* or **Service integration** → **Buses** → *bus_name* → [**Destination resources**] **Destinations** → *topic_space_name*.
5. Check **Override messaging engine blocked retry timeout default** and enter a value for the **Blocked retry timeout in milliseconds**.
6. Enter a value for the **Maximum failed deliveries per message**.
7. Save your changes to the master configuration..

Results

You have configured the enterprise application to protect itself from the sort of external resource problem that can occur at any time. This means that, in the event of a system resource problem, the MDB is stopped automatically when the Sequential failed message threshold is reached for any message.

What to do next

When the system resource that failed becomes available, you can restart the system resource and resume the MDB. The messages that failed during the system resource downtime are retried instead of being left on an exception destination.

Example 1: Handling a planned outage of a message-driven bean's external resource:

This task describes how to configure the system so that, in the event of a dependent external system resource problem, the enterprise application can continue.

Before you begin

During the time that the system resource is unavailable, there must be no exceptions in the enterprise application or messages on the exception destination that need to be resolved later.

About this task

Add a maintenance level to an external system resource that is used by the deployed message-driven bean (MDB) of one of the company's enterprise applications. The act of applying the maintenance level requires the system resource (for example, a database) to be unavailable for about five minutes.

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification, **Resources** → **JMS** → **Activation specifications** → *activation_specification_name* and click **Pause** on the administrative panel for the MDB.
3. When you receive a JMX notification and a log entry indicating that the MDB has been paused, stop the database and apply the maintenance level. While the MDB is paused, no messages are sent to the exception destination and no error messages appear in the console related to the stopped database.
4. Restart the database and test that it is working as expected.
5. Log onto the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB using scripting using the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have paused and resumed an application while an external resource that it uses is briefly not available.

Example 2: Automatically stopping a message-driven bean when a system resource becomes unavailable:

To prepare for a system resource becoming unavailable, configure the system to stop the message-driven bean automatically after a small number of message failures and alert you to the problem.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources. To complete this task an exception destination must be configured for the messaging engine, and you need the following information:

- The enterprise application that contains the MDB
- The dependent external system resources
- Set a value of 3 for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- Set a value of 5000 for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages may be delivered during this period, unless the **Sequential failed message threshold** and the maximum concurrency is set to 1.
- Set a value of 5 for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

Scenario: The enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

When this resource experiences a problem and is no longer available, the deployed MDB can no longer access this resource and so the transaction associated with the MDB is rolled back and the message (msg1 in this scenario) is put back on the queue.

Instead of msg1 being made available to the MDB immediately, it is hidden for the MDB's **Delay between failing message retries** retry delay of five seconds.

The next message on the queue (msg2) is processed by the MDB. The external resource is still unavailable so the processing of this message also fails and the message's transaction is rolled back. This message is also hidden for five seconds and the next message on the queue (msg3) is processed, fails and is also hidden.

When the number of hidden messages reaches the **Sequential failed message threshold**, the MDB will not process any further messages until one of the hidden messages becomes re-available.

When the **Delay between failing message retries** for msg1 expires, msg1 is unhidden and reprocessed. Because the resource is still unavailable, it is re-hidden. This also happens to msg2 and msg3.

Note: A message is considered a failed message when it is rolled back one less than the **Maximum failed deliveries per message** limit (five times in this scenario). So once msg1 is unhidden for the fourth time, rolled back and rehidden, the sequential failure count is incremented. At which point

msg2 becomes unhidden, rolled back and rehidden. Similarly, msg3 becomes unhidden, rolled back and rehidden. The sequential failure count reaches the **Sequential failed message threshold** and the MDB stops automatically. A JMX notification is emitted by the JCA MBean and a log entry alerts the system administrator that the MDB has stopped.

Note: In this scenario, the MDB is automatically stopped when the system resource has been unavailable for approximately 20 seconds. If the system resource was unavailable for less than this time, the system could continue normally, and without numerous messages being sent to the exception destination.

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification, **Resources** → **JMS** → **Activation specifications** → *activation_specification_name*.
3. Enter a value of 3 for the **Sequential failed message threshold**.
4. Save the configuration and navigate to the destination to which the MDB is listening, **Service integration** → **Buses** → *bus_name* → **[Destination resources] Destinations** → *queue_name* or **Service integration** → **Buses** → *bus_name* → **[Destination resources] Destinations** → *topic_space_name*.
5. Check **Override messaging engine blocked retry timeout default** and enter a value of 5000 for the **Blocked retry timeout in milliseconds**.
6. Enter a value of 5 for the **Maximum failed deliveries per message**.
7. Save your changes to the master configuration..
8. When you receive a JMX notification and a log entry indicating that the MDB (or endpoint) has been paused, investigate the problem with the system resource that the MDB was using. While the MDB is paused, no messages are sent to the exception destination and no error messages appear in the console related to the stopped database.
9. When the system resource that failed becomes available, restart it.
10. Log onto the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB using scripting using the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have configured the system to protect itself from external resource failures.

What to do next

When the MDB is resumed, the JCA MBean emits a JMX notification to indicate that the MDB has resumed. Messages on the queue are consumed, messages that had failed are retried, and the transaction commits.

Example 3: The system experiences problems with a problem message:

To prepare for a problem message, configure the system to move that message to an exception destination and allow other messages to be processed successfully.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources. To complete this task an exception destination must be configured for the messaging engine, and you need the following information:

- The enterprise application that contains the MDB
- The dependent external system resources

- Set a value of 3 for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- Set a value of 5000 for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages may be delivered during this period, unless the **Sequential failed message threshold** and the maximum concurrency is set to 1.
- Set a value of 5 for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

Scenario: The enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

When a problem message (msg1 in this scenario) is encountered, it is put back on the queue.

Instead of msg1 being made available to the MDB immediately, it is hidden for the MDB's **Delay between failing message retries** retry delay of five seconds.

The next message on the queue (msg2) is processed by the MDB. This message and subsequent messages succeeds.

When the **Delay between failing message retries** for msg1 expires, msg1 is unhidden and reprocessed. It is put back on the queue again.

The MDB continues to process subsequent messages normally but each time msg1 is processed, it is put back on the queue.

When the number of times msg1 has been unhidden, rolled back and rehidden reaches the **Maximum failed deliveries per message** limit (five times in this scenario), it is moved to the configured exception destination.

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification, **Resources** → **JMS** → **Activation specifications** → *activation_specification_name*.
3. Enter a value of 3 for the **Sequential failed message threshold**.
4. Save the configuration and navigate to the destination to which the MDB is listening, **Service integration** → **Buses** → *bus_name* → [**Destination resources**] **Destinations** → *queue_name* or **Service integration** → **Buses** → *bus_name* → [**Destination resources**] **Destinations** → *topic_space_name*.
5. Check **Override messaging engine blocked retry timeout default** and enter a value of 5000 for the **Delay between failing message retries**.
6. Enter a value of 5 for the **Maximum failed deliveries per message**.
7. Save your changes to the master configuration..

Results

You have configured the system to protect itself from external resource failures and send problem messages to the exception destination.

Example 4: Automatically stopping a message-driven bean when no exception destination has been defined:

To prepare for a system resource becoming unavailable or a problem message, configure the system to stop the message-driven bean automatically. To maintain message ordering, do not configure an exception destination.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources. To complete this task no exception destination must be configured for the messaging engine, and you need the following information:

- The enterprise application that contains the MDB
- The dependent external system resources
- Set a value of 1 for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- Set a value of 5000 for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages may be delivered during this period, unless the **Sequential failed message threshold** and the maximum concurrency is set to 1.
- An acceptable value for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

Scenario: The enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

When a problem message (msg1 in this scenario) is encountered, it is put back on the queue.

Instead of msg1 being made available to the MDB immediately, it is hidden for the MDB's **Blocked retry timeout in milliseconds** retry delay of 30 seconds.

When the number of hidden messages reaches the **Sequential failed message threshold**, the MDB will not process any further messages until one of the hidden messages becomes re-available. In this scenario, this threshold is reached as soon as msg1 is hidden.

When the **Blocked retry timeout in milliseconds** for msg1 expires, msg1 is unhidden and reprocessed.

This process is repeated until msg1 reaches its **Maximum failed deliveries per message** limit (five times in this scenario).

Once msg1 is unhidden for the fourth time, rolled back and rehidden, the **Sequential failed message threshold** is reached and the MDB stops automatically. A JMX notification is emitted by the JCA MBean and a log entry alerts the system administrator that the MDB has stopped.

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification, **Resources** → **JMS** → **Activation specifications** → *activation_specification_name*.
3. Enter a value of 1 for the **Sequential failed message threshold**.
4. Save the configuration and navigate to the destination to which the MDB is listening, **Service integration** → **Buses** → *bus_name* → **[Destination resources] Destinations** → *queue_name* or **Service integration** → **Buses** → *bus_name* → **[Destination resources] Destinations** → *topic_space_name*.

5. Check **Override messaging engine blocked retry timeout default** and enter a value of 30 for the **Blocked retry timeout in milliseconds..**
6. Enter a value of 5 for the **Maximum failed deliveries per message.**
7. Save your changes to the master configuration..
8. When you receive a JMX notification and a log entry indicating that the MDB (or endpoint) has been paused, investigate the problem. While the MDB is paused, as no exception destination is configured, msg1 remains on the queue. No other messages are processed
9. If you resume the MDB but the problem with the failing message continues, the maximum failed deliveries limit is reached on the first retry of the message, but as no exception destination is configured the message is not moved to another queue. Instead, the whole queue point is blocked to all consumers for the destination block retry interval (30 seconds). After this time, consumers begin again. If the failing message is still there, and fails again, the queue point is blocked for another 30 seconds. This continues until you remove the failing message from the queue, either by deleting it manually or solving the problem with it, and in doing so allowing the consuming application to succeed in processing
10. Log onto the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB using scripting using the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have configured the system to protect itself from external resource failures while maintaining message ordering.

What to do next

When the MDB is resumed, the JCA MBean emits a JMX notification to indicate that the MDB has resumed. Messages on the queue are consumed, messages that had failed are retried, and the transaction commits.

Sample JMS 1.1 application client

This topic provides a typical example of JMS 1.1 application client code.

About this task

```
import java.util.Hashtable;
import javax.jms.JMSException;
import javax.naming.Context;
import javax.naming.*;
import javax.jms.*;

public class JMSppSampleClient
{
    public static void main(String[] args)
        throws JMSException, Exception
    {
        String messageID          = null;
        String outString          = null;
        String cfName             = "jms/blueconfactory";
        String qnameIn            = "java:comp/env/jms/Q1";
        String qnameOut           = "jms/bluequename";
        boolean verbose           = false;

        Session session          = null;
        Connection connection    = null;
        ConnectionFactory cf     = null;
    }
}
```

```

MessageProducer      mp          = null;
Destination          destination = null;

try {

    Hashtable env = new Hashtable();
    env.put(Context.INITIAL_CONTEXT_FACTORY,
            "com.ibm.websphere.naming.WsnInitialContextFactory");
    env.put(Context.PROVIDER_URL, "iiop://localhost:2809");
    Context initialContext = new InitialContext(env);
    System.out.println("Getting Connection Factory");

    cf= (ConnectionFactory)initialContext.lookup( cfName );

    System.out.println("Getting Queue");
    destination =(Destination)initialContext.lookup(qnameOut);

        System.out.println("Getting Connection for Queue");
    connection = cf.createConnection();

        System.out.println("staring the connection");
    connection.start();

        System.out.println("creating session");
    session = connection.createSession(false, 1);

        System.out.println("creating messageProducer");
    mp = session.createProducer(destination);

        System.out.println("creating TextMessage");
    TextMessage outMessage = session.createTextMessage("this is test application");

        System.out.println("sending Message");
    mp.send(outMessage);

    mp.close();
    session.close();
    connection.close();
}
catch (Exception je)    {}

```

Interoperating with a WebSphere MQ network

The default messaging provider (service integration) can interoperate with a WebSphere MQ network by using a WebSphere MQ link or a WebSphere MQ server. Alternatively, you can use WebSphere MQ as your messaging provider. Each type of connectivity is designed for different situations, and provides different advantages. Choose the most appropriate interoperation method for each of your messaging applications.

About this task

WebSphere Application Server can interoperate with WebSphere MQ in the following ways:

- By configuring WebSphere MQ as an external JMS provider using the WebSphere MQ messaging provider.
- By connecting a service integration bus to a WebSphere MQ network using the default messaging provider and a WebSphere MQ link.
- By integrating WebSphere MQ queues into a bus using the default messaging provider and a WebSphere MQ server.

A WebSphere MQ link provides a traditional WebSphere MQ -style solution to connecting resources. A WebSphere MQ server adds the ability to directly access WebSphere MQ queues from within a bus.

Table 16. The different ways of interoperating with WebSphere MQ

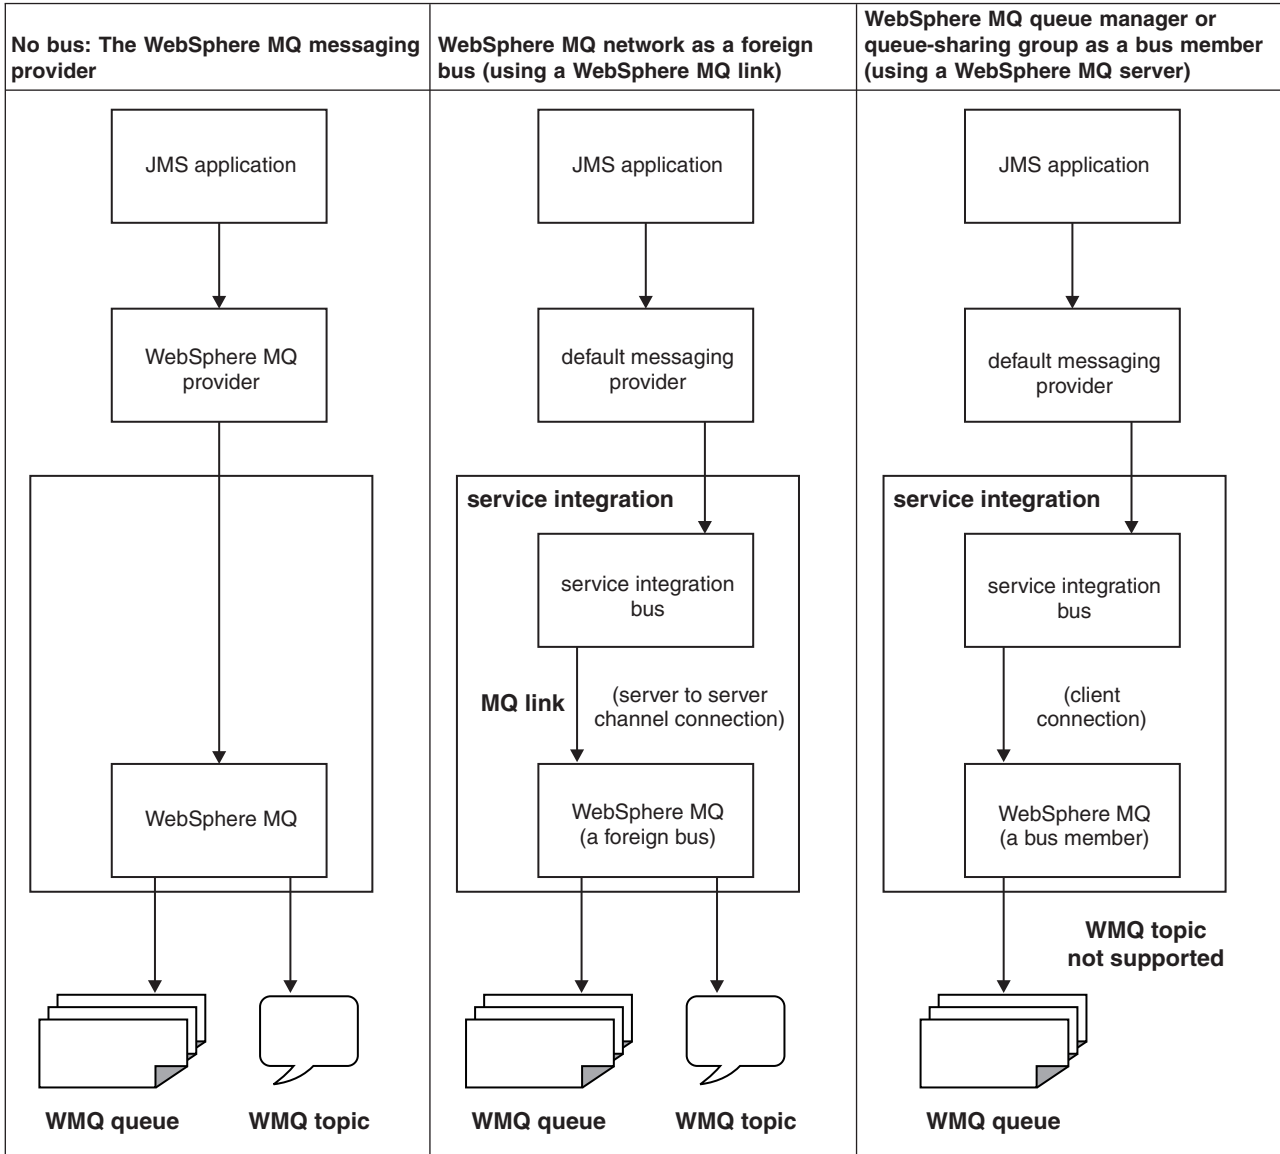

Table 16. The different ways of interoperating with WebSphere MQ (continued)

| No bus: The WebSphere MQ messaging provider | WebSphere MQ network as a foreign bus (using a WebSphere MQ link) | WebSphere MQ queue manager or queue-sharing group as a bus member (using a WebSphere MQ server) |
|--|--|--|
| <p>The WebSphere MQ messaging provider does not use service integration. It provides JMS messaging access to WebSphere MQ from WebSphere Application Server.</p> | <p>A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. When you use a WebSphere MQ link, the messaging bus is seen by the WebSphere MQ network as a virtual queue manager, and the WebSphere MQ network is seen by service integration as a foreign bus. A WebSphere MQ link allows WebSphere Application Server applications to send point-to-point messages to WebSphere MQ queues (defined as destinations in the service integration bus), and allows WebSphere MQ applications to send point-to-point messages to destinations in the service integration bus (defined as remote queues in WebSphere MQ). The link also allows WebSphere Application Server applications to subscribe to messages published by WebSphere MQ applications, and WebSphere MQ applications to subscribe to messages published by WebSphere Application Server applications. The link ensures that messages are converted between the formats used by WebSphere Application Server and those used by WebSphere MQ.</p> | <p>A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. For interoperation with WebSphere Application Server Version 7.0, the version of WebSphere MQ must be WebSphere MQ for z/OS Version 6 or later, or WebSphere MQ (distributed platforms) Version 7 or later. A WebSphere MQ server supports the high availability and optimum load-balancing characteristics provided by a WebSphere MQ for z/OS network. A WebSphere MQ server defines the connection and quality of service properties used for the connection, and also ensures that messages are converted between the formats used by WebSphere Application Server and those used by WebSphere MQ.</p> |

For more information about these approaches, see Learning about interoperating with a WebSphere MQ network.

To interoperate with a WebSphere MQ network complete one or more of the following steps.

- Choose the most appropriate interoperation method for each of your messaging applications. Complete this step if your existing or planned messaging environment involves both WebSphere MQ and WebSphere Application Server systems, and it is not clear to you whether you should use the default messaging provider, the WebSphere MQ messaging provider, or a mixture of the two.
- Configure WebSphere MQ as an external JMS provider (WebSphere MQ messaging provider).
- Use WebSphere MQ links to connect a bus to a WebSphere MQ network.
- Use WebSphere MQ server to integrate WebSphere MQ queues into a bus.

Using WebSphere MQ links to connect a bus to a WebSphere MQ network

If you operate within a WebSphere Application Server environment, sending messages across a service integration bus, you can also exchange point-to-point and publish/subscribe messages with applications in a WebSphere MQ network. To do this, you configure a foreign bus connection that links to a WebSphere MQ network through a WebSphere MQ link.

Before you begin

Decide on which method you want to use to configure these resources. You can configure a WebSphere MQ link by using the administrative console as described in this task, or you can configure a WebSphere MQ link by using the wsadmin tool.

About this task

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. The link operates on a messaging engine in a service integration bus to provide functions that simplify and automate interoperation with WebSphere MQ.

Using the WebSphere MQ link panels of the WebSphere Application Server administration console, you can choose:

- The WebSphere MQ queue manager or queue-sharing group in the WebSphere MQ network through which your messages will flow
- Whether to enable WebSphere Application Server applications to publish and subscribe to a message broker in the WebSphere MQ network
- Learn about interoperating with a WebSphere MQ network.
- Create a new WebSphere MQ link.
- Administer an existing WebSphere MQ link.
- Create applications that can interoperate with WebSphere MQ. For more information, see Learning about programming for interoperation with WebSphere MQ.

Creating a new WebSphere MQ link:

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. Use the foreign bus connection wizard to create a foreign bus and link it to the WebSphere MQ network through a WebSphere MQ link.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new WebSphere MQ link by using the administrative console as described in this task, or you can create a new WebSphere MQ link by using the wsadmin tool.

The following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from (known as the local bus) with at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- (optionally) A sender channel to receive messages on the local bus, a receiver channel to send messages from the local bus, or both.
- (For publish-subscribe messaging) A topic and input queue for broker publish-subscribe flow.

About this task

You use the foreign bus connection wizard to connect a bus and a WebSphere MQ network. You can configure the connection for either point-to-point or publish-subscribe messaging.

Specifically, the wizard helps you configure the following resources:

- The bus and messaging engine on which the WebSphere MQ link is defined.
- The foreign bus that represents the WebSphere MQ network.
- The WebSphere MQ link.

- (Optionally) The sender and receiver channels and protocol. Using the wizard you can choose to define no channels (and add them afterward), or one channel if your WebSphere MQ link is to be one-way, or both channels.
- (Optionally) Security for messages flowing across the link.
- (Optionally) A publish/subscribe broker profile and associated topic mappings, to allow publication and subscription with a broker in the WebSphere MQ network.

The wizard does not ask you to set all possible properties of a WebSphere MQ link, and many of the properties are set to default values. You can fine tune these properties afterward if necessary, by modifying the WebSphere MQ link.

For a sample configuration showing a systems view of the setup for a WebSphere MQ link, see “WebSphere MQ link sample configuration” on page 1712.

1. Use the foreign bus connection wizard to connect a bus and a WebSphere MQ network to use point-to-point messaging or publish-subscribe messaging.

A WebSphere MQ link is created and configured as part of the action of the wizard.

Note: You can subsequently convert a point-to-point connection to a publish/subscribe connection, by adding a publish/subscribe broker on the WebSphere MQ link for the connection.

2. Optional: Modify the new WebSphere MQ link.

When you create a new WebSphere MQ link, the following properties are set to default values:

- Description
- Adoptable
- Exception destination
- Initial state
- Nonpersistent message speed

You can fine tune these properties by modifying the link.

3. Optional: Add or modify the WebSphere MQ receiver channel.

If you did not choose to **Enable Service integration bus to WebSphere MQ message flow** in the foreign bus connection wizard, you have not yet defined a WebSphere MQ receiver channel. If you did choose this option in the wizard, you have defined the receiver channel name, host name and communication port, and the wizard has used default values for the following properties:

- Inbound nonpersistent message reliability
- Inbound persistent message reliability
- Prefer queue points local to this link’s messaging engine
- Initial state

You can fine tune these properties by modifying the channel.

4. Optional: Add or modify the WebSphere MQ sender channel

If you did not choose to **Enable WebSphere MQ to Service integration bus message flow** in the foreign bus connection wizard, you have not yet defined a WebSphere MQ sender channel. If you did choose this option in the wizard, you have defined the sender channel name, host name, communication port and transport chain, and the wizard has used default values for the following properties:

- Disconnect interval
- Short retry count
- Short retry interval
- Long retry count
- Long retry interval
- Initial state

You can fine tune these properties by modifying the channel.

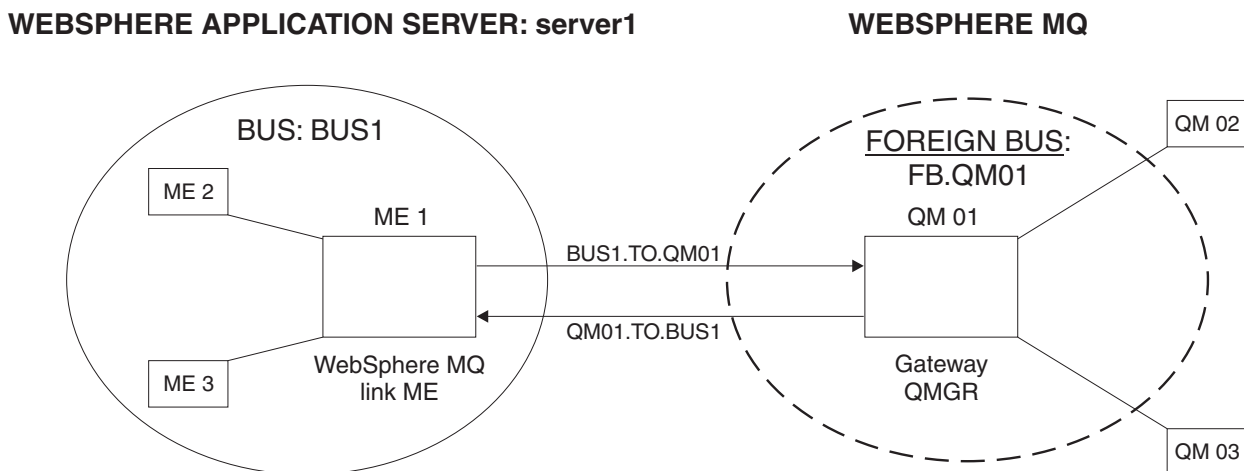

WebSphere MQ link sample configuration:

This topic describes a sample configuration sequence for connecting a WebSphere MQ link messaging engine on a WebSphere Application Server to a WebSphere MQ queue manager or queue-sharing group (known as a “gateway queue manager”) in a WebSphere MQ network.

Sample configuration context

This sample shows a set up required to achieve connectivity between a WebSphere Application Server messaging engine (ME), and a WebSphere MQ (Version 5.3 and above) network. Connectivity is achieved using WebSphere MQ link definitions (on a WebSphere Application Server) and WebSphere MQ channels (on a WebSphere MQ network). A WebSphere MQ link definition can be thought of as synonymous with a WebSphere MQ channel definition. A WebSphere MQ link defines the properties of both the sending and receiving ends of the link on a WebSphere Application Server.

The figure below shows an overview of the sample configuration.

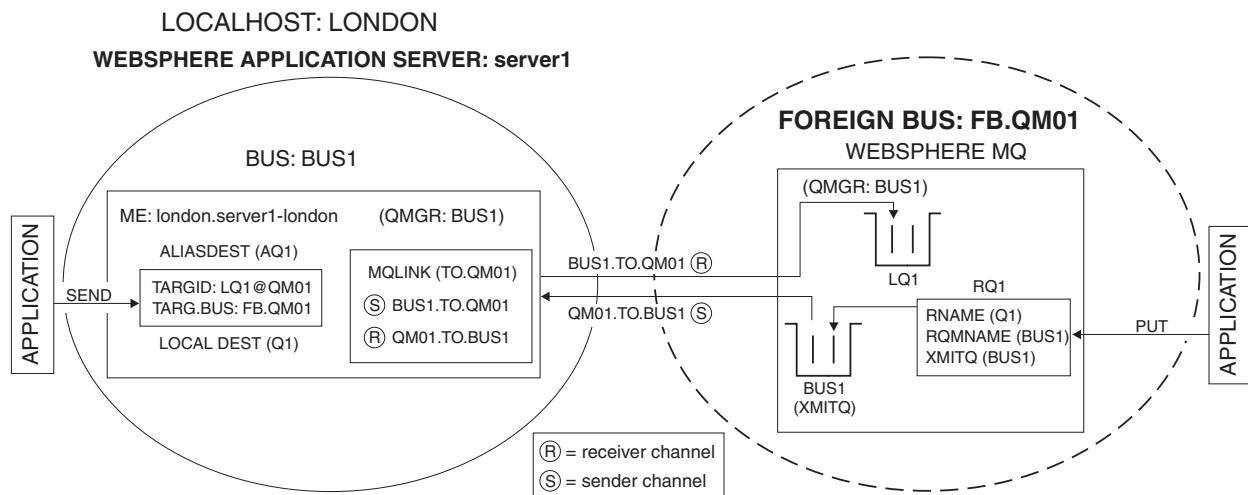

Configuration

- **Software:** IBM WebSphere Application Server and IBM WebSphere MQ.
- **Machine name:** LONDON (this is the local host).
- **WebSphere Application Server bus names:** Local Bus Name: BUS1. Foreign Bus Name: QM01 (this is the virtual bus name by which a remote WebSphere MQ queue manager is known to WebSphere Application Server; the remote WebSphere MQ queue manager may in turn be a part of a network of WebSphere MQ queue managers).
- **Name of WebSphere Application Server:** server1.
- **WebSphere Application Server messaging engine name:** london.server1-london.
- **WebSphere Application Server messaging engine virtual queue manager name:** BUS1 (this is the name by which the WebSphere Application Server messaging engine is known to a network of WebSphere MQ queue managers). As there is one messaging engine in the bus that is acting as a gateway to the WebSphere MQ network and, therefore, is used to send messages from, or receive messages for, any messaging engine in the bus, it is given the bus name.

- **WebSphere MQ queue manager name:** QM01 (This is the name of the gateway queue manager to the WebSphere MQ network. If the WebSphere MQ network consists only of this single queue manager, then it is also the name of the target queue manager. Otherwise, messages may first be routed to the gateway queue manager, from where they could be directed to the target queue manager.)
- **Listeners:**
 - By default, on a WebSphere Application Server, the listener for (unsecured) inbound connections from a WebSphere MQ JMS client, or from a WebSphere MQ queue manager, listens on port 5558.
 - By default, a listener is started on WebSphere MQ to listen on port 1414.

Overview of resource properties

The figure below shows the resources and their properties.

Properties of resources defined in WebSphere Application Server

- **WebSphere MQ link (a WebSphere MQ link is defined at the messaging engine level):**
 - **Name:** (TO.QM01).
 - **Description:** (Link to send and receive data to and from queue manager QM01).
 - **Foreign bus name:** (FB.QM01).
 - **Queue manager name:** (BUS1) - the virtual queue manager name by which WebSphere Application Server is known to WebSphere MQ.
 - **Batch Size:** 50 (default).
 - **Maximum message size:** 4194304 (default).
 - **Heartbeat:** 300 (default).
 - **Sequence wrap:** 999999999 (default).
 - **Nonpersistent message speed:** Fast (default).
 - **Adoptable:** *Ticked* (default).
 - **Initial state:** Started (default).
- **WebSphere MQ link receiver (this is defined at the messaging level when defining the WebSphere MQ link):**
 - **Receiver channel name:** (QM01.TO.BUS1).
 - **Inbound nonpersistent message reliability:** Reliable (default).
 - **Inbound persistent message reliability:** Assured (default).
 - **Initial State:** Started (default).

- **WebSphere MQ link sender (this is defined at the messaging level when defining the WebSphere MQ link):**
 - **Sender channel name:** (BUS1.TO.QM01).
 - **Host name:** (LONDON).
 - **Port:** 1414 (default).
 - **Disconnect interval:** 900 (default).
 - **Short retry count:** 10 (default).
 - **Short retry interval:** 60 (default).
 - **Long retry count:** 999999999 (default).
 - **Long retry interval:** 1200 (default).
 - **Initial State:** Started (default).
 - **Server:** By default server1 is created during installation (this has been used for this example).
 - **Local Bus:** When installing an application server, a default bus is created. The name for this is produced from the node name specified at install time. It is london in this example setup.
 - **Foreign Bus:** (This is defined at the bus level and needs to be specified on the WebSphere MQ link definition and also on alias destinations.)
 - **Name:** (FB.QM01).
 - **Description:** (Foreign bus needed to send messages to queue manager QM01).
 - **Destination defaults on foreign bus:**
 - **Default priority:** (0).
 - **Reliability:** Assured persistent (default).
 - **Maximum reliability:** Assured persistent (default).
 - **Send allowed:** *Ticked*.
- Note: In this example context security is not set.
- **Routing definition on foreign bus:**
 - **Routing type:** MQLink.
 - **Name:** (RD.QM01).

Routing definition can be created from the foreign bus collection panel which you navigate to through **Buses>busname**. The name you supply is for administration purposes only, it has no effect on routing capacity or operation.

 - **Inbound userid:** In this example this field is left set to blanks.
 - **Outbound userid:** In this example this field is left set to blanks.

Properties of resources defined in WebSphere MQ

These examples use the syntax of the runmqsc definitional program for WebSphere MQ.

1. Sender Channel

```
DEFINE    CHL(QM01.TO.BUS1)
          CHLTYPE(SDR)
          TRPTYPE(TCP)
          CONNAME('LONDON(5558)')
          XMITQ(BUS1)
```

Define a TCP sender channel called 'QM01.TO.BUS1' with transmission queue 'BUS1' to WebSphere MQ.

Let all other channel properties default.

2. Receiver Channel

```
DEFINE    CHL(BUS1.TO.QM01)
          CHLTYPE(RCVR)
          TRPTYPE(TCP)
```

Define a TCP receiver channel called 'BUS1.TO.QM01'.

Let all other channel properties default.

3. Transmission Queue

```
DEFINE QL(BUS1)
        USAGE(XMITQ)
```

Define a local queue called 'BUS1' which will be used as the transmission queue for the sender channel.

Let all other channel properties default.

Sending messages from WebSphere MQ to a WebSphere Application Server destination

To send messages from WebSphere MQ to WebSphere Application Server, the following resources are defined:

- Resources on WebSphere MQ

- Remote Queue

```
DEFINE QR(RQ1)
        RNAME(Q1)
        RQMNAME(BUS1)
        XMITQ(BUS1)
```

Define a remote queue definition called 'RQ1'. This definition specifies that the remote queue name is 'Q1' and the remote queue manager name is 'BUS1'. The transmission queue associated with the remote queue definition is 'BUS1'.

Let all other channel properties default.

- Resources on WebSphere Application Server

- Create a queue destination on the messaging engine with the MQ link (this is defined at the bus level):

- Identifier (Q1).
- Description: (Local queue to receive messages from a WebSphere MQ network).
- Reliability: Assured persistent (default).

- Create default messaging resources. The JMS queue points to the bus queue Q1:

Let this default to the local bus and server1 (london:server1).

- An application sending messages would have WebSphere MQ resources configured for the queue manager QM01 and the WebSphere MQ queue destination would use the RQ1 queue.

An application connected to queue manager QM01 would put messages to remote queue RQ1. These messages would be routed to Q1 on the target messaging engine.

Sending messages from WebSphere Application Server to a target local queue on WebSphere MQ

To send messages from WebSphere Application Server to WebSphere MQ, the following resources are defined:

- Resources on WAS: Alias Destination (this is defined at the bus level):

- Identifier(AQ1).
- Description(Alias for target queue LQ1).
- Bus() - leave this blank to let it default.
- Target Identifier(LQ1@QM01).
- Target Bus(FB.QM01).
- Reliability(Inherit) - default.
- Maximum Reliability(Inherit) - default.
- Producer can override quality of service(Inherit) - default.

- Send allowed(Inherit) - default.
- Receive allowed(Inherit) - default.
- Default priority(-1) - default.
- Reply destination() - default.
- Reply destination bus() - default.
- Default Forward Routing Path() - default.
- Resources on WebSphere MQ: Local Queue
 - DEFINE QL(LQ1)
 - Let all other channel properties default.

An application connected to server1 would put messages to alias destination AQ1. These messages would be routed to LQ1 on target queue manager QM01.

Administering an existing WebSphere MQ link:

The WebSphere MQ link enables the exchange of point-to-point and publish/subscribe messages with a WebSphere MQ network. After you have created a WebSphere MQ link you can perform various administrative actions on the link.

About this task

The WebSphere MQ link connects a WebSphere Application Server and a WebSphere MQ network. Because these two systems are working together, their functions need to be in step so that each is aware of the status of the other. Administrative actions on the WebSphere MQ link and its functions include the following:

- Modify individual functions of the WebSphere MQ link .
 - You can modify the link itself, add or modify the sender channel and receiver channel, or define a broker profile and associated topic mappings.
- Modify security for a WebSphere MQ link.
- View the status of a WebSphere MQ link and its components. You can view the status of a WebSphere MQ link and its sender and receiver channels, and you can view the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile.
- Start a WebSphere MQ link.
- Stop a WebSphere MQ link.
 - When you stop the link, all its functions are stopped too. For example, stopping a WebSphere MQ link with broker profiles on it might leave a message broker in the WebSphere MQ network with a backlog of messages. For more information, see “Stopping a WebSphere MQ link” on page 1728, “Stopping the sender channel on a WebSphere MQ link” on page 1730 and “Stopping the receiver channel on a WebSphere MQ link” on page 1729.
- Delete a WebSphere MQ link or one of its components. When you remove a foreign bus connection between a service integration bus and a WebSphere MQ network, you also delete the associated WebSphere MQ link along with any publish/subscribe broker profiles and topic mappings. You can also delete a WebSphere MQ link publish/subscribe broker profile or delete a topic mapping from a WebSphere MQ link.

Modifying a WebSphere MQ link:

How and when to modify the properties of a WebSphere MQ link.

Before you begin

Decide on which method you want to use to configure these resources. You can modify a WebSphere MQ link by using the administrative console as described in this task, or you can modify a WebSphere MQ link by using the wsadmin tool.

You need to know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link you want to modify.

About this task

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. At any time after you create a new WebSphere MQ link, you can modify its properties.

When you use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”) to use point-to-point messaging or publish-subscribe messaging, one or more WebSphere MQ links are created and configured as part of the task. However the wizard does not ask you to set all possible properties of a WebSphere MQ link, and some of the link properties are not set or are set to default values. You can fine tune these properties by modifying the link.

When you create a new WebSphere MQ link, you can also choose not to create sender or receiver channels. These channels can be added later by modifying the link.

When you use the foreign bus connection wizard to create a WebSphere MQ link for point-to-point messaging, you can later modify the link for publish-subscribe messaging by adding a publish/subscribe broker profile to the link.

1. In the navigation pane, click, **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name*.

2. Modify the properties of the link.

For information about all the properties that you can modify, see WebSphere MQ link [Settings].

When you create a new WebSphere MQ link, the following properties are set to default values:

Description

An optional description for the WebSphere MQ link, for administrative purposes.

Adoptable

Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started. By default, this option is not selected.

Exception destination

The destination to which a message is forwarded by the system when it cannot be delivered to this destination. By default, exceptions are sent to the “System” destination. However, it can aid problem-solving if you separate these exceptions out from other system messages by sending them to another destination.

Initial state

Whether the WebSphere MQ link is started or stopped when the hosting messaging engine is first started. Until started, the WebSphere MQ link is unavailable. By default, the value is "Started".

Nonpersistent message speed

The class of service for nonpersistent messages on channels of this WebSphere MQ link. By default, the value is "Fast".

3. Configure the additional properties. You can configure any of the following additional properties of this WebSphere MQ link:
 - Publish/subscribe broker profiles
 - Receiver channel
 - Sender channel
 - Sender channel transmitters
4. Configure the related items. You can configure any of the following related items of this WebSphere MQ link:
 - Foreign bus connection
 - Link transmitters
5. Save your changes to the master configuration.
6. If you have enabled dynamic configuration updates, the changes take effect immediately (or on channel restart if you also modified WebSphere MQ link sender or receiver channels), otherwise restart the application server.

Adding or modifying a publish/subscribe broker on the WebSphere MQ link:

Defining a broker profile, part of the WebSphere MQ link, that forms a publish/subscribe bridge with a WebSphere MQ network.

Before you begin

You need to know the name of the bus, messaging engine name, and the name of the WebSphere MQ link on which you intend to create or modify the broker profile. You also need to know the queue manager name for the message broker in the WebSphere MQ network where the input queues for the required publication message flows are located.

About this task

A publish/subscribe broker profile, and associated topic mappings, allows publication and subscription with a broker in the WebSphere MQ network.

When you use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager to use publish-subscribe messaging, you can define a publish/subscribe broker profile and associated topic mappings. Alternatively, you can use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager to use point-to-point messaging, then later modify the WebSphere MQ link for publish-subscribe messaging by adding a publish/subscribe broker profile and associated topic mappings to the link.

After you have created the broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests.

1. In the navigation pane, click one of the following paths:
 - **Service integration** → **Buses** → *bus_name* → **[Topology]** **Foreign bus connections** → *foreign_bus_name* → **[Related Items]** **WebSphere MQ links** → *link_name* → **[Additional Properties]** **Publish/subscribe broker profiles**

- **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Publish/subscribe broker profiles**
2. In the content pane, either click **New** to add a new broker profile, or click the name of a existing broker profile that you want to modify.
 3. Add or modify the properties of the broker profile.
For information about the broker profile properties (name, description, broker queue manager name), see Publish/subscribe broker profiles [Settings].
For an existing broker profile you can only modify the description. Note that, for an existing broker profile created through using the foreign bus connection wizard, the broker profile name was generated automatically by adding “_broker_profile” to the end of the broker queue manager name.
 4. Optional: Under Additional properties, configure the topic mappings for this broker profile. For more information, see “Adding or modifying topic mappings on the WebSphere MQ link publish/subscribe broker” on page 1720.
 5. Click **OK**.
 6. Save your changes to the master configuration.

What to do next

After you have created the broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests. You can do this either by modifying the message broker configuration on the WebSphere MQ network, or by modifying the service integration bus configuration. See “Defining permissions for a WebSphere MQ link publish/subscribe broker to work with WebSphere MQ.”

Defining permissions for a WebSphere MQ link publish/subscribe broker to work with WebSphere MQ:

This topic gives a choice of ways to ensure that a service integration bus has authority with a message broker (in a WebSphere MQ network) to send subscription requests.

Before you begin

Before you start this task, you must have created a broker profile, part of a publish/subscribe bridge on a WebSphere MQ link.

About this task

When you have created a broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests. You can do this either by:

- Modifying the message broker configuration in the WebSphere MQ network if you are a WebSphere MQ administrator. Or
- Modifying the service integration bus configuration if you are a WebSphere Application Server administrator.

To ensure authority, do one of the following steps:

1. Modify the message broker configuration by granting WebSphere MQ permissions for the user “SIBServer”, which is the user name under which the publish/subscribe bridge control messages will be published.
2. Modify the service integration bus by setting the OutboundUserID of the foreign bus that represents the WebSphere MQ network (which you defined as part of the WebSphere MQ link configuration). The OutboundUserID should be set to a user ID that already has the relevant WebSphere MQ permissions

on the message broker install image. By doing this you can be sure the publish/subscribe bridge control messages will arrive at the message broker in the WebSphere MQ network with the appropriate user ID set in them.

What to do next

You are now ready to define topic mappings on the publish/subscribe broker profile.

Adding or modifying topic mappings on the WebSphere MQ link publish/subscribe broker:

Define topic mappings on a publish/subscribe broker profile, part of the publish/subscribe bridge on a WebSphere MQ link. A topic mapping is a mapping between a topic on a service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

Before you begin

You need to know the bus name, messaging engine name, WebSphere MQ link name and the name of the broker profile on which you intend to define the topic mappings.

About this task

Topic mappings are associated with a WebSphere MQ link publish/subscribe broker profile. Together, the profile and topic mappings enable publication and subscription with a broker in a WebSphere MQ network.

Note: Publication messages forwarded to a message broker in the WebSphere MQ network are republished on the same topic as they were originally published to in the service integration bus topic space, and vice versa.

To define topic mappings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Publish/subscribe broker profiles** → *profile_name* → **[Additional Properties] Topic mappings**

2. In the content pane, either click **New** to add a new topic mapping, or click the name of an existing topic mapping that you want to modify. The Topic Mapping [Settings] form is displayed.
3. Type the topic name.

The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

The topic name can contain wild cards that are in the service integration bus syntax. For more information, see Wild cards in topic mapping.

4. Select the name of the topic space that contains the topic. If you don't select a name the default is used.
5. Select the direction of publication flow. The direction of publication flow can be:

Bi-directional

Messages flow in both directions between the bus and WebSphere MQ.

To WebSphere MQ

Messages flow only from the bus to WebSphere MQ. That is, from WebSphere Application Server to a message broker in the WebSphere MQ network.

From WebSphere MQ

Messages flow only to the bus from WebSphere MQ. That is, from a message broker in the WebSphere MQ network to WebSphere Application Server.

6. Select the broker stream queue you want to use. If the queue you require is not on the list, click **other, please specify** then enter the name of the broker stream queue.

The broker stream queue in this instance is a queue on the WebSphere MQ queue manager to which the message broker is connected. This queue is being used as the input node for a message flow containing a publication node. Messages sent to this queue are processed by the message broker, then published to applications that have subscribed on the topic specified in the message.

Stream names are case sensitive.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

7. Select the WebSphere MQ message broker subscription point from which the service integration bus receives messages. If the subscription point you require is not on the list, click **other, please specify** then enter the name of the subscription point.

The default subscription point is used if no value is specified.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

8. Click **OK**.
9. Save your changes to the master configuration.
10. Optional: If you have enabled dynamic configuration updates, the changes take effect immediately. Otherwise, restart the application server.

Adding or modifying a WebSphere MQ link receiver channel:

How you can define the properties of the receiver channel on a WebSphere MQ link. This channel receives messages from the WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”). The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

Before you begin

You need to know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link with the receiver channel you intend to add or modify.

About this task

When you use the foreign bus connection wizard to connect a bus and a gateway queue manager to use point-to-point messaging or publish-subscribe messaging, the wizard does not ask you to set all possible properties of a WebSphere MQ link. If you did not choose to **Enable Service integration bus to WebSphere MQ message flow** in the foreign bus connection wizard, you have not yet defined a Websphere MQ receiver channel. If you did choose this option in the wizard, you have defined the receiver channel name, host name and port number, and the wizard has set the other properties to default values.

To add or modify a WebSphere MQ link receiver channel, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Receiver channel**.
2. In the content pane, either click **New** to add a new receiver channel, or click the name of a existing receiver channel that you want to modify.
3. Add or modify the properties of the channel.

For information about all the properties that you can modify, see WebSphere MQ link receiver channel [Settings].

If you used the foreign bus connection wizard to create the channel, the wizard has used default values for the following properties:

Inbound nonpersistent message reliability

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability. By default, the value is “Reliable”.

Inbound persistent message reliability

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability. By default, the value is “Assured”.

Prefer queue points local to this link’s messaging engine

When this check box is selected, the link prefers to send inbound messages to available queue points of target queue destinations that are located on the same messaging engine as the link. By default the check box is selected, which corresponds to the behavior in WebSphere Application Server Version 6.x and can make it easier to handle links in a mixed-version cell. If you clear the check box, preference is not given to local queue points and inbound messages are workload balanced across all available queue points of target queue destinations. This option (not to give preference to local queue points) is available only on links running on WebSphere Application Server Version 7.0.

Initial state

Whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable. By default, the value is “Started”.

4. Click **OK**.
5. Save your changes to the master configuration.
6. Restart the application server.

Adding or modifying a WebSphere MQ link sender channel:

How you can define the properties of the sender channel on a WebSphere MQ link. This channel sends messages to the WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”). The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

Before you begin

You need to know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link with the sender channel you intend to add or modify.

About this task

When you use the foreign bus connection wizard to connect a bus and a gateway queue manager to use point-to-point messaging or publish-subscribe messaging, the wizard does not ask you to set all possible properties of a WebSphere MQ link. If you did not choose to **Enable WebSphere MQ to Service integration bus message flow** in the foreign bus connection wizard, you have not yet defined a WebSphere MQ sender channel. If you did choose this option in the wizard, you have defined the sender channel name, host name, communication port and transport chain, and the wizard has set the other properties to default values.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Sender channel**.
3. In the content pane, either click **New** to add a new sender channel, or click the name of a existing sender channel that you want to modify.
4. Add or modify the properties of the channel.

For information about all the properties that you can modify, see WebSphere MQ link sender channel [Settings].

If you used the foreign bus connection wizard to create the channel, the wizard has used default values for the following properties:

Disconnect interval

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering. By default, the value is 900 seconds.

Short retry count

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked. By default, the value is 10.

Short retry interval

The number of seconds between attempts by the sender channel to restart after a communication or partner failure. By default, the value is 60 seconds.

Long retry count

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped. By default, the value is 999999999.

Long retry interval

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure. By default, the value is 1200 seconds.

Initial state

Whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable. By default, the value is "Started".

5. Click **OK**.
6. Save your changes to the master configuration.
7. Restart the application server.

Modifying security for a WebSphere MQ link:

Securing access between a service integration bus and a WebSphere MQ Queue Manager.

About this task

When you create a new WebSphere MQ link, you can use the foreign bus connection wizard to enable security:

- If the WebSphere MQ queue manager requires a secure connection, you can set the WebSphere MQ receiver channel to accept only connections that have secure sockets layer (SSL) based encryption.
- If the local bus is secure, you can set the service integration bus inbound user ID to replace the user ID in messages from the WebSphere MQ queue manager, so that these messages are authorized to access their destinations.

Use this task to secure the local and foreign bus that are part of a WebSphere MQ links configuration, and to secure an existing WebSphere MQ link that was not secured when it was first created.

For more general information about service integration bus security, see "Security" on page 1184.

1. Enable security on the service integration bus and the foreign bus representing the WebSphere MQ network. See "Disabling bus security" on page 1346.

2. Secure the link between the buses - see *Securing connections to a WebSphere MQ network*.
3. Grant access to the local bus for users who will be sending messages to the foreign bus - see *“Disabling bus security”* on page 1346.
4. Grant access to the foreign bus for users who will be sending messages to it - see *“Administering foreign bus roles”* on page 1365.
5. Optional: Give users access to foreign or alias destinations that will forward messages to a foreign bus - see *“Administering destination roles”* on page 1314.

Viewing the status of a WebSphere MQ link and its sender and receiver channels:

This topic describes how you can view the status of a WebSphere MQ link and its components, such as the sender and receiver channels.

Before you begin

You may want to view the status of a WebSphere MQ link or its components because:

- You intend to stop the WebSphere MQ link and you need to see if there are any messages currently held on it.
- You are about to delete the WebSphere MQ link and you need to verify there are no messages on it.
- Messages have not arrived at their expected destination and you want to check if they are being held, pending transmission over the WebSphere MQ link.

Note: If you attempt to start a WebSphere MQ sender channel that is already in **RUNNING** state, the WebSphere Application Server administrative console might occasionally incorrectly report the channel status as **INACTIVE**. If this happens, you can ignore the error because the channel is still running. To return the channel status to **RUNNING**, stop and then restart the channel.

About this task

To view the status of a WebSphere MQ link, use the administrative console to complete the following steps:

1. In the navigation pane, click one of the following paths:
 - **Service integration** → **Buses** → *bus_name* → **[Topology] Foreign bus connections** → *foreign_bus_name* → **[Related Items] WebSphere MQ links**
 - **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links**
2. Click the WebSphere MQ link you want to view.
3. Click the **Runtime** tab. The content pane displays the status of the WebSphere MQ link.
4. Click the **Configuration** tab.
5. To view the status of the sender channel:
 - a. Click **Sender channel**.
 - b. Click the channel you want to view.
 - c. Click the **Runtime** tab. The content pane displays status information for the sender channel. Some of the more important fields to check are:
 - The status of the channel.
 - Whether or not the message on the channel is in doubt. If the message is in doubt, it has not been acknowledged by WebSphere MQ.
 - The number of messages in the current batch.
 - The number of batches that have been sent.
 - The time and date at which the channel was last started.
 - The time and date at which the last message was sent.

- d. Click **Saved batch status**. The content pane displays the saved status of message batches that have been saved for transmission to WebSphere MQ.
 - e. If a batch is in doubt, you can either commit or rollback the batch.
6. To view the status of the receiver channel:
- a. Return to the WebSphere MQ link page.
 - b. Click **Receiver channel**.
 - c. Click the **Runtime** tab. The content pane displays the status of the receiver channel.
 - d. Click **Receiver channel connections**. The content pane displays the connections existing on the receiver channel, and their current status. You can stop connections if required, by selecting the check box next to the connection and clicking **Stop**.
 - e. Return to the receiver channel page.
 - f. Click **Saved batch status**. The content pane displays the saved status of message batches that have been received from WebSphere MQ.

What to do next

You can also view the status of subscriptions for a broker profile on the WebSphere MQ link: "Viewing the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile."

Viewing the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile:

This topic describes how you can view the status of subscriptions for a broker profile on a WebSphere MQ link.

1. In the navigation pane, click one of the following paths:
 - **Service integration** → **Buses** → *bus_name* → **[Topology]** **Foreign bus connections** → *foreign_bus_name* → **[Related Items]** **WebSphere MQ links** → *link_name* → **[Additional Properties]** **Publish/subscribe broker profiles**
 - **Service integration** → **Buses** → *bus_name* → **[Topology]** **Messaging engines** → *engine_name* → **[Additional properties]** **WebSphere MQ links** → *link_name* → **[Additional Properties]** **Publish/subscribe broker profiles**
2. Click the broker profile containing the subscriptions you want to view.
3. Click the **Runtime** tab. The content pane displays the current number of subscriptions for the broker profile.
4. Click **Subscriptions**. The content pane displays the status of the subscriptions for the broker profile. Position the mouse over a status icon to view hover help for that icon. You can remove the runtime subscriptions if required, by clicking **Unsubscribe**.

States of the WebSphere MQ link and its channels:

This topic describes the various states of the WebSphere MQ link and its sender and receiver channels, on a service integration bus.

| State of WebSphere MQ link | WebSphere MQ link sender channel | WebSphere MQ link receiver channel |
|----------------------------|---|--|
| INACTIVE | Same as STOPPED for the WebSphere MQ link sender. If the administrator requests that the channel go into target state STOPPED it will transition into the STOPPED state. Similarly, an administrator starting the channel will cause it to transition into STANDBY state. | No network connection exists between the application server and the queue manager. If the attempts of a WebSphere MQ sender channel to establish a connection should succeed, it will become possible for messages to flow from the queue manager to the messaging engine. In this case the receiver channel will transition into RUNNING state. |
| STARTING | A transitional state. The channel should successfully pass through this into BINDING state with no intervention. | A transitional state. The channel should successfully pass through this into BINDING state with no intervention. |
| BINDING | A transitional state. The channel should successfully pass through this into RUNNING state with no intervention. The channel may transition into STOPPING state if a problem occurs. | A transitional state. The channel should successfully pass through this into RUNNING state with no intervention. The channel may transition into STOPPING state if a problem occurs. |
| INITIALIZING | A transitional state. The channel should successfully pass through this into STARTING state with no intervention. | A transitional state. The channel should successfully pass through this into STARTING state with no intervention. |
| RETRYING | A network connection to the queue manager has been lost. Whilst in this state the channel is attempting to reestablish the connection. If the retry intervals are exhausted without successfully establishing the connection then the channel transitions into STOPPED state. If a connection is successfully reestablished, the channel enters INITIALIZING state. | Not applicable to receiver channel. |
| STANDBY | When in this state, the sender channel is not network-connected to its WebSphere MQ counterpart receiver channel. It is waiting for a message to send before attempting to establish a connection. When a message arrives for transmission, the channel will transition into STARTING state and start the process of attempting to establish a network connection. The administrator may command the channel to transition into either INACTIVE or STOPPED state from this state. | Not applicable to receiver channel. |

| State of WebSphere MQ link | WebSphere MQ link sender channel | WebSphere MQ link receiver channel |
|----------------------------|--|--|
| RUNNING | In this state a network connection has been established between application server and queue manager. Messages destined for the queue manager will be transmitted. Either attempting to stop the channel by using the administrative console, or the loss of the network connection will cause transition into the STOPPING state. | Network connection established between application server and queue manager. Messages destined for the messaging engine will be received. Attempting to stop the channel, or the loss of the network connection will cause a transition into STOPPING state. |
| STOPPING | A transitional state. The channel should transition into either RETRYING state or STOPPED state without intervention. If the channel has been placed in STOPPING state by the administrative request to become INACTIVE then it will transition into the STANDBY state. If the channel has been placed in this state by administrator request to stop, it will transition into the STOPPED state. If the channel has been placed in this state by a broken network connection it will transition into the RETRYING state, assuming that it has non-zero retry intervals or is otherwise STOPPED. | A transitional state. The channel will transition from this state into STOPPED without intervention. |
| STOPPED | No network connection exists between the application server and the queue manager. Messages destined for the queue manager will not be transmitted. To transition from this state requires the administrator to start the channel, this will place it in STANDBY state. | No network connection exists between the application server and the queue manager. Any attempt by a sender channel in the WebSphere MQ network to establish a connection will be rejected. Messages destined for the messaging engine will not be received. Administrator action is required to move the channel out of this state. Starting the channel will move it into INACTIVE state. |

For information about the states of the channels in a WebSphere MQ network refer to the Intercommunications book available at the WebSphere MQ publications site

Starting a WebSphere MQ link:

Change the state of a WebSphere MQ link from stopped to started.

