How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-5250.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Changes to serve you more quickly

Print sections directly from the information center navigation

PDF books are provided as a convenience format for easy printing, reading, and offline use. The information center is the official delivery format for IBM WebSphere Application Server documentation. If you use the PDF books primarily for convenient printing, it is now easier to print various parts of the information center as needed, quickly and directly from the information center navigation tree.

To print a section of the information center navigation:

1. Hover your cursor over an entry in the information center navigation until the **Open Quick Menu** icon is displayed beside the entry.
2. Right-click the icon to display a menu for printing or searching your selected section of the navigation tree.
3. If you select **Print this topic and subtopics** from the menu, the selected section is launched in a separate browser window as one HTML file. The HTML file includes each of the topics in the section, with a table of contents at the top.
4. Print the HTML file.

For performance reasons, the number of topics you can print at one time is limited. You are notified if your selection contains too many topics. If the current limit is too restrictive, use the feedback link to suggest a preferable limit. The feedback link is available at the end of most information center pages.

Under construction!

The Information Development Team for IBM WebSphere Application Server is changing its PDF book delivery strategy to respond better to user needs. The intention is to deliver the content to you in PDF format more frequently. During a temporary transition phase, you might experience broken links. During the transition phase, expect the following link behavior:

- Links to Web addresses beginning with http:// work
- Links that refer to specific page numbers within the same PDF book work
- The remaining links will *not* work. You receive an error message when you click them

Thanks for your patience, in the short term, to facilitate the transition to more frequent PDF book updates.

Chapter 1. Web applications

Tuning URL invocation cache

The URL invocation cache holds information for mapping request URLs to servlet resources. A cache of the requested size is created for each worker thread that is available to process a request. The default size of the invocation cache is 50. If more than 50 unique URLs are actively being used (each JavaServer Page is a unique URL), you should increase the size of the invocation cache.

Before you begin

A larger cache uses more of the Java™ heap, so you might also need to increase the maximum Java heap size. For example, if each cache entry requires 2KB, maximum thread size is set to 25, and the URL invocation cache size is 100; then 5MB of Java heap are required.

The invocation cache is now Web container based instead of thread-based, and shared for all Web container threads.

About this task

To change the size of the invocation cache:

1. In the administrative console, click **Servers** → **Server Types** → **WebSphere application servers** and select the application server that you are tuning.
2. Click **Java and Process Management**.
3. Click **Process Definition** under Additional Properties, and then select either **control** or **servant** depending on whether you want this property defined in the control or the servant.
4. Click **Java Virtual Machine** under Additional Properties.
5. Click **Custom Properties** under Additional Properties.
6. Specify **invocationCacheSize** in the Name field and the size of the cache in the Value field. The default size for the invocation cache is 500 entries. Since the invocation cache is no longer thread-based, the invocation cache size specified by the user is multiplied by ten to provide similar function from previous releases. For example, if you specify an invocation cache size of 50, the Web container will create a cache size of 500.
7. Click **Apply** and then **Save** to save your changes.
8. Stop and restart the application server.

Results

The new cache size is used for the URL invocation cache.

Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Before you begin

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path Reference > APIs - Application Programming Interfaces.

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the AsyncRequestDispatcherWorkManager work manager that is used for the request dispatch threads.
7. Restart the application server.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

Asynchronous request dispatcher

Asynchronous request dispatcher (ARD) can improve Servlet response time when slow operations can be logically separated and performed concurrently with other operations required to complete the response. ARD enables Java™ servlet programmers to perform standard javax.servlet.RequestDispatcher include calls for the same request concurrently on separate threads. These javax.servlet.RequestDispatcher include calls are completed sequentially on the same thread. ARD is also useful in low CPU, long wait situations like waiting for a database connection.

If there are large CPU or memory requirements, ARD alone does not alleviate those issues. However, in combination with the remote request dispatcher, operations driven by one servlet request that can be performed concurrently on multiple application servers, alleviating resource demand on a single server and decreasing the risk of a system down situation.

Servlets, portlets, and JavaServer Pages (JSP) files can all utilize ARD. This functionality is an extension beyond the requirements of the Java Servlet Specification , which only describes synchronous request dispatching. ARD requires a new channel, called the ARD channel, between the HTTP and Web container channels to form a new channel chain. These new chains correspond only to the existing default host chains and reuse the same ports.

Each include can write output to the client and because ordering is important for valid results, there must be some aggregation of the data written. Typically, a servlet writes data to a buffer and once full, it is flushed to client. For server-side aggregation, the ARD channel cannot flush until any includes that had placeholders written to the current buffer are finished.