Before you begin

You might want to tell the WebSphere MQ administrator that you are about to start this WebSphere MQ link.

About this task

To start a WebSphere MQ link, use the administrative console to complete the following steps.

1. In the navigation pane, click one of the following paths:

- **Service integration** → **Buses** → *bus_name* → **[Topology] Foreign bus connections** → *foreign_bus_name* → **[Related Items] WebSphere MQ links**
 - **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links**
2. In the content pane, select the check box next to the WebSphere MQ link you want to start.
 3. Click **Start**.

Results

If the WebSphere MQ link starts successfully, the status icon changes to indicate that the WebSphere MQ link is running.

Stopping a WebSphere MQ link:

This topic describes how you change the state of a WebSphere MQ link from started or running to stopped.

Before you begin

You might want to tell the WebSphere MQ administrator that you are about to stop this WebSphere MQ link.

About this task

When you stop a WebSphere MQ link, all communication with the target WebSphere MQ network is stopped for both point-to-point and publication and subscription. Messages waiting for transmission are held on the service integration bus, and the MQ sender channel cannot start. If there is a publish/subscribe bridge on the WebSphere MQ link, its operations are stopped.

You can also stop either the sender or receiver channel on the WebSphere MQ link, while leaving the link itself running. See “Stopping the sender channel on a WebSphere MQ link” on page 1730, and “Stopping the receiver channel on a WebSphere MQ link” on page 1729.

To stop a WebSphere MQ link, use the administrative console to complete the following steps.

1. In the navigation pane, click one of the following paths:
 - **Service integration** → **Buses** → *bus_name* → **[Topology] Foreign bus connections** → *foreign_bus_name* → **[Related Items] WebSphere MQ links**
 - **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links**
2. In the content pane, select the check box next to the WebSphere MQ link you want to stop.
3. In the **Stop mode** list, select Quiesce or Force.
4. In the **Target state** list select **Inactive** or **Stopped**.
5. Click **Stop**.

Results

The resultant state of the WebSphere MQ link, its sender and receiver channels, and the WebSphere MQ sender channel which is connected to the WebSphere MQ link receiver channel, depends on the options you chose:

- Stopping the WebSphere MQ link to target state INACTIVE will cause the sender channel to go into state STANDBY and the receiver channel to go into state INACTIVE. The overall WebSphere MQ link status will be RUNNING.

- Stopping the WebSphere MQ link to target state STOP will cause the sender channel to go into state STOPPED and the receiver channel to go into state STOPPED. The overall WebSphere MQ link status will be STOPPED.

These are the final states that the sender, receiver and WebSphere MQ link transition into. If you specify a mode of QUIESCE for either of the two final states, the channels and link might not transition into their final states immediately. Instead they temporarily transition through other states required to reach their final state.

For more details about stopped states of the WebSphere MQ link, see “States of the WebSphere MQ link and its channels” on page 1725.

What to do next

You can restart the WebSphere MQ link by selecting the link again and clicking **Start**. When the WebSphere MQ link is stopped and not in doubt, you can delete the WebSphere MQ link and any associated publish/subscribe broker profiles and topic mappings as described in “Removing a foreign bus connection from a bus” on page 1239.

Stopping the receiver channel on a WebSphere MQ link:

This topic describes how to stop the receiver channel on a WebSphere MQ link while leaving the link itself running.

Before you begin

Note: If you stop the receiver channel on a WebSphere MQ link, communication with the target WebSphere MQ network on that channel will cease for both point-to-point messaging and publishing and subscribing. Messages will be held at their transmission locations.

You may wish to warn the administrator of the WebSphere MQ network that you are about to stop the channel.

About this task

If you stop a receiver channel, messages sent to the WebSphere MQ link engine are not received.

If a WebSphere MQ sender channel is started while an MQ link receiver channel is stopped, the request fails with an error indicating that the receiver channel is not available.

For more information on stopped states of the WebSphere MQ link and its channels, see “States of the WebSphere MQ link and its channels” on page 1725.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Receiver channel**.
3. Select the check box next to the channel you want to stop.
4. In the **Stop mode** list, select Quiesce or Force.
5. In the **Target state** list, select Inactive or Stopped.
6. Click **Stop**.

Results

Stopping a receiver channel stops all the receiver channel connections for that receiver. The resultant state of the receiver channel, and the sender channel in the WebSphere MQ network with which it is

communicating, depends on the options you choose:

| | | Stop mode | |
|--------------|----------|--|---|
| | | Quiesce | Force |
| Target state | Inactive | The receiver channel moves to the stopping state and the data flow to the WebSphere MQ sender channel stops. When the WebSphere MQ sender channel next tries to communicate with the receiver channel the WebSphere MQ sender channel enters a state of retrying. The receiver channel then becomes inactive. The retrying WebSphere MQ sender channel then reestablishes a session with the receiver channel, and both channels become running. | The receiver channel immediately becomes inactive. When the WebSphere MQ sender channel next tries to communicate with the receiver channel, the WebSphere MQ sender channel enters a state of retrying. The retrying WebSphere MQ sender channel then reestablishes a session with the receiver channel, and both channels become running. |
| | Stopped | The receiver channel moves to the stopping state and the data flow to the WebSphere MQ sender channel stops. When the WebSphere MQ sender channel next tries to communicate with the receiver channel the WebSphere MQ sender channel enters a state of retrying. The receiver channel then becomes stopped, so preventing the WebSphere MQ sender channel from reestablishing a session. The WebSphere MQ sender channel itself then becomes stopped. | The receiver channel immediately becomes stopped. When the WebSphere MQ sender channel next tries to communicate with the receiver channel, the WebSphere MQ sender channel enters a state of retrying, and then becomes stopped itself. |

Stopping the sender channel on a WebSphere MQ link:

This topic describes how to stop the sender channel on a WebSphere MQ link while leaving the link itself running.

Before you begin

You might want to tell the WebSphere MQ network administrator that you are about to stop a channel.

About this task

When you stop the sender channel on a WebSphere MQ link, communication with the target WebSphere MQ network on that channel is stopped for both point-to-point messaging and publishing and subscribing. Messages are held at their transmission locations.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional properties] WebSphere MQ links** → *link_name* → **[Additional Properties] Sender channel**.
3. Select the check box next to the channel you want to stop.
4. In the **Stop mode** list, select Quiesce or Force.
5. In the **Target state** list, select Inactive or Stopped.
6. Click **Stop**.

Results

Only the sender channel is affected by this procedure. The resultant state of the sender channel depends on the options you chose:

| | | Stop mode | |
|--------------|----------|--|--|
| | | Quiesce | Force |
| Target state | Inactive | The sender channel becomes inactive either when it has finished processing its current batch, or when it reaches a heartbeat interval. | The sender channel immediately becomes inactive. |
| | Stopped | The sender channel becomes stopped either when it has finished processing its current batch, or when it reaches a heartbeat interval. | The sender channel immediately becomes stopped. |

For more information on stopped states of the WebSphere MQ link and its channels, see “States of the WebSphere MQ link and its channels” on page 1725.

Deleting a WebSphere MQ link publish/subscribe broker profile:

This describes how you delete a broker profile and all topic mappings on a WebSphere MQ link, which forms a publish/subscribe bridge between WebSphere Application Server and a WebSphere MQ network.

Before you begin

Before you start you need to know the names of the bus, messaging engine, and WebSphere MQ link that has the broker profile that you intend to delete. You should also consider informing the WebSphere MQ administrator that you are about to delete the connection to the message broker in the WebSphere MQ network.

If you also intend to delete the associated WebSphere MQ link, you need not complete this task. Refer instead to “Removing a foreign bus connection from a bus” on page 1239.

About this task

Deleting a broker profile is a three-stage operation to ensure both the application server and the WebSphere MQ network and its message brokers are synchronized after the deletion:

- Remove the subscriptions by unsubscribing the topic mappings on the broker profile.
- When the Runtime view is empty, delete the broker profile.
- If you have enabled dynamic configuration updates, the changes take effect immediately, otherwise restart the application server.

Note: If you remove the subscriptions but do not delete the broker profile, then the subscriptions are recreated when the server is restarted (because they are still present in the static configuration information for the WebSphere MQ link). These subscriptions are unrelated to the original subscriptions so this can lead to some messages in a publication flow being missing for subscribers on the target side of the bridge. For example, any messages published on an unsubscribed topic between the time the unsubscribe took place and the application server was restarted are not republished to the target side of the WebSphere MQ link.

1. Start the administrative console.
2. In the navigation pane, click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional properties] WebSphere MQ links** → **link_name** → **[Additional Properties] Publish/subscribe broker profiles** → **profile_name**.

3. Remove the subscriptions:
 - a. Click the **Runtime** tab.
 - b. Click **Subscriptions**.
 - c. Click **Unsubscribe** to remove all the subscriptions listed. When an unsubscribe command is sent to the message broker in the WebSphere MQ network, the relevant topic mapping is put into an "in doubt" state until the unsubscribe is confirmed when the topic mapping is deleted. After the unsubscribe is confirmed the topic mapping is no longer shown in the runtime view. You might need to refresh the runtime view for all subscriptions to be shown as removed.
4. Delete the broker profile:
 - a. Return to the **Publish/subscribe broker profiles** page.
 - b. Select the check box next to the broker profile you want to delete.
 - c. Click **Delete**.
5. Save your changes to the master configuration.
6. If you have enabled dynamic configuration updates, the changes take effect immediately. Otherwise, restart the application server.

Deleting a topic mapping on a WebSphere MQ link publish/subscribe broker profile:

This describes how you delete a topic mapping on a broker profile on a WebSphere MQ link, which forms part of a publish/subscribe bridge between WebSphere Application Server and WebSphere MQ.

Before you begin

Before you start you need to know the bus name, messaging engine name, WebSphere MQ link name and broker profile name on which you intend to delete the topic mapping.

Note:

- If you intend to delete *all* topic mappings prior to deleting the broker profile or the WebSphere MQ link, you can avoid restarting the application server more than once by following the steps given in "Deleting a WebSphere MQ link publish/subscribe broker profile" on page 1731.
- Deleting a topic mapping is a two-stage operation to ensure both the WebSphere Application Server (base) and the message brokers in the WebSphere MQ network are synchronized once the deletions have taken place:
 1. Delete the topic mapping (see below).
 2. When you have deleted the topic mappings, the changes take effect immediately if you have enabled dynamic configuration updates, otherwise restart the application server.

About this task

To delete a topic mapping, use the administrative console to complete the following steps.

1. In the navigation pane, click **Service integration** → **Buses** → *bus_name* → [Topology] **Messaging engines** → *engine_name* → [Additional properties] **WebSphere MQ links** → *link_name* → [Additional Properties] **Publish/subscribe broker profiles** → *profile_name* → [Additional Properties] **Topic mappings**
2. Select the check box next to the topic mapping you want to delete.
3. Click **Delete**.
4. Save your changes to the master configuration.

What to do next

Any topic mappings that you have deleted are automatically cleaned up by the publish/subscribe bridge when the application server is restarted.

Using a WebSphere MQ server to integrate WebSphere MQ queues into a bus

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. For interoperation with WebSphere Application Server Version 7.0, the version of WebSphere MQ must be WebSphere MQ for z/OS Version 6 or later, or WebSphere MQ (distributed platforms) Version 7 or later.

Before you begin

WebSphere Application Server can interoperate with WebSphere MQ in any of the following ways:

- Using WebSphere MQ as an external JMS provider
- Using a WebSphere MQ link
- Using a WebSphere MQ server

Each type of interoperation is designed for different situations, and provides different advantages. For information about the differences between these approaches, see “Interoperating with a WebSphere MQ network” on page 1707.

Decide on which method you want to use to configure these resources. You can configure WebSphere MQ server resources by using the administrative console as described in this task, or by using the SIBAdminCommands: WebSphere MQ server administrative commands for the AdminTask object.

About this task

To set up and use a WebSphere MQ server, you configure the server properties, add the server to a service integration bus as a bus member, and create a WebSphere MQ queue-type destination. Destinations that are assigned to a WebSphere MQ server bus member can also be mediated.

You add the WebSphere MQ server as a bus member so that messaging engines on the bus can access queues on the target WebSphere MQ system. If your WebSphere MQ server is connected to a queue-sharing group, your bus applications can access shared queues on the target installation.

Note:

- You can configure a WebSphere MQ server to connect to a WebSphere MQ queue manager using either a bindings mode or a client mode connection. To use client mode with WebSphere MQ for z/OS, you need an additional product called the Client Attach Facility.
 - You should configure the queues on the WebSphere MQ network as “shareable”. This allows multiple server instances to get messages from the queues.
1. Create a new WebSphere MQ server and configure the server properties.
 2. Add the new WebSphere MQ server as a member of a bus so that messaging engines on the bus can access queues on the target WebSphere MQ installation.
 3. Create a WebSphere MQ queue type destination for the new bus member and assign it to a WebSphere MQ queue.
 4. Optional: Mediate the new destination using the WebSphere MQ queue as the mediation point.

Creating the WebSphere MQ server definition:

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. Creating a WebSphere MQ server involves using the administrative console to define the server’s connection and quality of service properties.

Before you begin

Decide on which method you want to use to configure these resources. You can create a new WebSphere MQ server by using the administrative console as described in this task, or by using the `createSIBWMQServer` command.

About this task

When you create a new WebSphere MQ server definition, you specify its connection and quality of service properties. When you subsequently add the server as a member of a service integration bus, you can optionally override the server connection settings with the bus connection settings. This means that you can create a WebSphere MQ server that is specific to a bus, yet reusable in a multiple bus topology.

1. Start the administrative console.
2. Navigate to **Servers** → **Server Types** → **WebSphere MQ servers**. The WebSphere MQ servers [Collection] form is displayed.
3. Click **New**. The WebSphere MQ servers wizard starts.
4. Complete the required fields.
 - Name: this is any administrative name that you want to use for this server configuration; ensure that the server name you specify is unique.
 - Server: this is the name of the WebSphere MQ queue or queue-sharing group that this server represents.
 - Connection properties: complete the fields and click **Test connection**.
 - Security: select “Trust user identifiers” if you do not want the user identifiers in messages to be overwritten with the administrative name of the WebSphere MQ server.
 - Resource discovery: Select the check box if you want resources on the WebSphere MQ network to be discovered automatically.
5. Click **OK** to confirm.
6. Save your changes to the master configuration.
7. Restart the application server.

What to do next

You are now ready to add the new WebSphere MQ server as a member of a bus.

Modifying a WebSphere MQ server:

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This topic describes how to modify a WebSphere MQ server definition.

Before you begin

Decide on which method you want to use to configure these resources. You can modify a WebSphere MQ server by using the administrative console as described in this task, or by using the `modifySIBWMQServer` command.

About this task

A WebSphere MQ server definition defines the connection to an underlying WebSphere MQ queue manager or queue-sharing group and the associated queues. You can modify some of the properties for this connection.

Note: When you modify a WebSphere MQ server definition, you do not change any configuration values previously inherited from this WebSphere MQ server by existing bus members. For example, suppose you create a WebSphere MQ server with the port number 1234, then add the server to a bus using that server's port number. If you subsequently modify the WebSphere MQ server's port number to 2345, the bus member you previously created is not affected and still has the port number 1234.

1. Start the administrative console.
2. Navigate to **Servers** → **Server Types** → **WebSphere MQ servers** → *server_name*. The WebSphere MQ server [Settings] form is displayed.
3. Make modifications as necessary.
4. Save your changes to the master configuration.
5. Restart the application server.

Deleting a WebSphere MQ server definition:

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This topic describes how to delete a WebSphere MQ server definition.

Before you begin

Decide on which method you want to use to configure these resources. You can delete a WebSphere MQ server by using the administrative console as described in this task, or by using the deleteSIBWMQServer command.

Ensure that no application is putting messages to the bus members located on the WebSphere MQ server.

Inform the WebSphere MQ administrator that the WebSphere MQ server is about to be deleted and therefore will no longer interoperate with its WebSphere MQ queue manager or queue-sharing group in the WebSphere MQ network.

About this task

When you delete a WebSphere MQ server definition, the deletion process also modifies the following associated resources:

- It deletes all WebSphere MQ server bus members that were created when the server was added to service integration buses.
- It unmediates all destinations that were assigned to those bus members.
- It removes all queue points that were assigned to those bus members.

Deleting a WebSphere MQ server definition does not affect the associated queue managers, queue-sharing groups, queues or messages on your WebSphere MQ network.

1. Start the administrative console.
2. Navigate to **Servers** → **Server Types** → **WebSphere MQ servers**. The WebSphere MQ servers [Collection] form is displayed.
3. Select the check box next to the WebSphere MQ server you want to delete.
4. Click **Delete**.
5. Save your changes to the master configuration.
6. Restart the application server.

Adding a WebSphere MQ server as a member of a bus:

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. A WebSphere MQ server bus member is used as a bus member for assigning queue points and mediation points to WebSphere MQ queues.

Before you begin

Get details of the client connection from your WebSphere MQ administrator.

Ensure that the WebSphere MQ server has been configured, that the bus has been defined and that the server is not already a member of the bus.

Decide on which method you want to use to configure these resources. You can add the WebSphere MQ server as a bus member by using the administrative console as described in this task, or by using the `addSIBusMember` command.

About this task

When you add a WebSphere MQ server to one or more buses, messaging engines on these buses can access queues on the target WebSphere MQ installation. When you make the server a bus member, you can override the server connection settings with settings that are specific to the new bus member. This can be useful in a multiple bus topology.

1. Start the administrative console.
2. Navigate to the list of bus members for the bus to which you are adding the WebSphere MQ server. Click **Service integration** → **Buses** → *bus_name* → **[Topology] Bus members**.
3. Click **Add**. The “Add a new bus member” wizard is displayed.
4. Select the WebSphere MQ server to add to the bus:
 - a. Select the **WebSphere MQ server** radio button.
 - b. From the drop-down list, select the server to add.
 - c. Click **Next**.
5. Specify the virtual queue manager name.

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
 - It must conform to the WebSphere MQ queue naming rules (see the WebSphere MQ topic Rules for naming WebSphere MQ objects).
6. Optional: To override the server connection settings, select the **Override WebSphere MQ server connection properties** check box.

When you select this option, the connection properties for the server are made available so that you can change them to settings that are specific to this bus member. For more information about these connection properties, see WebSphere MQ server bus member [Settings].
 7. Optional: If you have changed the server connection settings, you can click **Test connection** to test the connection to the associated WebSphere MQ network.
 8. Click **Next**.
 9. Click **Finish** to confirm.
 10. Save your changes to the master configuration.

What to do next

You are now ready to create a WebSphere MQ queue-type destination for the new bus member.

Creating a queue-type destination and assigning it to a WebSphere MQ queue:

You can use the administrative console to create a queue-type destination and assign it to a WebSphere MQ queue. Select the WebSphere MQ server to host the queue, then specify the WebSphere MQ queue to be hosted.

Before you begin

Get the name of the WebSphere MQ queue from your administrator, and ensure that the following configuration is established:

- The WebSphere MQ server is added as a member of a bus
- The WebSphere MQ queue for the queue point exists
- The WebSphere MQ administrator has set the queue attributes to “shareable”

Note: A shareable queue can be accessed by more than one service integration application.

Decide on which method you want to use to configure these resources. You can create a bus destination by using the administrative console as described in this task, or by using the createSIBDestinations command.

About this task

After you have added a WebSphere MQ server as a bus member, you can create a queue-type destination on the bus member that uses a WebSphere MQ queue as a queue point. This configuration enables service integration applications to send messages to and receive messages from that queue.

1. Start the administrative console.
2. Navigate to the list of destinations for the appropriate bus.
Click **Service integration** → **Buses** → *bus_name* → **[Destination resources] Destinations**.
The Destinations [Collection] form is displayed.
3. Click **New**. The “Create a new destination” panel is displayed.
4. Select **Queue** as the destination type, then click **Next**. The “create a new queue” wizard is displayed.
5. Set the queue attributes. Enter the name that you want WebSphere Application Server to use to refer to the associated WebSphere MQ queue, and (optionally) a description of the queue.
6. Assign the queue to the bus member that is to store and process the messages for the queue.
Select a WebSphere MQ server bus member from the list of available bus members.
7. Set the WebSphere MQ queue point attributes:
 - a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the WebSphere MQ topic Rules for naming WebSphere MQ objects).

You can also use the wildcard character (*) in conjunction with other text. For example, if you enter a value of PAYROLL*, then all available queues with names that start with PAYROLL are displayed.

- b. Specify a WebSphere MQ queue name.

Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled “other, please specify”. A text entry box is displayed next to the list box. Type the queue name into the text entry box.

If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

- c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages.

Applications receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the receiver because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this option specifies the reliability level for the service integration format message. For information about the available reliability levels, see WebSphere MQ queue points [Settings].

- d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether or not service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

If the consumer of the message is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that expects an MQRFH2 header, select this option. If the consumer is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

8. Click **Next**.
9. Click **Finish** to confirm queue creation.

Results

You have created a queue-type destination with a WebSphere MQ queue point.

What to do next

You are now ready to (optionally) mediate the new destination using the WebSphere MQ queue as the mediation point.

Mediating a destination using a WebSphere MQ queue as the mediation point:

Mediate a destination by using the administrative console to specify a WebSphere MQ server bus member where the mediation point is to be assigned, and a WebSphere MQ queue to use as the mediation point where messages are stored. To mediate the destination using a service integration mediation, you must also specify a second bus member (not a WebSphere MQ server) to use as the mediation execution point and process the messages.

Before you begin

Decide on which method you want to use to configure these resources. You can mediate a destination by using the administrative console as described in this task, or by using the mediateSIBDestination command.

Before performing this task, ensure that the following resources exist:

- The mediation that you want to apply to the destination
- The WebSphere MQ server bus member where the mediation point is to be assigned
- The WebSphere MQ queue to use as the mediation point
- For a service integration mediation, a second bus member (not a WebSphere MQ server bus member) to use as the mediation execution point where the mediation code runs

Note: When you complete this task, the queue manager on the WebSphere MQ network does not have to be available, but the destination is not usable until the queue manager is available.

About this task

You can mediate a destination with a WebSphere MQ mediation point. This ensures that messages arriving at the designated WebSphere MQ queue are mediated. In this scenario, the mediated messages are delivered to the queue point, or to another destination that is determined by the default forward routing path destination, or by the mediation code.

1. Start the administrative console.
2. Navigate to the list of destinations for the appropriate bus. Click **Service integration** → **Buses** → **bus_name** → **[Destination resources] Destinations**.
3. Select the check box beside the destination to mediate, then click **Mediate**. The Mediation wizard is displayed.
4. Select the mediation, then click **Next**. From the drop-down list, select the mediation to apply to the destination.
5. Assign the mediation to a bus member:
 - a. From the first drop-down list, select the WebSphere MQ server bus member where the mediation point is to be assigned.
 - b. From the second drop-down list, select the bus member where the mediation is to run.

When a mediation is assigned to a WebSphere MQ server bus member, you need a separate bus member that is not a WebSphere MQ server to act as the mediation execution point and process the messages.

6. Set the WebSphere MQ mediation point attributes:
 - a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

 - It must contain between 1 and 48 characters.
 - It must conform to the WebSphere MQ queue naming rules (see the WebSphere MQ topic Rules for naming WebSphere MQ objects).

You can also use the wildcard character (*) in conjunction with other text. For example, if you enter a value of PAYROLL*, then all available queues with names that start with PAYROLL are displayed.
 - b. Specify a WebSphere MQ queue name.

Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled “other, please specify”. A text entry box is displayed next to the list box. Type the queue name into the text entry box.

If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm

that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

- c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages.

Mediations receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the mediation because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this option specifies the reliability level for the service integration format message. For information about the available reliability levels, see WebSphere MQ queue points [Settings].

- d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether or not service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

If the consumer of the message (in this case, the mediation) is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that expects an MQRFH2 header, select this option. If the mediation is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

7. Click **Next**.
8. Click **Finish** to confirm mediation of the destination.

Results

You have mediated a destination using a WebSphere MQ queue as the mediation point.

Setting the WebSphere MQ encoding format for JMS Map entries

JMS Map messages use the class `javax.jms.MapMessage`. WebSphere MQ Version 6 provides an encoding format for the body of JMS Map messages that lets you allocate names that are not valid XML tags to Map entries.

Before you begin

This encoding format can interoperate with WebSphere MQ Version 5.3 and above, but not with the earlier WebSphere MQ versions. All WebSphere MQ JMS clients use the WebSphere MQ Version 6 encoding format by default.

About this task

To specify this encoding format, you use the administrative console to set the encoding name/value pair as custom properties of the connection factory. If you specify `TRUE` the WebSphere MQ Version 5 encoding format is used. If you specify `FALSE`, the WebSphere MQ Version 6 encoding format is used.

For related information, see the *WebSphere MQ Using Java* book in the WebSphere MQ library.

1. From the administrative console, navigate to **Resources** → **JMS** → **JMS providers** → **WebSphere MQ messaging provider** → **[Additional Properties] Connection factories** → *factory_name* → **Custom properties**.
2. Specify the encoding name and value in the Name and Value fields. The encoding name is `MAPNAMESTYLE` and the value is a Boolean expression, where `TRUE` is the WebSphere MQ Version 5 compatible format and `FALSE` is the WebSphere MQ Version 6 format.
3. Restart the application server for the properties to take effect.

Managing WebSphere Application Server Version 5.1 JMS use of messaging resources in later versions of the product

This task enables Java EE applications developed for WebSphere Application Server Version 5.1 to use messaging resources of the default messaging provider in WebSphere Application Server Version 7.0.

Before you begin

Throughout this topic, the abbreviation “Version 5.1” refers to “WebSphere Application Server Version 5.1” and “Version 7.0” refers to “WebSphere Application Server Version 7.0”. For example, “Version 5.1 JMS resources” refers to JMS resources provided by WebSphere Application Server Version 5.1.

This task refers to the *default messaging provider*. For related information, see “Managing messaging with the default messaging provider” on page 1183.

JMS connectivity between the Version 5.1 messaging provider and the default messaging provider in later versions of the product is enabled and managed by a *WebSphere MQ client link*. This does not mean that a WebSphere MQ system is involved. The Version 5.1 messaging provider uses WebSphere MQ client protocols, and is therefore handled as if it were a WebSphere MQ client by the default messaging provider in later versions of the product. The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1. Moreover, this JMS connectivity is only intended as an aid to migration from the Version 5.1 messaging provider to the Version 7.0 default messaging provider. For more information about migrating from the Version 5.1 messaging provider, see *Migrating from WebSphere Application Server Version 5 embedded messaging*.

Applications running in Version 7.0 can use the messaging resources of the Version 5.1 messaging provider without any need for a WebSphere MQ client link.

About this task

To enable JMS applications developed for WebSphere Application Server Version 5.1 to use messaging resources of the default messaging provider, a WebSphere MQ client link is created on the Version 7.0 node. Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by Version 5.1 and the protocols used by the default messaging provider in Version 7.0.

The following figure shows a JMS application running on Version 5.1 using JMS resources provided by the default messaging provider on a Version 7.0 node. The JMS queue hosted by Version 5.1 is backed by a service integration bus queue, which is normal for a JMS queue hosted by Version 7.0, but there is no configured link between the Version 5.1 JMS queue and the bus queue. The JMS application communicates with the bus queue through the WebSphere MQ client link and the messaging engine. To send messages to the bus queue or receive messages from the queue, the JMS application opens a connection on the WebSphere MQ client link. This is all invisible to the JMS application, but can be displayed and managed by the administrator.

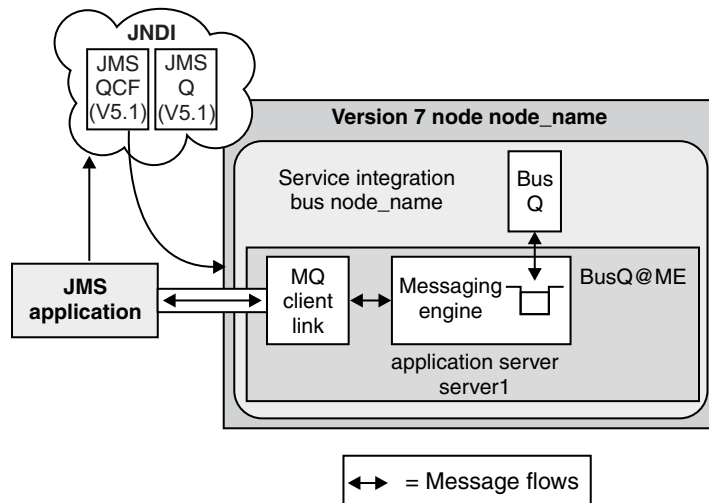

Figure 19. WebSphere Application Server Version 5.1 JMS application scenario

- Configure a Version 7.0 node to support Version 5.1 applications that use JMS resources. If you want a Version 7.0 node to provide JMS destinations for use by applications running on Version 5.1, complete the following steps:
 1. Create an application server. You can use an existing application server on the Version 7.0 node; for example, an application server onto which a Version 5.1 application is to be deployed.
 2. Create a service integration bus. You can use an existing bus.
 3. Add the application server as a bus member. This automatically creates a messaging engine on the application server.
 4. Create a WebSphere MQ client link on the messaging engine. Specify the following property values:

Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

MQ channel name

This is the name of the channel for the WebSphere MQ client link, used to flow messages between the application that is running on Version 5.1 and the bus. This name must match the receiving channel name configured for Version 5.1:

WAS.JMS.SVRCONN

This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name

This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to applications running on Version 5.1 . Type the queue manager name in the form:

WAS_node_name_server_name

Where:

node_name

is the name of the Version 7.0 node.

server_name

is the name of the application server.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

Default queue manager

Select this check box if you want the WebSphere MQ client link to be used as the default for applications that cannot find a suitable WebSphere MQ client link to use.

If an application running on Version 5.1 specifies that it wants to connect to a non-default queue manager name, you can configure a WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on another WebSphere MQ client link, which is used instead of rejecting the connection.

5. Define a port called `JMSERVER_QUEUED_ADDRESS` on the application server. The port number must be the same used by the `SIB_MQ_ENDPOINT_ADDRESS` port.

Specify the following property values:

Port name

For **Well-known Port**, select `JMSERVER_QUEUED_ADDRESS`

Host Type the IP address, domain name server (DNS) host name with domain name suffix, or the short DNS host name of the Version 7.0 node.

Port Type the port number used by the `SIB_MQ_ENDPOINT_ADDRESS` port. By default, this is 5558.

- Configure a Version 7.0 managed node to support applications running on Version 5.1 that use JMS resources. If you want a Version 7.0 managed node to provide JMS destinations for use by applications running on Version 5.1, complete the following steps:

1. Create an application server. Specify the name `jmsserver`.
2. Create a service integration bus. You can use an existing bus.
3. Add the application server as a bus member. This automatically creates a messaging engine on the application server.
4. Create a WebSphere MQ client link on the messaging engine. Specify the following property values:

Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

MQ channel name

This is the name of the channel for the WebSphere MQ client link, used to flow messages between the application running on Version 5.1 and the bus. This name must match the receiving channel name configured for Version 5.1:

```
WAS.JMS.SVRCONN
```

This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name

This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to applications running on Version 5.1. Type the queue manager name in the form:

```
WAS_node_name_jmsserver
```

Where:

node_name

is the name of the Version 7.0 node.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

Default queue manager

Select this check box if you want the WebSphere MQ client link to be used as the default for applications that cannot find a suitable WebSphere MQ client link to use.

If an application developed for WebSphere Application Server Version 5.1 specifies that it wants to connect to a non-default queue manager name, you can configure another WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on a WebSphere MQ client link, which is used instead of rejecting the connection.

5. Define a port called JMSSERVER_QUEUED_ADDRESS on the application server. The port number must be the same used by the SIB_MQ_ENDPOINT_ADDRESS port.

Specify the following property values:

Port name

For **Well-known Port**, select JMSSERVER_QUEUED_ADDRESS

Host Type the IP address, domain name server (DNS) host name with domain name suffix, or the short DNS host name of the Version 7.0 node.

Port Type the port number used by the SIB_MQ_ENDPOINT_ADDRESS port. By default, this is 5558.

- If the application looks up JMS resources in JNDI on the Version 7.0 application server, configure the JMS resources on the Version 7.0 application server as Version 5.1 default messaging JMS resources.
 1. For each JMS queue destination that the application uses, create a Version 5 Default Messaging WebSphere queue destination.
 2. For each JMS queue destination that the application uses, create a bus destination with the same name. Assign the bus destination to a bus member in the same bus as the jmsserver bus member. You must also create an alias destination with an identifier WQ_<destination_name>, that points to the service integration destination that has been created. The WQ_ prefix is needed because all destination names are prefixed with WQ_. If you are manually migrating the WebSphere JMS provider resources, you also need to create the "WQ_" queues.
 3. Configure JMS connection factories as Version 5.1 default messaging queue connection factories and topic connection factories.
- If the application looks up JMS resources outside the JNDI on the Version 7.0 application server, configure the JMS connection factory to point to the Version 7.0 node.

Results

The application running on Version 5.1 can continue to access the Version 5.1 JMS resources, which are now implemented through the Version 7.0 default messaging provider, as shown in the figure Figure 19 on page 1742. The JMS application communicates with the Version 5.1 JMS resources through the WebSphere MQ client link and the messaging engine. This is invisible to the JMS application. The JMS resources, a JMS queue connection factory, shown as JMS QCF(V5), and a JMS queue, shown as JMS Q(V5), are managed as Version 5.1 default messaging JMS resources. The new bus queue, shown as JMS Q, is managed as a resource of the service integration bus. Messages for JMS Q are stored and processed by the message point for the associated bus destination, a queue shown as Bus Q. The WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by JMS applications developed for WebSphere Application Server Version 5.1 and the protocols used by messaging engines on Version 7.0.

Creating a WebSphere MQ client link

Use this task to create a link that enables a messaging engine to handle message requests from JMS applications developed for WebSphere Application Server Version 5.1.

Before you begin

The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1.

About this task

The WebSphere MQ client link enables WebSphere Application Server Version 5.1 Java EE applications to use messaging resources of the WebSphere Application Server Version 7.0 default messaging provider that are backed by destinations on the service integration bus.

Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by WebSphere Application Server Version 5.1² JMS applications, and the WebSphere Application Server Version 7.0 protocols used by messaging engines.

If you migrate a Version 5.1 node to Version 7.0, a default WebSphere MQ client link, with the name `Default.MQClientLink`, is created for the application servers on that node. You only need to create another WebSphere MQ client link if you want some Version 5.1 JMS applications to use a different channel to connect to the messaging engine, or want to present a messaging engine as a non-default queue manager name.

If you create a WebSphere MQ client link, you only need to manually specify values for a subset of the available properties. You can choose to specify values for other optional properties in this task, or if wanted at a later time by changing the configuration of the client link.

Note: Creating a WebSphere MQ client link is only part of the task to enable WebSphere Application Server Version 5.1 applications to use messaging resources of the WebSphere Application Server Version 7.0 default messaging provider. For more information about the overall task, see “Managing WebSphere Application Server Version 5.1 JMS use of messaging resources in later versions of the product” on page 1741.

To create a WebSphere MQ client link, use the administrative console to complete the following steps.

1. List the WebSphere MQ client links for the messaging engine that the Version 5.1 JMS applications are to connect to. Click **Service integration** → **Buses** → *bus_name* → **[Topology] Messaging engines** → *engine_name* → **[Additional Properties] WebSphere MQ client links**. This displays any existing WebSphere MQ client links in the content pane.
2. Click **New** in the content pane.
3. Specify the following required properties for the WebSphere MQ client link:

Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

MQ channel name

This is the name of the channel for the WebSphere MQ client link, used to flow messages between the JMS application developed for WebSphere Application Server Version 5.1 and the bus. This name must match the receiving channel name configured for WebSphere Application Server Version 5.1:

`WAS.JMS.SVRCONN`

This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name

This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to WebSphere Application Server Version 5.1 applications. Type the queue manager name in the form:

`WAS_node_name_server_name`

2. To make reading easier in this topic, the abbreviation “Version 5.1” is sometimes used to refer to “WebSphere Application Server Version 5.1” and “Version 7.0” is used to refer to “WebSphere Application Server Version 7.0”. For example, “Version 5.1 JMS resources” refers to JMS resources provided by WebSphere Application Server Version 5.1.

Where:

node_name

is the name of the WebSphere Application Server Version 7.0 node.

server_name

is the name of the application server.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

On a managed node in a WebSphere Application Server Network Deployment cell, an application server with the name `jmsserver` is used for interoperation with WebSphere Application Server Version 5.1 applications, to represent the JMS server that was used in WebSphere Application Server Version 5.1. For this server, the WebSphere MQ client link has the queue manager name `WAS_nodeName_jmsserver`. You should not use this queue manager name on any other WebSphere MQ client link that is assigned to a messaging engine on the same node.

Default queue manager

Select this check box if you want the MQ client link to be used as the default for applications that cannot find a suitable MQ client link to use.

If a JMS application developed for WebSphere Application Server Version 5.1 specifies that it wants to connect to a non-default queue manager name, you can configure a WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on another WebSphere MQ client link, which is used instead of rejecting the connection.

4. Optional: If you want to specify other optional properties, see the property descriptions in WebSphere MQ client link [Settings].
5. Click **OK**.
6. Save your changes to the master configuration.

What to do next

To enable WebSphere Application Server Version 5.1 applications to use messaging resources of WebSphere Application Server Version 7.0, ensure you complete all the steps in the task “Managing WebSphere Application Server Version 5.1 JMS use of messaging resources in later versions of the product” on page 1741.

Configuring a WebSphere MQ client link

Use this task to browse or change the properties of a client link that enables a messaging engine to handle message requests from JMS applications developed for WebSphere Application Server Version 5.1.

Before you begin

The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1.

About this task

The WebSphere MQ client link enables WebSphere Application Server Version 5.1 Java EE applications to use messaging resources of the WebSphere Application Server Version 7.0 default messaging provider that are backed by destinations on the service integration bus.

Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by WebSphere Application Server Version 5.1³ JMS applications, and the Version 7.0 protocols used by messaging engines.

1. Start the administrative console.
2. Navigate to the settings page for the WebSphere MQ client link. Click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional Properties] WebSphere MQ client links** → **link_name**. This displays the properties of the selected WebSphere MQ client links in the content pane.
3. Optional: If you want to change any of the general properties, see the property descriptions in WebSphere MQ client link [Settings].
4. Optional: If you want to change any of the advanced properties, see the property descriptions in WebSphere MQ client link advanced properties [Settings], then complete the following steps.
5. If you have changed any properties, complete the following steps.
 - a. Click **OK**.
 - b. Save your changes to the master configuration.

Listing WebSphere MQ client links for a messaging engine

Use this task to display a list of WebSphere MQ links for a messaging engine.

About this task

To list the WebSphere MQ client links for a messaging engine, use the administrative console to complete the following steps.

Display the WebSphere MQ client links collection page. Click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional Properties] WebSphere MQ client links**.

Results

This displays a list of WebSphere MQ client links for the messaging engine in the content pane, with the following subset of properties for the link:

Name The name of the WebSphere MQ client link.

Description

An optional description for the WebSphere MQ client link, for administrative purposes.

MQ channel name

The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

Queue manager name

The queue manager name used to represent the bus as a WebSphere MQ queue manager to WebSphere MQ clients.

Default queue manager

Whether or not this is the default queue manager for the WebSphere MQ clients.

Status

The runtime status of the WebSphere MQ client link.

3. To make reading easier in this topic, the abbreviation “Version 5.1” is sometimes used to refer to “WebSphere Application Server Version 5.1” and “Version 7.0” is used to refer to “WebSphere Application Server Version 7.0”. For example, “Version 5.1 JMS resources” refers to JMS resources provided by WebSphere Application Server Version 5.1.

What to do next

You can use this panel to create, delete, start, or stop client links, as described in related tasks.

Starting and stopping WebSphere MQ client links

Use this task to start or stop WebSphere MQ client links, to stop message flows between the default messaging provider and JMS applications developed for WebSphere Application Server Version 5.1, connected through the client links.

About this task

You can start a WebSphere MQ client link that is not running (has a runtime status of Stopped) or stop a client link that is running (has a runtime status of Started). This also starts or stops all client connections on the selected WebSphere MQ client links. Alternatively, you can start or stop individual client connections on the WebSphere MQ client link, as described in “Starting and stopping WebSphere MQ client connections” on page 1750.

When stopping a client link, you can choose whether to force the client link to stop immediately or after any messages currently on its client connections have been processed. You can also choose the final state that you want the client link to be in when it has been stopped.

To start or stop one or more WebSphere MQ client links, use the administrative console to complete the following steps.

1. Display the WebSphere MQ client links collection page. Click **Service integration** → **Buses** → ***bus_name*** → **[Topology] Messaging engines** → ***engine_name*** → **[Additional Properties] WebSphere MQ client links**.
2. Select the check box next to the name of each client link that you want to start or stop.
3. Click the appropriate button:

| | |
|-------|---|
| Start | Click this button to start selected items. This enables JMS applications to use the client link to access JMS resources provided by the default messaging provider. |
|-------|---|

| | |
|-------------|--|
| <p>Stop</p> | <p>Click this button to stop a selected WebSphere MQ client link. You must first have selected the link to be stopped.</p> <p>You can choose the mode of stop action and the desired state when the link has been stopped:</p> <p>Stop mode:</p> <p>Force Stop the link immediately.</p> <p>Quiesce
Stop the link after any messages currently on its client connections have been processed.</p> <p>Target state:</p> <p>Inactive
Stop the link to an inactive state. If an application tries to use the link, the link is started again.</p> <p>Stopped
Stop the link to a stopped state. Applications cannot use the client link. The link can only be started again by administrator action.</p> |
|-------------|--|

Results

The status of the client link changes and a message stating that the link has started or stopped is displayed at the top the page.

Listing client connections for a WebSphere MQ client link

Use this task to display a list of client connections for a WebSphere MQ client link. Each client connection is created automatically for a version 5 JMS application using the WebSphere MQ client link.

About this task

To list the client connections for a WebSphere MQ client link, use the administrative console to complete the following steps.

Display the client connections collection page. Click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional Properties] WebSphere MQ client links** → **link_name** → **[Additional Properties] Client connections**.

Results

This displays a list of client connections for the WebSphere MQ client link in the content pane, with the following subset of properties for the link:

IP address

The TCP/IP IP address of the WebSphere MQ client.

Status

The runtime status of the WebSphere MQ client connection.

What to do next

You can use this panel to start or stop client connections, as described in related tasks.

Starting and stopping WebSphere MQ client connections

Use this task to start or stop client connections on a WebSphere MQ client link, to stop message flows between the default messaging provider and the JMS application developed for WebSphere Application Server Version 5.1 that uses the connections.

About this task

You can start a WebSphere MQ client connection that is not running (has a runtime status of Inactive) or stop a client connection that is running (has a runtime status of Started). Alternatively, you can start or stop all client connections on the WebSphere MQ client link, as described in “Starting and stopping WebSphere MQ client links” on page 1748.

When stopping a client connection, you can choose whether to force the client connection to stop immediately or after any messages currently on its client connections have been processed. Client connections are always stopped to an inactive state.

To start or stop one or more WebSphere MQ client connections, use the administrative console to complete the following steps.

- Display the WebSphere MQ client connections collection page. Click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional Properties] WebSphere MQ client links** → **link_name** → **[Additional Properties] Client connections**.
- Select the check box next to the name of each client connection that you want to start or stop.
- Click the appropriate button:

| | |
|-------|---|
| Start | Click this button to start selected items. |
| Stop | <p>Click this button to stop a selected WebSphere MQ client connection. You must first have selected the connection to be stopped.</p> <p>You can choose the mode of stop action, but connections are always stopped to an inactive state:</p> <p>Stop mode:</p> <p>Force Stop the connection immediately.</p> <p>Quiesce
Stop the connection after any messages currently on the connection have been processed.</p> <p>Target state:</p> <p>Inactive
Stop the link to an inactive state. If an application tries to use the link, the link is started again.</p> |

Results

The status of the client connection changes and a message stating that the connection has started or stopped is displayed at the top the page.

Deleting WebSphere MQ client links

Use this task to delete WebSphere MQ client links. This prevents JMS applications developed for WebSphere Application Server Version 5.1 from using those client links to exchange messages with the default messaging provider.

Before you begin

Before deleting a WebSphere MQ client link, you need to stop version 5 JMS applications using the client link.

- Stop all message-producing JMS applications in the WebSphere Application Server Version 5.1 environment that are using the client link. For example, you can use the administrative console to stop the applications, as described in Starting and stopping applications.
- Allow all message-consuming JMS applications (including those consuming publications as a result of durable subscriptions) to continue until all the JMS queues are drained, then stop those applications.

About this task

To start or stop one or more WebSphere MQ client links, use the administrative console to complete the following steps.

1. Display the WebSphere MQ client links collection page. Click **Service integration** → **Buses** → **bus_name** → **[Topology] Messaging engines** → **engine_name** → **[Additional Properties] WebSphere MQ client links**.
2. Select the check box next to the name of each client link that you want to delete.
3. Click **Delete**
4. Click **OK**.
5. Save any changes to the master configuration.

Configuring the messaging engine selection process for JMS applications

Configure the JMS connection factory for your application, in order to tune the process through which messaging engine connections are selected for your application.

About this task

To use JMS destinations of the default messaging provider, a client application connects to a messaging engine on the service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received.

For a JMS application, you apply the extra configuration to the associated JMS connection factory. For a message-driven bean (MDB) application, you apply the equivalent extra configuration to the associated activation specification.

For the default configuration, you only need to specify the one required connection property **Bus name**, which sets the name of the bus to which the application wants to connect. To further restrict the range of messaging engines to which your applications can connect, you can also configure the other connection properties:

- Target
- Target type

- Target significance
- Target inbound transport chain
- Connection proximity

For detailed information about these connection properties, and an overview of the process through which the default messaging provider chooses the messaging engine for your application, see [How JMS applications connect to a messaging engine on a bus](#).

The steps for this task are based on an application that uses a unified JMS connection factory. You can use the same task to configure a JMS queue connection factory or JMS topic connection factory, but during the task you need to select the appropriate type of connection factory instead of **JMS connection factory**. To configure any of these properties of a connection factory, complete the following steps:

- If the client application uses a JMS connection factory in the client container, use the Client Resource Configuration tool (ACRCT) to configure the Provider endpoint property:
 1. Start the tool and open the EAR file for which you want to configure the JMS connection factory. The EAR file contents are displayed in a tree view.
 2. From the tree, select the JAR file in which you want to configure the JMS connection factory.
 3. Expand the JAR file to view its contents.
 4. Expand **Messaging Providers > Default Provider > Connection Factories**.
 5. Optional: Display the general properties of the connection factory:
 - If you want to use an existing JMS connection factory, click the name of the connection factory.
 - If you want to create a new JMS connection factory, click **New**.

For more information about configuring a JMS connection factory in the JMS provider configuration for your application client, see [Configuring new JMS providers with the Application Client Resource Configuration Tool](#).
 6. On the General tab, configure the connection properties.
 7. Click **OK**.
 8. To save your changes, click **File > Save**.
- If the client application uses a JMS connection factory on the server, use the WebSphere Application Server administrative console to configure the connection properties:
 1. Display the default messaging provider. In the navigation pane, expand **Resources > JMS > JMS providers**.
 2. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
 3. In the content pane click **Default messaging provider**. This displays a table of properties for the default messaging provider, including links to the types of JMS resources that it provides.
 4. In the content pane, under Additional Properties, click **Connection factories**. This displays any existing connection factories in the content pane.
 5. Optional: Display the general properties of the connection factory:
 - If you want to use an existing JMS connection factory, click the name of the connection factory.
 - If you want to create a new JMS connection factory, click **New**.

For more information about configuring a JMS connection factory, see [Configuring a unified JMS connection factory for the default messaging provider](#).
 6. Configure the connection properties.
 7. Click **OK**.
 8. Save your changes to the master configuration.

Managing messages and subscriptions for JMS destinations

Use the following tasks to manage the messages and subscriptions that exist for JMS destinations of the default messaging provide.

About this task

- You can manage the messages on a JMS queue by acting on the queue point for the bus destination to which JMS queue has been assigned. The **Bus name** property of the JMS connection factory identifies the service integration bus. The **Queue name** property of the JMS queue identifies the name of the bus destination.
- You can manage the durable subscriptions on a JMS topic by acting on a publication point for the topic space to which JMS topic has been assigned. The **Bus name** property of the JMS connection factory identifies the service integration bus. The **Topic space** property of the JMS topic identifies the name of the topic space.

Other tasks that affect the runtime status of the default messaging provider are given in related tasks.

To change the configuration of JMS resources for the default messaging provider, see “Configuring resources for the default messaging provider” on page 1678.

- “Managing messages on message points” on page 1262
- “Administering durable subscriptions” on page 1324

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- “Listing messages on a message point” on page 1323
- “Deleting messages on a message point” on page 1323

Listing messages on a message point:

Use this task to list the messages that exist on a message point for a selected bus destination or messaging engine.

About this task

To display a list of messages on a message point, use the administrative console to complete the following steps:

1. In the navigation pane, click **Service integration** → **Buses**.
2. In the content pane, click the name of the service integration bus.
3. Optional: To list the message points for a bus destination, complete the following steps:
 - a. In the content pane, under **Destination resources**, click **Destinations**.
 - b. Click the destination name.
4. Optional: To list the message points for a messaging engine, complete the following steps:
 - a. In the content pane, under **Topology**, click **Messaging engines**
 - b. Click the messaging engine name.
5. Under Additional Properties, click **Message points** This displays a list of message points in the content pane.

6. Click the message point name. This displays the properties of the destination localization in the content pane.
7. Click the Runtime tab.
8. Under Additional Properties, click **Messages**

Results

A list of messages on the selected message point is displayed in the content pane.

What to do next

You can select one or more messages to act on; for example, to display the message content, delete messages.

Deleting messages on a message point:

Use this task to delete one or messages that exist on a message point for a selected bus destination or messaging engine.

About this task

You should not normally need to delete messages on a message point. This task is intended as part of a troubleshooting procedure.

To delete one or messages on a message point, use the administrative console to complete the following steps:

1. List the messages on the message point.
2. In the content pane, click the check box next to each message you want to delete. Alternatively, you

can select all messages in the list by clicking the Select all items button

3. Click **Delete**

Results

The selected messages are removed from the list.

Using JMS from standalone clients to interoperate with service integration resources

The Thin Client for JMS with WebSphere Application Server allows third party applications to interoperate with default messaging provider messaging engines on WebSphere Application Server.

Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine

The Thin Client for JMS with WebSphere Application Server is an embeddable technology that provides Java Message Service (JMS) V1.1 connections to a WebSphere Application Server default messaging provider messaging engine.

Installing and configuring the Thin Client for JMS with WebSphere Application Server:

To use the Thin Client for JMS with WebSphere Application Server copy the com.ibm.ws.sib.client.thin.jms_7.0.0.jar and any other required files from the application server or application client %WAS_HOME%/runtimes directory.

About this task

The Thin Client for JMS with WebSphere Application Server can be used for default messaging provider messaging engines for WebSphere Application Server Version 6.0.2 or later. The connection to the messaging engine can be either TCP or SSL. HTTP connectivity is not supported.

You can install the client in any location and run it in any supported Java 2 Platform Standard Edition 1.5.0 (also known as 5.0) or above Java Runtime Environment (JRE). The client supports the following JREs:

- IBM JRE 1.5.0 and above
- Sun JRE 1.5.0 and above
- HP-UX JRE 1.5.0 and above
- Lotus Expeditor v6.1 or above with J2SE 5.0 or above Device Runtime Environment. jclDesktop and jclDevice profiles are not supported.

The client does not require any further configuration after installation, apart from adding the jar file or files to the classpaths for your client application. You can choose either to create JMS connection factories programmatically, or use the Java Naming and Directory Interface (JNDI). If required, you can use secure connections by configuring Secure Sockets Layer (SSL) settings.

1. Install the client in the required location. The client is always installed in the /runtimes directory of a WebSphere Application Server installation, and may optionally be installed by the Application Client for WebSphere Application Server, which is a separate WebSphere Application Server deliverable. The client is shipped as three files:
 - com.ibm.ws.sib.client.thin.jms_7.0.0.jar - the regular JMS Client.
 - com.ibm.ws.sib.client_ExpeditorDRE_7.0.0.jar - the JMS Client packaged for Lotus Expeditor.
 - sibc.nls.zip - language-specific resource bundles. You can extract any combination of these files. The client jar already includes US English, so you only need the additional language files from sibc.nls.zip if you require languages other than non-US English.
2. Include the appropriate jar file or files in the classpaths for your client application:
 - a. To compile JMS code, include the client jar file in the CLASSPATH setting for the javac command.
 - b. To run JMS code, include the client jar file and any required optional language files extracted from sibx.nls.zip in the CLASSPATH setting for the java command.
3. Configure the required JMS resources as described in “Using JMS resources with the Thin Client for JMS with WebSphere Application Server” on page 1756.
4. If you require secure connections, configure SSL as described in “Securing client and resource adapter connections” on page 1758.

Migration to Thin Client for JMS with WebSphere Application Server:

There are a number of differences to consider when migrating to the Thin Client for JMS with WebSphere Application Server from an earlier version of the client.

Table 17. Migration from WebSphere Application Server Version 6.0.2 to WebSphere Application Server Version 7.0

| Area | WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server) | WebSphere Application Server Version 7.0 (Thin Client for JMS with WebSphere Application Server) |
|-------------------|--|---|
| Installation | Available for separate download and installation | Installed in the WebSphere Application Server or Application Client /runtimes directory |
| JMS jar file name | sibc.jms.jar | com.ibm.ws.sib.client.thin.jms_7.0.0.jar |

Table 17. Migration from WebSphere Application Server Version 6.0.2 to WebSphere Application Server Version 7.0 (continued)

| Area | WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server) | WebSphere Application Server Version 7.0 (Thin Client for JMS with WebSphere Application Server) |
|--|--|--|
| Performing JNDI lookups of JMS resources | Requires optional sibc.jndi.jar (and ORB sibc.orb.jar for non-IBM JREs) | Requires Thin Client for EJB with WebSphere Application Server jar com.ibm.ws.ejb.thinclient_7.0.0.jar/com.ibm.ws.ejb.thinclient.z_7.0.0.jar (and ORB com.ibm.ws.orb_7.0.0.jar for non-IBM JREs) |
| SSL configuration | Secure connections are configured using JRE global properties:

-Djavax.net.ssl.keyStore
-Djavax.net.ssl.keyStorePassword
-Djavax.net.ssl.trustStore
-Djavax.net.ssl.trustStorePassword | Two approaches to configuring secure connections.