Client-side aggregation of the asynchronous include is also supported. Web 2.0 programmers often use Asynchronous JavaScript™ and XML (Ajax) in the Web browser of the client to dynamically retrieve and aggregate remote resources. Unfortunately, this puts the burden on the programmer to aggregate the contents and learn new technologies. Client-side aggregation automatically adds the necessary JavaScript

to dynamically update the page. For non-JavaScript clients, you can switch ARD to server-side aggregation, which gives equivalent results. You can deny non-JavaScript clients when using client-side aggregation.

ARD uses the Web container APIs to plug in unique request dispatching logic. It interacts with WCCM to read in configuration information for enablement status per enterprise application as well as a global appserver setting. You can use the administrative console and wsAdmin to enable or disable ARD. Servlets, portlets, and JSP files can all utilize ARD.

Asynchronous request dispatcher application design considerations

Asynchronous request dispatcher (ARD) is not a one-size-fits-all solution to servlet programming. You must evaluate the needs of your application and the caveats of using ARD. Switching all includes to start asynchronously is not the solution for every scenario, but when used wisely, ARD can increase response time. This article contains important details about the ARD implementation and issues to consider when you design an application that leverages ARD.

Asynchronous request dispatcher client-side implementation

- JavaScript is dynamically written to the response output.
- This JavaScript results in Ajax requests back to a server-side results provider.
- Because of the Asynchronous Input/Output (AIO) features of the channel, the Ajax request does not tie up a thread and instead is notified for completion through an include callback.
- The client only makes one request at a time for the asynchronous includes because of browser limitations in the number of connections.
- Original connection has to be valid for the lifetime of the includes. It cannot be reused for the Ajax requests.
- Comment nodes, such as following,

  ```
  <!--uniquePlaceholderID--><!--1-->
  ```

  are placed in the browser object model since comment nodes have no effect on the page layout.
- Whenever a complete fragment exists, a response can be sent to the client and the comment node with the same ID is replaced. Requests are made until all the fragments are retrieved.
- Verify applications on all supported browsers when using client-side aggregation. Object oriented JavaScript principles are used so that applications only need avoid using the method name getDynamicDataIBMARD. Any previously specified window.onload is started before the ARD onload method.

Asynchronous request dispatcher channel results service

Requests for include data from the asynchronous JavaScript code are sent to known Uniform Resource Identifiers, URIs also known as URLs, that the ARD channel can intercept to prevent traveling through Web container request handling. These URIs are unique for the each server restart.

For example, `/IBMARD01234567/asyncInclude.js` is the URI for the JavaScript that forces the retrieval of the results, and `/IBMARD01234567/IBMARDQueryStringEntries?=12000` is used to retrieve the results for the entry with ID 12000.

To prevent unauthorized results access, unique IDs are generated for the service URI and for the ARD entries. A common ID generator is shared among the session and ARD, so uniqueness is configurable through session configuration. Session IDs are considered secure, but they are not as secure as using a Lightweight Third-Party Authentication (LTPA) token.

Custom client-side aggregation

If you want to perform your own client-side aggregation, the isUseDefaultJavascript method must return as false. The isUseDefaultJavascript method is part of the AsyncRequestDispatcherConfig method, which is set on the AsyncRequestDispatcher or for the AsyncRequestDispatcherConfigImpl.getRef method. The AsyncRequestDispatcherConfigImpl.getRef method is the global configuration object. You might want to perform your own client-side aggregation if the back button functionality is problematic. You must remove the results from the generic results service to prevent memory leaks, so that multiple requests with the same response results through an XMLHttpRequest fail. To facilitate proper location of position, placeholders are still written in the code as

```
<!--uniquePlaceholderID--><!--x-->
```

where x is the order of the includes. The endpoint to retrieve results are retrieved from the request attribute com.ibm.websphere.webcontainer.ard.endpointURI.

When making a request to the endpoint, ARD sends as many response fragments as possible when the request is made. Therefore, the client needs to re-request if all fragments are not initially returned. Trying to display the results directly in a browser without using an XMLHttpRequest can result in errors related to non well-formed XML. The response data is returned in the following format with a content type of text/xml:

```
<div id="2"><BR>Servlet 3--dispatcher3 requesting Servlet3 to sleep for 0 seconds at: 1187967704265
<BR> Servlet 3--Okay, all done!  This should print pop up: third at: 1187967704281 </div>
```

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path **Reference** → **APIs - Application Programming Interfaces**.

Server-side aggregation

Like client-side aggregation, server-side aggregation uses the ARD channel as a results service. The ARD channel knows which asynchronous includes have occurred for certain set of buffers. Those buffers can then be searched for an include placeholder. Because of the issues of JSP buffering, the placeholder for the include might not be in the searched buffers. If this occurs, the next set of buffers must also look for any include placeholders missed in the previous set. ARD attempts to iteratively aggregate as includes return so that response content can be sent to the client as soon as possible.