The first approach uses JRE global properties:

-Djavax.net.ssl.keyStore
-Djavax.net.ssl.keyStorePassword
-Djavax.net.ssl.trustStore
-Djavax.net.ssl.trustStorePassword

The second approach is to specify security settings that are specific to Thin Client for JMS with WebSphere Application Server connections:

-Dcom.ibm.ssl.keyStoreType
-Dcom.ibm.ssl.keyStore
-Dcom.ibm.ssl.keyManager
-Dcom.ibm.ssl.trustManager
-Dcom.ibm.ssl.keyStorePassword
-Dcom.ibm.ssl.protocol
-Dcom.ibm.ssl.contextProvider
-Dcom.ibm.ws.sib.jsseProvider |
| Minimum JRE level | 1.4.2 | 1.5 |
| Enable trace (set trace specification) | -Dcom.ibm.ws.sib.client.traceSetting | -Dcom.ibm.ejs.ras.lite.traceSpecification |
| Set trace filename | -Dcom.ibm.ws.sib.client.traceFile | -Dcom.ibm.ejs.ras.lite.traceFileName |
| Set max trace file size | Not applicable | -Dcom.ibm.ejs.ras.lite.maxFileSize |
| Set max number of trace files | Not applicable | -Dcom.ibm.ejs.ras.lite.maxFiles |
| Set trace format | Not applicable | -Dcom.ibm.ejs.ras.lite.traceFormat |
| Using alternative trace properties file | -DtraceSettingsFile | -DtraceSettingsFile

Thin Client for JMS with WebSphere Application Server supports new options described in "Trace user interface for standalone clients" on page 1760 |
| Enable and specify FFDC filename | -DffdcLogFile | -Dcom.ibm.ejs.ras.lite.ffdcLogFile |
| NLS support | Install time option for NLS support | Non-English versions are available in sibc.nls.jar |

Using JMS resources with the Thin Client for JMS with WebSphere Application Server:

Suitable JMS connection factories and references to JMS queues or topics may be obtained programmatically without using JNDI. Alternatively, full JNDI support may be obtained from the Thin Client for EJB with WebSphere Application Server.

- To obtain suitable connection factories programmatically, without using JNDI, use code similar to that shown in the following example:

```
import com.ibm.websphere.sib.api.jms.*;
...
JmsConnectionFactory jmsCF =
    JmsFactoryFactory.getInstance().createQueueConnectionFactory();
jmsCF.setBusName("myBus");
jmsCF.setProviderEndpoints("1.2.3.4");
```

To obtain a suitable reference to a JMS queue or topic programmatically, use code similar to that shown in the following example:

```
JmsQueue jmsQ = JmsFactoryFactory.getInstance().createQueue("myQueue");
```

For further information, see the `JmsFactoryFactory` class API documentation available with WebSphere Application Server.

- To obtain full JNDI support from the Thin Client for EJB with WebSphere Application Server:
 1. Include the `/runtimes/com.ibm.ws.ejb.thinclient_7.0.0.jar` file in the compile and runtime classpaths for your enterprise application as described in “Installing and configuring the Thin Client for JMS with WebSphere Application Server” on page 1754.
 2. Use the following code to create a suitable Initial Context, substituting the server IP address and port as appropriate:

```
import javax.naming.*;
...
Properties env = new Properties();
env.put(Context.PROVIDER_URL, "iiop:
    //<server IP address>:<server bootstrap address port>");
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
InitialContext ctx = new InitialContext(env);
```

In certain situations, for example when running with a Sun JRE, an additional ORB jar is also required. For additional information about when this jar is required, see *Running the IBM Thin Client for Enterprise JavaBeans (EJB)*.

Obtaining WebSphere MQ JMS resources in the thin client environment:

A standalone Java SE JMS thin client application that connects to an external WebSphere MQ queue manager can get administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server Java Naming and Directory Interface (JNDI) namespace.

1. To obtain WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace in the thin client environment, include the following jar files in the runtime classpath of your application:
 - A copy of the `/runtimes/com.ibm.ws.ejb.thinclient_7.0.0.jar`.
 - A copy of the `/runtimes/com.ibm.ws.messagingClient.jar`.
 - WebSphere MQ client jar files which must be obtained from the WebSphere MQ product.
2. Use the following code to create a suitable Initial Context, substituting the server IP address and port as appropriate:

```
import javax.naming.*;
...
Properties env = new Properties();
env.put(Context.PROVIDER_URL, "iiop:
    //<server IP address>:<server bootstrap address port>");
env.put(Context.INITIAL_CONTEXT_FACTORY,
    "com.ibm.websphere.naming.WsnInitialContextFactory");
InitialContext ctx = new InitialContext(env);
```

In certain situations, for example when running with a Sun JRE, an additional ORB jar is also required. For additional information about when this jar is required, see the *Thin Client for EJB with WebSphere Application Server* information.

Running with other standalone clients:

The WebSphere Application Server standalone clients are the clients found in the %WAS_HOME%/runtimes directory. You can run standalone clients either on their own, or in conjunction with one or more other standalone clients.

Before you begin

When you are executing two or more of the following WebSphere Application Server standalone clients together, you must obtain all the clients that you are using from the same WebSphere Application Server installation or service refresh.

- Thin Client for JMS with WebSphere Application Server
- Thin Client for EJB with WebSphere Application Server
- Thin Client for JAX-WS with WebSphere Application Server
- Thin Client for JAX-RPC with WebSphere Application Server

This is because the mixing of standalone clients from different builds could result in unpredictable behavior since different builds might contain slightly different versions of the same class. The CWSJE0001E error message appears if the in-built consistency checker detects that you are trying to run clients with different build levels together.

Securing client and resource adapter connections

There are two approaches to configuring Secure Sockets Layer (SSL) for the Thin Client for JMS with WebSphere Application Server and the Resource Adapter for JMS with WebSphere Application Server. The global configuration approach affects all standalone outbound connections from the process, and the private approach applies only to client or resource adapter connections from the process.

About this task

The Thin Client for JMS with WebSphere Application Server and the Resource Adapter for JMS with WebSphere Application Server use the standard Java Secure Socket Extension (JSSE) that all supported JREs provide for making Secure Sockets Layer (SSL) connections. For information about JSSE, see the JSSE documentation.

The global configuration approach uses JRE global properties and affects all outbound SSL connections that your application initiates. For a JRE configured to use SSL connections to connect to WebSphere Application Server, you typically need to set the following javax.net.ssl system properties:

```
-Djavax.net.ssl.keyStore=key.p12  
-Djavax.net.ssl.keyStorePassword={xor}Lz4sLCgwLTs=  
-Djavax.net.ssl.trustStore=trust.p12  
-Djavax.net.ssl.trustStorePassword={xor}PSo4LSov
```

The private configuration approach allows you to specify security settings that are specific to the Thin Client for JMS with WebSphere Application Server or the Resource Adapter for JMS with WebSphere Application Server connections. You can configure the com.ibm.ws.sib.client.ssl.properties system property to specify the location of an IBM SSL properties file. If this system property is not configured, an attempt is made load the properties file from the classpath instead.

The client obtains the value that it uses for any particular SSL property as follows:

- If the property has a value defined in the properties file containing the IBM SSL properties, the client uses this value.
- There is no value for the property in the properties file, the client next looks for a suitable property in the associated JRE system properties.
- If there is no suitable javax.net.ssl property, the client uses the default value.

The table below summarizes the IBM SSL property keys that can be configured inside the IBM SSL properties file, and the corresponding javax.net.ssl.* system property keys and default values.

Table 18. IBM SSL property values and corresponding JRE global property and default values

| IBM SSL property | JRE global property | Default value |
|--------------------------------|----------------------------------|--------------------------------|
| com.ibm.ssl.keyStoreType | javax.net.ssl.keyStoreType | JKS |
| com.ibm.ssl.keyStore | javax.net.ssl.keyStore | None |
| com.ibm.ssl.keyManager | javax.net.ssl.keyStoreProvider | IbmX509 |
| com.ibm.ssl.trustManager | javax.net.ssl.trustStoreProvider | IbmX509 |
| com.ibm.ssl.keyStorePassword | javax.net.ssl.keyStorePassword | None |
| com.ibm.ssl.protocol | None | SSL |
| com.ibm.ssl.contextProvider | None | IBMJSSE2 |
| com.ibm.ws.sib.jsseProvider | None | com.ibm.jsse2.IBMJSSEProvider2 |
| com.ibm.ssl.trustStore | javax.net.ssl.trustStore | None |
| com.ibm.ssl.trustStoreType | javax.net.ssl.trustStoreType | JKS |
| com.ibm.ssl.trustStorePassword | javax.net.ssl.trustStorePassword | None |

For example, you might create an ssl.properties file that contains the following properties and values:

```
com.ibm.ssl.keyStore=/thinclient/key.p12
com.ibm.ssl.keyStoreType=PKCS12
com.ibm.ssl.keyStorePassword=WebAS
com.ibm.ssl.trustStore=/thinclient/trust.p12
com.ibm.ssl.trustStoreType=PKCS12
com.ibm.ssl.trustStorePassword=WebAS
```

You can use the PropFilePasswordEncoder tool in the WebSphere Application Server bin directory to encode passwords stored in plain text property files. For further information see Encoding passwords in files.

Note:

1. SSL connections from SUN JREs using the Thin Client for JMS with WebSphere Application Server cannot use the default WebSphere Application Server PKCS12 key and trust stores. If you are running the client securely from SUN JREs, you must first extract the certificates from the trust store using an IBM software development kit (SDK). You can then import these certificates into a keystore that the Sun JRE can recognize correctly, such as a JKS keystore.
 2. SSL connections are not supported using the IBM JRE shipped with WebSphere Application Server - a non-WebSphere Application Server installed JRE must be used.
1. Obtain the necessary key and trust store files.
 2. Set the javax.net.ssl system properties required for the global configuration approach.
 3. For the private configuration approach, use the com.ibm.ws.sib.client.ssl.properties system property to specify the file from which the SSL properties are to be loaded, as shown in the following example:
 -Dcom.ibm.ws.sib.client.ssl.properties=c:/ssl.properties

Adding tracing and logging for standalone clients

You can add tracing and logging to help analyze performance and diagnose problems.

About this task

This information applies to the following WebSphere Application Server standalone clients:

- Thin Client for JMS with WebSphere Application Server
- Thin Client for EJB with WebSphere Application Server
- Thin Client for JAX-WS with WebSphere Application Server

- Thin Client for JAX-RPC with WebSphere Application Server
- To enable trace, use either a long form or short form system property.

Note: Trace settings are determined from the system property values the first time that a WebSphere Application Server client is called. The trace settings are then fixed. Therefore, any subsequent changes to the system property settings do not change the trace settings that the WebSphere Application Server client uses.

- To enable First Failure Data Capture (FFDC), use either a long or short form system property.

Note: FFDC settings are determined from the system property values the first time that a WebSphere Application Server client performs an FFDC. The FFDC settings are then fixed. Therefore, any subsequent changes to the system property settings do not change the FFDC settings that the WebSphere Application Server client uses.

Trace user interface for standalone clients:

To enable trace, you can either use a long form or a short form system property.

Long form system properties

The long form system property takes priority over the short form and uses system properties that are unique to WebSphere Application Server.

Table 19. Long form system properties

| Property | Description |
|---|---|
| com.ibm.ejs.ras.lite.traceSpecification | The trace specification string |
| com.ibm.ejs.ras.lite.traceFileName | The trace destination (<file>, stdout, stderr, java,util.logging) |
| com.ibm.ejs.ras.lite.maxFileSize | The maximum trace file size in mb (if the trace destination is a file) |
| com.ibm.ejs.ras.lite.maxFiles | The maximum number of trace files kept (if the trace destination is a file) |
| com.ibm.ejs.ras.lite.traceFormat | The trace output format, which can be either basic or advanced (the default is basic) |

Long form example:

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=SIB*=all
-Dcom.ibm.ejs.ras.lite.traceFileName=c:/trace.log
-Dcom.ibm.ejs.ras.lite.maxFileSize=20
-Dcom.ibm.ejs.ras.lite.maxFiles=8
```

Short form system property

The short form uses a system property which is compatible with existing WebSphere Application Server clients but which, since this property is unqualified, may clash with other third party technologies that are running in the same Java runtime environment (JRE).

The short form system property is:

```
traceSettingsFile
```

This property must specify a loadable properties file that can contain the following properties:

Table 20. Properties in loadable system properties file

| Property | Header |
|---------------|---|
| traceFileName | The trace destination (file, stdout, stderr, java.util.logging) |
| maxFileSize | The maximum trace file size in mb (if the trace destination is a file) |
| maxFiles | The maximum number of trace files kept (if the trace destination is a file) |
| <traceSpec> | The trace specification |
| traceFormat | The trace output format, which can be either basic or advanced (the default is basic) |

The following example shows how to use the short form system property:

```
SIBTrm=all:SIBMfp=all  
traceFileName=c:/trace.log
```

Special meanings for trace file name values

Some trace file name values have a special meaning:

- stdout - causes trace records to be written to stdout
- stderr - causes trace records to be written to stderr
- java.util.logging - causes trace records to be written to java.util.logging

Using any other name causes the trace records to be written to a file of that name.

First Failure Data Capture user interface for standalone clients:

To enable First Failure Data Capture (FFDC) output, you can either use a long or short form system property.

Long form system property

The long form takes priority over the short form and uses a system property that is unique to WebSphere Application Server to specify the FFDC dump file name. This property is:

```
com.ibm.ejs.ras.lite.ffdcLogFile
```

The following example shows how to use the long form system property to enable FFDC output:

```
-Dcom.ibm.ejs.ras.lite.ffdcLogFile=c:\ffdc.log
```

Short form system property

The short form system property is:

```
ffdcLogFile
```

The following example shows how to use the short form system property to enable FFDC output:

```
-DffdcLogFile=c:\ffdc.log
```

Using JMS from a third party application server

The Resource Adapter for JMS with WebSphere Application Server provides first class connectivity to service integration resources from the third party application server on which it is deployed.

About this task

The Resource Adapter for JMS with WebSphere Application Server is designed to be deployed into third party application servers, that is, into non-WebSphere Application Server application servers, that support Java EE Connector Architecture (JCA) 1.5 and are Java 2 Platform, Enterprise Edition (J2EE) 1.4 compliant. The standalone resource adapter provides these third party application servers with full connectivity to service integration resources running inside WebSphere Application Server Version 6.0.2 and later.

Supported third party application servers are:

- WebSphere Application Server Community Edition Version 2.0 and later
- Apache Geronimo v2.0 and later
- JBoss Application Server v4.0.5 and later

Note:

- The resource adapter does not support the unmanaged JCA environment. In an unmanaged environment use the Thin Client for JMS with WebSphere Application Server.
- If you want to use XA connections to a WebSphere Application Server Version 6.0.2 application server, contact IBM Support to obtain a required service update.

Deploying the Resource Adapter for JMS with WebSphere Application Server

To provide connections to service integration resources running inside WebSphere Application Server, the Resource Adapter for JMS with WebSphere Application Server must be installed into the third party application server.

Before you begin

The Resource Adapter for JMS with WebSphere Application Server requires JRE 1.5 or later. The resource adapter is called `sibc.jmsra.rar` and is available from the following runtime directories:

- WebSphere Application Server install
- Application Client for WebSphere Application Server install

Before starting the deployment of the resource adapter, you must first obtain the following information from the WebSphere Application Server administrator:

- Bus name
- Endpoint provider address
- Target transport chain
- Messaging engine name
- Any other required connection and destination properties
- One or more destination names

The general approach to deploying the resource adapter is to write a deployment XML file to configure the required and optional properties for the JMS connection factory and JMS resources that will be accessed, and then deploy the resource adapter using the deployment XML file. The way in which you perform the installation depends on the particular application server that you are using. Before starting this task, see the documentation specific to your application server for information about how to install and use a JMS resource adapter RAR file.

About this task

An enterprise application that looks up a Resource Adapter for JMS with WebSphere Application Server connection factory in the local Java Naming and Directory Interface (JNDI) repository can access service integration resources through the resource adapter, provided that the required messaging engine is

available in WebSphere Application Server. All outbound connections must access all queues and topics using Queue or Topic resources. These resources are configured using your particular application server configuration mechanism when the resource adapter is deployed.

The Resource Adapter for JMS with WebSphere Application Server supports full two-phase XA transactional connections (except under the JBoss Application Server) but can also be run using local transactions or no transaction connections.

Multiple deployments of the resource adapter are possible.

1. To deploy an outbound JMS resource on the Resource Adapter for JMS with WebSphere Application Server, use your particular application server configuration mechanism to configure the following service integration bus properties:
 - Bus name
 - Provider endpoints
2. If you want to use XA resources over a Resource Adapter for JMS with WebSphere Application Server connection, use your particular application server configuration mechanism to configure the following additional service integration bus properties:
 - Target type must be set to "ME"
 - Target significance must be set to "Required"
 - Target must be set to the name of the required messaging engine

These properties permit the recovery of indoubt transactions, should this be necessary. For further information about indoubt transactions, see [Resolving indoubt transactions](#).

See "Resource Adapter for JMS with WebSphere Application Server configuration properties" for a description of these property names and other properties that may also be configured.

Results

Subsequent usage of the resource adapter is in accordance with the Java EE programming specifications. That is, any enterprise bean or message-driven bean may obtain a Resource Adapter for JMS with WebSphere Application Server connection factory or use an activation specification to connect to a service integration messaging engine. Message-driven beans behave in just the same way as they would in any other Java EE environment.

What to do next

You can turn trace and First Failure Data Capture (FFDC) on for the resource adapter in the same way as for the Thin Client for JMS with WebSphere Application Server. For further information, see "Adding tracing and logging for standalone clients" on page 1759.

You can configure secure connections by configuring connection factories that require a secure bootstrap and/or connection transport chain in the same way as for the Thin Client for JMS with WebSphere Application Server. For further information, see "Securing client and resource adapter connections" on page 1758.

Resource Adapter for JMS with WebSphere Application Server configuration properties:

As part of deploying Resource Adapter for JMS with WebSphere Application Server, you must configure a set of JMS resources which the deployed resource adapter instance will support.

The following tables list the JMS properties and their values.

Note: Not all properties available to applications running inside the WebSphere Application Server environment are available in third party environments. Some properties have no meaning outside of the WebSphere Application Server environment and some have no meaning for remotely connected clients.

Table 21. Connection factory properties

| Property name | Description | Permitted values | Default |
|--------------------------|--|--|----------------------|
| BusName | The name of the service integration bus to connect to. | | |
| ClientID | The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory. | | |
| UserName | | | |
| Password | | | |
| NonPersistentMapping | The reliability applied to nonpersistent JMS messages sent using this connection factory. | BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent | ExpressNonPersistent |
| PersistentMapping | The reliability applied to persistent JMS messages sent using this connection factory. | ReliablePersistent, AssuredPersistent | ReliablePersistent |
| DurableSubscriptionHome | The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory. | | |
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, Default | Default |
| Target | The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property. | | |
| TargetType | The type of target named in the Target property. | BusMember, Custom, ME | BusMember |
| TargetSignificance | The significance of the target group. | Required, Preferred | Required |
| TargetTransportChain | The name of the protocol that resolves to a group of messaging engines. | | |
| ProviderEndpoints | The list of comma separated endpoints used to connect to a bootstrap server. | | |
| ConnectionProximity | The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine. | Server, Cluster, Host, Bus | Bus |
| TemporaryQueueNamePrefix | The prefix of up to twelve characters used for names of temporary queues created by applications that use this connection factory. | | |

Table 21. Connection factory properties (continued)

| Property name | Description | Permitted values | Default |
|--------------------------------------|---|--------------------------------------|---|
| TemporaryTopicNamePrefix | The prefix used at the start of temporary topics created by applications using this connection factory. | | |
| ShareDurableSubscriptions | Controls whether or not durable subscriptions are shared across connections with members of a server cluster. | InCluster, AlwaysShared, NeverShared | InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server) |
| ProducerDoesNotModifyPayloadAfterSet | When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message. | true, false | false |

Table 22. Queue Connection factory properties

| Property name | Description | Permitted values | Default |
|----------------------|---|--|----------------------|
| BusName | The name of the service integration bus to connect to. | | |
| UserName | | | |
| Password | | | |
| NonPersistentMapping | The reliability applied to nonpersistent JMS messages sent using this connection factory. | BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent | ExpressNonPersistent |
| PersistentMapping | The reliability applied to persistent JMS messages sent using this connection factory. | ReliablePersistent, AssuredPersistent | ReliablePersistent |
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, Default | Default |
| Target | The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property. | | |
| TargetType | The type of target named in the Target property. | BusMember, Custom, ME | BusMember |
| TargetSignificance | The significance of the target group. | Required, Preferred | Required |
| TargetTransportChain | The name of the protocol that resolves to a group of messaging engines. | | |
| ProviderEndpoints | The list of comma separated endpoints used to connect to a bootstrap server. | | |

Table 22. Queue Connection factory properties (continued)

| Property name | Description | Permitted values | Default |
|--------------------------------------|---|----------------------------|---------|
| ConnectionProximity | The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine. | Server, Cluster, Host, Bus | Bus |
| TemporaryQueueNamePrefix | The prefix of up to twelve characters used for names of temporary queues created by applications that use this connection factory. | | |
| ProducerDoesNotModifyPayloadAfterSet | When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message. | true, false | false |

Table 23. Topic Connection factory properties

| Property name | Description | Permitted values | Default |
|-------------------------|--|--|----------------------|
| BusName | The name of the service integration bus to connect to. | | |
| ClientID | The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory. | | |
| UserName | | | |
| Password | | | |
| NonPersistentMapping | The reliability applied to nonpersistent JMS messages sent using this connection factory. | BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent | ExpressNonPersistent |
| PersistentMapping | The reliability applied to persistent JMS messages sent using this connection factory. | ReliablePersistent, AssuredPersistent | ReliablePersistent |
| DurableSubscriptionHome | The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory. | | |
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, Default | Default |
| Target | The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property. | | |

Table 23. Topic Connection factory properties (continued)

| Property name | Description | Permitted values | Default |
|---------------------------------------|---|--------------------------------------|---|
| TargetType | The type of target named in the Target property. | BusMember, Custom, ME | BusMember |
| TargetSignificance | The significance of the target group. | Required, Preferred | Required |
| TargetTransportChain | The name of the protocol that resolves to a group of messaging engines. | | |
| ProviderEndpoints | The list of comma separated endpoints used to connect to a bootstrap server. | | |
| ConnectionProximity | The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine. | Server, Cluster, Host, Bus | Bus |
| TemporaryTopicNamePrefix | The prefix used at the start of temporary topics created by applications using this connection factory. | | |
| ShareDurableSubscriptions | Controls whether or not durable subscriptions are shared across connections with members of a server cluster. | InCluster, AlwaysShared, NeverShared | InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server) |
| ProducerDoesNotModify PayloadAfterSet | When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message. | true, false | false |

Table 24. Queue properties

| Property name | Description | Permitted values | Default |
|---------------|--|--|---------|
| QueueName | The name of the associated queue on the service integration bus. | | |
| DeliveryMode | The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination. | Application, Persistent, NonPersistent | |
| TimeToLive | The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system. | | |
| Priority | The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority. | | |

Table 24. Queue properties (continued)

| Property name | Description | Permitted values | Default |
|---------------------|---|--|--------------|
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, AsConnection, Default | AsConnection |
| BusName | The name of the service integration bus to connect to. | | |
| ScopeToLocalQP | Sets whether the service integration bus queue destination identified by this Queue is dynamically scoped to a single queue point if one exists on the messaging engine that the application is connected to. | On, Off | Off |
| ProducerPreferLocal | Sets whether a MessageProducer for this Queue should prefer a locally connected queue point of the service integration bus queue destination over any other queue points. | On, Off | On |
| ProducerBind | Set whether messages sent by a single MessageProducer to this Queue will go to the same service integration bus queue point, or whether no such restriction will be applied, and different messages will be sent to different queue points. | On, Off | Off |
| GatherMessages | Set whether messages on all service integration bus queue points or only a single queue point are visible to MessageConsumers and QueueBrowsers using this Queue. | On, Off | Off |

Table 25. Topic properties

| Property name | Description | Permitted values | Default |
|---------------|---|--|---------------------|
| TopicSpace | The name of the topic space that contains the topic, on the service integration bus defined by the BusName property. | | Default.Topic.Space |
| TopicName | The name of the topic that this JMS topic is assigned to, in the topic space defined by the TopicSpace property | | |
| DeliveryMode | The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination. | Application, Persistent, NonPersistent | |
| TimeToLive | The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system. | | |

Table 25. Topic properties (continued)

| Property name | Description | Permitted values | Default |
|---------------|--|--|--------------|
| Priority | The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority. | | |
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, AsConnection, Default | AsConnection |
| BusName | The name of the service integration bus to connect to. | | |

Table 26. Activation configuration properties

| Property name | Description | Permitted values | Default | Required/optional |
|------------------------|--|---------------------------------------|------------------|-------------------|
| Destination | The name of the destination on the service integration bus. | | | Required |
| ProviderEndpoints | The list of comma separated endpoints used to connect to a bootstrap server. | | | Required |
| DestinationType | Whether the message-driven bean uses a queue or topic destination. | javax.jms.Queue, javax.jms.Topic | | Required |
| BusName | The name of the service integration bus to connect to. | | | Required |
| MessageSelector | The JMS message selector used to determine which messages the message-driven bean receives. The value is a string that is used to select a subset of the available messages. The syntax is based on a subset of the SQL 92 conditional expression syntax, as described in the JMS specification. | | | Optional |
| AcknowledgeMode | How the session acknowledges any messages it receives. | Auto-acknowledge, Dups-ok-acknowledge | Auto-acknowledge | Optional |
| SubscriptionDurability | Whether a JMS topic subscription is durable or nondurable. | Durable, Nondurable | Nondurable | Optional |
| SubscriptionName | The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription. | | | Optional |

Table 26. Activation configuration properties (continued)

| Property name | Description | Permitted values | Default | Required/optional |
|---------------------------|--|--------------------------------------|---|-------------------|
| MaxBatchSize | The maximum number of messages received from the messaging engine in a single batch. | 1 through 2147483647 | 1 | Optional |
| MaxConcurrency | The maximum number of endpoints to which messages are delivered concurrently | 1 through 2147483647 | 10 | Optional |
| RetryInterval | The delay (in seconds) between attempts to connect to a messaging engine. | 1 through 2147483647 | 30 | Optional |
| UserName | | | | Optional |
| Password | | | | Optional |
| DurableSubscriptionHome | The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory. | | | Optional |
| ShareDurableSubscriptions | Controls whether or not durable subscriptions are shared across connections with members of a server cluster. | InCluster, AlwaysShared, NeverShared | InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server) | Optional |
| ClientID | The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory. | | | Optional |
| TargetTransportChain | The name of the protocol that resolves to a group of messaging engines. | | | Optional |
| ReadAhead | Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests. | AlwaysOn, AlwaysOff, Default | Default | Optional |
| Target | The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property. | | | Optional |
| TargetType | The type of target named in the Target property. | BusMember, Custom, ME | BusMember | Optional |
| TargetSignificance | This property specifies the significance of the target group. | Required, Preferred | Required | Optional |

Table 26. Activation configuration properties (continued)

| Property name | Description | Permitted values | Default | Required/optional |
|---------------------------------------|--|------------------|---------------------|-------------------|
| TopicSpace | The name of the topic space that contains the topic, on the service integration bus defined by the BusName property. | | Default.Topic.Space | Optional |
| ForwarderDoesNotModifyPayloadAfterSet | When enabled, Object/Bytes messages forwarded through this activation specification that have their payload modified will not have the data copied when it is set into the message and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message. | true, false | false | Optional |

Deploying inbound connections for the resource adapter

When deploying inbound connections, you must configure message-driven beans to use the Resource Adapter for JMS with WebSphere Application Server. A JMS activation configuration associated with one or more message-driven beans provides the configuration necessary for them to receive messages.

About this task

You can deploy message-driven beans within your application with a JMS activation configuration to access the Resource Adapter for JMS with WebSphere Application Server connection factories and destinations. When the message-driven bean is started, it uses the resource adapter to connect to the service integration bus, provided that the required messaging engine is available in WebSphere Application Server.

The Resource Adapter for JMS with WebSphere Application Server supports full two-phase XA transactional connections but it may also be run using local transactions or no transaction connections.

1. Configure the following properties for the activation configuration:

- Destination
- ProviderEndpoints
- DestinationType
- BusName

The Destination property value is the name of the destination from which the message-driven bean will be receiving messages.

See “Resource Adapter for JMS with WebSphere Application Server configuration properties” on page 1763 for a description of these property names and other properties that may also be configured.

2. Configure the following additional properties if the message-driven bean will be using XA resources over the Resource Adapter for JMS with WebSphere Application Server connection.

- TargetType must be set to “ME”
- TargetSignificance must be set to “Required”
- Target value must be the name of the required ME

See “Resource Adapter for JMS with WebSphere Application Server configuration properties” on page 1763 for a description of these property names and other properties that may also be configured.

These properties permit the recovery of in-doubt transactions, should this be necessary. For further information about in-doubt transactions, see Resolving indoubt transactions.

Configuring high availability for the resource adapter

For XA connections, the Resource Adapter for JMS with WebSphere Application Server must always connect to the same messaging engine in a bus. High availability is therefore an important consideration.

About this task

If you are using XA resources, a specific messaging engine must be targeted for connection to allow in-doubt transactions to be recovered, if this becomes necessary. Therefore, the availability of the messaging engine is critical to the ability of the Resource Adapter for JMS with WebSphere Application Server to connect to the bus. It is recommended that in this scenario the target messaging engine be made highly available by deploying it to a cluster so that in the event of a server failure the messaging engine will be failed over to an alternative server in the cluster.

This restriction does not apply to connections with no transactional context, or with local transactional context because in this case the transaction is always committed or rolled back immediately and there is therefore never an in-doubt state.

1. Make the messaging engine highly available by deploying it to a cluster. For further information, see Service integration high availability and workload sharing configurations
2. Ensure that you have provided the connection factories with a list of provider endpoints for highly available bootstrap servers that the resource adapter can use to bootstrap to the required messaging engine. See also “Deploying the Resource Adapter for JMS with WebSphere Application Server” on page 1762 and “Deploying inbound connections for the resource adapter” on page 1771.

Choosing a messaging provider

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominantly WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider. To choose the provider that is best suited to your needs, consider what the application needs to do, and the business need for the provider to integrate well with your enterprise infrastructure.

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

You can configure any of the following messaging providers:

- The default messaging provider (which uses service integration as the provider)
- The WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider)
- A third-party messaging provider (which uses another company’s product as the provider)

The types of messaging providers that can be configured in WebSphere Application Server are not mutually exclusive:

- All types of provider can be configured within one cell.
- Different applications can use the same, or different, providers.
- One application can access multiple providers.

No one of these providers is necessarily better than another. The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

Note: For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the “V5 default messaging provider”. For more information, see “Maintaining Version 5 default messaging resources” on page 1795.

1. Determine the environment and application requirements.

If you need to use a third-party messaging provider, or interoperate with WebSphere Application Server Version 5 resources, use the associated provider. For more information, see “Other ways of managing messaging” on page 1785.

If your existing or planned messaging environment involves both WebSphere MQ and WebSphere Application Server systems, and it is not clear to you whether you should use the default messaging provider, the WebSphere MQ provider, or a mixture of the two, complete the task “Choosing messaging providers for a mixed environment” on page 1779.

2. Choose the messaging provider:

- Choose the default messaging provider.

If you mainly want to use messaging between applications in WebSphere Application Server, perhaps with some interaction with a WebSphere MQ system, the default messaging provider is the natural choice because this provider is fully integrated with the WebSphere Application Server runtime environment. For more information, see “Default messaging provider” on page 1926. To configure and manage messaging with the default messaging provider, see Managing messaging with the default messaging provider.

- Choose the WebSphere MQ messaging provider.

If your business also uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider allows you to define resources for connecting directly to the queues in a WebSphere MQ system. For more information, see “WebSphere MQ messaging provider” on page 1927. To configure and manage messaging with the WebSphere MQ messaging provider, see “Managing messaging with the WebSphere MQ messaging provider” on page 1965.

- Choose a third-party messaging provider.

You can use any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

Note:

- To administer a third-party messaging provider, use the resource adaptor or client supplied by the third party. You can still use the WebSphere Application Server administrative console to administer the JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.
- To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adapter that conforms to the Java EE Connector Architecture (JCA) Version 1.5 specification.

To work with a third-party provider, see “Managing messaging with a third-party messaging provider” on page 1785.

JMS providers collection

In the administrative console page, to view this page click **Resources** → **JMS** → **JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define your own JMS provider, other than the default messaging provider or WebSphere MQ, select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

General properties

Name

Description

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

| | |
|--------|--|
| New | Click this button to create a new JMS resource of this type. |
| Delete | Click this button to delete the selected items. |

Select JMS resource provider

The variable, *{0}*, indicates the type of JMS resource that you are creating.

You select the scope setting on an earlier page. The choice of JMS providers depends on the scope that you selected. You might see a choice like the following list:

- Default messaging provider.
Select this option if you want the type of JMS resource to be provided by a service integration bus, as part of WebSphere Application Server.
- My JMSprovider
Select this option if you want the type of JMS resource to be provided by your own JMS provider; not the default messaging provider or WebSphere MQ. You assign the name, in this example “My JMSprovider”, when you define the JMS provider to WebSphere Application Server. You must have installed and configured your own JMS provider before applications can use the JMS resources.
- WebSphere MQ messaging provider

Select this option if you want the type of JMS resource to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use the JMS resources.

- V5 default messaging provider

Select this option if you want the type of JMS resource to be provided by a WebSphere Application Server Version 5 node.

Activation specification collection

In the administrative console page, to view this page click **Resources** → **JMS** → **Activation specification**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS activation specifications that are available to WebSphere applications at the scope indicated by the **Scope** field.

Use a JMS activation specification if you want to use a message-driven bean as a J2EE Connector Architecture (JCA) 1.5 resource, to act as a listener on the default messaging provider.

General properties

Name

Provider

Description

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

| | |
|--------|--|
| New | Click this button to create a new JMS resource of this type. |
| Delete | Click this button to delete the selected items. |

Connection factory collection

In the administrative console page, to view this page click **Resources** → **JMS** → **Connection factory**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the JMS provider named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

General properties

Name

Provider

Description

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

| | |
|--------|--|
| New | Click this button to create a new JMS resource of this type. |
| Delete | Click this button to delete the selected items. |

Queue connection factory collection

In the administrative console page, to view this page click **Resources** → **JMS** → **Queue connection factory**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

General properties

Name

Provider

Description

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

| | |
|--------|--|
| New | Click this button to create a new JMS resource of this type. |
| Delete | Click this button to delete the selected items. |

Queue collection

In the administrative console page, to view this page click **Resources** → **JMS** → **Queue**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere applications at the scope indicated by the **Scope** field.

Use topic destination administrative objects to manage JMS queues for the JMS provider that is named in the Provider column of the list. Connections to the queue are created by a connection factory (or queue connection factory) for that JMS provider.

General properties

Name

Provider

Description

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Choosing messaging providers for a mixed environment

If your existing or planned messaging environment involves both WebSphere MQ and WebSphere Application Server systems, choose between the default messaging provider, the WebSphere MQ messaging provider, or a mixture of the two, by considering your messaging requirements, your business environment, and the needs of each messaging application.

About this task

For messaging between application servers, with interaction with a WebSphere MQ system, you can use the default messaging provider or the WebSphere MQ provider. Neither provider is necessarily better than the other. The choice of providers depends primarily on factors relating to your business environment and planned changes to that environment, and also on what each JMS application needs to do. Moreover, these two types of messaging providers are not mutually exclusive:

- You can configure both types of providers within one cell.
- Different applications can use the same, or different, providers.

Factors relating to your business environment include the following:

- Messaging requirements
- Existing skill set
- Existing messaging infrastructure
- Planned changes to that infrastructure

Configuring and managing your messaging infrastructure is simpler if you use just one provider. If your messaging is primarily in WebSphere MQ, you should probably choose the WebSphere MQ messaging provider. Similarly, if your messaging is primarily in WebSphere Application Server, you should probably choose the default messaging provider.

If your business environment does not clearly indicate that you should use just one provider, then you should consider using a mixture of the two, and choosing the most appropriate messaging provider for each application. A useful way of doing this is to identify the types of destinations (service integration bus, or WebSphere MQ queue or topic) that the application is using. If the application uses only bus destinations, the natural choice is to use the default messaging provider (solution "DMP"). If the application needs to communicate with one or more WebSphere MQ destinations, you can choose any of the following solutions depending upon your business environment, usage scenarios, and system topologies:

- Use the WebSphere MQ messaging provider (solution "MQP").
- Use the default messaging provider to integrate a WebSphere MQ server (a WebSphere MQ queue manager or queue-sharing group) as a bus member (solution "DMP interop bus member").
- Use the default messaging provider to integrate a WebSphere MQ network as a foreign bus, using WebSphere MQ links (solution "DMP interop, foreign bus").

For more information about these solutions, see [Overview of interoperation with WebSphere MQ](#).

To help you choose between these solutions, several of the following steps contain tables in which each row represents a business or system requirement, and asterisks (*) indicate the solutions that are likely to be most effective for meeting the requirement. These tables are designed to provide general guidance,

rather than to identify precisely a “right” solution. Most requirements have multiple possible solutions, and the absence of an asterisk does not necessarily mean that you cannot use that solution. To derive best guidance from using each of these tables:

- Focus on the rows that reflect your most important requirements.
- For all the rows that you consider, count the number of asterisks for each solution.

The solutions with the largest number of asterisks are likely to be the most effective.

1. If you have limited experience of WebSphere MQ or WebSphere Application Server, and are trying to decide which product best meets your messaging needs, see “Service integration and WebSphere MQ messaging - a comparison” on page 1784.

Note: Whichever of these products you choose as the main focus for your messaging, you can still use either the default messaging provider or the WebSphere MQ provider for interoperation between the products.

2. Consider your business environment, to see if you can use just one provider.

In deciding which provider to use, consider the following constraints:

- The current and future messaging requirements
- The existing messaging infrastructure
- The skill set that you have in your organization

If the majority of your messaging is today performed in WebSphere MQ, continue with that approach and configure WebSphere MQ as an external JMS provider (that is, use the WebSphere MQ messaging provider) in WebSphere Application Server. If the JMS requirements of your WebSphere Application Server applications are limited, it is debatable whether using a service integration bus for those applications gives sufficient benefit.

If you have messaging applications in WebSphere Application Server that have no requirement to interoperate with your WebSphere MQ network, use the default messaging provider (the service integration bus). If your WebSphere Application Server messaging requirements demand a tighter integration with WebSphere Application Server, the service integration bus provides the following benefits:

- Integrated administration
- WebSphere Application Server high availability capabilities
- WebSphere Application Server scalability

If you choose to use the default messaging provider to interoperate between service integration and WebSphere MQ, be aware that there is an added cost involved in converting messages between service integration format and WebSphere MQ format.

Also consider the following messaging scenarios:

- A large installed backbone of WebSphere MQ queue managers, perhaps with WebSphere Message Broker.

If you want to use WebSphere Application Server to run a newly introduced messaging application, you can deploy a WebSphere Application Server (JMS) messaging application that will exchange messages with an existing application that uses a WebSphere MQ queue or topic.

- A WebSphere Application Server installation, perhaps with existing Web and enterprise applications, but no WebSphere Application Server messaging application.

If you have no existing messaging infrastructure, you can deploy a WebSphere Application Server (JMS) messaging application to exchange messages with an existing WebSphere Application Server messaging application that uses a service integration bus destination.

- An infrastructure that uses WebSphere Application Server to connect WebSphere Application Server messaging applications.

Introduce WebSphere Application Server (JMS) messaging between a pair of WebSphere Application Server applications.

- An infrastructure that includes both WebSphere MQ and service integration buses. This could be the result of a merger, or because the message traffic tends to be from WebSphere Application Server to WebSphere Application Server, or from WebSphere MQ to WebSphere MQ, but not typically between WebSphere Application Server and MQ.

Deploy a WebSphere Application Server (JMS) messaging application to exchange messages with an application that uses a WebSphere MQ queue or topic.

- A WebSphere Process Server or WebSphere Enterprise Service Bus infrastructure, which uses Service Component Architecture (SCA).

You can choose either a WebSphere MQ or a service integration bus binding for your SCA components.

3. If your business environment does not clearly indicate that you should use just one messaging provider, use a mixture of the two and choose the most appropriate provider for each application, based upon the destination types that the application uses.

The application might need to exchange messages with existing partner applications or services that use one or more known destinations of known type. Alternatively, the partner applications or services might not yet be deployed and the choice of destination type might still be open, in which case the solution architect needs to decide how best to connect the applications or services together.

If the application uses multiple destinations, there are four possible outcomes:

- The application uses only bus destinations.
- The application uses only WebSphere MQ destinations.
- The application uses a mixture of bus and WebSphere MQ destinations.
- The destination types are not yet known.

Note: If there is no clear business or technical reason why the application uses WebSphere MQ destinations rather than bus destinations, and the partner application is also a WebSphere Application Server JMS application, consider migrating the existing destinations to service integration so that the application uses only bus destinations.

4. If the application uses only bus destinations, configure the application and its JMS resources to use the default messaging provider.
5. If the application uses only WebSphere MQ destinations (queues or topics), use the following checklist to determine which provider solution to use.

Table 27. Provider checklist for an application that uses only WebSphere MQ destinations.

| Question: | MQP | DMP interop, bus member | DMP interop, foreign bus |
|--|-----|-------------------------|--------------------------|
| Is performance critical?
(If so, use WebSphere MQ directly, rather than perform message conversion.) | * | | |
| Does the application need to send or receive large messages (that is, messages > 500k.)? | * | | |
| Is location transparency desirable for simplifying programming and deployment of applications? | | * | * |
| Does the application need to consume from a WebSphere MQ queue, the configuration of which is fixed?
(That is, the queue cannot be moved to service integration and you do not want to deploy a push-style WebSphere MQ application to send messages to a bus destination.) | * | * | |

Table 27. Provider checklist for an application that uses only WebSphere MQ destinations. (continued)

| Question: | MQP | DMP interop, bus member | DMP interop, foreign bus |
|--|-----|-------------------------|--------------------------|
| Is the partner application a JMS application that will run outside WebSphere Application Server, as a bus or WebSphere MQ client?

(Do not mix service integration and WebSphere MQ unless you have to do so; a pure WebSphere MQ or service integration solution is simpler and avoids the cost of converting messages between service integration and WebSphere MQ formats.) | * | | |
| Is the partner application a non-JMS (non-WebSphere Application Server) application?

(Wherever possible choose a pure WebSphere MQ or service integration solution. Use the MQI WebSphere MQ client, or the XMS WebSphere MQ client, or the XMS bus client depending on your API preference.) | * | | |
| Do you prefer traffic passing between your WebSphere MQ network and WebSphere Application Server applications to be funneled into a single long-running connection? | | | * |
| Do you want to use the high availability features of WebSphere Application Server? | | | * |
| Is XA 2pc needed between the application and a WebSphere MQ queue sharing group? | | * | * |
| Is XA 2pc needed between the application and a WebSphere MQ cluster? | | * | |

6. If the application uses a mixture of bus and WebSphere MQ destinations, for example consuming from service integration and sending to WebSphere MQ, then either of the default messaging provider interoperation models can support this by using a single connection factory or activation specification. Use the following checklist to help you decide between a bus member and a foreign bus solution.

Table 28. Provider checklist for an application that uses a mixture of bus and WebSphere MQ destinations.

| Question: | DMP interop, bus member | DMP interop, foreign bus |
|---|-------------------------|--------------------------|
| Does the application need to consume from a WebSphere MQ shared queue? | * | |
| Is there a need to distribute work to a pool of WebSphere Application Server workers from a WebSphere MQ queue? | * | |
| Do you prefer traffic passing between your WebSphere MQ network and WebSphere Application Server applications to be funneled into a single long-running connection? | | * |
| Do you need distributed WebSphere MQ in versions earlier than WebSphere Application Server Version 7 and WebSphere MQ Version 7? | | * |
| Do you want store and forward capabilities to allow the application to continue to send messages when the WebSphere MQ queue manager is unavailable? | | * |
| Do you prefer not to configure server connection channels?

(This is because they open a port, which could be seen as a security risk.) | | * |
| Do you prefer to define a server connection channel, rather than a pair of sender and receiver channels? | * | |

7. If the destination types are not yet known, decide the relative priorities of the known concerns then use the following checklist to assess how well each of them is addressed by the possible provider solutions.

The choice is really over what type of destinations this application should use. The destination types are not yet fixed, so any of the four solutions is possible, but as a general rule you should aim for solution “DMP” or “MQP”, because a pure WebSphere MQ or service integration solution is simpler

and avoids the cost of converting messages between service integration and WebSphere MQ formats.

Table 29. Provider checklist for an application for which the destination types are not yet known.

| Question: | DMP | MQP | DMP interop, bus member | DMP interop, foreign bus |
|--|------------|------------|--------------------------------|---------------------------------|
| Do you have an existing base of strong skills in managing WebSphere MQ? | | * | * | * |
| Do you want management of all messaging to be handled by the WebSphere MQ team? | | * | | |
| Do you have administrators skilled in WebSphere Application Server but not in WebSphere MQ? | * | | | |
| Do you want a messaging product with a large installed base (including references) and a wide choice of ISV tools? | | * | | |
| Are you reluctant to buy a separately licensed product in addition to WebSphere Application Server? | * | | | |
| Are you reluctant to install and manage a separate product in addition to WebSphere Application Server? | * | | | |
| Are you already using WebSphere Message Broker?
(If so, you need WebSphere MQ anyway). | | * | * | * |
| Are you using the WebSphere Enterprise Service Bus to mediate messages from, or deliver them to, a WebSphere MQ queue?
(For example, using WebSphere Business Integration adapters, or connecting to a service provider such as CICS.) | | * | | |
| Does the application need to send or receive large messages (that is, messages > 500k.)? | | * | | |
| Is location transparency desirable for simplifying programming and deployment of applications? | * | | * | * |
| Do the throughput requirements need multiple parallel channels or routes? | | * | * | * |
| Does the application need to consume from a WebSphere MQ queue, the configuration of which is fixed?
(that is, the queue cannot be moved to service integration and you don't want to deploy a push-style WebSphere MQ application to send messages to a bus destination.) | * | * | * | |
| Is the partner application a JMS application that will also run in WebSphere Application Server?
(Service integration runs in the WebSphere Application Server application server. On distributed platforms that means it is in-process. On the z/OS platform it is in another region.) | * | | | |
| Is the partner application a JMS application that will run outside WebSphere Application Server, as a bus or WebSphere MQ client?
(Do not mix service integration and WebSphere MQ unless you have to do so; a pure WebSphere MQ or service integration solution is simpler and avoids the cost of converting messages between service integration and WebSphere MQ formats.) | * | * | | |
| Is the partner application a non-JMS (non-WebSphere Application Server) application?
(Wherever possible choose a pure WebSphere MQ or service integration solution. Use the MQI WebSphere MQ client, or the XMS WebSphere MQ client, or the XMS bus client depending on your API preference.) | * | * | | |

Table 29. Provider checklist for an application for which the destination types are not yet known. (continued)

| Question: | DMP | MQP | DMP interop, bus member | DMP interop, foreign bus |
|---|-----|-----|-------------------------|--------------------------|
| Is maintenance of strict message order important? | * | | | |
| Does the application require the flexibility and convenience of a WebSphere MQ cluster?

(WebSphere MQ clustering makes administration simpler and provides selective parallelism of clustered queues. That is, instances of a clustered queue can be created on any (but not necessarily all) queue managers in the WebSphere MQ cluster. Messages sent to the clustered queue can be addressed to a specific instance of the queue, or allowed to select an instance dynamically based on workload management statistics. WebSphere Application Server clustering provides some of this flexibility, but you cannot create partitions of a bus destination on a subset of the messaging engines in a cluster bus member.) | | * | * | * |
| Does the application need the level of high availability provided by WebSphere MQ for z/OS shared queues? | | * | * | * |
| Do you want to use the high availability or scalability features of WebSphere Application Server clustering? | * | | * | * |

Service integration and WebSphere MQ messaging - a comparison

If you are not already an established user of either WebSphere Application Server or WebSphere MQ, and you are considering whether the service integration platform or WebSphere MQ better meets your messaging needs, use this table to compare the main features of the two platforms.

Table 30. Comparison of service integration and WebSphere MQ main features

| service integration (the default messaging provider for WebSphere Application Server) | WebSphere MQ |
|---|---|
| Service integration is closely integrated with WebSphere Application Server, and is a natural fit if you are using the Java Platform, Enterprise Edition (Java EE). | WebSphere MQ can connect to almost anything. It provides a very heterogeneous environment . |
| Service integration supports multiple languages through XMS clients, and multiple platforms. | WebSphere MQ supports multiple languages and multiple platforms. |
| Service integration is a single process, pure Java implementation. | WebSphere MQ has many Independent Software Vendor (ISV) tools. |
| Service integration provides strong performance for both persistent and non-persistent messages for JMS. | WebSphere MQ supports JMS and non-JMS messaging interfaces, and provides strong performance for non-JMS applications. |
| Service integration is designed for a maximum message size of about 40 megabytes on a 32-bit operating system (subject to heap usage). | WebSphere MQ supports large message sizes up to about 100 megabytes. |
| Service integration is tightly integrated with some Web services implementations. | WebSphere MQ is a natural fit if you are using WebSphere Message Brokers. |
| Service integration messaging is included in a single administrative model for WebSphere Application Server, WebSphere Enterprise Service Bus and WebSphere Process Server. | WebSphere MQ can integrate existing infrastructure and applications (for example CICS). |
| Service integration bus clustering is integrated with WebSphere Application Server clustering for high availability and scalability. | WebSphere MQ clustering provides selective parallelism of clustered queues. |

Note: The messaging platform that you choose for a given task does not necessarily determine which JMS messaging provider you should use. For example:

- If you need to handle large messages, you probably need to use the WebSphere MQ messaging provider.
- If you are using WebSphere Message Brokers, you can use either the default messaging provider or the WebSphere MQ messaging provider.

Other ways of managing messaging

For messaging between application servers, most requirements are best met by either the default messaging provider or the WebSphere MQ messaging provider. However, you can instead use a third-party messaging provider (that is, use another company's product as the provider). For backwards compatibility with earlier releases, there is also support for the V5 default messaging provider.

Before you begin

If you are not sure which provider combination is best suited to your needs, see “Types of messaging providers” on page 1925.

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

- Choose a third-party messaging provider.

You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

To administer a third-party messaging provider, you use the resource adaptor or client supplied by the third party. You can still use the WebSphere Application Server administrative console to administer the JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adaptor that conforms to the Java EE Connector Architecture (JCA) Version 1.5 specification.

To work with a third-party provider, see “Managing messaging with a third-party messaging provider.”

- Choose the (deprecated) V5 default messaging provider.

This deprecated provider is identical to the WebSphere Application Server Version 5 default provider. Only the name has changed. It provides backwards compatibility that enables WebSphere Application Server Version 6 or later applications to connect to WebSphere Application Server Version 5 resources in a mixed cell. It also allows WebSphere Application Server Version 5 applications to connect to WebSphere Application Server Version 6 or later resources in a mixed cell. To configure and manage messaging to interoperate with WebSphere Application Server Version 5, see “Maintaining Version 5 default messaging resources” on page 1795.

Managing messaging with a third-party messaging provider

Enabling your messaging applications to use JMS resources provided by a third-party messaging provider other than WebSphere MQ.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see “Choosing a messaging provider” on page 1772.

About this task

You can install a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider.

WebSphere Application Server applications can use the JMS 1.1 interfaces or JMS 1.0.2 interfaces to access JMS resources provided by a third-party messaging provider, and you can use the administrative console to administer the JMS connection factories and destinations for the provider.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer third-party messaging resources on Version 7, Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

To use a third-party messaging provider with WebSphere Application Server, complete one or more of the following steps:

- Define a third-party messaging provider.
- List third-party JMS messaging resources.
- Configure JMS resources for a third-party messaging provider.

Defining a third-party messaging provider

Use this task to define a third-party messaging provider to WebSphere Application Server, for use instead of the default messaging provider or WebSphere MQ messaging provider.

Before you begin

Before you configure a third-party messaging provider, you might want to check whether your requirement can be met by the default messaging provider or the WebSphere MQ messaging provider that are supplied with WebSphere Application Server. To choose the provider that is best suited to your needs, see “Choosing a messaging provider” on page 1772.

About this task

You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

To administer a third-party messaging provider, you use the resource adaptor or client supplied by the third-party. You can still use the WebSphere Application Server administrative console to administer the JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adapter that conforms to the J2EE Connector Architecture (JCA) Version 1.5 specification.

To define a new third-party messaging provider to WebSphere Application Server, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS Providers** . The existing messaging providers are displayed, including the default messaging provider and the WebSphere MQ messaging provider.
2. To define a new third-party messaging provider, click **New** in the content pane. Otherwise, to change the definition of an existing messaging provider, click the name of the provider.
3. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this messaging provider is known for administrative purposes within IBM WebSphere Application Server.

External initial context factory

The Java classname of the initial context factory for the JMS provider.

External provider URL

The JMS provider URL for external JNDI lookups.

4. Optional: Click **Apply**. This enables you to specify additional properties.
5. Optional: Specify other properties for the messaging provider.
Under Additional Properties, you can use the **Custom Properties** link to specify custom properties for your initial context factory, in the form of standard javax.naming properties.
6. Click **OK**.
7. Save the changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

What to do next

You can now configure JMS resources for your messaging provider, as described in “Configuring JMS resources for a third-party messaging provider” on page 1793.

Listing third-party JMS messaging resources

Use this task with the WebSphere Application Server administrative console to display administrative lists of JMS resources provided by a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider.

About this task

You can use the WebSphere Application Server administrative console to display lists of the following types of JMS resources provided by a 3rd party messaging provider. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources for a third-party messaging provider, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
3. Click the name of the third-party messaging provider.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. For more information about the detailed settings displayed for each resource type, see the related reference topics.

JMS provider collection:

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** → **JMS** → **JMS providers**

To view or change the properties of a JMS provider or its resources, select its name in the list displayed.

To define a new third-party messaging provider, click **New**.

To act on one or more of the JMS providers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

For related information about JMS messaging providers and asynchronous messaging, see

- “Types of messaging providers” on page 1925
- “Asynchronous messaging in WebSphere Application Server using JMS” on page 291

Third-party JMS connection factory collection:

The JMS connection factories configured for a third-party messaging provider for both point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS connection factories, or to select a connection factory to browse or change its configuration properties.

This panel shows a list of the JMS connection factories configured for a third-party messaging provider, with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS connection factory.
3. Under Additional Properties, click **Connection factories**.

To define a new JMS connection factory, click **New**.

To view or change the properties of a JMS connection factory, select its name in the list displayed.

To act on one or more of the JMS connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Third-party JMS connection factory settings:

Use this panel to browse or change the configuration properties of a JMS connection factory configured for use with a third-party messaging provider. These configuration properties control how connections are created to the JMS destinations on the provider.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. If appropriate, in the content pane, change the scope of the third-party messaging provider.
3. In the content pane, click the name of the messaging provider that supports the JMS connection factory.
4. Under Additional Properties, click **Connection factories**.
5. Click the name of the JMS connection factory that you want to work with.

A JMS connection factory for a third-party messaging provider (that is, a provider other than the default, the V5 default or the WebSphere MQ messaging provider) has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated messaging provider.

Data type String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

QUEUE

A JMS queue connection factory for point-to-point messaging.

TOPIC

A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the WebSphere Application Server name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the connection factory into the name space of the third-party messaging provider.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (*res-auth*) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (*res-auth*) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Global Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

| | |
|------------------|---|
| Data type | Enum |
| Default | Null |
| Range | ClientContainer
The client container maps authentication aliases. |
| | WSLogin
The WSLogin module maps authentication aliases. |
| | DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password. |

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the messaging provider.

Third-party JMS destination collection:

The JMS destinations configured in an associated third-party messaging provider for point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS destinations, or to select a JMS destination to browse or change its configuration properties.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.

To define a new JMS destination, click **New**.

To view or change the properties of a JMS destination, select its name in the list displayed.

To act on one or more of the JMS destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Third-party JMS destination settings:

Use this panel to browse or change the configuration properties of the selected JMS destination for use with an associated third-party messaging provider.

A JMS destination is used to configure the properties of a JMS destination for the associated third-party messaging provider (that is, not the default messaging provider or the WebSphere MQ messaging provider). Connections to the JMS destination are created by the associated JMS connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.
4. Click the name of the JMS destination that you want to work with.

A JMS destination for use with a third-party messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `.jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `.jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Configuring JMS resources for a third-party messaging provider

Use the following tasks to configure the JMS connection factories and destinations for a third-party messaging provider (that is, a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider).

Before you begin

You only need to complete these tasks if your WebSphere Application Server environment uses a third-party messaging provider to support enterprise applications that use JMS. To enable use of a third-party messaging provider, you must have installed and configured the messaging provider, as described in *Defining a third-party messaging provider*.

About this task

To configure JMS resources for a third-party messaging provider, complete the following tasks:

- Configure a JMS connection factory for a third-party messaging provider.
- Configure a JMS destination for a third-party messaging provider.

Configuring a JMS connection factory for a third-party messaging provider:

Use this task to browse or change the properties of a JMS connection factory for use with a JMS messaging provider other than the default, V5 default or WebSphere MQ messaging providers.

About this task

To configure a JMS connection factory for use with a third-party messaging provider, use the administrative console to complete the following steps:

1. Display the third-party messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS Providers**.
2. Select the third-party provider for which you want to configure a connection factory.
3. Optional: Change the **Scope** setting to the level at which the connection factory is visible to applications.
4. In the content pane, under Additional Properties, click **Connection factories**. This displays a table listing any existing JMS connection factories, with a summary of their properties.
5. To browse or change an existing JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server.

Type Select whether the connection factory is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name

The JNDI name that is used to bind the JMS connection factory into the WebSphere Application Server name space.

External JNDI Name

The JNDI name that is used to bind the JMS connection factory into the name space of the messaging provider.

- c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS connection factory, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS destination for a third-party messaging provider:

Use this task to browse or change the properties of a JMS destination for use with a third-party messaging provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider).

About this task

To configure a JMS destination for use with a third-party messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Click the name of the third-party messaging provider.

3. In the content pane, under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging. This displays a table listing any existing JMS destinations, with a summary of their properties.
4. To browse or change an existing JMS destination, click its name in the list. Otherwise, to create a new destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS destination is known for administrative purposes within WebSphere Application Server.

Type Select whether the destination is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name
The JNDI name that is used to bind the JMS destination into the WebSphere Application Server name space.

External JNDI Name
The JNDI name that is used to bind the JMS destination into the name space of the messaging provider.
 - c. Click **Apply**. This defines the JMS destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. Optional: Change properties for the JMS destination, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Maintaining Version 5 default messaging resources

This topic is the entry-point into a set of topics about maintaining messaging resources provided for WebSphere Application Server Version 5.1 applications by the default messaging provider.

About this task

JMS applications running on WebSphere Application Server Version 5.1 can use JMS resources provided by the default messaging provider in WebSphere Application Server Version 7. You can use the WebSphere Application Server administrative console to manage the JMS connection factories and destinations for WebSphere Application Server Version 5.1 applications. Such JMS resources are maintained as *V5 Default Messaging resources*.

In a deployment manager cell, you can use V5 Default Messaging resources to maintain Version 5 default messaging resources for Version 7, Version 6 and Version 5 nodes in the cell.

- V5 Default Messaging configured against a Version 7 node provides a JMS transport to a messaging engine of a service integration bus that supports the default messaging provider in WebSphere Application Server Version 7. The messaging engine emulates the service of a JMS server running on WebSphere Application Server Version 5.1.
- V5 Default Messaging configured against a Version 5.1 node provides a JMS transport to a JMS server running on WebSphere Application Server Version 5.1.

You can also use the administrative console to manage a JMS server on a Version 5.1 node.

- List Version 5 default messaging resources.
- Configure Version 5 default JMS resources.
- Manage Version 5 JMS servers in a deployment manager cell.
- Configure authorization security for a Version 5 default messaging provider.

- Tune JMS destinations.

Listing Version 5 default messaging resources

Use the WebSphere Application Server administrative console to list JMS resources for the Version 5 default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Connection factory (unified)
- Queue connection factory
- Topic connection factory
- Queue
- Topic
- Activation specification

When you use the Administrative Console to locate these resources, two different navigation pathways are available:

- Provider-centric navigation. This lets you view all providers (or just those for a specified scope if required), then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider owns it. Any navigation that starts with **Resources** → **JMS** → **JMS providers** is provider-centric.
- Resource-centric navigation lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider owns it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** → **JMS** → **[resource]**, where [resource] is one of the resource types listed above is resource-centric.

You can use either of these navigation pathways to locate resources of any type.

- Using provider-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.
 2. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**. This opens the providers collection which lists all currently configured providers across all scopes (you can modify the scope if required).
 3. From the providers collection, select the required provider. This opens the configuration tab for that provider. The configuration tab contains a set of links to all the resources owned by that provider.
 4. From the configuration tab, click the link for a resource type, for example the connection factories link. This opens the connection factories collection which lists all the connection factories for that provider.
 5. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties
- Using resource-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.
 2. In the navigation pane, expand **Resources** → **JMS** → **Connection factories**. This opens the connection factories collection which lists all the connection factories across all providers.
 3. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties.

JMS provider settings:

Use this panel to view the configuration properties of a selected JMS provider. You cannot change the properties of a default messaging provider or a WebSphere MQ messaging provider.

To view this page, use the administrative console to complete one of the following steps:

- In the navigation pane, click **Resources** → **JMS** → **JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
- If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
- In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For default messaging providers and WebSphere MQ messaging providers, only the scope, name, and description properties are displayed for information only. You cannot change these properties.

For another type of JMS provider that you have defined yourself, extra properties are displayed that you can change.

The default messaging provider is installed and runs as part of WebSphere Application Server, and is based on service integration technologies.

Scope:

The level to which this resource definition is visible; the cell, node, or server level.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name:

The name by which the JMS provider is known for administrative purposes.

| | |
|------------------|--------|
| Data type | String |
|------------------|--------|

Default

- Default messaging provider.
For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*
For JMS resources to be provided by your own JMS provider; not the default messaging provider or WebSphere MQ. You assign the name, in this example “My JMSprovider”, when you define the JMS provider to WebSphere Application Server. You must have installed and configured your own JMS provider before applications can use the JMS resources.
- WebSphere MQ messaging provider
For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use the JMS resources.
- V5 default messaging provider.
For JMS resources to be provided by a WebSphere Application Server Version 5 node in a deployment manager cell.

Description:

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath:

A list of paths or JAR file names which together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted using a variable map. Check your driver installation notes for specific JAR file names that are required.

This property does not apply to default messaging providers or WebSphere MQ providers.

Data type String

Native library path:

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted using a variable map.

This property does not apply to default messaging providers or WebSphere MQ providers.

Data type String

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

This property does not apply to default messaging providers or WebSphere MQ providers.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

| | |
|------------------|--------|
| Data type | String |
| Default | Null |

External provider URL:

The JMS provider URL for external JNDI lookups.

This property does not apply to default messaging providers or WebSphere MQ providers.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

| | |
|------------------|--------|
| Data type | String |
| Default | Null |

Version 5 JMS server collection:

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. Use this panel to list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each Version 5 node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this page, use the administrative console to complete the following step:

1. In the navigation pane, select **Servers** → **Version 5 JMS Servers**.

To browse or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check box next to the server name, then use the buttons provided.

Version 5 JMS server settings:

The JMS functions on a Version 5 node in a deployment manager cell are served by a JMS server. Use this panel to view or change the configuration properties of the selected JMS server.

JMS servers are supported only to aid migration of WebSphere Application Server Version 5 nodes to WebSphere Application Server Version 6.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the Version 5 default messaging provider.

Before you set any of the values on this panel, configure the JMS Server for each node by using the WebSphere Application Server Profile Management Tool described in the topic “Using the Profile Management Tool” or by using the `zpm` command described in the topic “Configuring z/OS application-serving environments with the `zpm` command”.

Name:

The name by which the JMS server is known for administrative purposes within IBM WebSphere Application Server.

This name should not be changed.

| | |
|------------------|-------------------------------|
| Data type | String |
| Units | Not applicable |
| Default | WebSphere Internal JMS Server |
| Range | Not applicable |

Description:

A description of the JMS server, for administrative purposes within IBM WebSphere Application Server.

This string should not be changed.

| | |
|------------------|-------------------------------|
| Data type | String |
| Default | WebSphere Internal JMS Server |

Short Name: Specifies the short name of the server. For WebSphere Application Server for z/OS, the server short name must be unique within a cell. The short name is also the default z/OS job name, which identifies the server to the native facilities of the operating system, such as Workload Manager (WLM), Automatic Restart Manager, SAF (for example, RACF), started task control, and others.

The system assigns a default short name that is automatically unique within the cell.

Unique Id: Specifies a unique identifier for this server.

The unique ID property is read only. The system automatically generates the value.

Queue Names:

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

| | |
|------------------|---|
| Data type | String |
| Units | Queue name |
| Range | Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue. |

Initial State:

The state that you want the JMS server to have when it is next restarted.

| | |
|------------------|---------|
| Data type | Enum |
| Default | Started |

Range**Started**

The JMS server is started automatically.

Stopped

The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server.

To restart a JMS server on a Version 5 node, stop then restart that JMS server.

Version 5 WebSphere queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server Version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queue connection factories**. This displays a list of any existing JMS queue connection factories.
5. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type

String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type

String

Default

Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Default Null
Range Pull-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type
Default
Range

Enum

Null

ClientContainer

The client container maps authentication aliases.

WSLogin

The WSLogin module maps authentication aliases.

DefaultPrincipalMapping

The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

| | |
|--------------------|--|
| Data type | Checkbox |
| Default | Selected (enabled for XA coordination) |
| Range | Selected
The connection factory is enabled for XA-coordination of messages
Cleared
The connection factory is not enabled for XA coordination of messages |
| Recommended | Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved. |

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

WebSphere topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topic connection factories**. This displays a list of any existing JMS topic connection factories.
5. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

| | |
|------------------|--------|
| Data type | String |
| Default | Null |

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

| | |
|------------------|--------|
| Data type | String |
|------------------|--------|

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

| | |
|------------------|---|
| Data type | Enum |
| Default | Null |
| Range | Pull-down list of nodes in the WebSphere administrative domain. |

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to **Direct** cannot be used with message-driven beans.

| | |
|------------------|--|
| Data type | Enum |
| Units | Not applicable |
| Default | QUEUED |
| Range | QUEUED
The listener port used for full-function JMS-compliant, publish/subscribe support.
DIRECT
The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support. |

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

| | |
|------------------|------|
| Data type | Enum |
| Default | Null |

Range

ClientContainer

The client container maps authentication aliases.

WSLogin

The WSLogin module maps authentication aliases.

DefaultPrincipalMapping

The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type

Enum

Default

Cleared

Range

Selected

Clone support is enabled.

Cleared

Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type

String

Range

A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type

Checkbox

Default

Selected (enabled for XA coordination)

Range

Selected

The connection factory is enabled for XA-coordination of messages

Cleared

The connection factory is not enabled for XA coordination of messages

Recommended

Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Version 5 WebSphere queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server Version 5 applications. Connections to the queue are created by the associated V5 Default Messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queues**. This displays a list of any existing JMS queue destinations.
5. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the Queue Names field on the panel for the JMS server that hosts the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String
Default Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum

**Default
Range**

APPLICATION DEFINED
APPLICATION DEFINED

Messages on the destination have their persistence defined by the application that put them onto the queue.

NON PERSISTENT

Messages on the destination are not persistent.

PERSISTENT

Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

**Data type
Default
Range**

Enum

APPLICATION DEFINED

APPLICATION DEFINED

The priority of messages on this destination is defined by the application that put them onto the destination.

QUEUE DEFINED

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

SPECIFIED

The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

**Data type
Units
Default
Range**

Integer

Message priority level

0

0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

**Data type
Default**

Enum

APPLICATION DEFINED

Range

APPLICATION DEFINED

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED

Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to **Specified**, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type

Integer

Units

Milliseconds

Default

0

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Version 5 WebSphere topic destination settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere application server Version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node in a deployment manager cell. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topics**. This displays a list of any existing JMS topic destinations.
5. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String

Default Null

Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type
Default
Range

Enum
APPLICATION DEFINED
APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON-PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type
Units
Default
Range

Enum
Not applicable
APPLICATION DEFINED
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.

Configuring Version 5 default JMS resources

Use the following tasks to configure the JMS connection factories and destinations WebSphere Application Server Version 5 applications.

About this task

You only need to complete these tasks if you have WebSphere application server Version 5 applications that need to use JMS resources provided by the default messaging provider. Such JMS resources are maintained as *V5 Default Messaging* resources.

In a deployment manager cell, you can use *V5 Default Messaging* resources to maintain Version 5 default messaging resources for both Version 6 and Version 5 nodes in the cell.

- Configuring a connection for Version 5 default messaging
- Configuring a Version 5 default JMS queue connection factory
- Configuring a Version 5 default JMS topic connection factory
- Configuring a Version 5 default JMS queue destination
- Configuring a Version 5 default JMS topic destination

Configuring a connection for Version 5 default messaging:

Use this task to configure a connection to Version 5 default messaging. This task is provided to help you manually migrate nodes from v5 to v6. If you use the supplied tools to migrate existing v5 nodes to v6, the jmsserver, appserver and port that you create with this task are defined automatically.

About this task

To configure a connection for Version 5 default messaging, use the administrative console to complete the following steps:

1. Create an application server with the name `jmsserver` (only one of these can exist on each node). In the navigation pane, expand **Servers** → **Application servers**.
2. On the new server, define a new `JMSSERVER_QUEUED_ADDRESS` port with the host set to the v6 server host, and the port set to the same as the `SIB_MQ_ENDPOINT_ADDRESS` of the server which is a member of your bus. The appserver called `jmsserver` does not actually have to be started; it is only used for looking up the port address.
3. Define a queue connection factory and queue at the Node or Cell scope. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
4. In the content pane, click the name of the V5 default messaging provider.
5. Define a queue destination on your bus with the same name as your queue defined under v5 default messaging.
6. Define an alias destination on your bus with the same name as your queue defined under v5 default messaging but with `WQ_` appended to the front the name. For example, if your queue has the name `MyV5Queue`, your alias should have the name `WQ_MyV5Queue`.
7. Point the alias at your queue destination with the correct name. The migration process targets the queue with the `WQ_` prefix; defining the alias to point to the real queue helps migration.
8. Define the WebSphere MQ Client Link on your messaging engine on the bus. Keep the WebSphere MQ channel name `WAS.JMS.SVRCONN` and set the queue manager name so that it contains your node name. For example, if your node name is `MyNode`, you would set the queue manager name to `WAS_<MyNode>_jmsserver`. Now set the queue manager name to the same; in this example it would be `WAS_MyNode_jmsserver`. The WebSphere MQ Client Link will show a status of inactive, this is normal.
9. Restart your server so that the new JNDI definitions bind correctly. Your v5 client should now be able to connect to v6 using the host and bootstrap address of the v6 system in the provider url component of the initial context. Your client should now also be able to send messages to the destination on the bus.
10. If you open the Client connections view and click the refresh icon, the hostname of the connecting system is visible whilst the client is connected. In the navigation pane, expand **Buses** → [**bus name**] → **Messaging engines** → [**messaging engine name**] → **WebSphere MQ client links** → [**client link name**] → **Runtime** → **Client connections view**.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 queue connection factory:

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node in a deployment manager cell. This task contains an optional step for you to create a new JMS queue connection factory.

About this task

To configure a JMS queue connection factory for use by WebSphere application server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a queue connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.

5. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name
The JNDI name that is used to bind the JMS queue connection factory into the name space.
 - c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the queue connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 JMS topic connection factory:

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

About this task

To configure a JMS topic connection factory for use by WebSphere application server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topic connection factories**. This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
5. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name
The JNDI name that is used to bind the JMS topic connection factory into the name space.
 - c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere queue destination:

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Application Server Version 5 queue destinations” on page 1825.

To configure a JMS queue destination for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. Select the Version 5 provider for which you want to configure a queue destination.
4. In the content pane, under Additional Properties, click **Queues**. This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:

- a. Click **New** in the content pane.
- b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the queue destination into the name space.

- c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.

6. Optional: Change properties for the queue destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To make a queue destination available to applications, host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server.
To define the administrative name of the queue to the JMS server, see Managing Version 5 JMS servers in a deployment manager cell.
10. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere topic destination:

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere application server Version 5 applications.. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Application Server Version 5 topic destinations” on page 1826.

To configure a JMS topic destination for use WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a topic destination.
3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topics**. This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the topic destination into the name space.

Topic The name of the topic in the default messaging provider, to which messages are sent.

- c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic destination, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Managing Version 5 JMS servers in a deployment manager cell

Use this task to manage JMS servers on WebSphere Application Server Version 5 nodes in a deployment manager cell.

About this task

The use of JMS servers is only intended to support migration from WebSphere Application Server Version 5 nodes to WebSphere Application Server Version 6.

In a WebSphere Application Server deployment manager cell, each Version 5 node can have at most one JMS server, and any Version 5 application server within the cell can use JMS resources served by any of those JMS servers. Applications on WebSphere Application Server Version 6 can also use JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all Version 5 JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of properties configured automatically for the Version 5 default messaging provider.

Note: In general, the default values of properties for the Version 5 default messaging provider are adequate for JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a Version 5 JMS server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers** → **JMS Servers**. This displays a table of the JMS servers, showing their runtime status.
2. Optional: If you want to change the runtime status of a JMS server, complete the following steps:
 - a. In the table of JMS servers, select the JMS servers that you want to act on.
 - To act on one or more specific JMS servers, select the check box next to the JMS server name.
 - To act on all JMS servers, select the check box next to the JMS servers title of the table.
 - b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. Optional: If you want to change the properties of a JMS server, complete the following steps:
 - a. Click the name of the server
 - b. Set one or more of the following configuration properties:

Initial state

If you want the JMS server to be started automatically when the application server is next started, set this property to Started.

Number of threads

Set the number of concurrent threads to be used by the publish/subscribe matching engine. The number of concurrent threads should only be set to a small number.

4. Optional: If you want the JMS server to host a new JMS queue, add the queue name to the Queue Names field.

The name must match the name of a JMS Queue administrative object, including the use of upper- and lowercase.
5. Optional: If you want to stop the JMS server hosting a JMS queue, remove the queue name from the Queue Names field.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the JMS server.

Configuring authorization security for a Version 5 default messaging provider

Use this task to configure authorization security for the default messaging provider on a WebSphere Application Server Version 5 node in a deployment manager cell.

About this task

To configure authorization security for the Version 5 default messaging provider complete the following steps.

Note: Security for the Version 5 default messaging provider is enabled when you enable WebSphere Application Server security on the Version 5 node. For more information about enabling security, see *Enabling security*.

1. Configure authorization settings to access JMS resources owned by the embedded messaging subsystem.

Authorization to access JMS resources owned by the embedded messaging subsystem is controlled by settings in the *wempath/wempsname/config/integral-jms-authorizations.xml* file. The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the *integral-jms-authorisations.xml* file grants the following permissions:

- Read and write permissions to all queues.
- Pub, sub, and persist to all topics.

To configure authorization settings, edit the *integral-jms-authorisations.xml* file according to the information in this topic and in that file.

2. Edit the `queue-admin-userids` element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following `queue-admin-userids` section:

```
<queue-admin-userids>
  <userid>adminid1</userid>
  <userid>adminid2</userid>
</queue-admin-userids>
```

In this example the userids `adminid1` and `adminid2` are defined to have administrative access to all queues.

3. Edit the `queue-default-permissions` element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following `queue-default-permissions` element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

In this example for the queue `q1`, the userid `useridr` has read permission, the userid `useridw` has write permission, the userid `useridrw` has both read and write permissions, and all other userids have no access permissions (`<public></public>`).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then

permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

- a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```
<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>
```

In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

- b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid `useridpub` is granted publish permission for any topic whose name starts with a/b/c.

6. Save the `integral-jms-authorizations.xml` file.

Results

If the dynamic update setting is selected, changes to the `integral-jms-authorizations.xml` file become active when the changed file is saved, so there is no need to stop and restarted the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Dynamic updating is available, by ensuring proper tagging in the `integral-jms-authorizations.xml` file `<dyanmic-update>>true</dyanmic-update>`.

Authorization settings for Version 5 default JMS resources:

Use the `integral-jms-authorisations.xml` file to view or change the authorization settings for Java Message Service (JMS) resources owned by the default messaging provider on WebSphere Application Server Version 5 nodes.

Authorization to access default JMS resources owned by the default messaging provider on WebSphere Application Server nodes is controlled by the following settings in the `wempspath/wempsname/config/integral-jms-authorizations.xml` file.

This structure of the settings in `integral-jms-authorisations.xml` is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in Configuring authorization security for the Version 5 JMS providers

```

<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>

  <queue-default-permissions>
    <permission>write</permission>
  </queue-default-permissions>

  <queue>
    <name>q1</name>
    <public>
      </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
    <authorize>
      <userid>useridw</userid>
      <permission>write</permission>
    </authorize>
  </queue>

  <queue>
    <name>q2</name>
    <public>
      <permission>write</permission>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
  </queue>

  <topic>
    <name></name>
    <public>
      <permission>+pub</permission>
    </public>
  </topic>

  <topic>
    <name>a/b/c</name>
    <public>
      <permission>+sub</permission>
    </public>
    <authorize>
      <userid>useridpub</userid>
      <permission>+pub</permission>
    </authorize>
  </topic>

</integral-jms-authorizations>

```

dynamic-update: Controls whether or not the JMS Server checks dynamically for updates to this file.

true (Default) Enables dynamic update support.

false Disables dynamic update checking and improves authorization performance.

queue-admin-userids: This element lists those userids with administrative access to all Version 5 default queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

<userid>adminid</userid>

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

<permission>read-write</permission>

Where *read-write* is one of the following keywords:

read By default, userids have read access to Version 5 default queue destinations.

write By default, userids have write access to Version 5 default queue destinations.

queue: This element contains the following authorization settings for a single queue destination:

name The name of the queue.

public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

topic: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

Tuning JMS destinations

Use this task to configure the properties of a JMS destination to optimize performance of applications that use the WebSphere Application Version 5 default messaging provider or WebSphere MQ as a JMS provider.

About this task

To optimize performance, configure destination properties to best fit your applications. You should also consider queue attributes of the JMS server that are associated with the queue name. For more information, see the following topics:

- “Performance considerations for WebSphere Application Server Version 5 queue destinations”
- “Performance considerations for WebSphere Application Server Version 5 topic destinations” on page 1826
- “Performance considerations for WebSphere MQ queue destinations” on page 1826
- “Performance considerations for WebSphere MQ topic destinations” on page 1827

Performance considerations for WebSphere Application Server Version 5 queue destinations:

To optimize performance, configure the queue destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

For queue destinations configured on a WebSphere Application Server Version 5 node, you should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

BOQNAME

The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH

The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

For more information about using these properties, see:

- “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere Application Server Version 5 topic destinations:

To optimize performance, configure the JMS destination properties to best fit your applications.

For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

For JMS destinations configured on a WebSphere Application Server Version 5 node, ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
 - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
 - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

For more information about using these properties, see:

- The *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ queue destinations:

To optimize performance, configure the queue destination properties to best fit your message-driven beans or other applications that use the queue destinations.

For example:

- When MDB applications are configured to WebSphere MQ queues on z/OS, the INDEX by MSGID is very important.
- Setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for use by your message-driven beans or other applications that use the queue.

You should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

You should also consider the queue attributes associated with the queue name you created with WebSphere MQ. Inappropriate queue attributes can reduce the performance of WebSphere operations. You can use WebSphere MQ commands to change queue attributes for the queue name.

BOQNAME

The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH

The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

INDXTYPE

Set this to MSGID. This causes an index of message identifiers to be maintained, which can improve WebSphere MQ retrieval of messages.

DEFSOPT

Set this to SHARED (for shared input from the queue).

SHARE

This must be specified (so that multiple applications can get messages from this queue).

For more information about using these properties, see:

- For BOQNAME and BOTHRESH, see “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ topic destinations:

To optimize performance, configure the topic destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
 - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
 - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

For more information about using these properties, see:

- The *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

JMS components on Version 5 nodes

To provide messaging support on a WebSphere Application Server Version 5 node, there is at most one JMS server and some number of JMS resources configured for the default messaging JMS provider on that node.

A *JMS server* on a Version 5 node serves the JMS resources (connection factories and destinations) for that node. The JMS server is managed as a separate process to application servers on the same node. Any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A *connection factory* encapsulates the configuration properties used to create connections with the JMS provider, to enable applications to access JMS destinations.

The main components of JMS support on a Version 5 node are shown in the figure The main components of WebSphere JMS support.

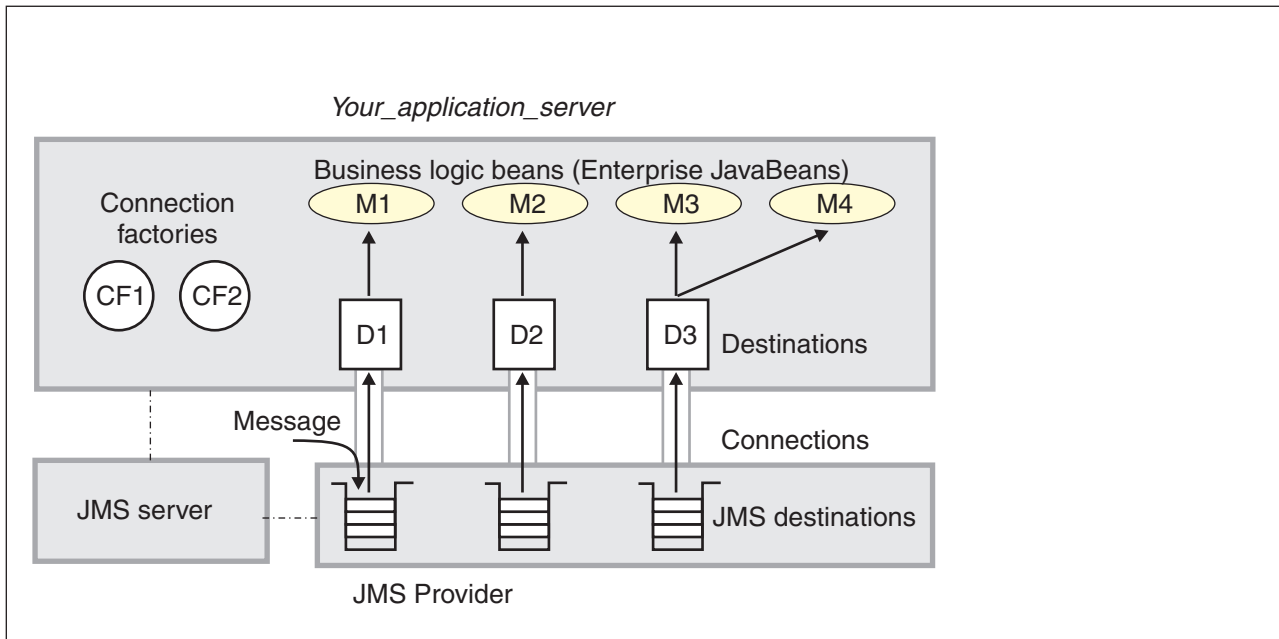

Figure 20. The main JMS components on a version 5 node. This figure shows the main JMS components on a version 5 node, from JMS provider through a connection to a destination, then to a WebSphere enterprise application (acting as a JMS client) that processes the message retrieved from the destination. For more information, see the text that accompanies this figure.

Administering listener ports and activation specifications for message-driven beans

Use these tasks to manage the listener ports and activation specifications used by message-driven beans (MDBs). If the JMS provider is implemented as a J2EE Connector Architecture (JCA) resource adapter use an activation specification, otherwise use a listener port. These tasks are supplementary to the tasks of administering resource adapters, and JMS provider resources.

About this task

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

Use the WebSphere Application Server administrative console to configure the following resources for message-driven beans:

- J2C activation specifications for JCA 1.5-compliant message-driven beans. Activation specifications must be provided when the application's resources are configured using the default messaging provider or any generic J2C Resource Adapter that supports inbound messaging.
- The message listener service, listener ports, and listeners for EJB 2.0 message-driven beans deployed against listener ports. Listener ports must be provided when using the following JMS providers: V5 Default Messaging, or Generic.

Listener port or activation specification?

WebSphere Application Server Version 6 or later supports the enhancements made to the EJB 2.1 and Java EE specifications that allow any resource that has a JCA 1.5 adapter to trigger an MDB (formerly only JMS resources could trigger MDBs). WebSphere Application Server Version 5 and EJB 2.0 used the listener port which specified a JMS connection factory and a destination. This allowed a pool of MDB instances to connect to the messaging system and listen to the designated destination. EJB 2.1 specifies an additional requirement of an MDB working with a JCA adapter using an activation specification.

If you are developing WebSphere Application Server Version 6 or later applications, you should consider the following questions:

- Should I use a listener port or an activation specification?
- Should I convert my existing listener ports to activation specifications?
- Will listener ports eventually not be supported anymore?

Here are some guidelines to help you decide:

- If you are using J2EE 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used, so you do not have to make a decision. WebSphere Application Server Version 4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server Version 5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server Version 5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using Java EE and EJB 2.1 with WebSphere Application Server Version 6 or later and not using JMS, you must use activation specifications. A connector MDB uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
- If you are using Java EE and EJB 2.1 with WebSphere Application Server Version 6 or later, the decision depends on whether your JMS provider API is implemented with JCA. In Java EE, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

To summarize: in WebSphere Application Server Version 6 or later, the decision on whether or not to use a listener port or an activation specification depends on the following scenarios:

- whether you upgrade your EJB 2.0 MDBs to EJB 2.1
- whether you want your EJB 2.1 MDB to use a JCA adapter
- whether you access your JMS provider via a JCA adapter.

If you have JMS API implementations that do not use JCA, WebSphere Application Server requires listener ports; if all JMS API implementations use JCA, listener ports are no longer required.

You can update the configuration data at any time, but some updates only take effect when the appropriate server is next started.

For additional information about administering support for message-driven beans, see the following topics:

- Configuring a JMS activation specification for MDBs used by the default messaging provider
- “Configuring a J2C activation specification”
- “Configuring a J2C administered object” on page 1834
- Configuring message listener resources for EJB 2.0 message-driven beans

Configuring a J2C activation specification

Use this task to configure a J2EE Connector (J2C) activation specification used to deploy message-driven beans with an external resource adapter.

About this task

Use this task if you want to use a message-driven bean as a listener on a Java Connector Architecture (JCA) 1.5 resource adapter other than the default messaging JMS provider.

You can create or modify a J2C activation specification under an installed resource adapter at the cell, node, or server scope. You can select the message listener type from those provided by the given resource adapter.

Configuring a J2C activation specification offers two distinct advantages:

- The activation specification configuration information can be shared among multiple message-driven beans across multiple applications.
- Updates to the configuration properties can be made without the need to redeploy the application.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using J2EE 1.2 and Enterprise JavaBeans (EJB) 1.1 with WebSphere Application Server Version 4, message-driven beans are not used so you do not need listener ports or activation specifications. WebSphere Application Server Version 4 uses message beans, but these are not message-driven beans or enterprise beans.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server Version 5, you must use listener ports. The message-driven beans are JMS message-driven beans that implement `MessageListener`, and there is no JCA support. WebSphere Application Server Version 5 uses listener ports to associate message-driven bean classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server Version 6, you must use activation specifications. A connector message-driven bean uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of message-driven beans from EJB 2.0 to EJB 2.1.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server Version 6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your message-driven bean is a JMS message-driven bean that is implemented as a connector message-driven bean, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 message-driven bean in the same way as you would configure an EJB 2.0 message-driven bean, which in WebSphere Application Server is to use a listener port.

To configure a J2C activation specification for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new activation specification.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Activation specifications heading, click **J2C Activation Specifications**. This lists any existing J2C activation specifications for the external resource adapter in the content pane.
4. Display the properties of the J2C activation specification. If you want to display an existing J2C activation specification, click one of the names listed.

Alternatively, if you want to create a new J2C activation specification, click **New**, then specify the following required properties:

Name Type the name by which the activation specification is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Message listener type

Select the message listener type that this activation specification instance should support. This list is based on the deployment descriptor of the external resource adapter.

Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new activation specification, you may need to click **Apply** before this custom property selection is available.

5. Specify properties for the activation specification, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Activation Specifications collection:

This page contains a list of J2C activation specifications for a resource adapter configuration and is used to create new J2C activation specifications, to select J2C activation specifications for configuration changes, or to delete J2C activation specifications.

Activation specification definitions and classes are provided by a resource adapter when it is installed. Using this information, the administrator can create and configure J2C activation specifications with JNDI names that are then available for applications to use. The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using Java 2 Platform, Enterprise Edition (J2EE) 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used so you do not need listener ports or activation specifications. WebSphere Application Server v4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ;ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, you must use activation specifications. A connector MDB uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C activation specifications**.
- **Resources** → **Resource Adapters** → **J2C activation specifications**.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Message Listener Type:

The Message Listener Type that is used by this activation specification.

The list of available classes is provided by the resource adapter.

Data type String

J2C Activation Specifications settings:

Use this page to specify the settings for a J2C activation specification.

The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C activation specifications** → *activation_specification*.
- **Resources** → **Resource Adapters** → **J2C activation specifications** → *activation_specification*.

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification. Name is required

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Authentication alias:

This optional field is used to bind the J2C activation specification to an authentication alias (configured through the security JAAS screens).

This alias is used to access a user name and password that are set on the configured J2C activation specification. This field is only meaningful if the J2C activation specification you are configuring has a UserName and Password field.

If you have defined security domains in the application server, you can click **Browse...** to select a J2C authentication alias for the resource that you are configuring. Security domains allow you to isolate J2C authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

Data type Text

Message Listener Type:

The Message Listener Type used by this activation specification.

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Destination JNDIName:

The destination JNDIName field only appears when a message of type `javax.jms.Destination` with name *Destination* is received.

Configuring a J2C administered object

Use this task to configure a J2C administered object used to configure objects with an external resource adapter.

About this task

To configure a J2C administered object for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new administered object.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Additional Properties heading, click **J2C Administered Objects**. This lists any existing J2C administered objects for the external resource adapter in the content pane.
4. Display the properties of the J2C administered object. If you want to display an existing J2C administered object, click one of the names listed.

Alternatively, if you want to create a new J2C administered object, click **New**, then specify the following required properties:

Name Type the name by which the J2C administered object is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Administered object class

Select the administered object class that this instance should support. This list is based on the deployment descriptor of the external resource adapter.

Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new administered object, you may need to click **Apply** before this custom property selection is available.

5. Specify properties for the administered object, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Administered Objects collection:

Use this page to specify administered object settings for a Resource Adapter.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C administered objects**
- **Resources** → **Resource Adapters** → **Resource adapters** → **J2C administered objects**

Name:

Specifies display name assigned to this administered object.

Data type String

JNDI Name:

Specifies the JNDI name of the administered object.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

Description:

Specifies a description for the administered object.

Data type String

Administered object class:

Specifies the Administered Object class that is associated with this J2C administered object. This class must be one that is provided by the resource adapter.

Data type String

J2C Administered Object settings:

Use this page to specify the settings for an administered object.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C administered objects** → *J2C_administered_object*
- **Resources** → **Resource Adapters** → **Resource adapters** → **J2C administered objects** → *J2C_administered_object*

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Data type String

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

Data type String

Name:

Specifies the name of the J2C administered object instance.

A string with no spaces meant to be a meaningful text identifier for the administered object. This name is required.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name that this administered object is bound under.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

Specifies a text description of the J2C administered object instance.

Data type String

Administered object class:

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. You can only select classes from this list.

After you create the administered object, you cannot modify the administered object class; it is read only.

Data type Class name

Configuring message listener resources for message-driven beans

Use the following tasks to configure resources needed by the message listener service to support message-driven beans for use with a JMS provider that does not have a J2EE Connector Architecture (JCA) 1.5 resource adapter.

Before you begin

Before configuring message listener resources for a message-driven bean, consider the Message Listener Service implementation on the z/OS platform, which affects how you should configure a listener port. For more information about the considerations, see “Message Listener Service on z/OS.”

About this task

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server Version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA resources to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server Version 5).

If the message-driven bean uses a queue hosted by WebSphere MQ as a JMS provider, you should optimize performance by configuring the queue destination properties to best fit your message-driven bean. For more information about performance considerations, see “Performance considerations for WebSphere MQ queue destinations” on page 1826.

Here are some guidelines on which scenarios use listener ports or activation specifications:

- If you are using J2EE 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used, so you do not use listener ports or activation specifications because WebSphere Application Server v4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can be implemented with the JCA 1.5 API.
 - If your JMS provider API is implemented with JCA, your MDB is a JMS MDB that is implemented as a connector MDB. A connector MDB uses JCA to access its resources, and so the connector must be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
 - If your JMS provider API is not implemented with JCA, you have the same JMS situation as for Java EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

If you want to deploy an enterprise application to use JMS message-driven beans with a JMS provider that does not have a JCA 1.5 resource adapter, refer to the following subtopics:

- “Message Listener Service on z/OS”
- “Configuring the message listener service” on page 1838
- “Creating a new listener port” on page 1845
- “Configuring a listener port” on page 1846
- “Deleting a listener port” on page 1847
- “Configuring security for message-driven beans that use listener ports” on page 1847
- “Administering listener ports” on page 1848

Message Listener Service on z/OS:

On the z/OS platform, the Message Listener Service implementation exploits the scalable server architecture provided by WebSphere Application Server for z/OS, by dividing the listener port functionality across the controller and servant processes.

A single message listener is registered in the controller portion of the ListenerPort, while application dispatch (that is, dispatch of the user application's `onMessage(Message)` EJB method) is then spread across the various servants comprising the server. This implementation is referred to as "listening in the controller" for the message-driven bean messages.

Note: An important point to note is that the WebSphere Application Server for z/OS Message Listener Service implementation does not use the just-described "listening in the controller" internal configuration in all cases, but rather only in the cases in which the message-driven bean is mapped to a queue (that is, listening on a Queue) or mapped (listening) to a topic through a durable subscription.

In the case in which the message-driven bean is listening to a topic through a nondurable subscription, the listener port registers a listener in *each servant*, rather than registering a single listener in the controller.

For a topic on which a message-driven bean is listening through a non-durable subscription, a single message published to that topic is dispatched once for each servant comprising the server. In contrast, if a message-driven bean is listening on a queue, or a topic through a durable subscription, a single message sent is dispatched once only, to a single servant, for the entire server.

The configuration of the listener port, in the "listening in the controller" case, is administered externally through the controls described in Tuning MDB processing on z/OS and Concepts and considerations for MDB settings on z/OS.

For a non-durable subscription message-driven bean, which is listening in each servant as described above, the listener ports are configured in the same manner as they are on distributed platforms. The single set of settings configured for the listener port are applied identically to each servant in this case.

Configuring the message listener service:

Use this task to configure the properties of the message listener service for an application server, to support message-driven beans deployed against listener ports.

About this task

If the JMS provider does not have a J2EE Connector Architecture (JCA) 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server Version 5).

If you want to deploy an enterprise application to use message-driven beans with listener ports, you can use this task to browse or change the configuration of the message listener service for an application server.

To configure the message listener service for an application server, use the administrative console to complete the following steps:

1. Display the listener service settings page:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
2. Optional: Browse or change the value of properties for the message-driven bean thread pool.
 - a. Click **Thread Pool**

- b. Change the following properties, to suit your needs:

Minimum size

The minimum number of threads to allow in the pool.

Maximum size

The maximum number of threads to allow in the pool.

Thread inactivity timeout

The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

Allow thread allocation beyond maximum thread size

Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.

- c. Click **OK**.

3. Optional: Specify any of the following optional properties that you need, as **Custom properties** of the message listener service:

NON.ASF.RECEIVE.TIMEOUT, MQJMS.POOLING.TIMEOUT, MQJMS.POOLING.THRESHOLD, MAX.RECOVERY.RETRIES, and RECOVERY.RETRY.INTERVAL.

For more information about these custom properties, see Custom Properties.

To browse or change the properties, complete the following steps:

- a. Click **Custom properties**

- b. For each custom property, specify a value to suit your needs.

If you have not specified a property before:

- 1) Click **New**.
- 2) Type the name of the property.
- 3) Type the value of the property.
- 4) Click **OK**.

4. Save your changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the Application Server.

Message listener service:

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports and Custom Properties for the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service**

Custom Properties:

An optional set of name and value pairs for custom properties of the message listener service.

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT

- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL
- “DYNAMIC.CONFIGURATION.ENABLED” on page 1845

Message listener port collection:

The message listener ports configured in the administrative domain

This panel displays a list of the message listener ports configured in the administrative domain. Each listener port is used with a message-driven bean to automatically receive messages from an associated JMS destination. You can use this panel to add new listener ports or to change the properties of existing listener ports.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

To view this administrative console panel, click **Servers** → **Application Servers** → *application_server* → **[Messaging] Message Listener Service** → **Listener Ports**

To manage a listener port, enable the **Select** check box beside the listener port name in the list and click a button:

Button	Resulting action
Convert to activation specification	Opens a wizard that helps you convert the selected listener port to an activation specification.
New	Accesses the panel to configure a new listener port.
Delete	Deletes the selected listener port or ports.
Start	Starts the selected listener port or ports.
Stop	Stops the selected listener port or ports.

For more information about asynchronous messaging, see “Asynchronous messaging in WebSphere Application Server using JMS” on page 291.

Listener port settings:

A listener port is used to simplify administration of the association between a connection factory, destination, and deployed message-driven bean.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Listener Ports** → *listener_port*

Name:

The name by which the listener port is known for administrative purposes.

Data type	String
Default	Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type	Enum
Units	Not applicable
Default	Started
Range	Started When the application server is next started, the listener port is started automatically. Stopped When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

Specifies the maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine and if you do not need to process messages in a specific message order.

Data type	Integer
Units	Sessions
Default	1

Range	1 through 2147483647
Recommended	<ul style="list-style-type: none"> • If you want to process messages in a strict message order, set the value to 1, so only one thread is ever processing messages. • If you want to process multiple messages simultaneously (known as “message concurrency”), set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you may need more sessions, which should be determined by experimentation.

Maximum retries:

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped, in the range 0 through 2147483647.

Note: A WebSphere MQ queue has a similar property called the **BackoutThreshold** property. If your listener port is reading from a WebSphere MQ queue, then the retry limit and the behavior when the limit is reached is determined by whichever of these two properties is set to the lower limit:

- If you exceed the WebSphere MQ queue **BackoutThreshold** limit, the message that cannot be delivered is moved to somewhere else by WebSphere MQ (for example, to the WebSphere MQ backout requeue queue or the WebSphere MQ dead letter queue) and the listener port services the next message on the queue. In this case, WebSphere Application Server might not know that the message has not been delivered successfully.
- If you exceed the listener port **maximum retries** limit, the listener port stops. You then manually intervene to investigate the problem, possibly to remove the message from the WebSphere MQ queue then restart the listener port.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For third-party messaging providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647

Recommended

For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, if you want to process multiple messages in a single transaction, then set this value to more than 1. If messages start accumulating on the queue, then a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the overhead of transactions on JMS messages.

Note:

- If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing.
- Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch.
- Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Message listener service custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Custom Properties**

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL
- DYNAMIC.CONFIGURATION.ENABLED

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

You should set this property to a non-zero value only if you want to enable the non-ASF mode of operation for all message-driven bean listeners on the application server.

The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF).

- The ASF mode is meant to provide concurrency and transactional support for applications. For publish/subscribe message-driven beans, the ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.

- The non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. The non-ASF mode is also transactional but, because the path length is shorter than the ASF mode, usually provides improved performance.

Use non-ASF if:

- Your third-party messaging provider does not provide JMS ASF support
- You are using message-driven beans with WebSphere topic connections with the DIRECT port, because the embedded publish/subscribe broker using that port does not support XA transactions or JMS ASF.
- Message order is a strict requirement

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds
	0 non-ASF mode is disabled
	1 or more
	The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives

Recommended

If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to lower than the transaction timeout, but leave spare at least the maximum duration of your message-driven bean's onMessage() method. For example, if your message-driven bean's onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the NON.ASF.RECEIVE.TIMEOUT property to no more than 110000 (110000 milliseconds, that is 110 seconds).

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes
Range	

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10
Range	

MAX.RECOVERY.RETRIES:

The maximum number of times that a listener port managed by this service tries to recover from a failure before giving up and stopping. When stopped the associated listener port is changed to the stop state. The interval between retry attempts is defined by the RECOVERY.RETRY.INTERVAL custom property.

A failure can be one of two things:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Retry attempts
Default	5
Range	0 (no retries) through 2147483647

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by a listener port to recover from a failure. The maximum number of retry attempts is defined by the MAX.RECOVERY.RETRIES custom property.

A failure can be one of two things:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Seconds
Default	60
Range	1 through 2147483647

DYNAMIC.CONFIGURATION.ENABLED:

This property controls whether the application server on which a listener port is created requires to be restarted. Set this property to true to enable dynamic configuration.

Data type	Boolean
Default	False (not selected)

Creating a new listener port:

Use this task to create a new listener port for the message listener service, so that message-driven beans can be associated with the port to retrieve messages.

About this task

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server Version 5), you are recommended to deploy such beans as J2EE Connector Architecture (JCA) 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you want to deploy an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to create a new listener port for a message-driven bean to retrieve messages from.

To create a new listener port, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Click **New**.
3. Specify the following required properties:

Name The name by which the listener port is known for administrative purposes.

Connection factory JNDI name

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`

Destination JNDI name

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

4. Optional: Change other properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

Results

If enabled, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port:

Use this task to browse or change the properties of an existing listener port, used by message-driven beans associated with the port to retrieve messages.

About this task

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server Version 5), you are recommended to deploy such beans as J2EE Connector Architecture (JCA) 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you have deployed an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to browse or change the configuration of a listener port that a message-driven bean retrieves messages from.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

To configure the properties of a listener port, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.

- b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Click the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
 3. Optional: Change properties for the listener port, according to your needs.
 4. Click **OK**.
 5. Save any changes to the master configuration.
 6. To have a changed configuration take effect, stop then restart the application server.

Deleting a listener port:

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

About this task

To delete a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. Under Communications, click **Messaging** → **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, click **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the check box for the listener port that you want to delete.
6. Click **Delete**. This action stops the port (needed to allow the port to be deleted) then deletes the port.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring security for message-driven beans that use listener ports:

Use this task to configure resource security and security permissions for message-driven beans.

About this task

There are two special security considerations when using message-driven beans (MDBs). In other respects, however, the security considerations for an MDB are identical to those of any other enterprise bean. For instance, access to JDBC resources and Java EE Connector Architecture (JCA) resources (for example CICS, IMS) is handled in the same way as for an entity or session bean. Access to other JMS resources is also handled in the same way as for other enterprise beans.

However to understand this last point about JMS access correctly, it is important to understand that the security considerations when configuring the MDB listener, which can be thought of as part of the application server infrastructure, are unique to MDBs. These considerations which are specific to MDBs are relevant when configuring authentication and authorization for the server to connect to a JMS provider and a Destination so that a message can be selected and so that the MDB can pass this message to the its onMessage() method.

The user's MDB onMessage() application code might not make additional JMS calls, however if the MDB application code accesses additional JMS resources, it is this access which is handled identically to JMS calls made by an entity or session EJB.

MBD security considerations:

The MDB listener's security information is established when the MDB listener's JMS Connection is created. This is the typical JMS programming pattern. The properties used to configure the MDB listener's JMS Connection Factory are also used for specifying these security parameters. By configuring the Connection Factory mapped to in the Listener Port definition, you can control the security parameters used by the MDB listener. The JMS Connection used by a given MDB listener is obtained in the order of precedence based on the configuration of the JMS Connection Factory used by the Message Listener Service Listener Port onto which a given MDB is mapped. For example, if an MDB, mdb1 is mapped onto Listener Port mylp1 and mylp1 uses ConnectionFactory qcf1, you would configure qcf1 to control the configuration of mdb1's MDB listener. The order of precedence is:

1. If a container-managed alias has been defined for this Connection Factory, the userid associated with the container-managed alias is used in the Connection creation call, for example `createQueueConnection(userid,password)`.
2. If a component-managed alias has been defined for this Connection Factory, the userid associated with the component-managed alias is used.
3. If neither alias is specified and the Connection Factory is defined in Bindings mode (that is, `TransportType = "BINDINGS"`), the server identity is used. The server identity translates more specifically into the servant identity in the servants, and the controller identity in the controller. In the case of listening-in controller, the controller identity is relevant as well as the servant identity. For related information about listening-in controllers, see "Message Listener Service on z/OS" on page 1837.

Note: The authentication aliases referred to here are those associated with the Connection Factory defined by the Administrator. No application resource reference is associated with the MDB listener and so no authentication alias has to be set at that level.

To set the container-managed alias, (if you elect that option), use the administrative console to complete the following steps:

1. To display the listener port settings, click **Servers** → **Server types** → **WebSphere application servers** → **application_server** → **[Communications] Messaging** → **Message listener service** → **[Additional properties] Listener ports** → **listener_port**
2. To get the name of the JMS connection factory, look at the Connection factory JNDI name property.
3. Display the JMS connection factory properties. For example, to display the properties of a queue connection factory, click **Resources** → **JMS** → **Queue Connection Factories** → **connection_factory**.
4. Set the "Container-managed authentication alias" property.
5. Click **OK**

Results

Considerations for invoking other EJBs:

Messages arriving at a listener port have no client credentials associated with them. The messages are anonymous. To call secure enterprise beans from a message-driven bean, the message-driven bean must be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see *Securing enterprise bean applications*. For more information about configuring security for your application, see *Securing applications during assembly and deployment*.

Administering listener ports:

Use the following tasks to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

About this task

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

You can use the WebSphere Application Server administrative console to administer listener ports, as described in the following tasks.

Note: If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. You do not normally need to start or stop a listener port manually.

- Adding a new listener port Use this task to create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configuring a listener port Use this task to browse or change the configuration properties of a listener port.
- Starting a listener port Use this task to start a listener port manually.
- Stopping a listener port Use this task to stop a listener port manually.

Starting a listener port:

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

About this task

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. However, you can start a listener port manually, as described in this topic.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

To start a listener port on an application server, use the administrative console to complete the following steps:

1. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
2. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
3. Select the check box for the listener port that you want to start.
4. Click **Start**.
5. Save your changes to the master configuration.

Stopping a listener port:

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

About this task

When you stop a listener port as described in this topic, the listener manager stops the listeners for all message-driven beans associated with the port.

To stop a listener port on an application server, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Select the check box for the listener port that you want to stop.
3. Click **Stop**.
4. Save your changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the application server.

Message-driven beans - listener port components:

The WebSphere Application Server support for message-driven beans deployed against listener ports is based on JMS message listeners and the message listener service, and builds on the base support for JMS.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provided, refer to related tasks.

The main components of WebSphere Application Server support for message-driven beans are shown in the following figure and described after the figure:

Figure 21. The main components for message-driven beans. This figure shows the main components of WebSphere support for message-driven beans, from JMS provider through a connection to a destination, listener port, then deployed message-driven bean that processes the message retrieved from the destination. Each listener port defines the association between a connection factory, destination, and a deployed message-driven bean. The other main components are the message listener service, which comprises a listener for each listener port, all controlled by the same listener manager. For more information, see the text that accompanies this figure.

The *message listener service* is an extension to the JMS functions of the JMS provider and provides a *listener manager*, which controls and monitors one or more JMS *listeners*.

Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging).

A *connection factory* is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A *listener port* defines the association between a connection factory, a destination, and a deployed *message-driven bean*. Listener ports are used to simplify the administration of the associations between these resources.

When a deployed message-driven bean is installed, it is associated with a listener port and the listener for a destination. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing.

When an application server is started, it initializes the listener manager based on the configuration data. The listener manager creates a dynamic session thread pool for use by listeners, creates and starts

listeners, and during server termination controls the cleanup of listener message service resources. Each listener completes several steps for the JMS destination that it is to monitor, including:

- Creating a JMS server session pool, and allocating JMS server sessions and session threads for incoming messages.
- Interfacing with JMS ASF to create JMS connection consumers to listen for incoming messages.
- If specified, starting a transaction and requesting that it is committed (or rolled back) when the EJB method has completed.
- Processing incoming messages by invoking the `onMessage()` method of the specified enterprise bean.

Important file for message-driven beans

The `server_name-durableSubscriptions.ser` file in the `WAS_HOME/temp` directory is important for the operation of the WebSphere Application Server messaging service, so should not be deleted.

If you do need to delete the `WAS_HOME/temp` directory or other files in it, ensure that you preserve the following file:

`server_name-durableSubscriptions.ser`

You should not delete this file, because the messaging service uses it to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription.

Choosing messaging providers for a mixed environment

If your existing or planned messaging environment involves both WebSphere MQ and WebSphere Application Server systems, choose between the default messaging provider, the WebSphere MQ messaging provider, or a mixture of the two, by considering your messaging requirements, your business environment, and the needs of each messaging application.

About this task

For messaging between application servers, with interaction with a WebSphere MQ system, you can use the default messaging provider or the WebSphere MQ provider. Neither provider is necessarily better than the other. The choice of providers depends primarily on factors relating to your business environment and planned changes to that environment, and also on what each JMS application needs to do. Moreover, these two types of messaging providers are not mutually exclusive:

- You can configure both types of providers within one cell.
- Different applications can use the same, or different, providers.

Factors relating to your business environment include the following:

- Messaging requirements
- Existing skill set
- Existing messaging infrastructure
- Planned changes to that infrastructure

Configuring and managing your messaging infrastructure is simpler if you use just one provider. If your messaging is primarily in WebSphere MQ, you should probably choose the WebSphere MQ messaging provider. Similarly, if your messaging is primarily in WebSphere Application Server, you should probably choose the default messaging provider.

If your business environment does not clearly indicate that you should use just one provider, then you should consider using a mixture of the two, and choosing the most appropriate messaging provider for each application. A useful way of doing this is to identify the types of destinations (service integration bus, or WebSphere MQ queue or topic) that the application is using. If the application uses only bus destinations, the natural choice is to use the default messaging provider (solution "DMP"). If the

application needs to communicate with one or more WebSphere MQ destinations, you can choose any of the following solutions depending upon your business environment, usage scenarios, and system topologies:

- Use the WebSphere MQ messaging provider (solution "MQP").
- Use the default messaging provider to integrate a WebSphere MQ server (a WebSphere MQ queue manager or queue-sharing group) as a bus member (solution "DMP interop bus member").
- Use the default messaging provider to integrate a WebSphere MQ network as a foreign bus, using WebSphere MQ links (solution "DMP interop, foreign bus").

For more information about these solutions, see Overview of interoperation with WebSphere MQ.

To help you choose between these solutions, several of the following steps contain tables in which each row represents a business or system requirement, and asterisks (*) indicate the solutions that are likely to be most effective for meeting the requirement. These tables are designed to provide general guidance, rather than to identify precisely a "right" solution. Most requirements have multiple possible solutions, and the absence of an asterisk does not necessarily mean that you cannot use that solution. To derive best guidance from using each of these tables:

- Focus on the rows that reflect your most important requirements.
- For all the rows that you consider, count the number of asterisks for each solution.

The solutions with the largest number of asterisks are likely to be the most effective.

1. If you have limited experience of WebSphere MQ or WebSphere Application Server, and are trying to decide which product best meets your messaging needs, see "Service integration and WebSphere MQ messaging - a comparison" on page 1784.

Note: Whichever of these products you choose as the main focus for your messaging, you can still use either the default messaging provider or the WebSphere MQ provider for interoperation between the products.

2. Consider your business environment, to see if you can use just one provider.

In deciding which provider to use, consider the following constraints:

- The current and future messaging requirements
- The existing messaging infrastructure
- The skill set that you have in your organization

If the majority of your messaging is today performed in WebSphere MQ, continue with that approach and configure WebSphere MQ as an external JMS provider (that is, use the WebSphere MQ messaging provider) in WebSphere Application Server. If the JMS requirements of your WebSphere Application Server applications are limited, it is debatable whether using a service integration bus for those applications gives sufficient benefit.

If you have messaging applications in WebSphere Application Server that have no requirement to interoperate with your WebSphere MQ network, use the default messaging provider (the service integration bus). If your WebSphere Application Server messaging requirements demand a tighter integration with WebSphere Application Server, the service integration bus provides the following benefits:

- Integrated administration
- WebSphere Application Server high availability capabilities
- WebSphere Application Server scalability

If you choose to use the default messaging provider to interoperate between service integration and WebSphere MQ, be aware that there is an added cost involved in converting messages between service integration format and WebSphere MQ format.

Also consider the following messaging scenarios:

- A large installed backbone of WebSphere MQ queue managers, perhaps with WebSphere Message Broker.

If you want to use WebSphere Application Server to run a newly introduced messaging application, you can deploy a WebSphere Application Server (JMS) messaging application that will exchange messages with an existing application that uses a WebSphere MQ queue or topic.

- A WebSphere Application Server installation, perhaps with existing Web and enterprise applications, but no WebSphere Application Server messaging application.

If you have no existing messaging infrastructure, you can deploy a WebSphere Application Server (JMS) messaging application to exchange messages with an existing WebSphere Application Server messaging application that uses a service integration bus destination.

- An infrastructure that uses WebSphere Application Server to connect WebSphere Application Server messaging applications.

Introduce WebSphere Application Server (JMS) messaging between a pair of WebSphere Application Server applications.

- An infrastructure that includes both WebSphere MQ and service integration buses. This could be the result of a merger, or because the message traffic tends to be from WebSphere Application Server to WebSphere Application Server, or from WebSphere MQ to WebSphere MQ, but not typically between WebSphere Application Server and MQ.

Deploy a WebSphere Application Server (JMS) messaging application to exchange messages with an application that uses a WebSphere MQ queue or topic.

- A WebSphere Process Server or WebSphere Enterprise Service Bus infrastructure, which uses Service Component Architecture (SCA).

You can choose either a WebSphere MQ or a service integration bus binding for your SCA components.

3. If your business environment does not clearly indicate that you should use just one messaging provider, use a mixture of the two and choose the most appropriate provider for each application, based upon the destination types that the application uses.

The application might need to exchange messages with existing partner applications or services that use one or more known destinations of known type. Alternatively, the partner applications or services might not yet be deployed and the choice of destination type might still be open, in which case the solution architect needs to decide how best to connect the applications or services together.

If the application uses multiple destinations, there are four possible outcomes:

- The application uses only bus destinations.
- The application uses only WebSphere MQ destinations.
- The application uses a mixture of bus and WebSphere MQ destinations.
- The destination types are not yet known.

Note: If there is no clear business or technical reason why the application uses WebSphere MQ destinations rather than bus destinations, and the partner application is also a WebSphere Application Server JMS application, consider migrating the existing destinations to service integration so that the application uses only bus destinations.

4. If the application uses only bus destinations, configure the application and its JMS resources to use the default messaging provider.
5. If the application uses only WebSphere MQ destinations (queues or topics), use the following checklist to determine which provider solution to use.

Table 31. Provider checklist for an application that uses only WebSphere MQ destinations.

Question:	MQP	DMP interop, bus member	DMP interop, foreign bus
Is performance critical? (If so, use WebSphere MQ directly, rather than perform message conversion.)	*		

Table 31. Provider checklist for an application that uses only WebSphere MQ destinations. (continued)

Question:	MQP	DMP interop, bus member	DMP interop, foreign bus
Does the application need to send or receive large messages (that is, messages > 500k.)?	*		
Is location transparency desirable for simplifying programming and deployment of applications?		*	*
Does the application need to consume from a WebSphere MQ queue, the configuration of which is fixed? (That is, the queue cannot be moved to service integration and you do not want to deploy a push-style WebSphere MQ application to send messages to a bus destination.)	*	*	
Is the partner application a JMS application that will run outside WebSphere Application Server, as a bus or WebSphere MQ client? (Do not mix service integration and WebSphere MQ unless you have to do so; a pure WebSphere MQ or service integration solution is simpler and avoids the cost of converting messages between service integration and WebSphere MQ formats.)	*		
Is the partner application a non-JMS (non-WebSphere Application Server) application? (Wherever possible choose a pure WebSphere MQ or service integration solution. Use the MQI WebSphere MQ client, or the XMS WebSphere MQ client, or the XMS bus client depending on your API preference.)	*		
Do you prefer traffic passing between your WebSphere MQ network and WebSphere Application Server applications to be funneled into a single long-running connection?			*
Do you want to use the high availability features of WebSphere Application Server?			*
Is XA 2pc needed between the application and a WebSphere MQ queue sharing group?		*	*
Is XA 2pc needed between the application and a WebSphere MQ cluster?		*	

6. If the application uses a mixture of bus and WebSphere MQ destinations, for example consuming from service integration and sending to WebSphere MQ, then either of the default messaging provider interoperation models can support this by using a single connection factory or activation specification. Use the following checklist to help you decide between a bus member and a foreign bus solution.

Table 32. Provider checklist for an application that uses a mixture of bus and WebSphere MQ destinations.

Question:	DMP interop, bus member	DMP interop, foreign bus
Does the application need to consume from a WebSphere MQ shared queue?	*	
Is there a need to distribute work to a pool of WebSphere Application Server workers from a WebSphere MQ queue?	*	
Do you prefer traffic passing between your WebSphere MQ network and WebSphere Application Server applications to be funneled into a single long-running connection?		*
Do you need distributed WebSphere MQ in versions earlier than WebSphere Application Server Version 7 and WebSphere MQ Version 7?		*
Do you want store and forward capabilities to allow the application to continue to send messages when the WebSphere MQ queue manager is unavailable?		*
Do you prefer not to configure server connection channels? (This is because they open a port, which could be seen as a security risk.)		*

Table 32. Provider checklist for an application that uses a mixture of bus and WebSphere MQ destinations. (continued)

Question:	DMP interop, bus member	DMP interop, foreign bus
Do you prefer to define a server connection channel, rather than a pair of sender and receiver channels?	*	

7. If the destination types are not yet known, decide the relative priorities of the known concerns then use the following checklist to assess how well each of them is addressed by the possible provider solutions.

The choice is really over what type of destinations this application should use. The destination types are not yet fixed, so any of the four solutions is possible, but as a general rule you should aim for solution “DMP” or “MQP”, because a pure WebSphere MQ or service integration solution is simpler and avoids the cost of converting messages between service integration and WebSphere MQ formats.

Table 33. Provider checklist for an application for which the destination types are not yet known.

Question:	DMP	MQP	DMP interop, bus member	DMP interop, foreign bus
Do you have an existing base of strong skills in managing WebSphere MQ?		*	*	*
Do you want management of all messaging to be handled by the WebSphere MQ team?		*		
Do you have administrators skilled in WebSphere Application Server but not in WebSphere MQ?	*			
Do you want a messaging product with a large installed base (including references) and a wide choice of ISV tools?		*		
Are you reluctant to buy a separately licensed product in addition to WebSphere Application Server?	*			
Are you reluctant to install and manage a separate product in addition to WebSphere Application Server?	*			
Are you already using WebSphere Message Broker? (If so, you need WebSphere MQ anyway).		*	*	*
Are you using the WebSphere Enterprise Service Bus to mediate messages from, or deliver them to, a WebSphere MQ queue? (For example, using WebSphere Business Integration adapters, or connecting to a service provider such as CICS.)		*		
Does the application need to send or receive large messages (that is, messages > 500k.)?		*		
Is location transparency desirable for simplifying programming and deployment of applications?	*		*	*
Do the throughput requirements need multiple parallel channels or routes?		*	*	*
Does the application need to consume from a WebSphere MQ queue, the configuration of which is fixed? (that is, the queue cannot be moved to service integration and you don't want to deploy a push-style WebSphere MQ application to send messages to a bus destination.)	*	*	*	

Table 33. Provider checklist for an application for which the destination types are not yet known. (continued)

Question:	DMP	MQP	DMP interop, bus member	DMP interop, foreign bus
Is the partner application a JMS application that will also run in WebSphere Application Server? (Service integration runs in the WebSphere Application Server application server. On distributed platforms that means it is in-process. On the z/OS platform it is in another region.)	*			
Is the partner application a JMS application that will run outside WebSphere Application Server, as a bus or WebSphere MQ client? (Do not mix service integration and WebSphere MQ unless you have to do so; a pure WebSphere MQ or service integration solution is simpler and avoids the cost of converting messages between service integration and WebSphere MQ formats.)	*	*		
Is the partner application a non-JMS (non-WebSphere Application Server) application? (Wherever possible choose a pure WebSphere MQ or service integration solution. Use the MQI WebSphere MQ client, or the XMS WebSphere MQ client, or the XMS bus client depending on your API preference.)	*	*		
Is maintenance of strict message order important?	*			
Does the application require the flexibility and convenience of a WebSphere MQ cluster? (WebSphere MQ clustering makes administration simpler and provides selective parallelism of clustered queues. That is, instances of a clustered queue can be created on any (but not necessarily all) queue managers in the WebSphere MQ cluster. Messages sent to the clustered queue can be addressed to a specific instance of the queue, or allowed to select an instance dynamically based on workload management statistics. WebSphere Application Server clustering provides some of this flexibility, but you cannot create partitions of a bus destination on a subset of the messaging engines in a cluster bus member.)		*	*	*
Does the application need the level of high availability provided by WebSphere MQ for z/OS shared queues?		*	*	*
Do you want to use the high availability or scalability features of WebSphere Application Server clustering?	*		*	*

Service integration and WebSphere MQ messaging - a comparison

If you are not already an established user of either WebSphere Application Server or WebSphere MQ, and you are considering whether the service integration platform or WebSphere MQ better meets your messaging needs, use this table to compare the main features of the two platforms.

Table 34. Comparison of service integration and WebSphere MQ main features

service integration (the default messaging provider for WebSphere Application Server)	WebSphere MQ
Service integration is closely integrated with WebSphere Application Server, and is a natural fit if you are using the Java Platform, Enterprise Edition (Java EE).	WebSphere MQ can connect to almost anything. It provides a very heterogeneous environment .
Service integration supports multiple languages through XMS clients, and multiple platforms.	WebSphere MQ supports multiple languages and multiple platforms.
Service integration is a single process, pure Java implementation.	WebSphere MQ has many Independent Software Vendor (ISV) tools.

Table 34. Comparison of service integration and WebSphere MQ main features (continued)

service integration (the default messaging provider for WebSphere Application Server)	WebSphere MQ
Service integration provides strong performance for both persistent and non-persistent messages for JMS.	WebSphere MQ supports JMS and non-JMS messaging interfaces, and provides strong performance for non-JMS applications.
Service integration is designed for a maximum message size of about 40 megabytes on a 32-bit operating system (subject to heap usage).	WebSphere MQ supports large message sizes up to about 100 megabytes.
Service integration is tightly integrated with some Web services implementations.	WebSphere MQ is a natural fit if you are using WebSphere Message Brokers.
Service integration messaging is included in a single administrative model for WebSphere Application Server, WebSphere Enterprise Service Bus and WebSphere Process Server.	WebSphere MQ can integrate existing infrastructure and applications (for example CICS).
Service integration bus clustering is integrated with WebSphere Application Server clustering for high availability and scalability.	WebSphere MQ clustering provides selective parallelism of clustered queues.

Note: The messaging platform that you choose for a given task does not necessarily determine which JMS messaging provider you should use. For example:

- If you need to handle large messages, you probably need to use the WebSphere MQ messaging provider.
- If you are using WebSphere Message Brokers, you can use either the default messaging provider or the WebSphere MQ messaging provider.

Other ways of managing messaging

For messaging between application servers, most requirements are best met by either the default messaging provider or the WebSphere MQ messaging provider. However, you can instead use a third-party messaging provider (that is, use another company's product as the provider). For backwards compatibility with earlier releases, there is also support for the V5 default messaging provider.

Before you begin

If you are not sure which provider combination is best suited to your needs, see "Types of messaging providers" on page 1925.

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

- Choose a third-party messaging provider.

You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

To administer a third-party messaging provider, you use the resource adaptor or client supplied by the third party. You can still use the WebSphere Application Server administrative console to administer the

JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adapter that conforms to the Java EE Connector Architecture (JCA) Version 1.5 specification.

To work with a third-party provider, see “Managing messaging with a third-party messaging provider” on page 1785.

- Choose the (deprecated) V5 default messaging provider.

This deprecated provider is identical to the WebSphere Application Server Version 5 default provider. Only the name has changed. It provides backwards compatibility that enables WebSphere Application Server Version 6 or later applications to connect to WebSphere Application Server Version 5 resources in a mixed cell. It also allows WebSphere Application Server Version 5 applications to connect to WebSphere Application Server Version 6 or later resources in a mixed cell. To configure and manage messaging to interoperate with WebSphere Application Server Version 5, see “Maintaining Version 5 default messaging resources” on page 1795.

Managing messaging with a third-party messaging provider

Enabling your messaging applications to use JMS resources provided by a third-party messaging provider other than WebSphere MQ.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see “Choosing a messaging provider” on page 1772.

About this task

You can install a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider.

WebSphere Application Server applications can use the JMS 1.1 interfaces or JMS 1.0.2 interfaces to access JMS resources provided by a third-party messaging provider, and you can use the administrative console to administer the JMS connection factories and destinations for the provider.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer third-party messaging resources on Version 7, Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

To use a third-party messaging provider with WebSphere Application Server, complete one or more of the following steps:

- Define a third-party messaging provider.
- List third-party JMS messaging resources.
- Configure JMS resources for a third-party messaging provider.

Defining a third-party messaging provider

Use this task to define a third-party messaging provider to WebSphere Application Server, for use instead of the default messaging provider or WebSphere MQ messaging provider.

Before you begin

Before you configure a third-party messaging provider, you might want to check whether your requirement can be met by the default messaging provider or the WebSphere MQ messaging provider that are supplied with WebSphere Application Server. To choose the provider that is best suited to your needs, see “Choosing a messaging provider” on page 1772.

About this task

You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

To administer a third-party messaging provider, you use the resource adaptor or client supplied by the third-party. You can still use the WebSphere Application Server administrative console to administer the JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adapter that conforms to the J2EE Connector Architecture (JCA) Version 1.5 specification.

To define a new third-party messaging provider to WebSphere Application Server, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS Providers** . The existing messaging providers are displayed, including the default messaging provider and the WebSphere MQ messaging provider.
2. To define a new third-party messaging provider, click **New** in the content pane. Otherwise, to change the definition of an existing messaging provider, click the name of the provider.
3. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this messaging provider is known for administrative purposes within IBM WebSphere Application Server.

External initial context factory

The Java classname of the initial context factory for the JMS provider.

External provider URL

The JMS provider URL for external JNDI lookups.

4. Optional: Click **Apply**. This enables you to specify additional properties.
5. Optional: Specify other properties for the messaging provider.
Under Additional Properties, you can use the **Custom Properties** link to specify custom properties for your initial context factory, in the form of standard javax.naming properties.
6. Click **OK**.
7. Save the changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

What to do next

You can now configure JMS resources for your messaging provider, as described in “Configuring JMS resources for a third-party messaging provider” on page 1793.

Listing third-party JMS messaging resources

Use this task with the WebSphere Application Server administrative console to display administrative lists of JMS resources provided by a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider.

About this task

You can use the WebSphere Application Server administrative console to display lists of the following types of JMS resources provided by a 3rd party messaging provider. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources for a third-party messaging provider, complete the following steps:

1. Start the administrative console.
2. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
3. Click the name of the third-party messaging provider.
4. In the content pane, under Additional Resources, click the link for the type of JMS resource. For more information about the detailed settings displayed for each resource type, see the related reference topics.

JMS provider collection:

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** → **JMS** → **JMS providers**

To view or change the properties of a JMS provider or its resources, select its name in the list displayed.

To define a new third-party messaging provider, click **New**.

To act on one or more of the JMS providers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

For related information about JMS messaging providers and asynchronous messaging, see

- “Types of messaging providers” on page 1925
- “Asynchronous messaging in WebSphere Application Server using JMS” on page 291

Third-party JMS connection factory collection:

The JMS connection factories configured for a third-party messaging provider for both point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS connection factories, or to select a connection factory to browse or change its configuration properties.

This panel shows a list of the JMS connection factories configured for a third-party messaging provider, with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS connection factory.
3. Under Additional Properties, click **Connection factories**.

To define a new JMS connection factory, click **New**.

To view or change the properties of a JMS connection factory, select its name in the list displayed.

To act on one or more of the JMS connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Third-party JMS connection factory settings:

Use this panel to browse or change the configuration properties of a JMS connection factory configured for use with a third-party messaging provider. These configuration properties control how connections are created to the JMS destinations on the provider.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. If appropriate, in the content pane, change the scope of the third-party messaging provider.
3. In the content pane, click the name of the messaging provider that supports the JMS connection factory.
4. Under Additional Properties, click **Connection factories**.
5. Click the name of the JMS connection factory that you want to work with.

A JMS connection factory for a third-party messaging provider (that is, a provider other than the default, the V5 default or the WebSphere MQ messaging provider) has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated messaging provider.

Data type String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

QUEUE

A JMS queue connection factory for point-to-point messaging.

TOPIC

A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the WebSphere Application Server name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the connection factory into the name space of the third-party messaging provider.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (*res-auth*) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Global Security** → **JAAS Configuration** → **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	ClientContainer The client container maps authentication aliases.
	WSLogin The WSLogin module maps authentication aliases.
	DefaultPrincipalMapping The JAAS configuration maps an authentication alias to its userid and password.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the messaging provider.

Third-party JMS destination collection:

The JMS destinations configured in an associated third-party messaging provider for point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS destinations, or to select a JMS destination to browse or change its configuration properties.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.

To define a new JMS destination, click **New**.

To view or change the properties of a JMS destination, select its name in the list displayed.

To act on one or more of the JMS destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

Third-party JMS destination settings:

Use this panel to browse or change the configuration properties of the selected JMS destination for use with an associated third-party messaging provider.

A JMS destination is used to configure the properties of a JMS destination for the associated third-party messaging provider (that is, not the default messaging provider or the WebSphere MQ messaging provider). Connections to the JMS destination are created by the associated JMS connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. In the content pane, click the name of the third-party messaging provider that you want to support the JMS destination.
3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.
4. Click the name of the JMS destination that you want to work with.

A JMS destination for use with a third-party messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Configuring JMS resources for a third-party messaging provider

Use the following tasks to configure the JMS connection factories and destinations for a third-party messaging provider (that is, a messaging provider other than the default messaging provider or the WebSphere MQ messaging provider).

Before you begin

You only need to complete these tasks if your WebSphere Application Server environment uses a third-party messaging provider to support enterprise applications that use JMS. To enable use of a third-party messaging provider, you must have installed and configured the messaging provider, as described in *Defining a third-party messaging provider*.

About this task

To configure JMS resources for a third-party messaging provider, complete the following tasks:

- Configure a JMS connection factory for a third-party messaging provider.
- Configure a JMS destination for a third-party messaging provider.

Configuring a JMS connection factory for a third-party messaging provider:

Use this task to browse or change the properties of a JMS connection factory for use with a JMS messaging provider other than the default, V5 default or WebSphere MQ messaging providers.

About this task

To configure a JMS connection factory for use with a third-party messaging provider, use the administrative console to complete the following steps:

1. Display the third-party messaging provider. In the navigation pane, click **Resources** → **JMS** → **JMS Providers**.
2. Select the third-party provider for which you want to configure a connection factory.
3. Optional: Change the **Scope** setting to the level at which the connection factory is visible to applications.
4. In the content pane, under Additional Properties, click **Connection factories**. This displays a table listing any existing JMS connection factories, with a summary of their properties.
5. To browse or change an existing JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server.

Type Select whether the connection factory is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name

The JNDI name that is used to bind the JMS connection factory into the WebSphere Application Server name space.

External JNDI Name

The JNDI name that is used to bind the JMS connection factory into the name space of the messaging provider.

- c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS connection factory, according to your needs.

7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS destination for a third-party messaging provider:

Use this task to browse or change the properties of a JMS destination for use with a third-party messaging provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider).

About this task

To configure a JMS destination for use with a third-party messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. Click the name of the third-party messaging provider.
3. In the content pane, under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging. This displays a table listing any existing JMS destinations, with a summary of their properties.
4. To browse or change an existing JMS destination, click its name in the list. Otherwise, to create a new destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS destination is known for administrative purposes within WebSphere Application Server.

Type Select whether the destination is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name

The JNDI name that is used to bind the JMS destination into the WebSphere Application Server name space.

External JNDI Name

The JNDI name that is used to bind the JMS destination into the name space of the messaging provider.

- c. Click **Apply**. This defines the JMS destination to WebSphere Application Server, and enables you to browse or change additional properties.
5. Optional: Change properties for the JMS destination, according to your needs.
 6. Click **OK**.
 7. Save any changes to the master configuration.
 8. To have the changed configuration take effect, stop then restart the application server.

Maintaining Version 5 default messaging resources

This topic is the entry-point into a set of topics about maintaining messaging resources provided for WebSphere Application Server Version 5.1 applications by the default messaging provider.

About this task

JMS applications running on WebSphere Application Server Version 5.1 can use JMS resources provided by the default messaging provider in WebSphere Application Server Version 7. You can use the

WebSphere Application Server administrative console to manage the JMS connection factories and destinations for WebSphere Application Server Version 5.1 applications. Such JMS resources are maintained as *V5 Default Messaging* resources.

In a deployment manager cell, you can use V5 Default Messaging resources to maintain Version 5 default messaging resources for Version 7, Version 6 and Version 5 nodes in the cell.

- V5 Default Messaging configured against a Version 7 node provides a JMS transport to a messaging engine of a service integration bus that supports the default messaging provider in WebSphere Application Server Version 7. The messaging engine emulates the service of a JMS server running on WebSphere Application Server Version 5.1.
- V5 Default Messaging configured against a Version 5.1 node provides a JMS transport to a JMS server running on WebSphere Application Server Version 5.1.

You can also use the administrative console to manage a JMS server on a Version 5.1 node.

- List Version 5 default messaging resources.
- Configure Version 5 default JMS resources.
- Manage Version 5 JMS servers in a deployment manager cell.
- Configure authorization security for a Version 5 default messaging provider.
- Tune JMS destinations.

Listing Version 5 default messaging resources

Use the WebSphere Application Server administrative console to list JMS resources for the Version 5 default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Connection factory (unified)
- Queue connection factory
- Topic connection factory
- Queue
- Topic
- Activation specification

When you use the Administrative Console to locate these resources, two different navigation pathways are available:

- Provider-centric navigation. This lets you view all providers (or just those for a specified scope if required), then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider owns it. Any navigation that starts with **Resources** → **JMS** → **JMS providers** is provider-centric.
- Resource-centric navigation lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider owns it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** → **JMS** → **[resource]**, where [resource] is one of the resource types listed above is resource-centric.

You can use either of these navigation pathways to locate resources of any type.

- Using provider-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.

2. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**. This opens the providers collection which lists all currently configured providers across all scopes (you can modify the scope if required).
 3. From the providers collection, select the required provider. This opens the configuration tab for that provider. The configuration tab contains a set of links to all the resources owned by that provider.
 4. From the configuration tab, click the link for a resource type, for example the connection factories link. This opens the connection factories collection which lists all the connection factories for that provider.
 5. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties
- Using resource-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.
 2. In the navigation pane, expand **Resources** → **JMS** → **Connection factories**. This opens the connection factories collection which lists all the connection factories across all providers.
 3. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties.

JMS provider settings:

Use this panel to view the configuration properties of a selected JMS provider. You cannot change the properties of a default messaging provider or a WebSphere MQ messaging provider.

To view this page, use the administrative console to complete one of the following steps:

- In the navigation pane, click **Resources** → **JMS** → **JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
- If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
- In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For default messaging providers and WebSphere MQ messaging providers, only the scope, name, and description properties are displayed for information only. You cannot change these properties.

For another type of JMS provider that you have defined yourself, extra properties are displayed that you can change.

The default messaging provider is installed and runs as part of WebSphere Application Server, and is based on service integration technologies.

Scope:

The level to which this resource definition is visible; the cell, node, or server level.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String
Default	<ul style="list-style-type: none">• Default messaging provider. For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.• <i>My JMSprovider</i> For JMS resources to be provided by your own JMS provider; not the default messaging provider or WebSphere MQ. You assign the name, in this example “My JMSprovider”, when you define the JMS provider to WebSphere Application Server. You must have installed and configured your own JMS provider before applications can use the JMS resources.• WebSphere MQ messaging provider For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use the JMS resources.• V5 default messaging provider. For JMS resources to be provided by a WebSphere Application Server Version 5 node in a deployment manager cell.

Description:

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type	String
------------------	--------

Classpath:

A list of paths or JAR file names which together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ':'). Class paths can contain variable (symbolic) names to be substituted using a variable map. Check your driver installation notes for specific JAR file names that are required.

This property does not apply to default messaging providers or WebSphere MQ providers.

Data type	String
------------------	--------

Native library path:

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names to be substituted using a variable map.

This property does not apply to default messaging providers or WebSphere MQ providers.

Data type	String
------------------	--------

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

This property does not apply to default messaging providers or WebSphere MQ providers.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type	String
Default	Null

External provider URL:

The JMS provider URL for external JNDI lookups.

This property does not apply to default messaging providers or WebSphere MQ providers.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Data type	String
Default	Null

Version 5 JMS server collection:

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. Use this panel to list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each Version 5 node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this page, use the administrative console to complete the following step:

1. In the navigation pane, select **Servers** → **Version 5 JMS Servers**.

To browse or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check box next to the server name, then use the buttons provided.

Version 5 JMS server settings:

The JMS functions on a Version 5 node in a deployment manager cell are served by a JMS server. Use this panel to view or change the configuration properties of the selected JMS server.

JMS servers are supported only to aid migration of WebSphere Application Server Version 5 nodes to WebSphere Application Server Version 6.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the Version 5 default messaging provider.

Before you set any of the values on this panel, configure the JMS Server for each node by using the WebSphere Application Server Profile Management Tool described in the topic “Using the Profile Management Tool” or by using the `zpm` command described in the topic “Configuring z/OS application-serving environments with the `zpm` command”.

Name:

The name by which the JMS server is known for administrative purposes within IBM WebSphere Application Server.

This name should not be changed.

Data type	String
Units	Not applicable
Default	WebSphere Internal JMS Server
Range	Not applicable

Description:

A description of the JMS server, for administrative purposes within IBM WebSphere Application Server.

This string should not be changed.

Data type	String
Default	WebSphere Internal JMS Server

Short Name: Specifies the short name of the server. For WebSphere Application Server for z/OS, the server short name must be unique within a cell. The short name is also the default z/OS job name, which identifies the server to the native facilities of the operating system, such as Workload Manager (WLM), Automatic Restart Manager, SAF (for example, RACF), started task control, and others.

The system assigns a default short name that is automatically unique within the cell.

Unique Id: Specifies a unique identifier for this server.

The unique ID property is read only. The system automatically generates the value.

Queue Names:

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

Data type	String
Units	Queue name
Range	Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue.

Initial State:

The state that you want the JMS server to have when it is next restarted.

Data type	Enum
Default	Started

Range**Started**

The JMS server is started automatically.

Stopped

The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server.

To restart a JMS server on a Version 5 node, stop then restart that JMS server.

Version 5 WebSphere queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server Version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queue connection factories**. This displays a list of any existing JMS queue connection factories.
5. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type

String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type

String

Default

Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
------------------	--------

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security → JAAS Configuration → Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type
Default
Range

Enum
Null
ClientContainer
The client container maps authentication aliases.
WSLogin
The WSLogin module maps authentication aliases.
DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always adopts non-XA coordination.

Data type	Checkbox
Default	Selected (enabled for XA coordination)
Range	Selected The connection factory is enabled for XA-coordination of messages Cleared The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

WebSphere topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topic connection factories**. This displays a list of any existing JMS topic connection factories.
5. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Pull-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Units	Not applicable
Default	QUEUED
Range	QUEUED The listener port used for full-function JMS-compliant, publish/subscribe support. DIRECT The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security → JAAS Configuration → Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null

Range**ClientContainer**

The client container maps authentication aliases.

WSLogin

The WSLogin module maps authentication aliases.

DefaultPrincipalMapping

The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

Data type

Enum

Default

Cleared

Range**Selected**

Clone support is enabled.

Cleared

Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type

String

Range

A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type

Checkbox

Default

Selected (enabled for XA coordination)

Range**Selected**

The connection factory is enabled for XA-coordination of messages

Cleared

The connection factory is not enabled for XA coordination of messages

Recommended

Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Version 5 WebSphere queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server Version 5 applications. Connections to the queue are created by the associated V5 Default Messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queues**. This displays a list of any existing JMS queue destinations.
5. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the Queue Names field on the panel for the JMS server that hosts the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String
Default Null

Category:

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum

**Default
Range**

APPLICATION DEFINED
APPLICATION DEFINED

Messages on the destination have their persistence defined by the application that put them onto the queue.

NON PERSISTENT

Messages on the destination are not persistent.

PERSISTENT

Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

**Data type
Default
Range**

Enum

APPLICATION DEFINED
APPLICATION DEFINED

The priority of messages on this destination is defined by the application that put them onto the destination.

QUEUE DEFINED

[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

SPECIFIED

The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

**Data type
Units
Default
Range**

Integer

Message priority level

0

0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

**Data type
Default**

Enum

APPLICATION DEFINED

Range

APPLICATION DEFINED

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED

Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type

Integer

Units

Milliseconds

Default

0

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Version 5 WebSphere topic destination settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere application server Version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node in a deployment manager cell. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** → **JMS** → **JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topics**. This displays a list of any existing JMS topic destinations.
5. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the Version 5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String

Default Null

Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type	Enum
Default	APPLICATION DEFINED
Range	<p>APPLICATION DEFINED Messages on the destination have their persistence defined by the application that put them onto the queue.</p> <p>NON-PERSISTENT Messages on the destination are not persistent.</p> <p>PERSISTENT Messages on the destination are persistent.</p>

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED
Range	<p>APPLICATION DEFINED The priority of messages on this destination is defined by the application that put them onto the destination.</p> <p>QUEUE DEFINED [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>SPECIFIED The priority of messages on this destination is defined by the Specified priority property. <i>If you select this option, you must define a priority on the Specified priority property.</i></p>

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Default	0
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type	Enum
Units	Not applicable
Default	APPLICATION DEFINED

Range

APPLICATION DEFINED

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED

Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to **Specified**, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type

Integer

Units

Milliseconds

Default

0

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Configuring Version 5 default JMS resources

Use the following tasks to configure the JMS connection factories and destinations WebSphere Application Server Version 5 applications.

About this task

You only need to complete these tasks if you have WebSphere application server Version 5 applications that need to use JMS resources provided by the default messaging provider. Such JMS resources are maintained as *V5 Default Messaging* resources.

In a deployment manager cell, you can use *V5 Default Messaging* resources to maintain Version 5 default messaging resources for both Version 6 and Version 5 nodes in the cell.

- Configuring a connection for Version 5 default messaging
- Configuring a Version 5 default JMS queue connection factory
- Configuring a Version 5 default JMS topic connection factory
- Configuring a Version 5 default JMS queue destination
- Configuring a Version 5 default JMS topic destination

Configuring a connection for Version 5 default messaging:

Use this task to configure a connection to Version 5 default messaging. This task is provided to help you manually migrate nodes from v5 to v6. If you use the supplied tools to migrate existing v5 nodes to v6, the `jmserver`, `appserver` and `port` that you create with this task are defined automatically.

About this task

To configure a connection for Version 5 default messaging, use the administrative console to complete the following steps:

1. Create an application server with the name `jmsserver` (only one of these can exist on each node). In the navigation pane, expand **Servers** → **Application servers**.
2. On the new server, define a new `JMSSERVER_QUEUED_ADDRESS` port with the host set to the v6 server host, and the port set to the same as the `SIB_MQ_ENDPOINT_ADDRESS` of the server which is a member of your bus. The appserver called `jmsserver` does not actually have to be started; it is only used for looking up the port address.
3. Define a queue connection factory and queue at the Node or Cell scope. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
4. In the content pane, click the name of the V5 default messaging provider.
5. Define a queue destination on your bus with the same name as your queue defined under v5 default messaging.
6. Define an alias destination on your bus with the same name as your queue defined under v5 default messaging but with `WQ_` appended to the front the name. For example, if your queue has the name `MyV5Queue`, your alias should have the name `WQ_MyV5Queue`.
7. Point the alias at your queue destination with the correct name. The migration process targets the queue with the `WQ_` prefix; defining the alias to point to the real queue helps migration.
8. Define the WebSphere MQ Client Link on your messaging engine on the bus. Keep the WebSphere MQ channel name `WAS.JMS.SVRCONN` and set the queue manager name so that it contains your node name. For example, if your node name is `MyNode`, you would set the queue manager name to `WAS_<MyNode>_jmsserver`. Now set the queue manager name to the same; in this example it would be `WAS_MyNode_jmsserver`. The WebSphere MQ Client Link will show a status of inactive, this is normal.
9. Restart your server so that the new JNDI definitions bind correctly. Your v5 client should now be able to connect to v6 using the host and bootstrap address of the v6 system in the provider url component of the initial context. Your client should now also be able to send messages to the destination on the bus.
10. If you open the Client connections view and click the refresh icon, the hostname of the connecting system is visible whilst the client is connected. In the navigation pane, expand **Buses** → **[bus name]** → **Messaging engines** → **[messaging engine name]** → **WebSphere MQ client links** → **[client link name]** → **Runtime** → **Client connections view**.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 queue connection factory:

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node in a deployment manager cell. This task contains an optional step for you to create a new JMS queue connection factory.

About this task

To configure a JMS queue connection factory for use by WebSphere application server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a queue connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.

5. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:

- a. Click **New** in the content pane.
- b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the JMS queue connection factory into the name space.

- c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the queue connection factory, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 JMS topic connection factory:

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

About this task

To configure a JMS topic connection factory for use by WebSphere application server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topic connection factories** This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
5. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the JMS topic connection factory into the name space.

- c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic connection factory, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere queue destination:

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Application Server Version 5 queue destinations” on page 1825.

To configure a JMS queue destination for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. Select the Version 5 provider for which you want to configure a queue destination.
4. In the content pane, under Additional Properties, click **Queues**. This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the queue destination into the name space.

- c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the queue destination, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To make a queue destination available to applications, host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server.

To define the administrative name of the queue to the JMS server, see Managing Version 5 JMS servers in a deployment manager cell.
 10. To have the changed configuration take effect, stop then restart the application server.

Configuring a Version 5 WebSphere topic destination:

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere application server Version 5 applications.. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see “Performance considerations for WebSphere Application Server Version 5 topic destinations” on page 1826.

To configure a JMS topic destination for use WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

1. Display the Version 5 default messaging provider. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the Version 5 provider for which you want to configure a topic destination.
3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topics**. This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the topic destination into the name space.

Topic The name of the topic in the default messaging provider, to which messages are sent.

- c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic destination, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Managing Version 5 JMS servers in a deployment manager cell

Use this task to manage JMS servers on WebSphere Application Server Version 5 nodes in a deployment manager cell.

About this task

The use of JMS servers is only intended to support migration from WebSphere Application Server Version 5 nodes to WebSphere Application Server Version 6.

In a WebSphere Application Server deployment manager cell, each Version 5 node can have at most one JMS server, and any Version 5 application server within the cell can use JMS resources served by any of those JMS servers. Applications on WebSphere Application Server Version 6 can also use JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all Version 5 JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of properties configured automatically for the Version 5 default messaging provider.

Note: In general, the default values of properties for the Version 5 default messaging provider are adequate for JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a Version 5 JMS server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers** → **JMS Servers**. This displays a table of the JMS servers, showing their runtime status.
2. Optional: If you want to change the runtime status of a JMS server, complete the following steps:
 - a. In the table of JMS servers, select the JMS servers that you want to act on.
 - To act on one or more specific JMS servers, select the check box next to the JMS server name.
 - To act on all JMS servers, select the check box next to the JMS servers title of the table.
 - b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. Optional: If you want to change the properties of a JMS server, complete the following steps:
 - a. Click the name of the server
 - b. Set one or more of the following configuration properties:

Initial state

If you want the JMS server to be started automatically when the application server is next started, set this property to Started.

Number of threads

Set the number of concurrent threads to be used by the publish/subscribe matching engine. The number of concurrent threads should only be set to a small number.

4. Optional: If you want the JMS server to host a new JMS queue, add the queue name to the Queue Names field.

The name must match the name of a JMS Queue administrative object, including the use of upper- and lowercase.
5. Optional: If you want to stop the JMS server hosting a JMS queue, remove the queue name from the Queue Names field.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the JMS server.

Configuring authorization security for a Version 5 default messaging provider

Use this task to configure authorization security for the default messaging provider on a WebSphere Application Server Version 5 node in a deployment manager cell.

About this task

To configure authorization security for the Version 5 default messaging provider complete the following steps.

Note: Security for the Version 5 default messaging provider is enabled when you enable WebSphere Application Server security on the Version 5 node. For more information about enabling security, see *Enabling security*.

1. Configure authorization settings to access JMS resources owned by the embedded messaging subsystem.

Authorization to access JMS resources owned by the embedded messaging subsystem is controlled by settings in the *wempath/wempsname/config/integral-jms-authorizations.xml* file. The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the *integral-jms-authorizations.xml* file grants the following permissions:

- Read and write permissions to all queues.
- Pub, sub, and persist to all topics.

To configure authorization settings, edit the *integral-jms-authorizations.xml* file according to the information in this topic and in that file.

2. Edit the `queue-admin-userids` element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following `queue-admin-userids` section:

```
<queue-admin-userids>
  <userid>adminid1</userid>
  <userid>adminid2</userid>
</queue-admin-userids>
```

In this example the userids `adminid1` and `adminid2` are defined to have administrative access to all queues.

3. Edit the `queue-default-permissions` element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following `queue-default-permissions` element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

In this example for the queue `q1`, the userid `useridr` has read permission, the userid `useridw` has write permission, the userid `useridrw` has both read and write permissions, and all other userids have no access permissions (`<public></public>`).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then

permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

- a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```
<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>
```

In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

- b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid `useridpub` is granted publish permission for any topic whose name starts with a/b/c.

6. Save the `integral-jms-authorizations.xml` file.

Results

If the dynamic update setting is selected, changes to the `integral-jms-authorizations.xml` file become active when the changed file is saved, so there is no need to stop and restarted the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Dynamic updating is available, by ensuring proper tagging in the `integral-jms-authorizations.xml` file `<dyanmic-update>>true</dynam ic-update>`.

Authorization settings for Version 5 default JMS resources:

Use the `integral-jms-authorisations.xml` file to view or change the authorization settings for Java Message Service (JMS) resources owned by the default messaging provider on WebSphere Application Server Version 5 nodes.

Authorization to access default JMS resources owned by the default messaging provider on WebSphere Application Server nodes is controlled by the following settings in the `wempspath/wempsname/config/integral-jms-authorizations.xml` file.

This structure of the settings in `integral-jms-authorisations.xml` is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in *Configuring authorization security for the Version 5 JMS providers*

```

<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>

  <queue-default-permissions>
    <permission>write</permission>
  </queue-default-permissions>

  <queue>

```

dynamic-update: Controls whether or not the JMS Server checks dynamically for updates to this file.

true (Default) Enables dynamic update support.

false Disables dynamic update checking and improves authorization performance.

queue-admin-userids: This element lists those userids with administrative access to all Version 5 default queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

<userid>adminid</userid>

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

<permission>read-write</permission>

Where *read-write* is one of the following keywords:

read By default, userids have read access to Version 5 default queue destinations.

write By default, userids have write access to Version 5 default queue destinations.

queue: This element contains the following authorization settings for a single queue destination:

name The name of the queue.

public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

topic: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

Tuning JMS destinations

Use this task to configure the properties of a JMS destination to optimize performance of applications that use the WebSphere Application Version 5 default messaging provider or WebSphere MQ as a JMS provider.

About this task

To optimize performance, configure destination properties to best fit your applications. You should also consider queue attributes of the JMS server that are associated with the queue name. For more information, see the following topics:

- “Performance considerations for WebSphere Application Server Version 5 queue destinations” on page 1825
- “Performance considerations for WebSphere Application Server Version 5 topic destinations” on page 1826
- “Performance considerations for WebSphere MQ queue destinations” on page 1826
- “Performance considerations for WebSphere MQ topic destinations” on page 1827

Performance considerations for WebSphere Application Server Version 5 queue destinations:

To optimize performance, configure the queue destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

For queue destinations configured on a WebSphere Application Server Version 5 node, you should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

BOQNAME

The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH

The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

For more information about using these properties, see:

- “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere Application Server Version 5 topic destinations:

To optimize performance, configure the JMS destination properties to best fit your applications.

For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

For JMS destinations configured on a WebSphere Application Server Version 5 node, ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
 - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
 - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

For more information about using these properties, see:

- The *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ queue destinations:

To optimize performance, configure the queue destination properties to best fit your message-driven beans or other applications that use the queue destinations.

For example:

- When MDB applications are configured to WebSphere MQ queues on z/OS, the INDEX by MSGID is very important.
- Setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for use by your message-driven beans or other applications that use the queue.

You should also consider queue attributes of the internal JMS server that are associated with the queue name. Inappropriate queue attributes can reduce the performance of WebSphere operations.

You should also consider the queue attributes associated with the queue name you created with WebSphere MQ. Inappropriate queue attributes can reduce the performance of WebSphere operations. You can use WebSphere MQ commands to change queue attributes for the queue name.

BOQNAME

The excessive backout requeue name. This can be set to a local queue name that can hold the messages which were rolled back by the WebSphere applications. This queue name can be a system dead letter queue.

BOTHRESH

The backout threshold and can be set to a number once the threshold is reached, the message will be moved to the queue name specified in BOQNAME.

INDXTYPE

Set this to MSGID. This causes an index of message identifiers to be maintained, which can improve WebSphere MQ retrieval of messages.

DEFSOPT

Set this to SHARED (for shared input from the queue).

SHARE

This must be specified (so that multiple applications can get messages from this queue).

For more information about using these properties, see:

- For BOQNAME and BOTHRESH, see “Handling poison messages” in the *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

Performance considerations for WebSphere MQ topic destinations:

To optimize performance, configure the topic destination properties to best fit your applications. For example, setting the Expiry property to SPECIFIED and the Specified Expiry property to 30000 milliseconds for the expiry timeout, reduces the number of messages that can be queued.

To ensure that there are enough underlying WebSphere MQ resources available for the queue, you must ensure that you configure the queue destination properties adequately for your application usage.

- Ensure the queue attribute, INDXTYPE is set to MSGID for the following system queues:
 - SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
- Ensure the queue attribute, INDXTYPE is set to CORRELID for the following system queues:
 - SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
 - SYSTEM.JMS.D.SUBSCRIBER.QUEUE

For more information about using these properties, see:

- The *WebSphere MQ Using Java* book
- The *WebSphere MQ Script (MQSC) Command Reference* book

JMS components on Version 5 nodes

To provide messaging support on a WebSphere Application Server Version 5 node, there is at most one JMS server and some number of JMS resources configured for the default messaging JMS provider on that node.

A *JMS server* on a Version 5 node serves the JMS resources (connection factories and destinations) for that node. The JMS server is managed as a separate process to application servers on the same node. Any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A *connection factory* encapsulates the configuration properties used to create connections with the JMS provider, to enable applications to access JMS destinations.

The main components of JMS support on a Version 5 node are shown in the figure The main components of WebSphere JMS support.

Figure 22. The main JMS components on a version 5 node. This figure shows the main JMS components on a version 5 node, from JMS provider through a connection to a destination, then to a WebSphere enterprise application (acting as a JMS client) that processes the message retrieved from the destination. For more information, see the text that accompanies this figure.

Administering listener ports and activation specifications for message-driven beans

Use these tasks to manage the listener ports and activation specifications used by message-driven beans (MDBs). If the JMS provider is implemented as a J2EE Connector Architecture (JCA) resource adapter use an activation specification, otherwise use a listener port. These tasks are supplementary to the tasks of administering resource adapters, and JMS provider resources.

About this task

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

Use the WebSphere Application Server administrative console to configure the following resources for message-driven beans:

- J2C activation specifications for JCA 1.5-compliant message-driven beans. Activation specifications must be provided when the application's resources are configured using the default messaging provider or any generic J2C Resource Adapter that supports inbound messaging.
- The message listener service, listener ports, and listeners for EJB 2.0 message-driven beans deployed against listener ports. Listener ports must be provided when using the following JMS providers: V5 Default Messaging, or Generic.

Listener port or activation specification?

WebSphere Application Server Version 6 or later supports the enhancements made to the EJB 2.1 and Java EE specifications that allow any resource that has a JCA 1.5 adapter to trigger an MDB (formerly only JMS resources could trigger MDBs). WebSphere Application Server Version 5 and EJB 2.0 used the listener port which specified a JMS connection factory and a destination. This allowed a pool of MDB instances to connect to the messaging system and listen to the designated destination. EJB 2.1 specifies an additional requirement of an MDB working with a JCA adapter using an activation specification.

If you are developing WebSphere Application Server Version 6 or later applications, you should consider the following questions:

- Should I use a listener port or an activation specification?
- Should I convert my existing listener ports to activation specifications?
- Will listener ports eventually not be supported anymore?

Here are some guidelines to help you decide:

- If you are using J2EE 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used, so you do not have to make a decision. WebSphere Application Server Version 4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server Version 5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server Version 5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using Java EE and EJB 2.1 with WebSphere Application Server Version 6 or later and not using JMS, you must use activation specifications. A connector MDB uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
- If you are using Java EE and EJB 2.1 with WebSphere Application Server Version 6 or later, the decision depends on whether your JMS provider API is implemented with JCA. In Java EE, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

To summarize: in WebSphere Application Server Version 6 or later, the decision on whether or not to use a listener port or an activation specification depends on the following scenarios:

- whether you upgrade your EJB 2.0 MDBs to EJB 2.1
- whether you want your EJB 2.1 MDB to use a JCA adapter
- whether you access your JMS provider via a JCA adapter.

If you have JMS API implementations that do not use JCA, WebSphere Application Server requires listener ports; if all JMS API implementations use JCA, listener ports are no longer required.

You can update the configuration data at any time, but some updates only take effect when the appropriate server is next started.

For additional information about administering support for message-driven beans, see the following topics:

- Configuring a JMS activation specification for MDBs used by the default messaging provider
- “Configuring a J2C activation specification” on page 1829
- “Configuring a J2C administered object” on page 1834
- Configuring message listener resources for EJB 2.0 message-driven beans

Configuring a J2C activation specification

Use this task to configure a J2EE Connector (J2C) activation specification used to deploy message-driven beans with an external resource adapter.

About this task

Use this task if you want to use a message-driven bean as a listener on a Java Connector Architecture (JCA) 1.5 resource adapter other than the default messaging JMS provider.

You can create or modify a J2C activation specification under an installed resource adapter at the cell, node, or server scope. You can select the message listener type from those provided by the given resource adapter.

Configuring a J2C activation specification offers two distinct advantages:

- The activation specification configuration information can be shared among multiple message-driven beans across multiple applications.
- Updates to the configuration properties can be made without the need to redeploy the application.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using J2EE 1.2 and Enterprise JavaBeans (EJB) 1.1 with WebSphere Application Server Version 4, message-driven beans are not used so you do not need listener ports or activation specifications. WebSphere Application Server Version 4 uses message beans, but these are not message-driven beans or enterprise beans.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server Version 5, you must use listener ports. The message-driven beans are JMS message-driven beans that implement `MessageListener`, and there is no JCA support. WebSphere Application Server Version 5 uses listener ports to associate message-driven bean classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server Version 6, you must use activation specifications. A connector message-driven bean uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of message-driven beans from EJB 2.0 to EJB 2.1.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server Version 6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your message-driven bean is a JMS message-driven bean that is implemented as a connector message-driven bean, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 message-driven bean in the same way as you would configure an EJB 2.0 message-driven bean, which in WebSphere Application Server is to use a listener port.

To configure a J2C activation specification for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new activation specification.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Activation specifications heading, click **J2C Activation Specifications**. This lists any existing J2C activation specifications for the external resource adapter in the content pane.
4. Display the properties of the J2C activation specification. If you want to display an existing J2C activation specification, click one of the names listed.

Alternatively, if you want to create a new J2C activation specification, click **New**, then specify the following required properties:

Name Type the name by which the activation specification is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Message listener type

Select the message listener type that this activation specification instance should support. This list is based on the deployment descriptor of the external resource adapter.

Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new activation specification, you may need to click **Apply** before this custom property selection is available.

5. Specify properties for the activation specification, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Activation Specifications collection:

This page contains a list of J2C activation specifications for a resource adapter configuration and is used to create new J2C activation specifications, to select J2C activation specifications for configuration changes, or to delete J2C activation specifications.

Activation specification definitions and classes are provided by a resource adapter when it is installed. Using this information, the administrator can create and configure J2C activation specifications with JNDI names that are then available for applications to use. The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using Java 2 Platform, Enterprise Edition (J2EE) 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used so you do not need listener ports or activation specifications. WebSphere Application Server v4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ;ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, you must use activation specifications. A connector MDB uses JCA to access its resources, so the connector must therefore be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C activation specifications**.
- **Resources** → **Resource Adapters** → **J2C activation specifications**.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification.

Data type	String
------------------	--------

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Message Listener Type:

The Message Listener Type that is used by this activation specification.

The list of available classes is provided by the resource adapter.

Data type String

J2C Activation Specifications settings:

Use this page to specify the settings for a J2C activation specification.

The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C activation specifications** → *activation_specification*.
- **Resources** → **Resource Adapters** → **J2C activation specifications** → *activation_specification*.

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification. Name is required

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Authentication alias:

This optional field is used to bind the J2C activation specification to an authentication alias (configured through the security JAAS screens).

This alias is used to access a user name and password that are set on the configured J2C activation specification. This field is only meaningful if the J2C activation specification you are configuring has a UserName and Password field.

If you have defined security domains in the application server, you can click **Browse...** to select a J2C authentication alias for the resource that you are configuring. Security domains allow you to isolate J2C authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

Data type Text

Message Listener Type:

The Message Listener Type used by this activation specification.

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Destination JNDIName:

The destination JNDIName field only appears when a message of type `javax.jms.Destination` with name *Destination* is received.

Configuring a J2C administered object

Use this task to configure a J2C administered object used to configure objects with an external resource adapter.

About this task

To configure a J2C administered object for an external resource adapter, use the administrative console to complete the following steps. This task contains an optional step for you to create a new administered object.

1. Display the external resource adapter. In the navigation pane, click **Resources** → **Resource Adapters** → *adapter_name*. This displays in the content pane a table of properties for the external resource adapter, including links to the types of J2C resources that it provides.
2. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
3. In the content pane, under the Additional Properties heading, click **J2C Administered Objects**. This lists any existing J2C administered objects for the external resource adapter in the content pane.
4. Display the properties of the J2C administered object. If you want to display an existing J2C administered object, click one of the names listed.

Alternatively, if you want to create a new J2C administered object, click **New**, then specify the following required properties:

Name Type the name by which the J2C administered object is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Administered object class

Select the administered object class that this instance should support. This list is based on the deployment descriptor of the external resource adapter.

Depending on the external resource adapter, there can be additional required properties that need to be supplied. To provide values for these properties, click **Custom properties**. When creating a new administered object, you may need to click **Apply** before this custom property selection is available.

5. Specify properties for the administered object, according to your needs .
6. Click **OK**.
7. Save your changes to the master configuration.

J2C Administered Objects collection:

Use this page to specify administered object settings for a Resource Adapter.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C administered objects**
- **Resources** → **Resource Adapters** → **Resource adapters** → **J2C administered objects**

Name:

Specifies display name assigned to this administered object.

Data type String

JNDI Name:

Specifies the JNDI name of the administered object.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

Description:

Specifies a description for the administered object.

Data type String

Administered object class:

Specifies the Administered Object class that is associated with this J2C administered object. This class must be one that is provided by the resource adapter.

Data type String

J2C Administered Object settings:

Use this page to specify the settings for an administered object.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** → **Resource Adapters** → **Resource adapters** → *resource_adapter* → **J2C administered objects** → *J2C_administered_object*
- **Resources** → **Resource Adapters** → **Resource adapters** → **J2C administered objects** → *J2C_administered_object*

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Data type String

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

Data type String

Name:

Specifies the name of the J2C administered object instance.

A string with no spaces meant to be a meaningful text identifier for the administered object. This name is required.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name that this administered object is bound under.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

Specifies a text description of the J2C administered object instance.

Data type String

Administered object class:

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. You can only select classes from this list.

After you create the administered object, you cannot modify the administered object class; it is read only.

Data type Class name

Configuring message listener resources for message-driven beans

Use the following tasks to configure resources needed by the message listener service to support message-driven beans for use with a JMS provider that does not have a J2EE Connector Architecture (JCA) 1.5 resource adapter.

Before you begin

Before configuring message listener resources for a message-driven bean, consider the Message Listener Service implementation on the z/OS platform, which affects how you should configure a listener port. For more information about the considerations, see “Message Listener Service on z/OS” on page 1837.

About this task

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, such as the default messaging provider that is part of WebSphere Application Server Version 6. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA resources to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server Version 5).

If the message-driven bean uses a queue hosted by WebSphere MQ as a JMS provider, you should optimize performance by configuring the queue destination properties to best fit your message-driven bean. For more information about performance considerations, see “Performance considerations for WebSphere MQ queue destinations” on page 1826.

Here are some guidelines on which scenarios use listener ports or activation specifications:

- If you are using J2EE 1.2 and EJB 1.1 with WebSphere Application Server v4, MDBs are not used, so you do not use listener ports or activation specifications because WebSphere Application Server v4 uses message beans, but these are not MDBs or EJBs.
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can be implemented with the JCA 1.5 API.
 - If your JMS provider API is implemented with JCA, your MDB is a JMS MDB that is implemented as a connector MDB. A connector MDB uses JCA to access its resources, and so the connector must be configured with an activation specification. This is for new bean development, and does not affect the conversion of MDBs from EJB 2.0 to EJB 2.1.
 - If your JMS provider API is not implemented with JCA, you have the same JMS situation as for Java EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

If you want to deploy an enterprise application to use JMS message-driven beans with a JMS provider that does not have a JCA 1.5 resource adapter, refer to the following subtopics:

- “Message Listener Service on z/OS” on page 1837
- “Configuring the message listener service” on page 1838
- “Creating a new listener port” on page 1845
- “Configuring a listener port” on page 1846
- “Deleting a listener port” on page 1847
- “Configuring security for message-driven beans that use listener ports” on page 1847
- “Administering listener ports” on page 1848

Message Listener Service on z/OS:

On the z/OS platform, the Message Listener Service implementation exploits the scalable server architecture provided by WebSphere Application Server for z/OS, by dividing the listener port functionality across the controller and servant processes.

A single message listener is registered in the controller portion of the ListenerPort, while application dispatch (that is, dispatch of the user application's `onMessage(Message)` EJB method) is then spread across the various servants comprising the server. This implementation is referred to as "listening in the controller" for the message-driven bean messages.

Note: An important point to note is that the WebSphere Application Server for z/OS Message Listener Service implementation does not use the just-described "listening in the controller" internal configuration in all cases, but rather only in the cases in which the message-driven bean is mapped to a queue (that is, listening on a Queue) or mapped (listening) to a topic through a durable subscription.

In the case in which the message-driven bean is listening to a topic through a nondurable subscription, the listener port registers a listener in *each servant*, rather than registering a single listener in the controller.

For a topic on which a message-driven bean is listening through a non-durable subscription, a single message published to that topic is dispatched once for each servant comprising the server. In contrast, if a message-driven bean is listening on a queue, or a topic through a durable subscription, a single message sent is dispatched once only, to a single servant, for the entire server.

The configuration of the listener port, in the "listening in the controller" case, is administered externally through the controls described in Tuning MDB processing on z/OS and Concepts and considerations for MDB settings on z/OS.

For a non-durable subscription message-driven bean, which is listening in each servant as described above, the listener ports are configured in the same manner as they are on distributed platforms. The single set of settings configured for the listener port are applied identically to each servant in this case.

Configuring the message listener service:

Use this task to configure the properties of the message listener service for an application server, to support message-driven beans deployed against listener ports.

About this task

If the JMS provider does not have a J2EE Connector Architecture (JCA) 1.5 resource adapter, such as the V5 Default Messaging and WebSphere MQ, you must configure JMS message-driven beans against a listener port (as in WebSphere Application Server Version 5).

If you want to deploy an enterprise application to use message-driven beans with listener ports, you can use this task to browse or change the configuration of the message listener service for an application server.

To configure the message listener service for an application server, use the administrative console to complete the following steps:

1. Display the listener service settings page:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
2. Optional: Browse or change the value of properties for the message-driven bean thread pool.
 - a. Click **Thread Pool**

- b. Change the following properties, to suit your needs:

Minimum size

The minimum number of threads to allow in the pool.

Maximum size

The maximum number of threads to allow in the pool.

Thread inactivity timeout

The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

Allow thread allocation beyond maximum thread size

Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.

- c. Click **OK**.

3. Optional: Specify any of the following optional properties that you need, as **Custom properties** of the message listener service:

NON.ASF.RECEIVE.TIMEOUT, MQJMS.POOLING.TIMEOUT, MQJMS.POOLING.THRESHOLD, MAX.RECOVERY.RETRIES, and RECOVERY.RETRY.INTERVAL.

For more information about these custom properties, see Custom Properties.

To browse or change the properties, complete the following steps:

- a. Click **Custom properties**

- b. For each custom property, specify a value to suit your needs.

If you have not specified a property before:

- 1) Click **New**.
- 2) Type the name of the property.
- 3) Type the value of the property.
- 4) Click **OK**.

4. Save your changes to the master configuration.

5. To have the changed configuration take effect, stop then restart the Application Server.

Message listener service:

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports and Custom Properties for the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service**

Custom Properties:

An optional set of name and value pairs for custom properties of the message listener service.

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT

- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL
- “DYNAMIC.CONFIGURATION.ENABLED” on page 1845

Message listener port collection:

The message listener ports configured in the administrative domain

This panel displays a list of the message listener ports configured in the administrative domain. Each listener port is used with a message-driven bean to automatically receive messages from an associated JMS destination. You can use this panel to add new listener ports or to change the properties of existing listener ports.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

To view this administrative console panel, click **Servers** → **Application Servers** → *application_server* → **[Messaging] Message Listener Service** → **Listener Ports**

To manage a listener port, enable the **Select** check box beside the listener port name in the list and click a button:

Button	Resulting action
Convert to activation specification	Opens a wizard that helps you convert the selected listener port to an activation specification.
New	Accesses the panel to configure a new listener port.
Delete	Deletes the selected listener port or ports.
Start	Starts the selected listener port or ports.
Stop	Stops the selected listener port or ports.

For more information about asynchronous messaging, see “Asynchronous messaging in WebSphere Application Server using JMS” on page 291.

Listener port settings:

A listener port is used to simplify administration of the association between a connection factory, destination, and deployed message-driven bean.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Listener Ports** → *listener_port*

Name:

The name by which the listener port is known for administrative purposes.

Data type	String
Default	Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type	Enum
Units	Not applicable
Default	Started
Range	Started When the application server is next started, the listener port is started automatically. Stopped When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

Specifies the maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine and if you do not need to process messages in a specific message order.

Data type	Integer
Units	Sessions
Default	1

Range	1 through 2147483647
Recommended	<ul style="list-style-type: none"> • If you want to process messages in a strict message order, set the value to 1, so only one thread is ever processing messages. • If you want to process multiple messages simultaneously (known as “message concurrency”), set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you may need more sessions, which should be determined by experimentation.

Maximum retries:

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped, in the range 0 through 2147483647.

Note: A WebSphere MQ queue has a similar property called the **BackoutThreshold** property. If your listener port is reading from a WebSphere MQ queue, then the retry limit and the behavior when the limit is reached is determined by whichever of these two properties is set to the lower limit:

- If you exceed the WebSphere MQ queue **BackoutThreshold** limit, the message that cannot be delivered is moved to somewhere else by WebSphere MQ (for example, to the WebSphere MQ backout requeue queue or the WebSphere MQ dead letter queue) and the listener port services the next message on the queue. In this case, WebSphere Application Server might not know that the message has not been delivered successfully.
- If you exceed the listener port **maximum retries** limit, the listener port stops. You then manually intervene to investigate the problem, possibly to remove the message from the WebSphere MQ queue then restart the listener port.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For third-party messaging providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647

Recommended

For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, if you want to process multiple messages in a single transaction, then set this value to more than 1. If messages start accumulating on the queue, then a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the overhead of transactions on JMS messages.

Note:

- If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing.
- Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch.
- Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Message listener service custom properties:

Use this panel to view or change an optional set of name and value pairs for custom properties of the message listener service.

To view this administrative console page, click **Servers** → **Application Servers** → *application_server* → **[Communications] Messaging** → **Message Listener Service** → **Custom Properties**

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL
- DYNAMIC.CONFIGURATION.ENABLED

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

You should set this property to a non-zero value only if you want to enable the non-ASF mode of operation for all message-driven bean listeners on the application server.

The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF).

- The ASF mode is meant to provide concurrency and transactional support for applications. For publish/subscribe message-driven beans, the ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.

- The non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. The non-ASF mode is also transactional but, because the path length is shorter than the ASF mode, usually provides improved performance.

Use non-ASF if:

- Your third-party messaging provider does not provide JMS ASF support
- You are using message-driven beans with WebSphere topic connections with the DIRECT port, because the embedded publish/subscribe broker using that port does not support XA transactions or JMS ASF.
- Message order is a strict requirement

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds
	0 non-ASF mode is disabled
	1 or more The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives

Recommended

If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to lower than the transaction timeout, but leave spare at least the maximum duration of your message-driven bean's onMessage() method. For example, if your message-driven bean's onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the NON.ASF.RECEIVE.TIMEOUT property to no more than 110000 (110000 milliseconds, that is 110 seconds).

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes
Range	

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10
Range	

MAX.RECOVERY.RETRIES:

The maximum number of times that a listener port managed by this service tries to recover from a failure before giving up and stopping. When stopped the associated listener port is changed to the stop state. The interval between retry attempts is defined by the RECOVERY.RETRY.INTERVAL custom property.

A failure can be one of two things:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Retry attempts
Default	5
Range	0 (no retries) through 2147483647

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by a listener port to recover from a failure. The maximum number of retry attempts is defined by the MAX.RECOVERY.RETRIES custom property.

A failure can be one of two things:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Seconds
Default	60
Range	1 through 2147483647

DYNAMIC.CONFIGURATION.ENABLED:

This property controls whether the application server on which a listener port is created requires to be restarted. Set this property to true to enable dynamic configuration.

Data type	Boolean
Default	False (not selected)

Creating a new listener port:

Use this task to create a new listener port for the message listener service, so that message-driven beans can be associated with the port to retrieve messages.

About this task

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server Version 5), you are recommended to deploy such beans as J2EE Connector Architecture (JCA) 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you want to deploy an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to create a new listener port for a message-driven bean to retrieve messages from.

To create a new listener port, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Click **New**.
3. Specify the following required properties:

Name The name by which the listener port is known for administrative purposes.

Connection factory JNDI name

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`

Destination JNDI name

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

4. Optional: Change other properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

Results

If enabled, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port:

Use this task to browse or change the properties of an existing listener port, used by message-driven beans associated with the port to retrieve messages.

About this task

Although you can continue to deploy an EJB 2.0 message-driven bean against a listener port (as in WebSphere Application Server Version 5), you are recommended to deploy such beans as J2EE Connector Architecture (JCA) 1.5-compliant resources and to upgrade them to be EJB 2.1 message-driven beans.

If you have deployed an enterprise application to use EJB 2.0 message-driven beans with listener ports, use this task to browse or change the configuration of a listener port that a message-driven bean retrieves messages from.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

To configure the properties of a listener port, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.

- b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Click the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
 3. Optional: Change properties for the listener port, according to your needs.
 4. Click **OK**.
 5. Save any changes to the master configuration.
 6. To have a changed configuration take effect, stop then restart the application server.

Deleting a listener port:

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

About this task

To delete a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. Under Communications, click **Messaging** → **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, click **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the check box for the listener port that you want to delete.
6. Click **Delete**. This action stops the port (needed to allow the port to be deleted) then deletes the port.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring security for message-driven beans that use listener ports:

Use this task to configure resource security and security permissions for message-driven beans.

About this task

There are two special security considerations when using message-driven beans (MDBs). In other respects, however, the security considerations for an MDB are identical to those of any other enterprise bean. For instance, access to JDBC resources and Java EE Connector Architecture (JCA) resources (for example CICS, IMS) is handled in the same way as for an entity or session bean. Access to other JMS resources is also handled in the same way as for other enterprise beans.

However to understand this last point about JMS access correctly, it is important to understand that the security considerations when configuring the MDB listener, which can be thought of as part of the application server infrastructure, are unique to MDBs. These considerations which are specific to MDBs are relevant when configuring authentication and authorization for the server to connect to a JMS provider and a Destination so that a message can be selected and so that the MDB can pass this message to the its onMessage() method.

The user's MDB onMessage() application code might not make additional JMS calls, however if the MDB application code accesses additional JMS resources, it is this access which is handled identically to JMS calls made by an entity or session EJB.

MDB security considerations:

The MDB listener's security information is established when the MDB listener's JMS Connection is created. This is the typical JMS programming pattern. The properties used to configure the MDB listener's JMS Connection Factory are also used for specifying these security parameters. By configuring the Connection Factory mapped to in the Listener Port definition, you can control the security parameters used by the MDB listener. The JMS Connection used by a given MDB listener is obtained in the order of precedence based on the configuration of the JMS Connection Factory used by the Message Listener Service Listener Port onto which a given MDB is mapped. For example, if an MDB, mdb1 is mapped onto Listener Port mylp1 and mylp1 uses ConnectionFactory qcf1, you would configure qcf1 to control the configuration of mdb1's MDB listener. The order of precedence is:

1. If a container-managed alias has been defined for this Connection Factory, the userid associated with the container-managed alias is used in the Connection creation call, for example `createQueueConnection(userid,password)`.
2. If a component-managed alias has been defined for this Connection Factory, the userid associated with the component-managed alias is used.
3. If neither alias is specified and the Connection Factory is defined in Bindings mode (that is, `TransportType = "BINDINGS"`), the server identity is used. The server identity translates more specifically into the servant identity in the servants, and the controller identity in the controller. In the case of listening-in controller, the controller identity is relevant as well as the servant identity. For related information about listening-in controllers, see "Message Listener Service on z/OS" on page 1837.

Note: The authentication aliases referred to here are those associated with the Connection Factory defined by the Administrator. No application resource reference is associated with the MDB listener and so no authentication alias has to be set at that level.

To set the container-managed alias, (if you elect that option), use the administrative console to complete the following steps:

1. To display the listener port settings, click **Servers** → **Server types** → **WebSphere application servers** → *application_server* → **[Communications] Messaging** → **Message listener service** → **[Additional properties] Listener ports** → *listener_port*
2. To get the name of the JMS connection factory, look at the Connection factory JNDI name property.
3. Display the JMS connection factory properties. For example, to display the properties of a queue connection factory, click **Resources** → **JMS** → **Queue Connection Factories** *connection_factory*.
4. Set the "Container-managed authentication alias" property.
5. Click **OK**

Results

Considerations for invoking other EJBs:

Messages arriving at a listener port have no client credentials associated with them. The messages are anonymous. To call secure enterprise beans from a message-driven bean, the message-driven bean must be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see *Securing enterprise bean applications*. For more information about configuring security for your application, see *Securing applications during assembly and deployment*.

Administering listener ports:

Use the following tasks to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

About this task

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provider, refer to related tasks.

You can use the WebSphere Application Server administrative console to administer listener ports, as described in the following tasks.

Note: If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. You do not normally need to start or stop a listener port manually.

- Adding a new listener port Use this task to create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configuring a listener port Use this task to browse or change the configuration properties of a listener port.
- Starting a listener port Use this task to start a listener port manually.
- Stopping a listener port Use this task to stop a listener port manually.

Starting a listener port:

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

About this task

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. However, you can start a listener port manually, as described in this topic.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

To start a listener port on an application server, use the administrative console to complete the following steps:

1. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
2. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
3. Select the check box for the listener port that you want to start.
4. Click **Start**.
5. Save your changes to the master configuration.

Stopping a listener port:

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

About this task

When you stop a listener port as described in this topic, the listener manager stops the listeners for all message-driven beans associated with the port.

To stop a listener port on an application server, use the administrative console to complete the following steps:

1. Display the collection list of listener ports:
 - a. In the navigation pane, select **Servers** → **Application Servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging** → **Message Listener Service**.
 - d. Click **Listener Ports**.
2. Select the check box for the listener port that you want to stop.
3. Click **Stop**.
4. Save your changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the application server.

Message-driven beans - listener port components:

The WebSphere Application Server support for message-driven beans deployed against listener ports is based on JMS message listeners and the message listener service, and builds on the base support for JMS.

Note: From WebSphere Application Server Version 7 listener ports are deprecated. For information about the facilities available to aid migration of configuration information from a listener port to an activation specification for use with the Websphere MQ messaging provided, refer to related tasks.

The main components of WebSphere Application Server support for message-driven beans are shown in the following figure and described after the figure:

Figure 23. The main components for message-driven beans. This figure shows the main components of WebSphere support for message-driven beans, from JMS provider through a connection to a destination, listener port, then deployed message-driven bean that processes the message retrieved from the destination. Each listener port defines the association between a connection factory, destination, and a deployed message-driven bean. The other main components are the message listener service, which comprises a listener for each listener port, all controlled by the same listener manager. For more information, see the text that accompanies this figure.

The *message listener service* is an extension to the JMS functions of the JMS provider and provides a *listener manager*, which controls and monitors one or more JMS *listeners*.

Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging).

A *connection factory* is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A *listener port* defines the association between a connection factory, a destination, and a deployed *message-driven bean*. Listener ports are used to simplify the administration of the associations between these resources.

When a deployed message-driven bean is installed, it is associated with a listener port and the listener for a destination. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing.

When an application server is started, it initializes the listener manager based on the configuration data. The listener manager creates a dynamic session thread pool for use by listeners, creates and starts

listeners, and during server termination controls the cleanup of listener message service resources. Each listener completes several steps for the JMS destination that it is to monitor, including:

- Creating a JMS server session pool, and allocating JMS server sessions and session threads for incoming messages.
- Interfacing with JMS ASF to create JMS connection consumers to listen for incoming messages.
- If specified, starting a transaction and requesting that it is committed (or rolled back) when the EJB method has completed.
- Processing incoming messages by invoking the `onMessage()` method of the specified enterprise bean.

Important file for message-driven beans

The `server_name-durableSubscriptions.ser` file in the `WAS_HOME/temp` directory is important for the operation of the WebSphere Application Server messaging service, so should not be deleted.

If you do need to delete the `WAS_HOME/temp` directory or other files in it, ensure that you preserve the following file:

`server_name-durableSubscriptions.ser`

You should not delete this file, because the messaging service uses it to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription.

Learning about messaging with WebSphere Application Server

Use this topic to learn about the use of asynchronous messaging for enterprise applications with WebSphere Application Server.

About this task

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) and J2EE Connector Architecture (JCA) programming interfaces. These interfaces provide a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as messages. For additional information about messaging resources, see: Messaging resources.

- “Types of messaging providers”
- “Styles of messaging in applications” on page 1930
- “JMS interfaces - explicit polling for messages” on page 1931
- “Message-driven beans - automatic message retrieval” on page 1932
- “Configuring JMS resources for the WebSphere MQ messaging provider” on page 1966
- “Message-driven beans - JCA components” on page 1933
- “WebSphere Application Server cloning and WebSphere MQ clustering” on page 1937
- “Asynchronous messaging - security considerations” on page 1939

Types of messaging providers

You can configure any of three main types of Java Message Service (JMS) providers in WebSphere Application Server: The WebSphere Application Server default messaging provider (which uses service integration as the provider), the WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider) and third-party messaging providers (which use another company’s product as the provider).

Overview

WebSphere Application Server supports JMS messaging through the following providers:

- “Default messaging provider” on page 1926
- “WebSphere MQ messaging provider” on page 1927

- “Third-party messaging provider” on page 1927

Your applications can use messaging resources from any of these JMS providers. The choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you might already have a messaging infrastructure based on WebSphere MQ. In this case, you can either connect directly using the WebSphere MQ messaging provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Note: For backwards compatibility with earlier releases, WebSphere Application Server Version 7 also includes support for the Version 5 default messaging provider and the Version 6 WebSphere MQ messaging provider. This support enables your applications that still use these resources to communicate with Version 5 and Version 6 nodes in Version 7 mixed cells.

Default messaging provider

If you mainly want to use messaging between applications in WebSphere Application Server, perhaps with some interaction with a WebSphere MQ system, the default messaging provider is the natural choice. This provider is based on service integration technologies and is fully integrated with the WebSphere Application Server runtime environment. To use the default messaging provider, you configure the following resources:

- Configure a connection factory or activation specification to connect your application to a service integration bus.
- Assign a queue or topic to a bus destination on the bus. This topic or queue is then available to any application that can access the bus destination.

A service integration bus comprises messaging engines that run in WebSphere Application Server processes and dynamically connect to one another using dynamic discovery. A messaging application connects to the bus through a messaging engine. Messaging engines use WebSphere Application Server clustering to provide high availability and scalability, and they use the same management framework as the rest of WebSphere Application Server. Bus client applications can run from within WebSphere Application Server (JMS), or run as stand-alone Java clients (using the J2SE Client for JMS) or run as non-Java clients (XMS).

In a pure WebSphere Application Server environment, service integration provides the following benefits:

- An all-Java implementation for JMS within a single server process, yielding good performance for local JMS traffic.

Note: On z/OS systems, WebSphere Application Server employs a multi-region architecture. The service integration runtime artefacts are in the same application server, but not in the same region as the applications. This contrasts with distributed platforms, on which the application server is a single process and the service integration runtime artefacts and the applications all run in that process.

- Direct delivery of messages to a consumer application that is ready to receive them, without first writing the messages to disk.
- Avoidance of copying and serialization of message payloads, if the application is written in accordance with the typical pattern of a messaging application. For more information, see *Why and when to pass the JMS message payload by reference*.
- Full integration of the administration model with WebSphere Application Server, providing management of single and federated nodes within a cell.
- Full use of the provided WebSphere Application Server infrastructure for tracing and threading, and for a range of communications protocols with a single point of administration.
- Extensive interoperation with WebSphere MQ networks.

There are two ways in which you can connect to a WebSphere MQ system through the default messaging provider:

- Connect a bus to a WebSphere MQ network, using a *WebSphere MQ link*. The WebSphere MQ network appears to the service integration bus as a foreign bus, and the service integration bus appears to WebSphere MQ as another queue manager.
- Connect directly to WebSphere MQ queues located on WebSphere MQ queue managers or (for WebSphere MQ for z/OS) queue-sharing groups, using a *WebSphere MQ server* bus member. Each WebSphere MQ queue is made available at a queue-type destination on the bus.

For more information about these two approaches, see Overview of interoperation with WebSphere MQ.

To configure and manage messaging with the default messaging provider, see Managing messaging with the default messaging provider.

WebSphere MQ messaging provider

If your business also uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, choose the WebSphere MQ messaging provider, which allows you to define resources for connecting to any queue manager on the WebSphere MQ network.

WebSphere MQ is characterized as follows:

- Messaging is handled by a network of queue managers, each running in its own set of processes and having its own administration.
- Features such as shared queues (on WebSphere MQ for z/OS) and WebSphere MQ clustering simplify administration and provide dynamic discovery.
- Many IBM and partner products support WebSphere MQ with (for example) monitoring and control, high availability and clustering.
- WebSphere MQ clients can run within WebSphere Application Server (JMS), or almost any other messaging environment using a variety of APIs.

For more information about the WebSphere MQ messaging provider, see “Enhanced features of the WebSphere MQ messaging provider” on page 1928. To configure and manage messaging with this provider, see “Managing messaging with the WebSphere MQ messaging provider” on page 1965. For more information about scenarios and considerations for using WebSphere MQ with WebSphere Application Server, see the white papers and IBM Redbooks publications provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at <http://www.ibm.com/software/ts/mqseries/library/>.

Third-party messaging provider

You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

To administer a third-party messaging provider, use the resource adaptor or client supplied by the third party. You can still use the WebSphere Application Server administrative console to administer the JMS connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans (MDBs), third-party messaging providers must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification, or use an inbound resource adaptor that conforms to the Java EE Connector Architecture (JCA) Version 1.5 specification.

To work with a third-party provider, see “Managing messaging with a third-party messaging provider” on page 1785.

Enhanced features of the WebSphere MQ messaging provider

The WebSphere MQ messaging provider enables WebSphere Application Server applications and clients to connect to and use WebSphere MQ resources in a JMS-compliant manner. For WebSphere Application Server Version 7.0, this provider includes the enhanced features described in this topic.

Overview

For WebSphere Application Server Version 7.0, the WebSphere MQ messaging provider has enhanced administrative options supporting the following functions:

- “WebSphere MQ channel compression”
- “WebSphere MQ client channel definition table”
- “Client channel exits” on page 1929
- “Transport-level encryption using SSL” on page 1929
- “Automatic selection of the WebSphere MQ transport type” on page 1929

WebSphere MQ channel compression

Data sent over the network between WebSphere Application Server and WebSphere MQ can be compressed, reducing the amount of data that is transferred. Channel compression can be beneficial in the following situations:

- If a cost is incurred that is proportional to the amount of data transferred over a network. For example, nodes in a network might span a leased line for which a utilization charge is applied.
- If the rate at which messaging data can be transferred across a network is the limiting factor in the performance of an application.
- If compressing the data might reduce the cost of its encryption and decryption.

To use WebSphere MQ channel compression, configure the message compression properties of an existing connection factory or activation specification. For more information, see the appropriate step within “Configuring JMS resources for the WebSphere MQ messaging provider” on page 1966.

For more information, see the WebSphere MQ topic Channel compression.

WebSphere MQ client channel definition table

The client channel definition table reduces the effort required to configure a connection to a queue manager. Your WebSphere MQ administrator can create a single table of all the WebSphere MQ channels supported by queue managers in the enterprise, then in WebSphere Application Server you configure a connection to a queue manager by pointing to a table entry and providing any additional information not already contained within the table.

You can also use the client channel definition table to provide a basic failover capability, by specifying that a connection is attempted against several entries in the table. Each specified entry is tried in turn until a queue manager connection is successfully established.

You can use the client channel definition table, with WebSphere MQ messaging provider activation specifications and connection factories, to select the client channel definition to use when establishing a connection to WebSphere MQ. The table can be configured to select from a number of queue managers, depending on their availability.

When you use a client channel definition table, you must bear in mind the following considerations:

- If your client channel definition table can select from more than one queue manager, you might not be able to recover global transactions. Activation specifications and connection factories that specify a client channel definition table must either do so without ambiguity as to the target queue manager, or must avoid using the resources with applications that enlist in global transactions.
- If your client channel definition table contains entries that reference native WebSphere MQ channel exits, the use of these entries is not supported in the WebSphere Application Server environment.

For more information about client channel definition tables, see the developerWorks article [WebSphere MQ V6 Java and JMS clients and the client channel definition table](#), and the WebSphere MQ topic [Client channel definition table](#).

To use a client channel definition table, point to it when you create a new activation specification or connection factory.

Client channel exits

Client channel exits are pieces of Java code that you develop, and that are executed in the application server at key points during the life cycle of a WebSphere MQ channel. Your code can change the runtime characteristics of the communications link between the WebSphere MQ messaging provider and the WebSphere MQ queue manager.

Note: Only client channel exits written in Java are supported for use within the WebSphere Application Server environment.

For more information about client channel exits, see the WebSphere MQ topic [Channel exit programs](#). For a list of the channel exits that work with the WebSphere MQ messaging provider, see the client connection channel row of the table in the WebSphere MQ topic [What are channel exit programs?](#).

To use client channel exits, configure the client transport properties of an existing connection factory or activation specification.

Transport-level encryption using SSL

Transport-level encryption using SSL is the supported way to configure SSL for JMS resources associated with the WebSphere MQ messaging provider. The SSL configuration is associated with the communication link for the connection factory or activation specification. You either define the SSL information in the connection factory, or your WebSphere MQ administrator defines the SSL information in an associated client channel definition table.

Automatic selection of the WebSphere MQ transport type

The WebSphere MQ messaging provider supports the following ways to connect to a WebSphere MQ queue manager:

- Bindings mode (or *call attach*)
 Bindings mode attachment is only possible if the queue manager is located on the same physical machine as the WebSphere Application Server. Bindings mode attachment, where available, typically offers better performance.
- Client mode (or *socket attach*)
 Client mode attachment can be used wherever the WebSphere MQ queue manager and WebSphere Application Server can establish a network connection to one another.
- Bindings mode, then client mode (automatic selection)
 This method tries a bindings mode connection first and, if that fails, a client mode connection is tried.

Every node in a WebSphere Application Server cluster shares identical configuration information. With automatic selection of the WebSphere MQ transport type, all the servers in a cluster can be configured to automatically select their transport. This has the effect that any clustered server that is co-located with a queue manager establishes a bindings mode connection to the queue manager, whereas other servers in the cluster establish client mode connection to the queue manager.

Styles of messaging in applications

This topic describes the ways that applications can use point-to-point and publish/subscribe messaging.

Applications can use the following styles of asynchronous messaging:

Point-to-Point

Point-to-point applications use *queues* to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

Publish/subscribe

Publish/subscribe systems provide named collection points for messages, called *topics*. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

One-way

An application sends a message, and does not want a response. This pattern of use is often referred to as a *datagram*.

Request and response

An application sends a request to another application and expects to receive a response in return.

One-way and forward

An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:

- “JMS interfaces - explicit polling for messages” on page 1931
- “Message-driven beans - automatic message retrieval” on page 1932

For more information about these messaging techniques and the Java Message Service (JMS), see Sun's Java Message Service (JMS) specification documentation (<http://developer.java.sun.com/developer/technicalArticles/Networking/messaging/>).

For more information about message-driven bean and inbound messaging support, see Sun's Enterprise JavaBeans specification (<http://java.sun.com/products/ejb/docs.html>).

For information about JCA inbound messaging processing, see Sun's J2EE Connector Architecture specification (<http://java.sun.com/j2ee/connector/download.html>).

JMS interfaces - explicit polling for messages

This topic provides an overview of applications that use JMS interfaces to explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interfaces. JMS provides a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

The base support for asynchronous messaging using JMS, shown in the following figure, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics).

Applications can use both point-to-point and publish/subscribe messaging (referred to as “messaging domains” in the JMS specification), while supporting the different semantics of each domain.

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification). With JMS 1.1, the preferred approach for implementing applications is to use the common interfaces. The JMS 1.1 common interfaces provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction.

The common interfaces are also parents of domain-specific interfaces. These domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server Version 5) are supported only to provide inter-operation and backward compatibility with applications that have already been implemented to use those interfaces.

A WebSphere application can use the JMS interfaces to explicitly poll a JMS destination to retrieve an incoming message, then pass the message to a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination.

Figure 24. Asynchronous messaging using JMS. This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

WebSphere applications can use standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction.

WebSphere applications can also use message-driven beans, as described in related topics.

For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

Message-driven beans - automatic message retrieval

WebSphere Application Server supports the use of message-driven beans as asynchronous message consumers.

Messaging with message-driven beans is shown in the figure Figure 25 on page 1933.

A client sends messages to the destination (or endpoint) for which the message-driven bean is deployed as the message listener. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination. The message-driven bean implements some business logic to process incoming messages on the destination.

Message-driven beans can be configured as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter or against a listener port (as in WebSphere Application Server Version 5). With a JCA 1.5 resource adapter, message-driven beans can handle generic message types, not just JMS messages. This makes message-driven beans suitable for handling generic requests inbound to WebSphere Application Server from enterprise information systems through the resource adapter. In the JCA 1.5 specification, such message-driven beans are commonly called *message endpoints* or simply *endpoints*.

All message-driven beans must implement the `MessageDrivenBean` interface. For JMS messaging, a message-driven bean must also implement the message listener interface, `javax.jms.MessageListener`.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

Messages arriving at a destination being processed by a message-driven bean have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see *Securing enterprise bean applications*.

For JMS messaging, message-driven beans can use a JMS provider that has a JCA 1.5 resource adapter, for example the default messaging provider that is part of WebSphere Application Server or the WebSphere MQ messaging provider. With a JCA 1.5 resource adapter, you deploy EJB 2.1 message-driven beans as JCA 1.5-compliant resources, to use a J2C activation specification. If the JMS provider does not have a JCA 1.5 resource adapter, for example the V5 default messaging provider, you must configure JMS message-driven beans against a listener port.

Figure 25. Messaging with message-driven beans. This figure shows an incoming message being passed automatically to the `onMessage()` method of a message-driven bean that is deployed as a listener for the destination. The message-driven bean processes the message, in this case passing the message on to a business logic bean for business processing. For more information, see the text that accompanies this figure.

Message-driven beans - JCA components

This topic provides an overview of the administrative components that you configure for message-driven beans (MDBs) as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter.

Components for a JCA resource adapter

When a resource adapter is installed, it provides definitions and classes for administered objects such as activation specifications. The administrator creates and configures activation specifications with Java™ Naming and Directory Interface (JNDI) names that are then available for applications to use.

The JCA resource adapter uses an activation specification to configure a specific endpoint. Each application that configures one or more endpoints must specify the resource adapter that sends messages to the endpoint

The application uses the activation specification to provide the configuration properties related to the processing of inbound messages.

JMS components used with a JCA messaging provider

MDBs that implement the `javax.jms.MessageListener` interface can be used for JMS messaging.

An application that uses JMS messaging needs access at runtime to configured objects such as connection factories and destinations.

When the JMS provider is the default JMS provider or the WebSphere MQ messaging provider, the administrator configures these objects for the JMS provider. For example, to configure a JMS activation specification for the WebSphere MQ messaging provider, in the WebSphere Application Server administrative console navigate to **Resources** → **JMS** → **Activation specifications**.

Otherwise the administrator configures these objects for the JMS resource adapter, which connects the application to a JMS provider, by navigating to **Resources** → **Resource Adaptors**.

If the application contains one or more MDBs, the administrator must configure either a JMS activation specification or a message listener port. For JCA-compliant messaging providers, the administrator usually configures an activation specification. But for the WebSphere MQ messaging provider there is a choice; the administrator can configure an activation specification or, for compatibility with previous versions of WebSphere Application Server, the administrator can configure a message listener port.

The JMS activation specification provides the deployer with information about the configuration properties of an MDB related to the processing of the inbound messages. For example, a JMS activation specification specifies the name of the service integration bus to connect to, information about the message acknowledgement modes, message selectors, destination types, and whether or not durable subscriptions are shared across connections with members of a server cluster.

The activation specification identifies a JMS destination by specifying its JNDI name. The MDB acts as a listener on a specific JMS destination.

The JMS destination refers to a service integration bus destination (or WebSphere MQ destination) which the administrator must also configure. For more information about JMS resources and service integration, see Learning about the default messaging provider.

J2C activation specification configuration and use

This topic provides an overview about the configuration and use of J2C activation specifications, used in the deployment of message-driven beans for JCA 1.5 resources.

J2C activation specifications are part of the configuration of inbound messaging support that can be part of a JCA 1.5 resource adapter. Each JCA 1.5 resource adapter that supports inbound messaging defines one or more types of message listener in its deployment descriptor (`messageListener` in the `ra.xml`). The message listener is the interface that the resource adapter uses to communicate inbound messages to the message endpoint. A message-driven bean (MDB) is a message endpoint and implements one of the message listener interfaces provided by the resource adapter. By allowing multiple types of message listener, a resource adapter can support a variety of different protocols. For example, the interface `javax.jms.MessageListener`, is a type of message listener that supports JMS messaging. For each type of message listener that a resource adapter implements, the resource adapter defines an associated activation specification (`activationSpec` in the `ra.xml`). The activation specification is used to set configuration properties for a particular use of the inbound support for the receiving endpoint.

When an application containing a message-driven bean is deployed, the deployer must select a resource adapter that supports the same type of message listener that the message-driven bean implements. As part of the message-driven bean deployment, the deployer needs to specify the properties to set on the J2C activation specification. Later, during application startup, a J2C activation specification instance is created, and these properties are set and used to activate the endpoint (that is, to configure the resource adapter's inbound support for the specific message-driven bean).

Applications with message-driven beans can also specify all, some, or none of the configuration properties needed by the `ActivationSpec` class, to override those defined by the resource adapter-scoped definition. These properties, specified as activation-config properties in the application's deployment descriptor, are configured when the application is assembled. To change any of these properties requires redeploying the application. These properties are unique to this applications use and are not shared with other message-driven beans. Any properties defined in the application's deployment descriptor take precedence over those defined by the resource adapter-scoped definition. This allows application developers to choose the best defaults for their applications.

WebSphere Application Server activation specification optional binding properties

Binding properties that you can specify for activation specifications to be deployed on WebSphere Application Server.

J2C authentication alias

If you provide values for user name and password as custom properties on an activation specification, you may not want to have those values exposed in clear text for security reasons. WebSphere security allows you to securely define an authentication alias for such cases. Configuration of activation specifications, both as an administrative object and during application deployment, enable you to use the authentication alias instead of providing the user name and password.

If you set the authentication alias field, then you should not set the user name and password custom properties fields. Also, authentication alias properties set as part of application deployment take precedence over properties set on an activation specification administrative object.

Only the authentication alias is ever written to file in an unencrypted form, even for purposes of transaction recovery logging. The security service is used to protect the real user name and password.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the authentication alias to retrieve the real user name and password from security then set it on the activation specification instance.

Destination JNDI name

For resource adapters that support JMS you need to associate `javax.jms.Destinations` with an activation specification, such that the resource adapter can service messages from the JMS destination. In this case, the administrator configures a J2C Administered Object which implements the `javax.jms.Destination` interface and binds it into JNDI.

You can configure a J2C Administered Object to use an `ActivationSpec` class that implements a `setDestination(javax.jms.Destination)` method. In this case, you can specify the destination JNDI name (that is, the JNDI name for the J2C Administered object that implements the `javax.jms.Destination`).

A destination JNDI name set as part of application deployment take precedence over properties set on an activation specification administrative object.

During application startup, when the activation specification is being initialized as part of endpoint activation, the server uses the destination JNDI name to look up the destination administered object then set it on the activation specification instance.

Message-driven beans - transaction support

Message-driven beans can handle messages on destinations (or endpoints) within the scope of a transaction.

Transaction handling when using the Message Listener Service with WebSphere MQ JMS

There are three possible cases, based on the MDB deployment descriptor setting you choose: container-managed transaction (required), container-managed transaction (not supported), and bean-managed transaction. For related information see Message-driven bean deployment descriptor properties.

Container-managed transaction (required)

In this situation, the application server starts a global transaction before it reads any incoming message from the destination, and before the `onMessage()` method of the MDB is invoked by the application server. This means that other EJBs that are invoked in turn by the message, and interactions with resources such as databases can all be scoped inside this single global transaction, within which the incoming message was obtained.

If this application flow completes successfully, the global transaction is committed. If the flow does not complete successfully, (if the transaction is marked for rollback or if a runtime exception occurs), the transaction is rolled back, and the incoming message is rolled back onto the MDB destination.

Container-managed transaction (not supported)

In this situation there is obviously no global transaction, however the JMS provider can still deliver a message from an MDB destination to the application server in a unit of work. You can consider this as a local transaction, because it does not involve other resources in its transactional scope.

The application server acknowledges message delivery on successful completion of the `onMessage()` dispatch of the MDB (using the acknowledgement mode specified by the assembler of the MDB).

However, the application server does not perform an acknowledge, if an unchecked runtime exception is thrown from the `onMessage()` method. So, does the message roll back onto the MDB destination (or is it acknowledged and deleted)?

The answer depends on whether or not a syncpoint is used by the WebSphere MQ JMS provider and can vary depending on the operating platform (in particular the z/OS operating platform can impart different behavior here).

If WebSphere MQ establishes a syncpoint around the MDB message consumption in this container-managed transaction (not supported) case, the message is rolled back onto the destination after an unchecked exception.

If a syncpoint is not used, then the message is deleted from the destination after an unchecked exception.

For related information, see the technote 'MDB behavior is different on z/OS than on distributed when getting nonpersistent messages within syncpoint' at <http://www.ibm.com/support/docview.wss?uid=swg21231549>.

Bean-managed transaction

This situation is similar to the container-managed transaction (not supported) case. Even though there might be a user transaction in this case, any user transaction started within the `onMessage` dispatch of the MDB does not include consumption of the message from the message-driven bean destination within the transaction scope. To do this, use the container-managed transaction (required) scenario.

Message redelivery

In each of the previous three cases, a message that is rolled back onto the MDB destination is eventually re-dispatched. If the original rollback was due to a temporary system problem, you would expect the re-dispatch of the MDB with this message to succeed on re-dispatch. If, however, the rollback was due to a specific message-related problem, the message would repeatedly be rolled back and re-dispatched. This would be an inefficient use of processing resources.

The application server handles this scenario which is known as a poison message scenario, by tracking the frequency with which a message is dispatched, and by stopping the associated listener port after a specified number of redeliveries has occurred. This is a configurable value on the Maximum Retries property on a listener port. For more information, see “Listener port settings” on page 1840.

Note: A Maximum Retries value of zero stops the listener port after a single failure to successfully complete an `onMessage()`.

Because stopping the listener port stops the processing for all MDBs mapped to that listener port, this solution is rather unspecific. Instead of relying on the WebSphere Application Server message listener service to stop the listener port if a poison message scenario occurs, the other solution is to set up a backout queue (BOQUEUE), and a backout threshold value (BOTHRESH). If you do this, WebSphere MQ handles the poison message. For more information on handling poison messages, see the *WebSphere MQ Using Java* book, which is available from the WebSphere MQ library page at <http://www.ibm.com/software/integration/wmq/library/>.

Inbound resource adapter transaction handling

An MDB can be configured for bean or container transaction handling. The owner of the resource adapter owner must tell the MDB developer how to set up the MDB for transaction handling.

WebSphere Application Server cloning and WebSphere MQ clustering

Here is a summary of information about using WebSphere Application Server horizontal cloning with WebSphere MQ server clustering support. It describes a scenario that shows how the message listener service can be configured to take advantage of WebSphere MQ server clustering and provides some information about how to resolve potential runtime failures in the clustering scenario.

The information in this topic is based on the scenario shown in the figure Figure 26 on page 1938.

Note: WebSphere MQ server clustering is only available with the full WebSphere MQ product installed as a JMS provider.

Each JMS listener is used to retrieve messages from a destination defined to the server. In the following information the listener configurations are the same for each WebSphere application server. Each application server host contains a WebSphere application server and a WebSphere MQ server. If a host is only used to distribute messages, it only contains a WebSphere MQ server. There can be many servers defined in the configuration, although for simplicity the information in this topic is based on a scenario containing only three servers as shown in the following figure:

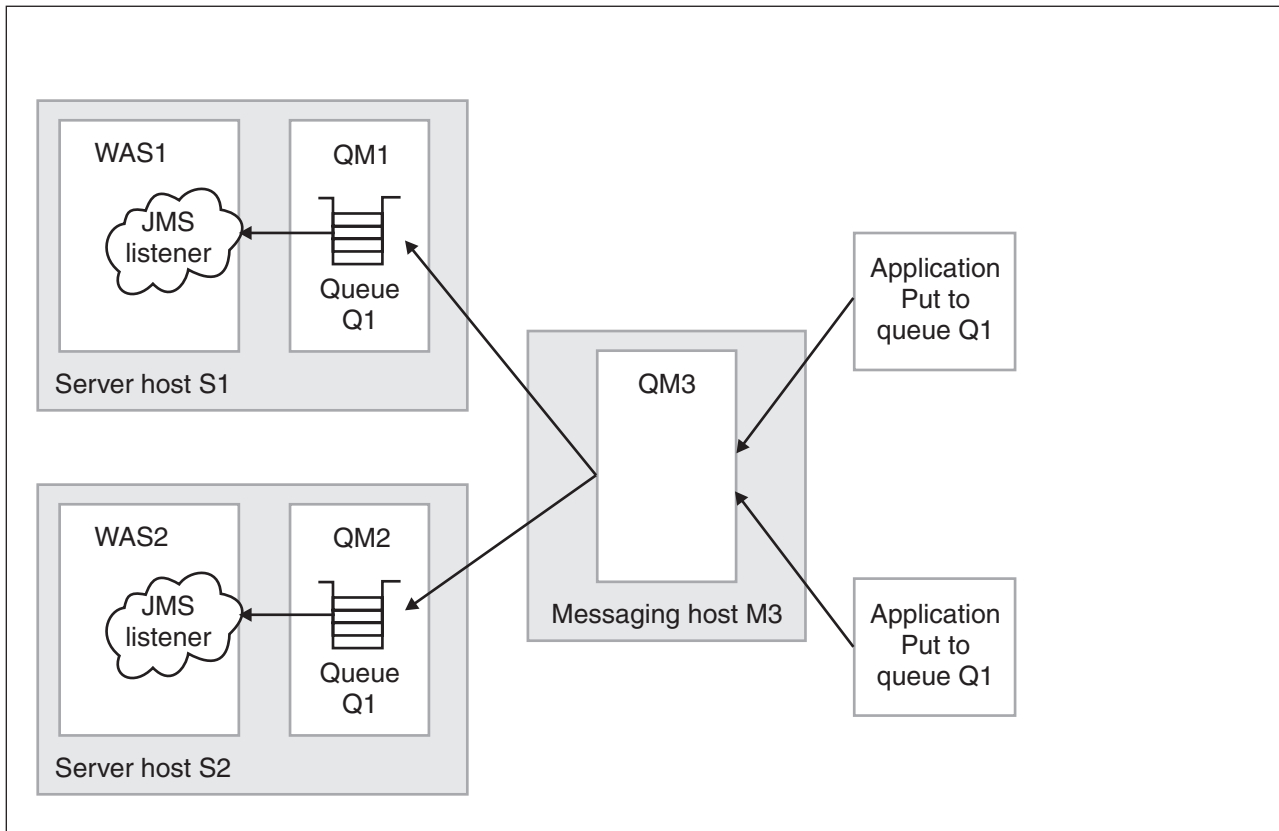

Figure 26. WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues. This figure shows two WebSphere Application Server hosts, with horizontal clustering, and a messaging host used to distribute messages for WebSphere MQ server clustering. For more information, see the text that accompanies this figure.

The scenario shown in the previous figure comprises the following three hosts:

- Server host S1 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM1, and a local queue, Q1. The queue manager belongs to a cluster. The queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the WebSphere MQ cluster.

WebSphere Application Server

This contains a cloned application server, WAS1, which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Server host S2 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM2, and a local queue, Q1. The queue manager belongs to the same cluster as QM1 on host S1. As with QM1, the queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the MQ cluster.

WebSphere Application Server

This contains a cloned application server, WAS2 (identical to WAS1 on host S1), which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Messaging host M3 contains the following servers:

WebSphere MQ server.

The server is defined to have a queue manager, QM3, which also belongs to the same cluster as QM1 and QM2. Applications add messages to the queue manager and queue Q1. The cluster to which this queue manager belongs causes messages to be distributed to all other queue managers in the cluster which have queue Q1 defined.

Note: Queue Q1 is not defined as a local queue on this host. If the queue was defined locally, then messages would remain on the server for local processing; messages would not be distributed by the queue manager cluster control to the other queue managers in the cluster that do have the queue defined.

This host does not have a WebSphere application server defined. All message retrieval processing is performed by the other two application servers on hosts S1 and S2.

Recovery scenarios

There are several failure scenarios that could occur with the clustering configuration; for example:

- WAS server failures.

In this scenario the failure of any single WebSphere application server results in the messages for the specified destination remaining on the queue, until the server is restarted.

- WebSphere MQ Queue Manager failures.

There are two different failures to consider:

1. Failure of a queue manager on the same host as a WebSphere application server (for example, failure of QM2 on host S2). In this case messages are delivered to the other available application servers, until the WebSphere MQ server is back online, when messages are processed as expected.
2. Failure of the messaging host M3 and its queue manager, QM3. In this case, the result of an outage is more significant because no messages are delivered to the other queue managers in the cluster. In a fully-deployed and scaled production system, host M3 would not be designed to be a single point of failure, and additional messaging servers would be added to the cluster configuration.

Asynchronous messaging - security considerations

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server.

Security for messaging is enabled only when WebSphere Application Server administrative security is enabled. In this case:

- JMS connections made to the JMS provider are authenticated.
- Access to JMS resources owned by the JMS provider is controlled by access authorizations.
- Requests to create new connections to the JMS provider must provide a user ID and password for authentication.
- The user ID and password do not need to be provided by the application.

Note: Users exploiting the connector thread identity support do not have to provide a user ID and password for authentication (see the subsequent links).

If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. If your resource authentication (res-auth) is set to Application, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

If your res-auth property is set to Container, you can set the Container-managed Authentication Alias on the Connection Factory, and specify the user ID and password within this alias. If you are running in Bindings transport mode (that is, the TransportType property on the Connection Factory is set to

“BINDINGS”), then you can also exploit the connector thread identity function instead of specifying a container-managed alias. For more information, see *Connection thread identity* and *Using thread identity support*.

For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971.

If you are working with a message-driven bean and are configuring a message-driven bean listener under the Message Listener Service, see “Configuring security for message-driven beans that use listener ports” on page 1847 for more information.

Note: In addition to the authorization needed for creating a connection to a JMS provider that you set up when creating a JMS Connection, you also typically need authorization to access specific JMS resources associated with that JMS Provider for example, permission to write to a given queue. For more information about using WebSphere MQ as your JMS provider, see the WebSphere MQ documentation library page at <http://www.ibm.com/software/integration/wmq/library/>.

Note:

1. User IDs longer than 12 characters cannot be used for authentication with the Version 5 default messaging provider or WebSphere MQ. For example, the default Windows NT user ID, **Administrator**, is not valid for use because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider or WebSphere MQ connection factory must specify a user ID no longer than 12 characters.

Authorization to access messages stored by the default messaging provider is controlled by authorization to access the service integration bus destinations on which the messages are stored. For information about authorizing permissions for individual bus destinations, see *Administering destination roles*.

Configuring messaging with scripting

Use these topics to learn about configuring messaging with the wsadmin tool. You can configure the message listener service, Java Messaging Service settings, queue and connection factories, and WebSphere MQ settings.

About this task

You can use the wsadmin tool to configure various messaging connections and settings.

- Configure the message listener service.

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

- Configure Java Messaging Service (JMS) providers, destinations, and connections.

The application server supports asynchronous messaging through the use of a JMS provider and its related messaging system. You can use the wsadmin tool to configure new JMS providers, destinations, and connections.

A JMS destination is used to configure the properties for the associated messaging provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS connection factory is used to create connections to the associated JMS provider of JMS destinations, for both point-to-point and publish/subscribe messaging.

- Configure queue and topic connection factories for the application server. Use queue and topic connection factories to create connections between providers and destinations. A queue connection factory creates a connection to the associated JMS provider of the JMS queue destinations, for point-to-point messaging. A topic connection factory creates a connection to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

- Configure WebSphere MQ settings. A WebSphere MQ server represents either a WebSphere MQ queue manager or a WebSphere MQ queue sharing group. It is used by Service Integration Bus messaging to define properties used for connecting to WebSphere MQ. Setting up a WebSphere MQ server involves using the administrative console to create the server definition, add it to a service integration bus, and create a WebSphere MQ queue type destination.

Configuring the message listener service using scripting

Use scripting to configure the message listener service.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure the message listener service for an application server:

1. Identify the application server and assign it to the server variable:

- Using Jacl:

```
set server [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
server = AdminConfig.getid('/Cell:mycell/Node:mynode/Server:server1/')
print server
```

Example output:

```
server1(cells/mycell/nodes/mynode/servers/server1|server.xml#Server_1)
```

2. Identify the message listener service belonging to the server and assign it to the mls variable:

- Using Jacl:

```
set mls [$AdminConfig list MessageListenerService $server]
```

- Using Jython:

```
mls = AdminConfig.list('MessageListenerService', server)
print mls
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1|server.xml#MessageListenerService_1)
```

3. Modify various attributes with one of the following examples:

- This example command changes the thread pool attributes:

- Using Jacl:

```
$AdminConfig modify $mls {{threadPool {{inactivityTimeout 4000}
{isGrowable true} {maximumSize 100} {minimumSize 25}}}}
```

- Using Jython:

```
AdminConfig.modify(mls, [['threadPool', [['inactivityTimeout', 4000],
['isGrowable', 'true'], ['maximumSize', 100], ['minimumSize', 25]]])
```

- This example modifies the property of the first listener port:

- Using Jacl:

```
set lports [$AdminConfig showAttribute $mls listenerPorts]
set lport [lindex $lports 0]
$AdminConfig modify $lport {{maxRetries 2}}
```

- Using Jython:

```
lports = AdminConfig.showAttribute(mls, 'listenerPorts')
cleanLports = lports[1:len(lports)-1]
lport = cleanLports.split(" ")[0]
AdminConfig.modify(lport, [['maxRetries', 2]])
```

- This example adds a listener port:

- Using Jacl:

```
set new [$AdminConfig create ListenerPort $mls {{name my}
{destinationJNDIName di} {connectionFactoryJNDIName jndi/fs}}]
$AdminConfig create StateManageable $new {{initialState START}}
```

- Using Jython:

```
new = AdminConfig.create('ListenerPort', mls, [['name', 'my'],
['destinationJNDIName', 'di'], ['connectionFactoryJNDIName', 'jndi/fsi']])
print new
print AdminConfig.create('StateManageable', new, [['initialState', 'START']])
```

Example output:

```
my(cells/mycell/nodes/mynode/servers/server1:server.xml#ListenerPort_1079471940692)
(cells/mycell/nodes/mynode/servers/server1:server.xml#StateManageable_107947182623)
```

4. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
5. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS providers using scripting

You can use the wsadmin tool and scripting to configure a new JMS provider.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new JMS provider:

1. Identify the parent ID:

- Using Jacl:

```
set node [$AdminConfig getid /Cell:mycell/Node:mynode/]
```

- Using Jython:

```
node = AdminConfig.getid('/Cell:mycell/Node:mynode/')
print node
```

Example output:

```
mynode(cells/mycell/nodes/mynode|node.xml#Node_1)
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required JMSProvider
```

- Using Jython:

```
print AdminConfig.required('JMSProvider')
```

Example output:

Attribute	Type
name	String
externalInitialContextFactory	String
externalProviderURL	String

3. Set up required attributes:

- Using Jacl:

```

set name [list name JMSP1]
set extICF [list externalInitialContextFactory
"Put the external initial context factory here"]
set extPURL [list externalProviderURL "Put the external provider URL here"]
set jmsAttrs [list $name $extICF $extPURL]

```

- Using Jython:

```

name = ['name', 'JMSP1']
extICF = ['externalInitialContextFactory',
"Put the external initial context factory here"]
extPURL = ['externalProviderURL', "Put the external provider URL here"]
jmsAttrs = [name, extICF, extPURL]
print jmsAttrs

```

Example output:

```

{name JMSP1} {externalInitialContextFactory {Put the external
initial context factory here }} {externalProviderURL
{Put the external provider URL here}}

```

4. Create the JMS provider:

- Using Jacl:

```

set newjmsp [$AdminConfig create JMSProvider $node $jmsAttrs]

```

- Using Jython:

```

newjmsp = AdminConfig.create('JMSProvider', node, jmsAttrs)
print newjmsp

```

Example output:

```

JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)

```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS destinations using scripting

You can use scripting and the wsadmin tool to configure a new JMS destination.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new JMS destination:

1. Identify the parent ID:

- Using Jacl:

```

set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]

```

- Using Jython:

```

newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp

```

Example output:

```

JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)

```

2. Get required attributes:

- Using Jacl:

```

$AdminConfig required GenericJMSDestination

```

- Using Jython:

```
print AdminConfig.required('GenericJMSDestination')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
externalJNDIName String
```

3. Set up required attributes:

- Using Jacl:

```
set name [list name JMSD1]
set jndi [list jndiName jms/JMSDestination1]
set extJndi [list externalJNDIName jms/extJMSD1]
set jmsdAttrs [list $name $jndi $extJndi]
```

- Using Jython:

```
name = ['name', 'JMSD1']
jndi = ['jndiName', 'jms/JMSDestination1']
extJndi = ['externalJNDIName', 'jms/extJMSD1']
jmsdAttrs = [name, jndi, extJndi]
print jmsdAttrs
```

Example output:

```
{name JMSD1} {jndiName jms/JMSDestination1} {externalJNDIName jms/extJMSD1}
```

4. Create generic JMS destination:

- Using Jacl:

```
$AdminConfig create GenericJMSDestination $newjmsp $jmsdAttrs
```

- Using Jython:

```
print AdminConfig.create('GenericJMSDestination', newjmsp, jmsdAttrs)
```

Example output:

```
JMSD1(cells/mycell/nodes/mynode|resources.xml#GenericJMSDestination_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new JMS connections using scripting

Use scripting and the wsadmin tool to configure a new JMS connection.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new JMS connection:

1. Configure a connection pool for your generic connection factories.

Because Java 2 Connector (J2C) manages the generic connection factories, you must configure a connection pool to indicate the policy for connection management by J2C. The following example commands configure a connection pool in your environment:

- Using Jacl:

```
set connectionPool [$AdminConfig create ConnectionPool $yourGenericCF {} connectionPool]
set sessionPool [$AdminConfig create ConnectionPool $yourGenericCF {} sessionPool]
```

- Using Jython:

```

connectionPool = AdminConfig.create('ConnectionPool', '[yourGenericCF {}, connectionPool]')
sessionPool = AdminConfig.create('ConnectionPool', '[yourGenericCF {}, sessionPool]')

```

2. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:myNode/JMSProvider:JMSP1]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

3. Get required attributes:

- Using Jacl:

```
$AdminConfig required GenericJMSConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('GenericJMSConnectionFactory')
```

Example output:

Attribute	Type
name	String
jndiName	String
externalJNDIName	String

4. Set up required attributes:

- Using Jacl:

```
set name [list name JMSCF1]
set jndi [list jndiName jms/JMSConnFact1]
set extJndi [list externalJNDIName jms/extJMSCF1]
set jmscfAttrs [list $name $jndi $extJndi]
```

Example output:

```
{name JMSCF1} {jndiName jms/JMSConnFact1} {externalJNDIName jms/extJMSCF1}
```

- Using Jython:

```
name = ['name', 'JMSCF1']
jndi = ['jndiName', 'jms/JMSConnFact1']
extJndi = ['externalJNDIName', 'jms/extJMSCF1']
jmscfAttrs = [name, jndi, extJndi]
print jmscfAttrs
```

Example output:

```
[[name, JMSCF1], [jndiName, jms/JMSConnFact1], [externalJNDIName, jms/extJMSCF1]]
```

5. Create generic JMS connection factory:

- Using Jacl:

```
$AdminConfig create GenericJMSConnectionFactory $newjmsp $jmscfAttrs
```

- Using Jython:

```
print AdminConfig.create('GenericJMSConnectionFactory', newjmsp, jmscfAttrs)
```

Example output:

```
JMSCF1(cells/mycell/nodes/mynode|resources.xml#GenericJMSConnectionFactory_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere queue connection factories using scripting

You can use scripting and the wsadmin tool to configure new queue connection factories in WebSphere Application Server.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WebSphere queue connection factory:

1. Identify the parent ID:

- Using Jacl:

```
set v5jmsp [$AdminConfig getid "/Cell:mycell/Node:mynode/JMSProvider:WebSphere JMS Provider/"]
```

- Using Jython:

```
v5jmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:WebSphere JMS Provider/')
print v5jmsp
```

Example output:

```
"WebSphere JMS Provider(cells/mycell/nodes/mynode|resources.xml#builtin_jmsprovider)"
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASQueueConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('WASQueueConnectionFactory')
```

Example output:

Attribute	Type
name	String
jndiName	String

3. Set up required attributes:

- Using Jacl:

```
set name [list name WASQCF]
set jndi [list jndiName jms/WASQCF]
set mqcfAttrs [list $name $jndi]
```

Example output:

```
{name WASQCF} {jndiName jms/WASQCF}
```

- Using Jython:

```
name = ['name', 'WASQCF']
jndi = ['jndiName', 'jms/WASQCF']
mqcfAttrs = [name, jndi]
print mqcfAttrs
```

Example output:

```
[[name, WASQCF], [jndiName, jms/WASQCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates WASQueueConnectionFactory] 0]
```

- Using Jython:

```
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('WASQueueConnectionFactory').split(lineseparator)[0]
print template
```

5. Create was queue connection factories:

- Using Jacl:

```
$AdminConfig createUsingTemplate WASQueueConnectionFactory $v5jmsp $mqcfAttrs $template
```

- Using Jython:

```
AdminConfig.createUsingTemplate('WASQueueConnectionFactory', v5jmsp, mqcfAttrs, template)
```

Example output:

```
WASQCF(cells/mycell/nodes/mynode|resources.xml#WASQueueConnectionFactory_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere topic connection factories using scripting

Use scripting and the wsadmin tool to configure new WebSphere topic connection factories.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WebSphere topic connection factory:

1. Identify the parent ID:

- Using Jacl:

```
set v5jmsp [$AdminConfig getid "/Cell:mycell/Node:mynode/JMSProvider:WebSphere JMS Provider/"]
```

- Using Jython:

```
v5jmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:WebSphere JMS Provider/')  
print v5jmsp
```

Example output:

```
"WebSphere JMS Provider(cells/mycell/nodes/mynode|resources.xml#builtin_jmsprovider)"
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASTopicConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('WASTopicConnectionFactory')
```

Example output:

Attribute	Type
name	String
jndiName	String
port	ENUM(DIRECT, QUEUED)

3. Set up required attributes:

- Using Jacl:

```
set name [list name WASTCF]  
set jndi [list jndiName jms/WASTCF]  
set port [list port QUEUED]  
set mtcfAttrs [list $name $jndi $port]
```

Example output:

```
{name WASTCF} {jndiName jms/WASTCF} {port QUEUED}
```

- Using Jython:

```

name = ['name', 'WASTCF']
jndi = ['jndiName', 'jms/WASTCF']
port = ['port', 'QUEUED']
mtcfAttrs = [name, jndi, port]
print mtcfAttrs

```

Example output:

```
[[name, WASTCF], [jndiName, jms/WASTCF], [port, QUEUED]]
```

4. Create was topic connection factories:

- Using Jacl:

```
$AdminConfig create WASTopicConnectionFactory $v5jmsp $mtcfAttrs
```

- Using Jython:

```
print AdminConfig.create('WASTopicConnectionFactory', v5jmsp, mtcfAttrs)
```

Example output:

```
WASTCF(cells/mycell/nodes/mynode|resources.xml#WASTopicConnectionFactory_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere queues using scripting

You can use scripting to configure a new WebSphere queue.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WebSphere queue:

1. Identify the parent ID:

- Using Jacl:

```
set v5jmsp [$AdminConfig getid "/Cell:mycell/Node:mynode/JMSProvider:WebSphere JMS Provider/"]
```

- Using Jython:

```
v5jmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:WebSphere JMS Provider/')
print v5jmsp
```

Example output:

```
"WebSphere JMS Provider(cells/mycell/nodes/mynode|resources.xml#builtin_jmsprovider)"
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASQueue
```

- Using Jython:

```
print AdminConfig.required('WASQueue')
```

Example output:

```
Attribute      Type
name           String
jndiName       String
```

3. Set up required attributes:

- Using Jacl:

```
set name [list name WASQ1]
set jndi [list jndiName jms/WASQ1]
set wqAttrs [list $name $jndi]
```

Example output:

```
{name WASQ1} {jndiName jms/WASQ1}
```

- Using Jython:

```
name = ['name', 'WASQ1']
jndi = ['jndiName', 'jms/WASQ1']
wqAttrs = [name, jndi]
print wqAttrs
```

Example output:

```
[[name, WASQ1], [jndiName, jms/WASQ1]]
```

4. Create was queue:

- Using Jacl:

```
$AdminConfig create WASQueue $v5jmsp $wqAttrs
```

- Using Jython:

```
print AdminConfig.create('WASQueue', v5jmsp, wqAttrs)
```

Example output:

```
WASQ1(cells/mycell/nodes/mynode|resources.xml#WASQueue_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring new WebSphere topics using scripting

You can configure new WebSphere topics using the wsadmin tool and scripting.

Before you begin

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new WebSphere topic:

1. Identify the parent ID:

- Using Jacl:

```
set v5jmsp [$AdminConfig getid "/Cell:mycell/Node:mynode/JMSProvider:WebSphere JMS Provider/"]
```

- Using Jython:

```
v5jmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:WebSphere JMS Provider/')
print v5jmsp
```

Example output:

```
"WebSphere JMS Provider(cells/mycell/nodes/mynode|resources.xml#builtin_jmsprovider)"
```

2. Get required attributes:

- Using Jacl:

```
$AdminConfig required WASTopic
```

- Using Jython:

```
print AdminConfig.required('WASTopic')
```

Example output:

Attribute	Type
name	String
jndiName	String
topic	String

3. Set up required attributes:

- Using Jacl:

```
set name [list name WAST1]
set jndi [list jndiName jms/WAST1]
set topic [list topic "Put your topic here"]
set wtAttrs [list $name $jndi $topic]
```

Example output:

```
{name WAST1} {jndiName jms/WAST1} {topic {Put your topic here}}
```

- Using Jython:

```
name = ['name', 'WAST1']
jndi = ['jndiName', 'jms/WAST1']
topic = ['topic', "Put your topic here"]
wtAttrs = [name, jndi, topic]
print wtAttrs
```

Example output:

```
[[name, WAST1], [jndiName, jms/WAST1], [topic, "Put your topic here"]]
```

4. Create was topic:

- Using Jacl:

```
$AdminConfig create WASTopic $v5jmsp $wtAttrs
```

- Using Jython:

```
print AdminConfig.create('WASTopic', v5jmsp, wtAttrs)
```

Example output:

```
WAST1(cells/mycell/nodes/mynode|resources.xml#WASTopic_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Configuring a new connection factory for the WebSphere MQ messaging provider using scripting

You can use scripting to configure a new connection factory for the WebSphere MQ messaging provider.

Before you begin

You can also use the “createWMQConnectionFactory command” on page 2078 to create a connection factory for the WebSphere MQ messaging provider.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a connection factory for the WebSphere MQ messaging provider:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/
JMSProvider:WebSphere MQ JMS Provider/]
```

- Using Jython:

```

newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/
JMSProvider:WebSphere MQ JMS Provider')
print newjmsp

```

Example output:

```

WebSphere MQ JMS Provider(cells/mycell/nodes/mynode|
resources.xml#builtin_mqprovider)

```

2. Get the required attributes:

- Using Jacl:

```
$AdminConfig required MQConnectionFactory
```
- Using Jython:

```
print AdminConfig.required('MQConnectionFactory')
```

Example output:

```

attribute  Type
name       String
jndiName   String

```

3. Set up the required attributes:

- Using Jacl:

```
set name [list name MQCF]
set jndi [list jndiName jms/MQCF]
set mqcfAttrs [list $name $jndi]
```

Example output:

```
{name MQCF} {jndiName jms/MQCF}
```

- Using Jython:

```
name = ['name', 'MQCF']
jndi = ['jndiName', 'jms/MQCF']
mqcfAttrs = [name, jndi]
print mqcfAttrs
```

Example output:

```
[[name, MQCF], [jndiName, jms/MQCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQConnectionFactory] 0]
```
- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template =
AdminConfig.listTemplates('MQConnectionFactory').split(lineseparator)[0]
print template
```

Example output:

```

Example non-XA WMQ ConnectionFactory(templates/
system:JMS-resource-provider-templates.xml
#MQConnectionFactory_3)

```

5. Create a connection factory for the WebSphere MQ messaging provider:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQConnectionFactory
$newjmsp $mqcfAttrs $template
```
- Using Jython:

```
print AdminConfig.createUsingTemplate('MQConnectionFactory',
newjmsp, mqcfAttrs, template)
```

Example output:

```
MQCF(cells/mycell/nodes/mynode:resources.xml#MQConnectionFactory_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Defining a connection factory for the WebSphere MQ messaging provider by supplying custom connection data

The following example creates a connection factory, specifying custom connection data. Due to the default values assumed for the unspecified parameters, applications using this connection factory expect to be co-located with a queue manager installed on the same node.

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name cf1 -jndiName "jms/cf/cf1" -type CF}
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1205322636000)
```

The following example creates an connection factory for which the user must specify and maintain all the parameters used for establishing a connection to WebSphere MQ.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)", [{"-name cf2
-jndiName 'jms/cf/cf2' -type CF -description 'Must remember to keep each
of these connection factories in sync with the WebSphere MQ queue manager
to which they refer' -qmgrName QM1 -qmgrHostname 192.168.0.22 -qmgrPort 1415
-qmgrSvrconnChannel QM1.SVRCONN"}])
cf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263601)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name cf2 -jndiName "jms/cf/cf2" -type CF -description "Must remember to
keep each of these connection factories in sync with the WebSphere MQ queue
manager to which they refer" -qmgrName QM1 -qmgrHostname 192.168.0.22
-qmgrPort 1415 -qmgrSvrconnChannel QM1.SVRCONN}
cf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263601)
```

Configuring a new queue connection factory for the WebSphere MQ messaging provider using scripting

You can use scripting to configure a new queue connection factory for the WebSphere MQ messaging provider.

Before you begin

You can also use the “createWMQConnectionFactory command” on page 2078 to create a queue connection factory for the WebSphere MQ messaging provider.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new queue connection factory for the WebSphere MQ messaging provider:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get the required attributes:

- Using Jacl:

```
$AdminConfig required MQQueueConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('MQQueueConnectionFactory')
```

Example output:

```
attribute Type
name       String
jndiName   String
```

3. Set up the required attributes:

- Using Jacl:

```
set name [list name MQQCF]
set jndi [list jndiName jms/MQQCF]
set mqccfAttrs [list $name $jndi]
```

Example output:

```
{name MQQCF} {jndiName jms/MQQCF}
```

- Using Jython:

```
name = ['name', 'MQQCF']
jndi = ['jndiName', 'jms/MQQCF']
mqccfAttrs = [name, jndi]
print mqccfAttrs
```

Example output:

```
[[name, MQQCF], [jndiName, jms/MQQCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQQueueConnectionFactory] 0]
```

- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQQueueConnectionFactory').
split(lineseparator)[0]
print template
```

Example output:

```
Example non-XA WMQ QueueConnectionFactory(templates/
system:JMS-resource-provider-templates.xml
#MQQueueConnectionFactory_3)
```

5. Create a queue connection factory for the WebSphere MQ messaging provider:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQQueueConnectionFactory
$newjmsp $mqqcAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQQueueConnectionFactory',
newjmsp, mqqcAttrs, template)
```

Example output:

```
MQQCF(cells/mycell/nodes/mynode:resources.xml#MQQueueConnectionFactory_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.
7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Defining a queue connection factory for the WebSphere MQ messaging provider by supplying custom connection data

The following example creates a queue connection factory, specifying custom connection data.

```
wsadmin>AdminTask.createWMQConnectionFactory('WebSphere MQ JMS Provider
(cells/EXAMPLECell01|resources.xml#builtin_mqprovider)', '
[-type QCF -name MQQueueConnectionFactory1 -jndiName
jms/MQQueueConnectionFactory1 -description -qmgrName
QueueManagerName -wmqTransportType BINDINGS_THEN_CLIENT
-qmgrHostname HostName -qmgrSvrconnChannel ServerConnectionChannel ]')
```

The following example creates a queue connection factory, specifying CCDT connection data.

```
wsadmin>AdminTask.createWMQConnectionFactory('WebSphere MQ JMS Provider
(cells/EXAMPLECell01|resources.xml#builtin_mqprovider)', '
[-type QCF -name MQQueueConnectionFactory2 -jndiName
jms/MQQueueConnectionFactory2 -description -ccdtUrl
http://ClientChannelDefinitionTableURL -ccdtQmgrName QueueManager ]')
```

Configuring a new topic connection factor for the WebSphere MQ messaging provider using scripting

You can use scripting to configure a new topic connection factory for the WebSphere MQ messaging provider.

Before you begin

You can also use the “createWMQConnectionFactory command” on page 2078 to create a topic connection factory for the WebSphere MQ messaging provider.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a topic connection factory for the WebSphere MQ messaging provider:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/
JMSPProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/
JMSPProvider:JMSP1')
print newjmsp
```

Example output:

```
JMSPI(cells/mycell/nodes/mynode:resources.xml#JMSProvider_1)
```

2. Get the required attributes:

- Using Jacl:

```
$AdminConfig required MQTopicConnectionFactory
```

- Using Jython:

```
print AdminConfig.required('MQTopicConnectionFactory')
```

Example output:

```
attribute  Type
name       String
jndiName   String
```

3. Set up the required attributes:

- Using Jacl:

```
set name [list name MQTCF]
set jndi [list jndiName jms/MQTCF]
set mqtcfAttrs [list $name $jndi]
```

Example output:

```
{name MQTCF} {jndiName jms/MQTCF}
```

- Using Jython:

```
name = ['name', 'MQTCF']
jndi = ['jndiName', 'jms/MQTCF']
mqtcfAttrs = [name, jndi]
print mqtcfAttrs
```

Example output:

```
[[name, MQTCF], [jndiName, jms/MQTCF]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQTopicConnectionFactory] 0]
```

- Using Jython:

```
import java
lineseparator = java.lang.System.getProperty('line.separator')
template = AdminConfig.listTemplates('MQTopicConnectionFactory').
split(lineseparator)[0]
print template
```

Example output:

```
Example non-XA WMQ TopicConnectionFactory(templates/
system: JMS-resource-provider-templates.xml
#MQTopicConnectionFactory_5)
```

5. Create a topic connection factory for the WebSphere MQ messaging provider:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQTopicConnectionFactory
$mjqmsp $mqtcfAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQTopicConnectionFactory',
mqjmsp, mqtcfAttrs, template)
```

Example output:

```
MQTCF(cells/mycell/nodes/mynode:resources.xml#MQTopicConnectionFactory_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Defining a topic connection factory for the WebSphere MQ messaging provider by supplying custom connection data

The following example creates a topic connection factory, specifying custom connection data.

Using Jython:

```
wsadmin>AdminTask.createWMQConnectionFactory('"WebSphere MQ JMS Provider
(cells/EXAMPLECell101|resources.xml#builtin_mqprovider)"', '
[-type TCF -name MQTopicConnectionFactory1 -jndiName
jms/MQTopicConnectionFactory1 -description -qmgrName
QueueManagerName -wmqTransportType BINDINGS_THEN_CLIENT
-qmgrHostname HostName -qmgrSvrconnChannel ServerConnectionChannel ]')
```

The following example creates a topic connection factory, specifying CCDT connection data.

Using Jython:

```
wsadmin>AdminTask.createWMQConnectionFactory('"WebSphere MQ JMS Provider
(cells/EXAMPLECell101|resources.xml#builtin_mqprovider)"', '
[-type TCF -name MQTopicConnectionFactory2 -jndiName
jms/MQTopicConnectionFactory2 -description -ccdtUrl
http://ClientChannelDefinitionTableURL -ccdtQmgrName QueueManager ]')
```

Configuring a new queue for the WebSphere MQ messaging provider using scripting

You can use scripting to configure a new queue for the WebSphere MQ messaging provider.

Before you begin

You can also use the “createWMQQueue command” on page 2103 to create a queue for the WebSphere MQ messaging provider.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new queue for the WebSphere MQ messaging provider:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1') print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSProvider_1)
```

2. Get the required attributes:

- Using Jacl:

```
AdminConfig required MQQueue
```

- Using Jython:

```
print AdminConfig.required('MQQueue')
```

Example output:

```
Attribute      Type name      String jndiName      String baseQueueName String
```

3. Set up the required attributes:

- Using Jacl:

```
set name [list name MQQ] set jndi [list jndiName jms/MQQ] set baseQN [list baseQueueName "Put the
base queue name here"] set mqAttrs [list $name $jndi $baseQN]
```

Example output:

```
{name MQQ} {jndiName jms/MQQ} {baseQueueName {Put the base queue name here}}
```

- Using Jython:

```
name = ['name', 'MQQ'] jndi = ['jndiName', 'jms/MQQ'] baseQN = ['baseQueueName', "Put the base
queue name here"] mqAttrs = [name, jndi, baseQN] print mqAttrs
```

Example output:

```
[[name, MQQ], [jndiName, jms/MQQ], [baseQueueName, "Put the base queue name here"]]
```

4. Set up a template:

- Using Jacl:

```
set template [lindex [$AdminConfig listTemplates MQQueue] 0]
```

- Using Jython:

```
import java lineseparator = java.lang.System.getProperty('line.separator') template =
AdminConfig.listTemplates('MQQueue').split(lineseparator)[0] print template
```

Example output:

```
Example.JMS.WMQ.Q1(templates/system:JMS-resource-provider- templates.xml#MQQueue_1)
```

5. Create a queue for the WebSphere MQ messaging provider:

- Using Jacl:

```
$AdminConfig createUsingTemplate MQQueue $newjmsp $mqAttrs $template
```

- Using Jython:

```
print AdminConfig.createUsingTemplate('MQQueue', newjmsp, mqAttrs, template)
```

Example output:

```
MQQ(cells/mycell/nodes/mynode|resources.xml#MQQueue_1)
```

6. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

7. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Defining a queue for the WebSphere MQ messaging provider

```
AdminTask.createMQQueue('EXAMPLECell101(cells/EXAMPLECell101|cell.xml)', ['-name MQQueue
-jndiName jms/MQQueue -queueName QueueName -qmgr QueueManager -description ]')
```

Configuring a new topic for the WebSphere MQ messaging provider using scripting

You can use scripting to configure a new topic for the WebSphere MQ messaging provider.

Before you begin

You can also use the “createWMQTopic command” on page 2092 to create a queue for the WebSphere MQ messaging provider.

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

About this task

Perform the following steps to configure a new topic for the WebSphere MQ messaging provider:

1. Identify the parent ID:

- Using Jacl:

```
set newjmsp [$AdminConfig getid /Cell:mycell/Node:mynode/JMSProvider:JMSP1/]
```

- Using Jython:

```
newjmsp = AdminConfig.getid('/Cell:mycell/Node:myNode/JMSProvider:JMSP1') print newjmsp
```

Example output:

```
JMSP1(cells/mycell/nodes/mynode|resources.xml#JMSPProvider_1)
```

2. Get the required attributes:

- Using Jacl:

```
$AdminConfig required MQTopic
```

- Using Jython:

```
print AdminConfig.required('MQTopic')
```

Example output:

Attribute	Type name	String jndiName	String baseTopicName
String			

3. Set up the required attributes:

- Using Jacl:

```
set name [list name MQT] set jndi [list jndiName jms/MQT] set baseTN [list baseTopicName "Put the base topic name here"] set mqtAttrs [list $name $jndi $baseTN]
```

Example output:

```
{name MQT} {jndiName jms/MQT} {baseTopicName {Put the base topic name here}}
```

- Using Jython:

```
name = ['name', 'MQT'] jndi = ['jndiName', 'jms/MQT'] baseTN = ['baseTopicName', "Put the base topic name here"] mqtAttrs = [name, jndi, baseTN] print mqtAttrs
```

Example output:

```
[[name, MQT], [jndiName, jms/MQT], [baseTopicName, "Put the base topic name here"]]
```

4. Create a topic for the WebSphere MQ messaging provider:

- Using Jacl:

```
$AdminConfig create MQTopic $newjmsp $mqtAttrs
```

- Using Jython:

```
print AdminConfig.create('MQTopic', newjmsp, mqtAttrs)
```

Example output:

```
MQT(cells/mycell/nodes/mynode|resources.xml#MQTopic_1)
```

5. Save the configuration changes. See the Saving configuration changes with the wsadmin tool article for more information.

6. In a network deployment environment only, synchronize the node. See the Synchronizing nodes with the wsadmin tool article for more information.

Defining a topic for the WebSphere MQ messaging provider

```
AdminTask.createWMQTopic('DRAPERDCe1101(cells/DRAPERDCe1101|cell.xml)', '[-name MQQueue -jndiName jms/MQQueue -topicName TopicName -qmgr QueueManager -description ]')
```

JCAManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages to configure messaging with scripting. The commands and parameters in the JCA management group can be used to create and manage resource adapters, Java EE Connector Architecture (J2C) activation specifications, administrative objects, connection factories, administrative object interfaces, and message listener types.

The JCAManagement command group for the AdminTask object includes the following commands:

- “copyResourceAdapter” on page 1959
- “createJ2CActivationSpec” on page 1959
- “createJ2CAdminObject” on page 1960
- “createJ2CConnectionFactory” on page 1961
- “listAdminObjectInterfaces” on page 1962
- “listConnectionFactoryInterfaces” on page 1962
- “listJ2CActivationSpecs” on page 1963

- “listJ2CAdminObjects” on page 1963
- “listJ2CConnectionFactories” on page 1964
- “listMessageListenerTypes” on page 1965

copyResourceAdapter

Use the `copyResourceAdapter` command to create a Java 2 Connector (J2C) resource adapter under the scope that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

-name

Indicates the name of the new J2C resource adapter. This parameter is required.

-scope

Indicates the scope object ID. This parameter is required.

-useDeepCopy

If you set this parameter to `true`, all of the J2C connection factory, J2C activation specification, and J2C administrative objects will be copied to the new J2C resource adapter (deep copy). If you set this parameter to `false`, the objects are not created (shallow copy). The default is `false`.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask copyResourceAdapter $ra [subst {-name newRA -scope $scope}]
```

- Using Jython string:

```
AdminTask.copyResourceAdapter(ra, ['-name newRA -scope scope'])
```

- Using Jython list:

```
AdminTask.copyResourceAdapter(ra, ['-name', 'newRA', '-scope', 'scope'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask copyResourceAdapter {-interactive}
```

- Using Jython:

```
AdminTask.copyResourceAdapter('-interactive')
```

createJ2CActivationSpec

Use the `createJ2CActivationSpec` command to create a Java 2 Connector (J2C) activation specification under a J2C resource adapter and the attributes that you specify. Use the `messageListenerType` parameter to indicate the activation specification that is defined for the J2C resource adapter.

Target object

J2C Resource Adapter object ID

Parameters and return values

- messageListenerType

Identifies the activation specification for the J2C activation specification to be created. Use this parameter to identify the activation specification template for the J2C resource adapter that you specify.

-name

Indicates the name of the J2C activation specification that you are creating.

-jndiName

Indicates the name of the Java Naming and Directory Interface (JNDI).

-destinationJndiName

Indicates the name of the Java Naming and Directory Interface (JNDI) of corresponding destination.

-authenticationAlias

Indicates the authentication alias of the J2C activation specification that you are creating.

-description

Description of the created J2C activation specification.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask createJ2CActivationSpec $ra {-name J2CAct Spec -jndiName eis/ActSpec1
-messageListenerType javax.jms.MessageListener }
```

- Using Jython string:

```
AdminTask.createJ2CActivationSpec(ra, ['-name J2CActSpec -jndiName eis/ActSpec1
-messageListenerType javax.jms.MessageListener'])
```

- Using Jython list:

```
AdminTask.createJ2CActivationSpec(ra, ['-name', 'J2CActSpec', '-jndiName', 'eis/ActSpec1',
'-messageListenerType', 'javax.jms.MessageListener'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask createJ2CActivationSpec {-interactive}
```

- Using Jython:

```
AdminTask.createJ2CActivationSpec('-interactive')
```

createJ2CAdminObject

Use the createJ2CAdminObject command to create an administrative object under a resource adapter with attributes that you specify. Use the administrative object interface to indicate the administrative object that is defined in the resource adapter.

Target object

J2C Resource Adapter object ID

Parameters and return values

-adminObjectInterface

Specifies the administrative object interface to identify the administrative object for the resource adapter that you specify. This parameter is required.

-name

Indicates the name of the administrative object.

-jndiName

Specifies the name of the Java Naming and Directory Interface (JNDI).

-description

Description of the created J2C admin object.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask createJ2CAdminObject $ra {-adminObjectInterface fvt.adapter.message.FVTMessageProvider
-name J2CA01 -jndiName eis/J2CA01}
```

- Using Jython string:

```
AdminTask.createJ2CAdminObject(ra, ['-adminObjectInterface fvt.adapter.message.FVTMessageProvider
-name J2CA01 -jndiName eis/J2CA01'])
```

- Using Jython list:

```
AdminTask.createJ2CAdminObject(ra, ['-adminObjectInterface',
'fvt.adapter.message.FVTMessageProvider', '-name', 'J2CA01', '-jndiName', 'eis/J2CA01'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask createJ2CAdminObject {-interactive}
```

- Using Jython:

```
AdminTask.createJ2CAdminObject('-interactive')
```

createJ2CConnectionFactory

Use the createJ2CConnectionFactory command to create a Java 2 connection factory under a Java 2 resource adapter and the attributes that you specify. Use the connection factory interfaces to indicate the connection definitions that are defined for the Java 2 resource adapter.

Target object

J2C Resource Adapter object ID

Parameters and return values

-connectionFactoryInterface

Identifies the connection definition for the Java 2 resource adapter that you specify. This parameter is required.

-name

Indicates the name of the connection factory.

-jndiName

Indicates the name of the Java Naming and Directory Interface (JNDI).

-description

Description of the created J2C connection factory.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask createJ2CConnectionFactory $ra {-connectionFactoryInterfaces javax.sql.DataSource
-name J2CCF1 -jndiName eis/J2CCF1}
```

- Using Jython string:

```
AdminTask.createJ2CConnectionFactory(ra, ['-connectionFactoryInterfaces javax.sql.DataSource
-name J2CCF1 -jndi Name eis/J2CCF1'])
```

- Using Jython list:

```
AdminTask.createJ2CConnectionFactory(ra, ['-connectionFactoryInterfaces',
'javax.sql.DataSource', '-name', 'J2CCF1', '-jndiName', 'eis/J2CCF1'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask createJ2CConnectionFactory {-interactive}
```

- Using Jython:

```
AdminTask.createJ2CConnectionFactory('-interactive')
```

listAdminObjectInterfaces

Use the listAdminObjectInterfaces command to list the administrative object interfaces that are defined under the resource adapter that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

- Parameters: None
- Returns: A list of administrative object interfaces.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listAdminObjectInterfaces $ra
```

- Using Jython string:

```
AdminTask.listAdminObjectInterfaces(ra)
```

- Using Jython list:

```
AdminTask.listAdminObjectInterfaces(ra)
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listAdminObjectInterfaces {-interactive}
```

- Using Jython:

```
AdminTask.listAdminObjectInterfaces('-interactive')
```

listConnectionFactoryInterfaces

Use the listConnectionFactoryInterfaces command to list all of the connection factory interfaces that are defined under the Java 2 connector resource adapter that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

- Parameters: None
- Returns: A list of connection factory interfaces.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listConnectionFactoryInterfaces $ra
```

- Using Jython string:

```
AdminTask.listConnectionFactoryInterfaces(ra)
```

- Using Jython list:

```
AdminTask.listConnectionFactoryInterfaces(ra)
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listConnectionFactoryInterfaces {-interactive}
```

- Using Jython:

```
AdminTask.listConnectionFactoryInterfaces('-interactive')
```

listJ2CActivationSpecs

Use the listJ2CActivationSpecs command to list the activation specifications that are contained under the resource adapter and message listener type that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

-messageListenerType

Specifies the message listener type for the resource adapter for which you are making a list. This parameter is required.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listJ2CActivationSpecs $ra {-messageListener Type javax.jms.MessageListener}
```

- Using Jython string:

```
AdminTask.listJ2CActivationSpecs(ra, ['-messageListener Type javax.jms.MessageListener'])
```

- Using Jython list:

```
AdminTask.listJ2CActivationSpecs(ra, ['-messageListener Type', 'javax.jms.MessageListener'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listJ2CActivationSpecs {-interactive}
```

- Using Jython:

```
AdminTask.listJ2CActivationSpecs('-interactive')
```

listJ2CAdminObjects

Use the listJ2CAdminObjects command to list administrative objects that contain the administrative object interface that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

-adminObjectInterface

Specifies the administrative object interface for which you want to list. This parameter is required.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listJ2CAdminObjects $ra {-adminObjectInterface  
  fvt.adaptor.message.FVTMessageProvider}
```

- Using Jython string:

```
AdminTask.listJ2CAdminObjects(ra, '[-adminObjectInterface  
  fvt.adaptor.message.FVTMessageProvider]')
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listJ2CAdminObjects {-interactive}
```

- Using Jython:

```
AdminTask.listJ2CAdminObjects('-interactive')
```

listJ2CConnectionFactories

Use the listJ2CConnectionFactories command to list the Java 2 connector connection factories under the resource adapter and connection factory interface that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

-connectionFactoryInterface

Indicates the name of the connection factory that you want to list. This parameter is required.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listJ2CConnectionFactories $ra {-connectionFactoryInterface javax.sql.DataSource}
```

- Using Jython string:

```
AdminTask.listJ2CConnectionFactories(ra, '[-connectionFactoryInterface javax.sql.DataSource]')
```

- Using Jython list:

```
AdminTask.listJ2CConnectionFactories(ra, ['-connectionFactoryInterface',  
  'javax.sql.DataSource'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listJ2CConnectionFactories {-interactive}
```

- Using Jython:

```
AdminTask.listJ2CConnectionFactories('-interactive')
```

listMessageListenerTypes

Use the `listMessageListenerTypes` command to list the message listener types that are defined under the resource adapter that you specify.

Target object

J2C Resource Adapter object ID

Parameters and return values

- Parameters: None
- Returns: A list of message listener types.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask listMessageListenerTypes $ra
```

- Using Jython string:

```
AdminTask.listMessageListenerTypes(ra)
```

- Using Jython list:

```
AdminTask.listMessageListenerTypes(ra)
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listMessageListenerTypes {-interactive}
```

- Using Jython:

```
AdminTask.listMessageListenerTypes('-interactive')
```

Managing messaging with the WebSphere MQ messaging provider

Through this messaging provider, Java Message Service (JMS) messaging applications can use your WebSphere MQ system as an external provider of JMS messaging resources.

Before you begin

If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see “Choosing messaging providers for a mixed environment” on page 1779.

About this task

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces). This enables applications to use the same interfaces for both point-to-point and publish/subscribe messaging, and also enables both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, this approach is recommended for new applications. The domain-specific interfaces are supported for backwards compatibility for applications developed to use domain-specific queue interfaces, as described in section 1.5 of the JMS 1.1 specification.

The WebSphere MQ messaging provider also supports the J2EE Connector Architecture (JCA) 1.5 activation specification mechanism for message-driven beans (MDBs) across all platforms supported by WebSphere Application Server.

You can use WebSphere Application Server to configure WebSphere MQ resources for applications (for example queue connection factories) and to manage messages and subscriptions associated with JMS destinations. You administer security through WebSphere MQ.

In a mixed-version WebSphere Application Server cell, you can administer WebSphere MQ resources on nodes of all versions. However, some properties are not available on all versions. In this situation, the administrative console displays only the properties of that particular node.

The preferred solution for publish and subscribe messaging with WebSphere MQ as an external JMS messaging provider is to use a message broker such as WebSphere MQ Event Broker.

To use WebSphere MQ as a messaging provider for WebSphere Application Server, complete one or more of the following steps.

- Learn about interoperating with a WebSphere MQ network.
- Configure JMS resources for the WebSphere MQ messaging provider.

You can do this through the WebSphere Application Server administrative console, or through the WebSphere Application Server set of WebSphere MQ administrative commands.

- List JMS resources for the WebSphere MQ messaging provider..

Related tasks

Learning about interoperating with a WebSphere MQ network

Configuring JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to configure activation specifications, connection factories and destinations for the WebSphere MQ JMS provider.

Before you begin

This task assumes that you are working in a mixed WebSphere Application Server and WebSphere MQ environment, and that you have decided to use the WebSphere MQ messaging provider to handle JMS messaging between the two systems. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, the

WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see “Choosing messaging providers for a mixed environment” on page 1779.

You can configure JMS resources for the WebSphere MQ messaging provider through the administrative console as described in this task, or you can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands.

About this task

Note: The set of WebSphere Application Server administrative console panels used to configure JMS resources for the WebSphere MQ messaging provider has been redesigned to simplify the configuration process, and new panels have been introduced. A corresponding set of WebSphere MQ administrative commands has been introduced. There are new wizards for creating activation specifications and connection factories for the WebSphere MQ messaging provider and for converting listeners ports to activation specifications.

Using the administrative console, if you set the scope of the WebSphere MQ messaging provider to a scope which contains only WebSphere Application Server Version 6 or 7 nodes, you can configure JMS 1.1 resources and properties. This includes unified JMS connection factories for use by both point-to-point and publish/subscribe JMS 1.1 applications. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.

If you set the scope of the WebSphere MQ messaging provider to a scope which contains only WebSphere Application Server Version 7 nodes, you can also configure JMS activations specifications.

If you set the scope to a WebSphere Application Server Version 5 node, you can only configure domain-specific JMS resources, and the subset of properties that apply to WebSphere Application Server Version 5.

For more information about configuring JMS resources for the WebSphere MQ messaging provider, see the following topics. These topics include optional steps for you to create a new JMS resource.

Creating an activation specification for the WebSphere MQ messaging provider using the Create Activation Specification wizard

Use this task create an activation specification for use with the WebSphere MQ messaging provider.

About this task

To modify an existing activation specification, see the related tasks.

To create an activation specification for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to create an activation specification.
2. Change the **Scope** setting to the level at which you want to create the activation specification.
3. Click **New** in the content pane to start the **Create WebSphere MQ activation specification** wizard.
 - a. Select the WebSphere MQ messaging provider and click **OK**.
 - b. In the **Configure basic attributes** panel, specify the following properties:

Name The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

JNDI name

The name that is used to bind this activation specification into the JNDI name space.

Description

Optional. A description of this activation specification for administrative purposes within WebSphere Application Server.

Click **Cancel** to cancel all actions and leave the wizard or click **Next** to continue.

4. In the **Select connection method** panel, specify how to connect to the WebSphere MQ messaging provider by selecting one of the following radio buttons:

Enter all the required information into this wizard

Click **Next** to proceed to the **Supply queue connection details** panel.

Use a client channel definition table

Click **Next** to proceed to the **Specify client channel definition table** panel.

5. In the **Specify client channel definition table** panel, enter information about the client channel definition table (CCDT) that is used to establish a connection to the WebSphere MQ messaging provider. Optionally, in the **Queue manager** field, enter the name of the queue manager to identify one or more entries to use from the CCDT. Click **Next** to continue to the **Test connection** panel.
6. In the **Supply queue connection details** panel, enter the name of the queue manager or queue sharing group that you want to connect to. Click **Next** to continue to the **Enter connection details** panel.
7. In the **Enter connection details** panel, specify the following properties:

Transport

Optional. The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ. For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971 and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Port Optional. The port number on which WebSphere MQ is listening.

Server connection channel

Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue sharing group.

Click **Cancel** to cancel all actions and leave the wizard or click **Next** to continue.

- Optional: In the **Test connection** panel, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
- In the **Summary** panel, click **Cancel** to cancel all actions and leave the wizard, or **Previous** to return to the previous panel, or **Finish** to complete the creation of the new activation specification.
- Stop then restart the application server.

Configuring an existing activation specification for the WebSphere MQ messaging provider

Use this task to browse or change an activation specification for use with the WebSphere MQ messaging provider.

About this task

To browse or change an activation specification for use with WebSphere MQ, use the administrative console to complete the following steps:

- In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to view existing activation specifications, with a summary of their properties.
- Change the **Scope** setting to the level at which the activation specification is visible to applications.
- Click the name of the activation specification that you want to work with.
- Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
- Click **Apply** to save the configuration.
- Optional: Click **Advanced properties** to display or change the list of advanced properties of your activation specification.
- Optional: Click **Broker properties** to display or change the list of broker properties of your activation specification.
- Optional: Click **Custom properties** to display or change the list of custom properties of your activation specification.
- Optional: Click **Client transport properties** to display or change the list of client transport properties of your activation specification. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
- Click **OK**.
- Save any changes to the master configuration.
- On the z/OS platform WebSphere MQ activation specifications run partly in the control region adjunct (CRA) process and partly in the servant region (SR) process. You must enable the CRA process if using WebSphere MQ activation specifications on the z/OS platform. Use either the WebSphere MQ CRA settings panel or the manageWMQ command to enable the CRA process to start up when starting an application server.
- To have the changed configuration take effect, stop then restart the application server.

Configuring a listener port to an activation specification for use with the WebSphere MQ messaging provider

Use this task to configure a listener port to an activation specification for use with the WebSphere MQ messaging provider.

About this task

Note: From WebSphere Application Server Version 7 listener ports are deprecated.

To migrate information from an deprecated listener port to an activation specification for use the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Servers** → **Application Servers** → *application_server*.
2. Under Communications, expand **Messaging** → **Message listener service** and click **Listener Ports** to view existing listener ports, with a summary of their properties.
3. Select the listener port that you want to work with by selecting the check box to its left.
4. Click **Convert to activation specification** to start the **Convert listener port to activation specification** wizard.
5. In the **Step1: Supply activation specification name** panel, enter the name of the new activation specification to be created, the JNDI name of the new activation specification, and the scope of the new activation specification (Server, Node, Cluster, Cell). Note that Cluster only appears when the server is in a cluster. Click **Next** to continue.
6. In the **Step2: Summary** panel, click **Finish** to complete the creation of the new activation specification.
7. Stop then restart the application server.
8. To complete the configuration of the activation specification, refer to Related tasks.

Creating a connection factory for the WebSphere MQ messaging provider using the Create JMS Resource wizard

Use this task create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories.

To modify an existing connection factory, see the related tasks.

To create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories**, → **Queue connection factories or** → **Topic connection factories**. to create a connection factory, a queue connection factory or a topic connection factory.
2. Change the **Scope** setting to the level at which you want to create the connection factory.
3. Click **New** in the content pane to start the **Create JMS resource** wizard.
 - a. Select the WebSphere MQ messaging provider and click **OK**.
 - b. In the **Configure basic attributes** panel, specify the following properties:

Name The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

JNDI name

The name that is used to bind this connection factory into the JNDI name space.

Description

Optional. A description of this connection factory for administrative purposes within WebSphere Application Server.

Click **Cancel** to cancel all actions and leave the wizard or click **Next** to continue.

4. In the **Select connection method** panel, specify how to connect to the WebSphere MQ messaging provider by selecting one of the following radio buttons:

Enter all the required information into this wizard

Click **Next** to proceed to the **Supply queue connection details** panel.

Use a client channel definition table

Click **Next** to proceed to the **Specify client channel definition table** panel.

5. In the **Specify client channel definition table** panel, enter information about the client channel definition table (CCDT) that is used to establish a connection to the WebSphere MQ messaging provider. Optionally, in the **Queue manager** field, enter the name of the queue manager to identify one or more entries to use from the CCDT. Click **Next** to continue to the **Test connection** panel.
6. In the **Supply queue connection details** panel, enter the name of the queue manager or queue sharing group that you want to connect to. Click **Next** to continue to the **Enter connection details** panel.
7. In the **Enter connection details** panel, specify the following properties:

Transport

Optional. The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ. For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Port Optional. The port number on which WebSphere MQ is listening.

Server connection channel

Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue sharing group.

Click **Cancel** to cancel all actions and leave the wizard or click **Next** to continue.

8. Optional: In the **Test connection** panel, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
9. In the **Summary** panel, click **Cancel** to cancel all actions and leave the wizard, or **Previous** to return to the previous panel, or **Finish** to complete the creation of the new connection factory.
10. Stop then restart the application server.

Configuring the WebSphere MQ messaging provider with native libraries information:

To connect to a WebSphere MQ queue manager or queue sharing group in bindings mode, the WebSphere MQ messaging provider needs to know where to load native libraries from. This information is known as native path information. The way native path information is set depends on whether the connection is established in an application client or in an application server environment. Use this task to configure the WebSphere MQ messaging provider with native path information.

About this task

If you are running in a client environment, use `launchClient` to start a client application. In the system property `MQ_INSTALL_ROOT` enter the name of a directory which contains the WebSphere MQ native libraries, in a subdirectory of `java/lib` or `java/lib64` depending on whether you are using 32 bit or 64 bit native libraries. For example, on Linux specify `./launchClient.sh myappclient.ear -CCDMQ_INSTALL_ROOT=/opt/mqm/`.

If you are running in an application server environment, you can configure the WebSphere MQ messaging provider with native path information using the command line, as described in “WMQAdminCommands command group for the AdminTask object” on page 2063, or you can use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. Select the WebSphere MQ messaging provider that is at the correct **Scope** for the connection factory or activation specification that will create the bindings mode connection. Note that native path

- information at Server scope is used in preference to native path information at higher scopes, and native path information at Node scope is used in preference to native path information at Cell scope
3. Under General Properties, in the **Native library path** property, enter the full name of the directory that contains the WebSphere MQ native libraries. For example, on Linux enter `/opt/mqm/java/lib`. Enter only one directory name.
 4. Click **OK**.
 5. Save any changes to the master configuration.
 6. To have the changed configuration take effect, stop then restart the application server.

Sizing the thread pools used by the WebSphere MQ messaging provider:

Use this task to calculate the number of thread pools required by the WebSphere MQ messaging provider.

Before you begin

In IBM® WebSphere® Application Server, almost all of the work that is done by the WebSphere MQ messaging provider uses threads from the WMQCommonServices thread pool. By default, this thread pool has a maximum size of 40 threads in an application server environment and 10 threads in a client environment. If the number of threads is exceeded, work that is submitted by the WebSphere MQ messaging provider might not complete and errors might be output to the log files.

About this task

To prevent the thread pool from becoming exhausted, use the following guidelines to size the thread pool correctly for the application environment.

1. Application server environment If you are using a WebSphere MQ messaging provider connection factory, topic connection factory or queue connection factory, and all the following conditions apply:
 - The connection factory is enabled for two-phase commit
 - The transport mode is *bindings* or *bindings, then client*
 - The bindings leg is used

then:

- You require one thread for each connection. Allow enough threads to fill up the connection pool, which has a default maximum size of 10.
- You require one thread for each session. Allow enough threads to fill up the session pool, which has a default maximum size of 10. There is one session pool for every connection in the connection pool.

For example, each WebSphere MQ messaging provider connection factory with a *bindings* transport mode, and that is enabled for two-phase commit, requires 110 threads.

Note: The previous information does not apply with WebSphere Application Server for z/OS®, even when you use a connection factory that is enabled for two-phase commit.

If you use a WebSphere MQ messaging provider connection factory, topic connection factory or queue connection factory and both the following conditions apply:

- The transport mode is *client* or *bindings, then client*
- The client leg is used

then:

- You require one thread for each connection. Allow enough threads to fill up the connection pool, which has a default maximum size of 10.
- You require one thread for each session. Allow enough threads to fill up the session pool, which has a default maximum size of 10. There is one session pool for every connection in the connection pool.

For example, each WebSphere MQ messaging provider connection factory with a transport mode of *bindings, then client*, and that uses the client leg, requires 110 threads.

If you use WebSphere MQ messaging provider activation specifications in either of the following circumstances:

- To deliver messages to message-driven beans inside a transaction with any transport type
- You are using a transport mode of *client* or *bindings, then client*, the client leg is used, and a transaction does not exist

then:

- You require one thread for each running message-driven bean (MDB) instance. The number of instances is determined by the maximum server sessions setting on a WebSphere MQ messaging provider activation specification. By default this value is 10.
- You require one thread for each five MDB installations, if they all connect to the same queue manager. The default value for the WebSphere MQ messaging provider connectionConcurrency setting is 5. For more information on how to set the connectionConcurrency setting, refer to the Information Center for WebSphere MQ.
- You require one extra thread to perform the dispatching of messages if the transport mode is *client* or *bindings, then client* and the client leg is used.

For example, each WebSphere MQ messaging provider activation specification with a *client* transport mode, and that is enabled for two-phase commit, requires 12 threads.

If you use message listener ports that use WebSphere MQ messaging provider resources to deliver messages to MDBs, you need to take account of the thread pool considerations for the connections and sessions that are used by the message listener port instances.

The message listener port uses one session for each server session. By default, there is one server session for each message listener port instance.

Then:

- You require one thread for each connection that is used by a message listener port instance. This thread is for the exception listener with which it is registered.
- You require one thread for each connection that is used by a message listener port instance. This thread is for the exception listener with which it is registered.
 - The message listener port is using a WebSphere MQ messaging provider connection factory that is enabled for two-phase commit
 - The transport mode is *bindings*, or *bindings, then client*
 - Uses the bindings leg

If the WebSphere MQ messaging provider connection factory has a transport mode of *client* or *bindings, then client*, and uses the client leg, one thread is required regardless of whether the connection factory is enabled for two-phase commit.

You require one thread for each message listener port instance for the dispatch thread that is used by the connection consumer object, if the message listener port conditions are true:

- Uses a WebSphere MQ messaging provider connection factory
- Has a transport mode of *client* or *bindings, then client*
- Uses the client leg

Note: For each installed MDB that is configured to use a particular message listener port, there is a single message listener port instance. For example, if three MDBs are configured to use the same message listener port, there are three message listener port instances.

If you install a single MDB using a message listener port which uses a WebSphere MQ messaging provider connection factory in *bindings* mode, and that is enabled for two-phase commit, you require at least four threads:

- One thread for the connection

- One thread for the session that is used inside the server session, which is used by the message listener port
- One thread for the exception listener
- One thread for the connection consumer

However, if the MDB is stopped and started, a different connection and therefore a different set of sessions might be retrieved from the pool. You need to allow 112 threads: 10 for the connection pool, 100 for the session pools, one for the exception listener, and one for the connection consumer.

2. Application server environment In the application client environment, the rules for thread requirements are similar to those rules in the application server environment. However, the rules are simplified because connection and session pooling is not used, and connection factories cannot take part inside a transaction. For most application clients, the default maximum thread pool size of 10 should be sufficient.

If you use a WebSphere MQ messaging provider connection factory, topic connection factory or queue connection factory and both the following conditions apply:

- The transport mode is *client* or *bindings, then client*
- The client leg is used

then:

- You require one thread for each connection
- You require one thread for each session

If you are registering a message listener implementation with a session for asynchronous delivery of messages, you require an extra thread if the WebSphere MQ messaging provider connection factory that created the session has a transport mode of *client*, or *bindings, then client*, and the client leg is used.

If you register an exception listener implementation with a connection, you need an extra thread.

Consider the following scenario:

An IBM AIX[®] application server installation has a single MDB installed. The MDB has transactions managed by the Enterprise JavaBeans (EJB) container and has a transaction attribute of *required*, so messages are delivered to the MDB under an XA transaction. The MDB is configured to use a WebSphere MQ messaging provider activation specification with transport mode of *bindings*. When a message is received, the MDB performs some processing and then sends a reply message using WebSphere MQ messaging provider connection factory with a transport mode of *bindings*. The connection factory has the default connection and session pool settings.

The number of threads that are used by this scenario is 121 and consists of the following threads:

- 10 (one thread * default maximum number of MDB instances)
- 1 (the thread that is shared across deployments)
- 10 (the thread used by pooled connection * default pool size of 10)
- 100 (the thread used by pooled session * default connection pool size(10) * default session pool size (10))

3. Configuring WMQCommonServices thread pool size in an application server You need to configure every application server that uses WebSphere MQ messaging provider resources and the default WMQCommonServices thread pool size is not enough. For example, if the MDB that is used in the previous example is deployed in a clustered environment with two servers, perform the following procedure on both application servers to set the size of the WMQCommonServices thread pool to at least 121.

To configure the maximum size of the WMQCommonServices thread pool in the application server, perform the following steps using the administrative console:

- a. Click **Servers** → **Server Types** → **WebSphere application servers** *server name*.
- b. Under Additional Properties, click **Thread pools** → **WMQCommonServices** .
- c. Update the value of the **Maximum size** field to the relevant value and click **OK**.
- d. Click **Save** and restart the application server.

4. Configuring WMQCommonServices thread pool size in an application client To configure the maximum size of the WMQCommonServices thread pool in the application client container, complete the following steps:
 - a. Create a file called *wmq.client.props*, and put it in the application client class path.
 - b. Edit the *wmq.client.props* file and add the following text to the file:

```
com.ibm.ws.wmqcsi.threadPoolMaximumSize=<desired size of thread pool>
```

For example: `com.ibm.ws.wmqcsi.threadPoolMaximumSize=15`
 - c. Save the changes.

Configuring a JMS connection factory for the WebSphere MQ messaging provider

Use this task to browse or configure an existing domain-independent connection factory for the WebSphere MQ messaging provider on an Application Server Version 7 node.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories. If you want to browse or configure a queue connection factory or topic connection factory, see the related tasks.

To create a connection factory, see the related tasks.

To browse or configure an existing connection factory for use with WebSphere MQ, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories** to view existing connection factories, with a summary of their properties.
2. Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. Click the name of the connection factory that you want to work with.
4. Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Optional: Click **Connection pools** to display or change the connection pools detail of your connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your connection factory.
12. Click **OK**.
13. Save any changes to the master configuration.
14. To have the changed configuration take effect, stop then restart the application server.

Configuring an existing JMS queue connection factory for the WebSphere MQ messaging provider

Use this task to browse or change an existing JMS queue connection factory for point-to-point messaging with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories.

If you want to browse or change a connection factory, see the related tasks.

To browse or change a queue connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queue connection factories** to view existing queue connection factories, with a summary of their properties.
2. Change the **Scope** setting to the level at which the queue connection factory is visible to applications.
3. Click the name of the queue connection factory that you want to work with.
4. Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your queue connection factory.
7. Optional: Click **Custom properties** to display or change the list of custom properties of your queue connection factory.
8. Optional: Click **Client transport properties** to display or change the list of client transport properties of your queue connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
9. Optional: Click **Connection pools** to display or change the connection pools detail of your queue connection factory.
10. Optional: Click **Session pools** to display or change the session pools detail of your queue connection factory.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

Configuring an existing JMS topic connection factory for the WebSphere MQ messaging provider

Use this task to browse or change an existing JMS topic connection factory for publish/subscribe messaging with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories. If you want to browse or configure a connection factory, see the related tasks.

To browse or configure a topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topic connection factories** to view existing topic connection factories, with a summary of their properties.

2. Change the **Scope** setting to the level at which the topic connection factory is visible to applications.
3. Click the name of the topic connection factory that you want to work with.
4. Under **General properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your topic connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your topic connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your topic connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your topic connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Optional: Click **Connection pools** to display or change the connection pools detail of your topic connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your topic connection factory.
12. Click **OK**.
13. Save any changes to the master configuration.
14. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS queue destination for the WebSphere MQ messaging provider

Use this task to browse or change a JMS queue destination for point-to-point messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS queue destination.

About this task

To optimize performance, configure the queue destination properties to best fit your message-driven beans or other applications that use the queue destinations. For more information about performance considerations, see the related tasks.

To browse or change a queue destination for use with WebSphere MQ, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queues** to view existing queue destinations, with a summary of their properties.
2. Change the **Scope** setting to the level at which the queue destination is visible to applications.
3. To browse or change the properties of an existing queue destination, click its name in the list. Otherwise, to create a new queue, complete the following steps:
 - a. Click **New** in the content pane. Select the **WebSphere MQ messaging provider** radio button and click **OK**.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this queue destination is known for administrative purposes within WebSphere Application Server.

JNDI name

The JNDI name that is used to bind the queue destination into the name space.

Queue name

The name of the WebSphere MQ queue to which messages are sent.

- c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
4. Optional: Change WebSphere MQ queue settings, according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring a JMS topic destination for the WebSphere MQ messaging provider

Use this task to browse or change a JMS topic destination for publish/subscribe messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see the related task.

To browse or change a topic destination for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topics** to view existing topic destinations, with a summary of their properties.
2. Change the **Scope** setting to the level at which the topic destination is visible to applications.
3. To browse or change the properties of an existing topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
 - a. Click **New** in the content pane. Select the **WebSphere MQ messaging provider** radio button and click **OK**.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this topic destination is known for administrative purposes within WebSphere Application Server.

JNDI name

The JNDI name that is used to bind the topic destination into the name space.

Topic name

The name of the WebSphere MQ topic to which messages are sent.

- c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
4. Optional: Change WebSphere MQ topics settings according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring WebSphere MQ connection pooling

Browse or change properties of WebSphere MQ connection pooling for JMS connections from an application server to WebSphere MQ as a JMS provider.

About this task

Support for connection pooling does not affect the performance of a message listener, because it retains its connections while listening on a destination, but does affect the overall JMS system performance. When a connection is no longer required, WebSphere MQ can pool the connection then reuse it later instead of destroying it.

Note: This support is only available for use with WebSphere MQ as a JMS provider.

To enable WebSphere MQ connection pooling for an application server, use the administrative console to complete the following steps:

1. Display the Message Listener Service properties for the application server
 - a. In the navigation pane, click **Servers** → **Application Servers**
 - b. In the content pane, click the name of the application server.
 - c. Under Additional Properties, click **Message Listener Service properties**.
2. Select Custom Properties, to enable WebSphere MQ connection pooling, add the following custom properties:
 - mjms.pooling.threshold**
The maximum number of unused connections in the pool.
 - mjms.pooling.timeout**
The timeout in milliseconds for unused connections in the pool.
3. Click **OK**.
4. Save any changes to the master configuration.
5. To have the changed configuration take effect, stop then restart the application server.

What to do next

For additional information, see the books in the WebSphere MQ library.

Listing JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for the WebSphere MQ provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Connection factory (unified)
- Queue connection factory
- Topic connection factory
- Queue
- Topic
- Activation specification

When you use the Administrative Console to locate these resources, two different navigation pathways are available:

- Provider-centric navigation. This lets you view all providers (or just those for a specified scope if required), then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider owns it. Any navigation that starts with **Resources** → **JMS** → **JMS providers** is provider-centric.
- Resource-centric navigation lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider owns it (you can list all

resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** → **JMS** → **[resource]**, where [resource] is one of the resource types listed above is resource-centric.

You can use either of these navigation pathways to locate resources of any type.

- Use provider-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.
 2. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**. This opens the providers collection which lists all currently configured providers across all scopes (you can modify the scope if required).
 3. From the providers collection, select the required provider. This opens the configuration tab for that provider. The configuration tab contains a set of links to all the resources owned by that provider.
 4. From the configuration tab, click the link for a resource type, for example the connection factories link. This opens the connection factories collection which lists all the connection factories for that provider.
 5. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties
- Use resource-centric navigation, for example to navigate to a specified connection factory
 1. Start the WebSphere Application Server administrative console.
 2. In the navigation pane, expand **Resources** → **JMS** → **Connection factories**. This opens the connection factories collection which lists all the connection factories across all providers.
 3. From the connection factories collection, select the required connection factory. You can now view and work with the connection factory's properties.

WebSphere MQ messaging provider activation specification collection

Use this panel to select an activation specification to view or change its configuration properties. The activation specification is configured for the WebSphere MQ messaging provider for both point-to-point and publish/subscribe messaging.

This panel shows a list of the WebSphere MQ activation specifications with a summary of their configuration properties. In a mixed release cell, these activation specifications are not available for Version 5, 6.0 or 6.1 nodes.

To view a list of WebSphere MQ activation specifications, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Optional: To define a new activation specification, click **New** to start the Create Activation Specification wizard.
4. Optional: To view or change the properties of an activation specification, click its name in the list displayed.

Configuring an existing activation specification for the WebSphere MQ messaging provider:

Use this task to browse or change an activation specification for use with the WebSphere MQ messaging provider.

About this task

To browse or change an activation specification for use with WebSphere MQ, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to view existing activation specifications, with a summary of their properties.
2. Change the **Scope** setting to the level at which the activation specification is visible to applications.
3. Click the name of the activation specification that you want to work with.
4. Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your activation specification.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your activation specification.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your activation specification.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your activation specification. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Click **OK**.
11. Save any changes to the master configuration.
12. On the z/OS platform WebSphere MQ activation specifications run partly in the control region adjunct (CRA) process and partly in the servant region (SR) process. You must enable the CRA process if using WebSphere MQ activation specifications on the z/OS platform. Use either the WebSphere MQ CRA settings panel or the manageWMQ command to enable the CRA process to start up when starting an application server.
13. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider activation specification settings:

Use this panel to view or change the configuration properties of the selected activation specification for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated queues and topics.

To view WebSphere MQ activation specification settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Click the name of the activation specification that you want to work with.

Under General Properties there are four groups of properties:

- Administration
- Connection
- Destination
- Advanced

There are two variations of the **Connection** group:

- CCDT Connection settings group: A WebSphere MQ administrator can create a single Client Channel Definition Table (CCDT) of all the WebSphere MQ channels supported by queue managers in their enterprise. Additional WebSphere MQ configuration information can be associated with the entries in a CCDT. If the selected activation specification was created using a CCDT, only the following information is required to configure a connection:

- Client channel definition table URL: The URL that specifies the location of the CCDT.
- Queue manager: The queue manager name that specifies the CCDT entry, or entries, to use.
- SSL configuration
- Explicitly-defined Connection settings group: If the selected activation specification was not created using a CCDT, the following information must be entered explicitly to configure a connection:
 - Queue manager
 - Transport
 - Hostname
 - Port
 - Server connection channel
 - Use SSL to secure communication with Websphere MQ: If you clear this property, the following properties cannot be used.
 - Centrally managed
 - Specific configuration
 - SSL configuration

Make any required changes to the Administration, Connection, Destination and Advanced groups of properties and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ activation specification
- **Broker properties** to display or change the broker properties of your WebSphere MQ activation specification
- **Custom properties** to display or change the custom properties of your WebSphere MQ activation specification
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ activation specification. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the activation specification.

You can also specify the **localAddress** property using WebSphere MQ administrative commands. For more information about this property, refer to the “createWMQActivationSpec command” on page 2064.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

A WebSphere MQ activation specification has the following properties.

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Scope:

The scope specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ activation specification collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the activation specification is created.

For all activation specifications created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of activation specifications defined to the cell.

JNDI name:

The JNDI name that is used to bind the activation specification into the JNDI name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this activation specification for administrative purposes within WebSphere Application Server.

Data type String

Client channel definition table URL:

A URL that points to a WebSphere MQ CCDT.

Data type String

Queue manager:

If this activation specification is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue sharing group to connect to. A connection is established to this WebSphere MQ resource to receive messages.

Data type String
Range If this activation specification is based on a CCDT, the value must be one of the following:

- a valid queue manager name
- a valid queue manager name with the last character an asterisk
- an asterisk
- blank

If this connection factory is based on a CCDT, the value must be a valid queue manager name.

Transport:

The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list
Default **bindings then client**
Range **client** Use a TCP/IP based network connection to communicate with the WebSphere MQ queue manager.
bindings then client Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.
bindings Establish a cross memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Hostname
- Port
- Server connection channel

For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971 and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname:

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type	Integer
Default	1414
Range	The value must be in the range 1 to 65536 (inclusive).

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN
Range	The value must be a server connection channel defined to the WebSphere MQ queue manager being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

When using a WebSphere MQ messaging provider activation specification in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** → **SSL certificate and key management** panel.

WebSphere MQ messaging provider activation specifications can only be configured with a single SSL cipher suite. If you specify more than one cipher suite in the SSL configuration for a WebSphere MQ messaging provider activation specification, only the first one is used.

Data type	Checkbox. If this checkbox is cleared, the following SSL properties are disabled: <ul style="list-style-type: none">• Centrally managed• Specific configuration• SSL configuration
------------------	--

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the hostname and port attributes from the WebSphere MQ messaging provider activation specification are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the activation specification, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type	Radio button
------------------	--------------

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

Data type Radio button

SSL configuration:

The specific SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if a SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Destination JNDI name:

The JNDI name for the JMS destination from which messages are consumed for delivery to an MDB that is configured to use this activation specification.

Data type String

Message selector:

A message selector expression specifying which messages are to be delivered.

Data type String

Destination type:

The type of destination (queue or topic) from which to consume messages.

Data type Drop-down list

Range **Queue** The Destination JNDI name refers to a JMS destination that is a queue.

Topic The Destination JNDI name refers to a JMS destination that is a topic.

Durable subscription:

Whether a durable or nondurable subscription is used to deliver messages to an MDB subscribing to the topic.

Data type Checkbox

Default Cleared (nondurable)

Subscription name:

The name of a durable subscription. This is available only when the **Durable subscription** checkbox is selected.

Data type String

Authentication alias:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ.

Data type Drop-down list
Default (none)
Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

Client identifier:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type String

Allow cloned durable subscriptions:

Determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Checkbox
Default Cleared
Range **Selected** Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared Multiple instances of a durable subscription can not be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functionality required by the client.

Data type String
Range The value entered must be either the empty string or be must be in one of the following formats: n.n.n.n or n.n.n or n.n or n, where n is a numeric value greater than or equal to zero.

WebSphere MQ messaging provider activation specification advanced properties:

Use this panel to view or change the advanced properties of the selected activation specification for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ activation specification advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Click the name of the activation specification that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:

- Message compression
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ activation specification has the following advanced properties.

Compress message headers:

Enables the compression of message headers.

Data type	Checkbox
Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	RLE ZLIBFAST ZLIBHIGH NONE

Retain messages, even if no matching consumer is available:

Determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type	Checkbox
Default	Selected
Range	Cleared Do not retain messages. Selected Retain messages.

Rescan interval:

When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS) this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to consume messages from another WebSphere MQ queue in the set, which is being asynchronously consumed from.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum server sessions:

The maximum number of server sessions in the server session pool used by the connection consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Server session pool timeout:

The period of time, in milliseconds, that an unused server session is held open in the server session pool before being closed due to inactivity.

Data type	Integer
Units	Milliseconds
Default	300,000
Range	A value greater than zero.

Start timeout:

The period of time, in milliseconds, within which delivery of a message to an MDB must start after the work to deliver the message has been scheduled. If this period of time elapses, the message is rolled back onto the queue.

Data type	Integer
Units	Milliseconds
Default	10,000
Range	A value greater than zero.

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. Must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www.ibm.com/software/integration/wmq/library>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

Selected JMS operations fail when the queue manager is put into a quiescing state. This enables the queue manager to quiesce successfully and shutdown.

Data type	Checkbox
Default	Selected
Range	Cleared Do not fail JMS operations if the queue manager is quiescing. Selected Fail JMS operations if the queue manager is quiescing.

Stop endpoint if message delivery fails:

Determines whether message delivery is suspended to a failing endpoint.

Data type	Checkbox
Default	Selected
Range	Cleared Message delivery is not suspended to a failing endpoint. Selected Message delivery is suspended to a failing endpoint when the Number of sequential delivery failures before suspending endpoint is exceeded.

Number of sequential delivery failures before suspending endpoint:

Sets the number of sequential message delivery failures to an endpoint that are allowed before message delivery to that endpoint is suspended. This property is enabled only when **Suspend message delivery to failing endpoints** is selected.

Data type	Integer
Default	0
Range	A value greater than or equal to zero.

WebSphere MQ messaging provider activation specification broker properties:

Use this panel to view or change the broker settings of the selected activation specification for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ activation specification broker properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Click the name of the activation specification that you want to work with.
4. In the content pane under Additional properties, click **Broker properties** to view a list of the broker properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:

- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ activation specification has the following broker properties.

Broker control queue:

The queue to which broker control messages are sent.

Data type	String
Default	SYSTEM.BROKER.CONTROL.QUEUE

Broker subscriber queue:

The queue from which subscription messages are received.

Data type	String
Default	SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to receive subscription messages for connection consumers from.

Data type	String
Default	SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Broker connection consumer durable subscription queue:

The queue to receive subscription messages for durable connection consumers from.

Data type String
Default SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE

Version:

This determines some of the capabilities the broker is assumed to have. For example, whether to use a RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection can not be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

This determines where message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT
Range

CLIENT
Message selection is performed in the application server process.

BROKER
Message selection is performed in the broker process.

Subscription store:

This determines how subscriptions are tracked.

Data type Drop-down list
Default MIGRATE

Range

MIGRATE

Any information that is held using queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of Migrate is equivalent to specifying a value of Broker.

BROKER

Internal broker mechanisms are used to track subscription information.

QUEUE

A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

This setting determines how often to recreate a long running transaction used to clean up durable subscriptions, for some versions of the queue manager.

Data type	Integer
Default	60000
Range	Any positive integer

Subscription cleanup level:

This setting determines how aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type	Drop-down list
Default	SAFE
Range	SAFE A conservative algorithm is used to clean up subscriptions. ASPROP The cleanup algorithm is determined by a system property. NONE No cleanup of subscriptions is performed. STRONG An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

This setting determines how often to check for orphaned subscriptions and clean up messages.

Data type	Integer
Default	3600000
Range	Any positive integer

Subscription wildcard format:

This setting determines the wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type
Default
Range

Drop-down list
character wildcards

character wildcards

The following characters can stand for characters, or strings of characters in a topic name: '*' and '?'

'*' is interpreted as matching many characters

'?' is interpreted as matching a single character.

topic level wildcards

The following characters can stand for topics in a multilevel topic hierarchy: '+' and '#'

'+' is interpreted as matching a single topic name

'#' is interpreted as matching many topics in the hierarchy. '/' is used to delimit topics.

Optimize for sparse subscription patterns:

Specifies whether this activation specification is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type
Default
Range

Checkbox
Cleared
Cleared

Subscriptions frequently receive matching messages.

Selected

Subscriptions do not frequently receive matching messages.

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the activation specification connects.

Data type
Default

String
The same queue manager name as specified in the activation specification.

WebSphere MQ messaging provider activation specification client transport properties:

Use this panel to view or change the client transport properties of an activation specification for use with the WebSphere MQ messaging provider. These properties affect how a client connection is established with a WebSphere MQ queue manager or queue sharing group. Updates to the properties take effect when the server is restarted.

To view WebSphere MQ activation specification client transport properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Click the name of the activation specification that you want to work with.

4. In the content pane, under Additional properties, click **Client transport properties** to display a list of the client transport properties of the WebSphere MQ activation specification.

Under General Properties there are two groups of properties:

- Additional SSL settings
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *WebSphere MQ Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ activation specification has the following client transport properties:

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer's SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer's certificate.
Range	Validated using the rules for a WebSphere MQ SSLPEER channel parameter.

Receive exit or exits:

A comma-separated list of Java class names corresponding to receive exits to load.

Data type String

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type String

Send exit or exits:

A comma-separated list of Java class names corresponding to send exits to load.

Data type String

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type String

Security exit:

A Java class name corresponding to the security exit to load.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

WebSphere MQ connection factory collection

Use this task to select a connection factory to view or change its configuration properties. The unified JMS connection factory is configured for the WebSphere MQ messaging provider for both point-to-point and publish/subscribe messaging.

This panel shows a list of the WebSphere MQ connection factories with a summary of their configuration properties. In a mixed release cell, these connection factories are not available for Version 5, 6.0 or 6.1 nodes.

To view a list of the WebSphere MQ connection factories, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Optional: To define a new connection factory, click **New** to start the Create Connection Factory wizard.
4. Optional: To view or change the properties of a connection factory, click its name in the list displayed.

Configuring a JMS connection factory for the WebSphere MQ messaging provider:

Use this tasks to browse or configure an existing domain-independent connection factory for the WebSphere MQ messaging provider on an Application Server Version 7 node.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories. If you want to browse or configure a queue connection factory or topic connection factory, see the related tasks.

To create a connection factory, see the related tasks.

To browse or configure an existing connection factory for use with WebSphere MQ, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories** to view existing connection factories, with a summary of their properties.
2. Change the **Scope** setting to the level at which the connection factory is visible to applications.
3. Click the name of the connection factory that you want to work with.
4. Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Optional: Click **Connection pools** to display or change the connection pools detail of your connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your connection factory.
12. Click **OK**.
13. Save any changes to the master configuration.
14. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider connection factory settings:

Use this panel to view or change the configuration properties of the selected connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queues and topics.

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces, such as the unified JMS connection factory. A domain-independent application can use the same interface for both point-to-point and publish/subscribe messaging, and can support both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, you are recommended to use domain-independent unified JMS connection factories for new applications. A domain-specific interface extends the domain-independent equivalent, so an application using domain-specific queue and topic connection factories can choose to use either interface.

To view WebSphere MQ connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Click the name of the connection factory that you want to work with.

Under General Properties there are three groups of properties:

- Administration
- Connection
- Advanced

There are two variations of the **Connection** group:

- **CCDT Connection settings group:** A WebSphere MQ administrator can create a single Client Channel Definition Table (CCDT) of all the WebSphere MQ channels supported by queue managers in their enterprise. Additional WebSphere MQ configuration information can be associated with the entries in a CCDT. If the selected connection factory was created using a CCDT, only the following information is required to configure a connection:
 - Client channel definition table URL: The URL that specifies the location of the CCDT.
 - Queue manager: The queue manager name that specifies the CCDT entry, or entries, to use.
 - SSL configuration
- **Explicitly-defined Connection settings group:** If the selected connection factory was not created using a CCDT, the following information must be entered explicitly to configure a connection:
 - Queue manager
 - Transport
 - Hostname
 - Port
 - Server connection channel
 - Use SSL to secure communication with Websphere MQ: If you clear this property, the following properties cannot be used.
 - Centrally managed
 - Specific configuration
 - SSL configuration

Make any required changes to the Administration, Connection and Advanced groups of properties and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ connection factory
- **Broker properties** to display or change the broker properties of your WebSphere MQ connection factory
- **Custom properties** to display or change the custom properties of your WebSphere MQ connection factory
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all the information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
- **Connection pools** to display or change the connection pools detail of your WebSphere MQ connection factory

- **Session pools** to display or change the session pools detail of your WebSphere MQ connection factory

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the connection factory.

You can specify the following additional properties using WebSphere MQ administrative commands:

- **localAddress**
- **clonedSubs**
- **containerAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 2078.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

A WebSphere MQ unified connection factory has the following properties:

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Scope:

Specifies the level at which this connection factory definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change other resources at a different scope, change the scope on the WebSphere MQ connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all connection factories using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

Data type	String
Range	The name must be unique within the set of connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the connection factory into the JNDI name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type	String
------------------	--------

Description:

A description of this connection factory for administrative purposes within WebSphere Application Server.

Data type	String
------------------	--------

Client channel definition table URL:

A URL that points to a WebSphere MQ CCDT.

Data type	String
------------------	--------

Queue manager:

If this connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue sharing group to connect to. A connection is established to this WebSphere MQ resource to send or receive messages.

Data type	String
Range	If this connection factory is based on a CCDT, the value must be one of the following: <ul style="list-style-type: none">• a valid queue manager name• a valid queue manager name with the last character an asterisk• an asterisk• blank If this connection factory is not based on a CCDT, the value must be a valid queue manager name.

Transport:

The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type	Drop-down list
Default	bindings then client

Range

client Use a TCP/IP based network connection to communicate with the WebSphere MQ queue manager

bindings then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

bindings

Establish a cross memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Hostname
- Port
- Server connection channel

For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971 and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname:

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN
Range The value must be a server connection channel defined to the WebSphere MQ queue manager being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

When using a WebSphere MQ messaging provider connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** → **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider connection factory in the client environment, the client takes SSL configuration information from the `ssl.client.props` file. Use of this file is detailed in the related reference information for this topic.

A WebSphere MQ messaging provider connection factory can only be configured with a single SSL cipher suite in the SSL configuration. If you specify more than one cipher suite in the SSL configuration for a WebSphere MQ messaging provider connection factory, only the first one is used.

Data type Checkbox. If this checkbox is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the hostname and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

Data type Drop-down list

SSL configuration:

The specific SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if a SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Component-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

Client identifier:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type	String
------------------	--------

Allow cloned durable subscriptions:

Determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type	Checkbox
Default	Cleared
Range	Selected Multiple instances of a durable subscription can be accessed concurrently by different servers. Cleared Multiple instances of a durable subscription can not be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functionality required by the client.

Data type	String
Range	The value entered must be either the empty string or be must be in one of the following formats: n.n.n.n or n.n.n or n.n or n, where n is a numeric value greater than or equal to zero.

Support distributed two phase commit protocol:

Specifies whether the connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Checkbox
Default	Selected
Range	Selected The connection factory supports the use of distributed two phase commit protocols for the coordination of transacted work. Cleared The connection factory does not support the use of distributed two phase commit protocols for the coordination of transacted work.
Recommendation	Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager connected to using this queue connection is the only resource in the transaction.

Authentication alias for XA recovery:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the connection factory, under Related items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)
Range	ClientContainer WSLogin WSKRB5Login DefaultPrincipalMapping TrustedConnectionMapping KerberosMapping

WebSphere MQ messaging provider connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Click the name of the connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ connection factory.

Under General Properties there are five groups of properties:

- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory.

Note:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ connection factory has the following advanced properties:

Compress message headers:

Enables the compression of message headers.

Data type	Checkbox
Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	RLE ZLIBFAST ZLIBHIGH NONE

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue creation.

Data type String
Default SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix to append to the beginning of the names generated for temporary queues.

Data type String

Temporary topic prefix:

The prefix to append to the beginning of the names generated for temporary topics.

Data type String

Retain messages, even if no matching consumer is available:

Determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type Checkbox
Default Selected
Range **Cleared** Do not retain messages.
Selected Retain messages.

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS) this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set from which it is being asynchronously consumed.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Rescan interval:

When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS) this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to consume messages from another WebSphere MQ queue in the set which is being asynchronously consumed from.

Data type Integer

Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages to remove from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www.ibm.com/software/integration/wmq/library>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Append an RFH version 2 header to reply messages:

The action to take when replying to a message without an RFH version 2 header.

Data type	Checkbox
Default	Selected
Range	<p>Selected Append an RFH version 2 header to reply messages.</p> <p>Cleared Do not append an RFH version 2 header to reply messages.</p>

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

Selected JMS operations fail when the queue manager is put into a quiescing state. This enables the queue manager to quiesce successfully and shutdown.

Data type	Checkbox
Default	Selected

Range**Cleared**

Do not fail JMS operations if the queue manager is quiescing.

Selected

Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory broker properties:

Use this panel to view or change the broker settings of the selected connection factory or topic connection factory, for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory or topic connection factory, broker properties, use the administrative console to complete the following steps:

1. In the navigation pane, either expand **Resources** → **JMS** → **Connection factories** to display existing connection factories or expand **Resources** → **JMS** → **Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Click the name of the connection factory or topic connection factory that you want to work with.
4. In the content pane, under Additional Properties, click **Broker properties** to display the broker properties of the WebSphere MQ connection factory or topic connection factory.

Under General Properties there are four groups of properties:

- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ connection factory or topic connection factory has the following broker properties:

Broker control queue:

The queue to which broker control messages are sent.

Data type

String

Default

SYSTEM.BROKER.CONTROL.QUEUE

Broker publication queue:

The queue to which publication messages are sent.

Data type String
Default SYSTEM.BROKER.DEFAULT.STREAM

Broker subscriber queue:

The queue to which subscription messages are sent.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to which subscription messages that are destined for a connection consumer are sent.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Version:

This determines some of the capabilities the broker is assumed to have. For example, whether to use a RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection can not be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

This determines where message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT
Range

CLIENT
Message selection is performed in the application server process.

BROKER
Message selection is performed in the broker process.

Subscription store:

This setting determines how subscriptions are tracked.

Data type Drop-down list
Default MIGRATE

Range**MIGRATE**

Any information that is held using queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of Migrate is equivalent to specifying a value of Broker.

BROKER

Internal broker mechanisms are used to track subscription information.

QUEUE

A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

This setting determines how often to recreate a long running transaction used to clean up durable subscriptions, for some versions of the queue manager.

Data type	Integer
Default	60000
Range	Any positive integer

Subscription cleanup level:

This setting determines how aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type	Drop-down list
Default	SAFE
Range	<p>SAFE A conservative algorithm is used to clean up subscriptions.</p> <p>ASPROP The cleanup algorithm is determined by a system property.</p> <p>NONE No cleanup of subscriptions is performed.</p> <p>STRONG An aggressive algorithm is used to clean up subscriptions.</p>

Subscription cleanup interval:

This setting determines how often to check for orphaned subscriptions and clean up messages.

Data type	Integer
Default	3600000
Range	Any positive integer

Subscription wildcard format:

This setting determines the wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type
Default
Range

Drop-down list
character wildcards

character wildcards

The following characters can stand for characters, or strings of characters in a topic name: '*' and '?'

'*' is interpreted as matching many characters

'?' is interpreted as matching a single character.

topic level wildcards

The following characters can stand for topics in a multilevel topic hierarchy: '+' and '#'

'+' is interpreted as matching a single topic name

'#' is interpreted as matching many topics in the hierarchy. '/' is used to delimit topics.

Publish acknowledgement window:

Specifies the number of messages to publish before publishing a message which requires broker acknowledgement

Data type
Default
Range

Integer
25
Any positive integer

Optimize for sparse subscription patterns:

Specifies whether this connection factory is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type
Default
Range

Checkbox
Cleared
Cleared

Subscriptions frequently receive matching messages.

Selected

Subscriptions do not frequently receive matching messages.

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

Data type
Default

String
The same queue manager name as specified in the connection factory.

WebSphere MQ resource custom properties settings:

Use this page to specify custom properties that your enterprise information system (EIS) requires for the resource providers and resource factories that you configure. For example, most database vendors require additional custom properties for data sources that access the database.

To view this administrative console page, complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If **Scope** is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, click the **WebSphere MQ messaging provider** that you want to support the JMS destination.
4. In the content pane, under Additional Properties, click the type of resource that you want to change, for example **Queues**.
5. Click the name of the resource that you want to work with.
6. In the content pane, under General Properties, complete the groups of fields, for example **Administration** and **WebSphere MQ Queue**.
7. In the content pane, under Additional Properties, click **Custom properties** to display a list of the custom properties of a WebSphere MQ resource.

A resource for use with the WebSphere MQ messaging provider has the following custom properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Name:

The name by which the resource is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Value:

The value of the resource.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the resource, for administrative purposes within IBM WebSphere Application Server.

Data type String

Default Null

Required:

Whether or not the resource is required, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory or topic connection factory, client transport settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS**.
2. Click **Connection factories**, **Queue connection factories** or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Click the name of the connection factory, queue connection factory or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory or topic connection factory.

Under General Properties there are two groups of properties:

- Additional SSL settings
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ connection factory, queue connection factory or topic connection factory has the following client transport settings properties:

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer's SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer's certificate.
Range	Validated using the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to load.

Data type	String
------------------	--------

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String
------------------	--------

Send exits:

A comma-separated list of Java class names corresponding to send exits to load.

Data type	String
------------------	--------

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String
------------------	--------

Security exit:

A Java class name corresponding to the security exit to load.

Data type	String
------------------	--------

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types, like JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**.

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

For example: click **Resources** → **JDBC** → **JDBC Providers** → *JDBC_provider* → **Data Sources** → *data_source* → **Connection pool properties**

The path for JMS queue connection factories is: **Resources** → **JMS** → **Queue connection factories** → *JMS_queue_connection_factory* → **[Additional properties]** **Connection pool properties**.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection Timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown. For example: If the `Max Connections` value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in `Connection Timeout` for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend (such as a DB2 database or a CICS server) helps you determine a value for the `Maximum Connections` property.

Consider the number of servants that access the same resource; at runtime, this number essentially multiplies your `Maximum Connections` setting. When servants invoke the same JDBC data source or J2C connection factory configuration, WebSphere Application Server implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your `Maximum Connections` setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a `Maximum Connections` value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer
	If <code>Max Connections</code> is set to 0, the <code>Connection Timeout</code> value is ignored.

Note: For better performance, set the value for the connection pool lower than the value for the `Max Connections` option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the `Percent Used` value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the `Unused Timeout` thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for `Aged Timeout`, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the `Minimum Connections` value is set to 3, and one physical connection is created, the `Unused Timeout` thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the `Minimum Connections` setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused Timeout and Aged Timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged Timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance.

For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only

exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	<ul style="list-style-type: none">• EntirePool for J2C connection factories and JMS-related connection factories• EntirePool for WebSphere Version 4.0 data sources• EntirePool for current version data sources that you create through the administrative console• EntirePool for current version data sources that you script through wsadmin AdminConfig commands, invoking JDBC templates that are built into WebSphere Application Server (For information on the command createUsingTemplate, see the information center article “Commands for the AdminConfig object.”)• FailingConnectionOnly for data sources that you script in wsadmin without invoking JDBC templates
	:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to a range of resource types; for example, JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Session pools**. For example: click **Resources** → **JMS** → **JMS providers** → *default messaging provider* → **Queue connection factories** → *connection_factory* → **Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached. For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method,

because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type

String

Default

FailingConnectionOnly

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

WebSphere MQ queue connection factory collection

Use this panel to select a queue connection factory to view or change its configuration properties. The queue connection factory is configured for the WebSphere MQ messaging provider for point-to-point messaging with JMS queues.

This panel shows a list of WebSphere MQ queue connection factories with a summary of their configuration properties.

To view the WebSphere MQ queue connection factory collection, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** to restrict the set of queue connection factories displayed. If **Scope** is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. Optional: To define a new queue connection factory, click **New**.
4. Optional: Optional: To view or change the properties of a queue connection factory, click its name in the list displayed.

Configuring an existing JMS queue connection factory for the WebSphere MQ messaging provider:

Use this task to browse or change an existing JMS queue connection factory for point-to-point messaging with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories.

If you want to browse or change a connection factory, see the related tasks.

To browse or change a queue connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queue connection factories** to view existing queue connection factories, with a summary of their properties.
2. Change the **Scope** setting to the level at which the queue connection factory is visible to applications.
3. Click the name of the queue connection factory that you want to work with.
4. Under **General Properties** make modifications as necessary. Use the administrative console help for information about each of the available fields.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your queue connection factory.
7. Optional: Click **Custom properties** to display or change the list of custom properties of your queue connection factory.
8. Optional: Click **Client transport properties** to display or change the list of client transport properties of your queue connection factory. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
9. Optional: Click **Connection pools** to display or change the connection pools detail of your queue connection factory.
10. Optional: Click **Session pools** to display or change the session pools detail of your queue connection factory.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queue destinations.

A WebSphere MQ queue connection factory is used to create JMS connections to queues provided by WebSphere MQ for point-to-point messaging.

To view WebSphere MQ queue connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. This restricts the set of queue connection factories displayed.

3. Click the name of the queue connection factory that you want to work with.

Under General Properties there are three groups of properties:

- Administration
- Connection
- Advanced

There are two variations of the **Connection** group:

- **CCDT Connection settings group:** A WebSphere MQ administrator can create a single Client Channel Definition Table (CCDT) of all the WebSphere MQ channels supported by queue managers in their enterprise. Additional WebSphere MQ configuration information can be associated with the entries in a CCDT. If the selected connection factory was created using a CCDT, only the following information is required to configure a connection:
 - Client channel definition table URL: The URL that specifies the location of the CCDT.
 - Queue manager: The queue manager name that specifies the CCDT entry, or entries, to use.
 - SSL configuration
- **Explicitly-defined Connection settings group:** If the selected connection factory was not created using a CCDT, the following information must be entered explicitly to configure a connection:
 - Queue manager
 - Transport
 - Hostname
 - Port
 - Server connection channel
 - Use SSL to secure communication with Websphere MQ: If you clear this property, the following properties do not appear on the panel.
 - Centrally managed
 - Specific configuration
 - SSL configuration

Make any required changes to the Administration, Connection and Advanced groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display the advanced properties of your WebSphere MQ queue connection factory
- **Custom properties** to display the custom properties of your WebSphere MQ queue connection factory
- **Client transport properties** to display the client transport properties of your WebSphere MQ queue connection factory. This link is only present on the explicitly-specified variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
- **Connection pools** to display the connection pool detail of your WebSphere MQ queue connection factory
- **Session pools** to display the session pools detail of your WebSphere MQ queue connection factory

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the connection factory.

You can specify the following additional properties using WebSphere MQ administrative commands:

- **localAddress**
- **containerAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 2078.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

A WebSphere MQ queue connection factory has the following properties:

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ queue connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all queue connection factories created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of queue connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the queue connection factory into the name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Client channel definition table URL:

A URL that points to a WebSphere MQ CCDT.

Data type String

Queue manager:

If this queue connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue sharing group to connect to. A connection is established to this WebSphere MQ resource to send or receive messages.

Data type String
Range If this queue connection factory is based on a CCDT, the value must be one of the following:

- a valid queue manager name
- a valid queue manager name with the last character an asterisk
- an asterisk
- blank

If this connection factory is not based on a CCDT, the value must be a valid queue manager name.

Transport:

The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list
Default **bindings then client**

Range

client Use a TCP/IP based network connection to communicate with the WebSphere MQ queue manager

bindings then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

bindings

Establish a cross memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Hostname
- Port
- Server connection channel

For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971 and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname:

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN
Range The value must be a server connection channel defined to the WebSphere MQ queue manager being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

When using a WebSphere MQ messaging provider queue connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** → **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider queue connection factory in the client environment, the client takes SSL configuration information from the `ssl.client.props` file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider queue connection factory. If you specify more than one cipher suite, only the first one is used.

Data type Checkbox. If this checkbox is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the hostname and port attributes from the WebSphere MQ messaging provider queue connection factory are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the queue connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

Data type Radio button

SSL configuration:

The specific SSL configuration to use when SSL is to be used to secure network communications with the WebSphere queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if a SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Component-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

Client identifier:

The client identifier to specify when connecting to WebSphere MQ messaging provider.

Data type	String
------------------	--------

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functionality required by the client.

Data type	String
Range	The value entered must be either the empty string or be must be in one of the following formats: n.n.n.n or n.n.n or n.n or n, where n is a numeric value greater than or equal to zero.

Support distributed two phase commit protocol:

Specifies whether the connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Checkbox
Default	Selected
Range	Selected The queue connection factory supports the use of distributed two phase commit protocols for the coordination of transacted work. Cleared The queue connection factory does not support the use of distributed two phase commit protocols for the coordination of transacted work.
Recommended	Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager connected to using this queue connection factory is the only resource in the transaction.

Authentication alias for XA recovery:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the connection factory, under Related items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)
Range	ClientContainer WSLogin WSKRB5Login DefaultPrincipalMapping TrustedConnectionMapping KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider queue connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. This restricts the set of queue connection factories displayed.

3. Click the name of the queue connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ queue connection factory.

Under General Properties there are five groups of properties:

- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A WebSphere MQ queue connection factory has the following advanced properties.

Compress message headers:

Enables the compression of message headers.

Data type	Checkbox
Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	RLE ZLIBFAST ZLIBHIGH NONE

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue definitions.

Data type	String
Default	SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix to append to the beginning of the names generated for temporary queues.

Data type String

Retain messages, even if no matching consumer is available:

Determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type Checkbox
Default Selected
Range **Cleared** Do not retain messages.
Selected Retain messages.

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set from which is being asynchronously consumed.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Rescan interval:

When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS) this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to consume messages from another WebSphere MQ queue in the set which is being asynchronously consumed from.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Maximum batch size:

The maximum number of messages to remove from a queue before at least one must be delivered to an asynchronous consumer.

Data type Integer
Default 10
Range A value greater than zero.

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www.ibm.com/software/integration/wmq/library>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Append an RFH version 2 header to reply messages:

The action to take when replying to a message without an RFH version 2 header.

Data type	Checkbox
Default	Selected
Range	Selected Append an RFH version 2 header to reply messages. Cleared Do not append an RFH version 2 header to reply messages.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

Selected JMS operations fail when the queue manager is put into a quiescing state. This enables the queue manager to quiesce successfully and shutdown

Data type	Checkbox
Default	Selected
Range	Cleared Do not fail JMS operations if the queue manager is quiescing. Selected Fail JMS operations if the queue manager is quiescing.

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types, like JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**.

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()`

request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

For example: click **Resources** → **JDBC** → **JDBC Providers** → **JDBC_provider** → **Data Sources** → **data_source** → **Connection pool properties**

The path for JMS queue connection factories is: **Resources** → **JMS** → **Queue connection factories** → **JMS_queue_connection_factory** → **[Additional properties]** **Connection pool properties**.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection Timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown. For example: If the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend (such as a DB2 database or a CICS server) helps you determine a value for the Maximum Connections property.

Consider the number of servants that access the same resource; at runtime, this number essentially multiplies your Maximum Connections setting. When servants invoke the same JDBC data source or J2C

connection factory configuration, WebSphere Application Server implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your Maximum Connections setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a Maximum Connections value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer
	If Max Connections is set to 0, the Connection Timeout value is ignored.

Note: For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused Timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged Timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused Timeout and Aged Timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged Timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance.

For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type

String

Defaults

- EntirePool for J2C connection factories and JMS-related connection factories
- EntirePool for WebSphere Version 4.0 data sources
- EntirePool for current version data sources that you create through the administrative console
- EntirePool for current version data sources that you script through wsadmin AdminConfig commands, invoking JDBC templates that are built into WebSphere Application Server (For information on the command **createUsingTemplate**, see the information center article "Commands for the AdminConfig object.")
- FailingConnectionOnly for data sources that you script in wsadmin without invoking JDBC templates

:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

WebSphere MQ topic connection factory collection

Use this panel to select a topic connection factory to view or change its configuration properties. The topic connection factory is configured for the WebSphere MQ messaging provider for publish/subscribe messaging with JMS topics.

This panel shows a list of WebSphere MQ topic connection factories with a summary of their configuration properties.

To view the WebSphere MQ topic connection factory collection, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** to restrict the set of topic connection factories displayed. If **Scope** is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. Optional: To define a new connection factory, click **New** to start the Create Connection Factory wizard.
4. Optional: To view or change the properties of a connection factory, click its name in the list displayed.

WebSphere MQ messaging provider topic connection factory settings:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to the associated JMS topic destination.

A WebSphere MQ topic connection factory is used to create JMS connections to topic destinations provided by WebSphere MQ for publish/subscribe messaging.

To view WebSphere MQ topic connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. This restricts the set of topic connection factories displayed.
3. Click the name of the topic connection factory that you want to work with.

Under General Properties there are three groups of properties:

- Administration
- Connection
- Advanced

There are two variations of the **Connection** group:

- **CCDT Connection settings group:** A WebSphere MQ administrator can create a single Client Channel Definition Table (CCDT) of all the WebSphere MQ channels supported by queue managers in their enterprise. Additional WebSphere MQ configuration information can be associated with the entries in a CCDT. If the selected connection factory was created using a CCDT, only the following information is required to configure a connection:
 - Client channel definition table URL: The URL that specifies the location of the CCDT.
 - Queue manager: The queue manager name that specifies the CCDT entry, or entries, to use.
 - SSL configuration
- **Explicitly-defined Connection settings group:** If the selected connection factory was not created using a CCDT, the following information must be entered explicitly to configure a connection:
 - Queue manager

- Transport
- Hostname
- Port
- Server connection channel
- Use SSL to secure communication with Websphere MQ: If you clear this property, the following properties cannot be used.
 - Centrally managed
 - Specific configuration
 - SSL configuration

Make any required changes to the Administration, Connection and Advanced groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display the advanced properties of your WebSphere MQ topic connection factory
- **Broker properties** to display the broker properties of your WebSphere MQ topic connection factory
- **Custom properties** to display the custom properties of your WebSphere MQ topic connection factory
- **Client transport properties** to display the client transport properties of your WebSphere MQ topic connection factory. This link is only present on the explicitly-specified variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
- **Connection pools** to display the connection pools detail of your WebSphere MQ topic connection factory
- **Session pools** to display the session pools detail of your WebSphere MQ topic connection factory

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the connection factory.

You can specify the following additional properties using WebSphere MQ administrative commands:

- **localAddress**
- **clonedSubs**
- **containerAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 2078.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

A WebSphere MQ topic connection factory has the following properties.

For more information about setting the SSL properties for WebSphere MQ, see the section SSL properties in the *WebSphere MQ Using Java* book.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the topic connection factory is created.

For all topic connection factories using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of JMS topic connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the topic connection factory into the JNDI name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Client channel definition table URL:

A URL that points to a WebSphere MQ CCDT.

Data type String

Queue manager:

If this topic connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue sharing group to connect to. A connection is established to this WebSphere MQ resource to send or receive messages.

Data type	String
Range	If this topic connection factory is based on a CCDT, the value must be one of the following: <ul style="list-style-type: none">• A valid queue manager name• A valid queue manager name with the last character an asterisk• An asterisk• Blank If this topic connection factory is not based on a CCDT, the value must be a valid queue manager name.

Transport:

The WebSphere MQ transport type for the connection. This is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type	Drop-down list
Default	bindings then client
Range	client Use a TCP/IP based network connection to communicate with the WebSphere MQ queue manager bindings then client Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport. bindings Establish a cross memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled: <ul style="list-style-type: none">• Hostname• Port• Server connection channel

For more information about configuring a transport type of *bindings then client* or *bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 1971 and “Sizing the thread pools used by the WebSphere MQ messaging provider” on page 1972.

Hostname:

The hostname, IPv4 or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type	String
------------------	--------

Port:

The port number on which WebSphere MQ is listening.

Data type	Integer
Default	1414
Range	The value must be in the range 1 to 65536 (inclusive).

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN
Range	The value must be a server connection channel defined to the WebSphere MQ queue manager being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

When using a WebSphere MQ messaging provider topic connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** → **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider topic connection factory in the client environment, the client takes SSL configuration information from the ssl.client.props file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider topic connection factory. If you specify more than one cipher suite, only the first one is used.

Data type	Checkbox. If this checkbox is cleared, the following SSL properties are disabled: <ul style="list-style-type: none">• Centrally managed• Specific configuration• SSL configuration
------------------	--

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the hostname and port attributes from the WebSphere MQ messaging provider topic connection factory are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the topic connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type	Radio button
------------------	--------------

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

Data type Radio button

SSL configuration:

The specific SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if a SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Component-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ.

Data type Drop-down list
Default (none)
Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

Client identifier:

The client identifier to specify when connecting to WebSphere MQ messaging provider.

Data type String

Allow cloned durable subscriptions:

Determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Checkbox
Default Cleared
Range **Selected** Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared Multiple instances of a durable subscription can not be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functionality required by the client.

Data type	String
Range	The value entered must be either the empty string or be must be in one of the following formats: n.n.n.n or n.n.n or n.n or n, where n is a numeric value greater than or equal to zero.

Support distributed two phase commit protocol:

Specifies whether the connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Checkbox
Default	Selected
Range	Selected The connection factory supports the use of distributed two phase commit protocols for the coordination of transacted work. Cleared The connection factory does not support the use of distributed two phase commit protocols for the coordination of transacted work.

Recommended	Do not enable XA when the queue manager specified by the topic connection factory is the only resource in the transaction. Enable XA if transactions involve other resources, including other queues or topics.
--------------------	---

Authentication alias for XA recovery:

The authentication alias which specifies the user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the connection factory, under Related items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)
Range	ClientContainer WSLogin WSKRB5Login DefaultPrincipalMapping TrustedConnectionMapping KerberosMapping

WebSphere MQ messaging provider topic connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ topic connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. This restricts the set of topic connection factories displayed.
3. Click the name of the topic connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ topic connection factory.

Under General Properties there are five groups of properties:

- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the topic connection factory.

A WebSphere MQ topic connection factory has the following advanced properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book which is available from the WebSphere MQ library page at <http://www.ibm.com/software/integration/wmq/library/>.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Compress message headers:

Enables the compression of message headers.

Data type	Checkbox
Default	Cleared

Range

Cleared

Do not compress message headers.

Selected

Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type

Drop-down list

Default

NONE

Range

RLE

ZLIBFAST

ZLIBHIGH

NONE

Temporary topic prefix:

The prefix to append to the beginning of the names generated for temporary topics.

Data type

String

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers. It is used when the set of WebSphere MQ queues being asynchronously consumed from exceeds the number of threads available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set from which is being asynchronously consumed.

Data type

Integer

Units

Milliseconds

Default

5000

Range

A value greater than zero.

Maximum batch size:

The maximum number of messages to remove from a queue before at least one must be delivered to an asynchronous consumer.

Data type

Integer

Default

10

Range

A value greater than zero.

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type

Integer

Default

819

Range

A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ library page at <http://www.ibm.com/software/integration/wmq/library>, or the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Fail JMS method calls if the WebSphere MQ messaging provider queue manager is quiescing:

Selected JMS operations fail when the queue manager is put into a quiescing state. This enables the queue manager to quiesce successfully and shutdown.

Data type

Checkbox

Default

Selected

Range**Cleared**

Do not fail JMS operations if the queue manager is quiescing.

Selected

Fail JMS operations if the queue manager is quiescing.

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types, like JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**.

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

For example: click **Resources** → **JDBC** → **JDBC Providers** → *JDBC_provider* → **Data Sources** → *data_source* → **Connection pool properties**

The path for JMS queue connection factories is: **Resources** → **JMS** → **Queue connection factories** → *JMS_queue_connection_factory* → **[Additional properties]** **Connection pool properties**.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection Timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a ConnectionWaitTimeout exception. In most cases you should not retry the getConnection() method; if a longer wait time is required you should increase the Connection Timeout setting value. If a ConnectionWaitTimeout exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection Timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, allowing a new physical connection to be created.

If Maximum Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown. For example: If the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend (such as a DB2 database or a CICS server) helps you determine a value for the Maximum Connections property.

Consider the number of servants that access the same resource; at runtime, this number essentially multiplies your Maximum Connections setting. When servants invoke the same JDBC data source or J2C connection factory configuration, WebSphere Application Server implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your Maximum Connections setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a Maximum Connections value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer

If Max Connections is set to 0, the Connection Timeout value is ignored.

Note: For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused Timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged Timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused Timeout and Aged Timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged Timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance.

For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 1478 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
------------------	--------

Defaults

- EntirePool for J2C connection factories and JMS-related connection factories
- EntirePool for WebSphere Version 4.0 data sources
- EntirePool for current version data sources that you create through the administrative console
- EntirePool for current version data sources that you script through wsadmin AdminConfig commands, invoking JDBC templates that are built into WebSphere Application Server (For information on the command **createUsingTemplate**, see the information center article "Commands for the AdminConfig object.")
- FailingConnectionOnly for data sources that you script in wsadmin without invoking JDBC templates

:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next getConnection() request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

WebSphere MQ queue destination collection

The JMS queue destinations configured in the WebSphere MQ messaging provider for point-to-point messaging with JMS queues. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

This panel shows a list of JMS queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If **Scope** is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, click the **WebSphere MQ messaging provider** that you want to support the JMS destination.
4. In the content pane, under Additional Properties, click **Queues**. This displays a list of any existing JMS queue destinations.

To create a new queue destination, click **New**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check box next to the name of the queue, then use the buttons provided.

WebSphere MQ messaging provider queue settings:

Use this panel to view or change the configuration properties of the selected queue destination for point-to-point messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ queue destination is used to configure the properties of a queue for the WebSphere MQ messaging provider. Connections to the queue are created using an associated WebSphere MQ queue connection factory or connection factory.

To view WebSphere MQ queue settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queues** to display existing queue destinations.
2. Click the name of the queue destination that you want to work with.
3. Optional: To create a new queue destination, click **New**.
4. Optional: To view or change the queue destination settings, click its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click one of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ queue destination
- **WebSphere MQ queue connection properties** to display or change the connection properties of your WebSphere MQ queue destination
- **Custom properties** to display or change the custom properties of your WebSphere MQ queue destination

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the queue destination.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the WebSphere MQ *Using Java* book and the *WebSphere MQ System*

Administration book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

A queue destination for use with the WebSphere MQ messaging provider has the following properties.

Scope:

The scope assigned to the queue when it is created. The scope specifies the level to which this queue definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on WebSphere MQ queue destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue is created.

For all queues created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the queue into the JNDI name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the queue, for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Queue name:

The WebSphere MQ name for the queue that holds the messages for the JMS destination.

Data type String

Queue manager or queue sharing group name:

The name of the WebSphere MQ queue manager or queue sharing group where the queue resides.

Data type String

WebSphere MQ queue connection properties:

Use this panel to specify how to connect to the queue manager that hosts the queue.

The system uses these connection properties to retrieve, display and update the queue configuration details that are shown on the **WebSphere MQ queue settings** panel.

To set of change the queue connection properties, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Queues** to display existing queue destinations.
2. Click the name of the queue destination that you want to work with.
3. To view or change the queue destination settings, click its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click the **WebSphere MQ queue connection properties** link to display or change the connection properties of your WebSphere MQ queue destination.

Make any required changes to the General properties and then click **Apply** before, in the content pane under Additional Properties, you click **WebSphere MQ configuration** to return to the **WebSphere MQ queue settings** panel.

A queue destination for use with the WebSphere MQ messaging provider has the following WebSphere MQ queue connection properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Queue Manager Host:

The name of host for the queue manager on which the queue destination is created.

Data type String

Queue Manager Port:

The number of the port used by the queue manager on which this queue is defined.

Data type	Integer
Range	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

Server Connection Channel Name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type	String
Range	1 through 20 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String
------------------	--------

Password:

The password, used with the **User ID** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String
------------------	--------

WebSphere MQ topic destination collection

The JMS topic destinations configured in the WebSphere MQ messaging provider for point-to-point messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of JMS topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **JMS providers**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider. If **Scope** is set to node or server scope for a Version 5 node, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.
3. In the content pane, click the name of the WebSphere MQ messaging provider that you want to support the JMS destination.
4. In the content pane, under Additional Properties, click **Topics**. This displays a list of any existing JMS topic destinations.

To create a new topic destination, click **New**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, select the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

WebSphere MQ messaging provider topic settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ topic destination is used to configure the properties of a topic for the WebSphere MQ messaging provider. Connections to the topic are created using an associated WebSphere MQ topic connection factory or connection factory.

To view WebSphere MQ topic settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS** → **Topics** to display existing topic destinations.
2. Click the name of the topic destination that you want to work with.
3. Optional: To create a new topic destination, click **New**.
4. Optional: To view or change the topic destination settings, click its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ topic

Make any required changes to the Administration and WebSphere MQ topic groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click either of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ topic
- **Custom properties** to display or change the custom properties of your WebSphere MQ topic

Under Related items, click **JAAS - J2C authentication data** to configure authentication information for use with the topic.

You can specify the following additional properties using WebSphere MQ administrative commands:

- **wildcardFormat**
- **brokerVersion**

For more information about these properties, refer to the “createWMQTopic command” on page 2092.

A topic for use with the WebSphere MQ messaging provider has the following properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Scope:

The scope assigned to the topic when it is created. The scope specifies the level to which this topic definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the topic is created.

For all topics created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the topic into the JNDI name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

Data type String

Topic name:

The WebSphere MQ name for the topic.

Data type String

Broker durable subscriber queue:

The queue to use for durable subscribers.

Data type Drop-down list
Default As connection

Range

As connection

The connection factory values are used.

Override connection

Enter the name of a queue in the associated text box.

Broker durable subscription connection consumer queue:

The queue to use for durable subscribers that use a connection consumer.

Data type

Drop-down list

Default

As connection

Range

As connection

The connection factory values are used.

Override connection

Enter the name of a queue in the associated text box.

Broker publication queue:

The queue to use for publishing messages.

Data type

Drop-down list

Default

As connection

Range

As connection

The connection factory values are used.

Override connection

Enter the name of a queue in the associated text box.

Broker publication queue manager:

The queue manager that hosts the topic.

Data type

Drop-down list

Default

As connection

Range

As connection

The connection factory values are used.

Override connection

Enter the name of a queue manager in the associated text box.

WebSphere MQ messaging provider queue and topic advanced properties settings:

Use this panel to view or change the advanced properties for the selected queue or topic destination for messaging with the WebSphere MQ messaging provider.

To view WebSphere MQ queue or topic advanced properties settings, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources** → **JMS**.
2. Click **Queues** or **Topics** to display existing queue or topic destinations.
3. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue or topic destinations are defined. This restricts the set of queue or topic destinations displayed.
4. Click the name of the queue or topic destination that you want to work with.

- In the content pane, under Additional properties, click **Advanced properties** to display a list of the advanced properties of the WebSphere MQ queue or topic destination.

Under General Properties there are three groups of properties:

- Delivery
- Message format
- Optimizations

Make any required changes to these groups and then click **Apply** to return to the queue or topic.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* book at <http://www.ibm.com/software/integration/wmq/library/>.

A queue or topic for use with the WebSphere MQ messaging provider has the following advanced properties.

Persistence:

The level of persistence used to store messages sent to this destination.

Data type	Drop-down list
Default	As set by application
Range	<p>As set by application Messages on the destination have their persistence defined by the application that put them onto the queue.</p> <p>As for WebSphere MQ queue definition Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>WebSphere MQ Persistent Messages on the destination are persistent.</p> <p>WebSphere MQ Non-persistent Messages on the destination are not persistent.</p> <p>WebSphere MQ High Permit persistent messages to be sent as non-persistent messages when using an underlying WebSphere MQ queue with a NPMCLASS of 'HIGH'.</p>

Priority:

The priority assigned to messages sent to this destination.

Data type	Drop-down list
Default	As set by application

Range**As set by application**

The priority of messages on this destination is defined by the application that put them onto the destination.

As for WebSphere MQ queue definition

Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties.

Specified

The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property was set to *Specified*, select the priority assigned to messages sent to this queue type destination.

Data type

Drop-down list

Units

Message priority level

Default

As set by application

Range

0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this destination is defined by the application or the **Specified expiry** property, or messages on the destination never expire.

Data type

Drop-down list

Default

As set by application

Range**As set by application**

The expiry timeout for messages on this destination is defined by the application that put them onto the destination.

Specified

The expiry timeout for messages on this destination is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.

Unlimited

Messages on this destination have no expiry timeout, so those messages never expire.

Specified expiry:

If the **Expiry** property is set to *Specified*, enter the number of milliseconds after which messages expire and are removed from this destination.

Data type

Integer

Units

Milliseconds

Default

0

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	1208
Range	1 through 65535. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www.ibm.com/software/integration/wmq/library>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Use native encoding:

Whether or not the destination should use native encoding to provided appropriate encoding values for the Java platform.

Data type	Checkbox
Default	Selected
Range	Selected Native encoding is used. Cleared Native encoding is not used, so specify the properties for Integer encoding , Decimal encoding , and Floating point encoding .

Integer encoding:

If the **Use native encoding** checkbox is cleared, select the type of integer encoding to be used.

Data type	Drop-down list
Default	Normal
Range	Normal Normal integer encoding is used. Reversed Reversed integer encoding is used.

Decimal encoding:

If the **Use native encoding** is cleared, select the type of decimal encoding to be used.

Data type	Drop-down list
Units	Not applicable
Default	Normal
Range	Normal Normal decimal encoding is used. Reversed Reversed decimal encoding is used.

Floating point encoding:

If the **Use native encoding** is cleared, select the type of floating point encoding to be used.

Data type	Drop-down list