Asynchronous beans

An AsynchBeans work manager is used to start the includes. If the number of currently requested includes is greater than the work manager maximum thread pool size and this size is not growable, it starts the work on the current thread and skips the placeholder write. Utilizing AsynchBeans suppports propagation

of the J2EE context of the original thread including work area, internationalization, application profile, z/OS® operation system work load management, security, transaction, and connection context.

Timer

A single timer is used for ARD and timer tasks are created for all the timeout types of ARD requests. Tasks registered with the timer are not guaranteed to run at the exact time specified because the timer runs on a single thread, therefore one timeout might have to wait for the other timeout actions to complete. The timer is used as a last resort.

Remote request dispatcher

Optionally, ARD can be used in concert with the remote request dispatcher. The remote request dispatcher was introduced in WebSphere® Application Server Network Deployment 6.1. The remote request dispatcher runs the include on a different application server in a core group by serializing the request context into a SOAP message and using Web services to call the remote server. This is useful when the expense of creating and sending a SOAP message through Web services is outweighed by issuing the request locally. For more information, see this developerWorks article.

Exceptions

In the case of an exception in an included servlet, the Web container goes through the error page definitions mapped to exception types. So an error page defined in the deployment descriptor shows up as a portion of the aggregated page. Insert logic into the error page itself if behavior is different for an include. Because the include runs asynchronously, there is no guarantee that the top level servlet is still in service, therefore the exception is not propagated back from an asynchronous include like a normal include. Other includes finish so that partial pages can be displayed.

If the ARD work manager runs out of worker threads, the include is processed like a synchronous include. This is the default setting, but the work manager can also grow such that it does not result in this condition. This change in processing is invisible to the user during processing but is noted once in the system logs as a warning message and the rest of the time in the trace logs when enabled. Other states that can trigger the include to occur synchronously are reaching the maximum percentage of expired requests over a time interval and reaching the maximum size of the results store.

There are cases where exceptions happen outside of the scope of normal error page handling. For example, work can be rejected by the work manager. A timer can expire waiting for an include response to return. The ARD channel, acting as a generic service to retrieve the results, might receive an ID that is not valid. In these cases, there is no path to the error page handling because the context is missing, such as ServletRequest, ServletResponse, and ServletContext, for the request to work. To mitigate these issues, you can use the AsyncRequestDispatcherConfig interface to provide custom error messages. Defaults are provided and internationalized as needed.

Exceptions can also occur outside the scope of the request the custom configuration was set on, such as on the subsequent client-side XMLHttpRequests. In this case, the global configuration must be altered. This can be retrieved through com.ibm.wsspi.ard.AsyncRequestDispatcherConfigImpl.getRef().

Include start
: The work manager provides a timeout for how long to wait for an include to start. Since this typically happens immediately, there is not a programmatic way to enable this. However, this is configurable in the work manager settings. By default, you will not encounter this because of the maximum thread check before scheduling the work. Work can be retried if setRetriable(true) is called on the in use AsyncRequestDispatcherConfig.

Include finish
: The initiated timeout starts after the work is accepted. It can be configured through the console or programmatically through the AsyncRequestDispatcherConfig.setExecutionTimeoutOverride

method; The default value is 60000 ms, or one minute. In place of the include results, the message from the AsyncRequestDispatcherConfig.setExecutionTimeoutMessage is sent. If this intiated timeout is reached, but the actual include results are ready when the data can be flushed, preference is given to the actual results. Also, this does not apply to insertFragmentBlocking calls which always wait until the include is completed.

Expiration of results

Since the client-side has to hold the results in a service to send for the Ajax request, we want a way to expire the results if the client goes down and never retrieves the entry. The default of a minute is sufficient for a typical request because the Ajax request would come in immediately after sending the response. The timer can be configured programmatically via the setExpirationTimeoutOverride method the of AsyncRequestDispatcherConfig. The message from the getOutputRetrievalFailureMessage method of AsyncRequestDispatcherConfig is displayed when someone tries to access an entry that has expired and been removed from cache. This message is the same message that is sent to someone requesting a result with an ID that never existed.

Includes versus fragments

Consider which operations can be done asynchronously and when they can start. Ideally, all the includes are completed when the getFragment calls are made at the beginning of the request so that the includes can have more time to complete, and upon inserting the fragments, there would be less extra buffering and aggregating if they have completed. However, simply calling an asynchronous include is easier because it follows the same pattern as a normal request dispatcher include.

Web container

ServletContext

When doing cross-context includes, the context that is a target of the include must also have ARD enabled because the Web application must have been initialized for ARD for its servlet context to have valid methods to retrieve an AsyncRequestDispatcher. The aggregation type is determined by the original context's configuration because you cannot mix aggregation types.

ServletRequest

You must clone the request for each include. Otherwise, conflicts between threads might occur. Because applications can wrap the default request objects, your wrappers must implement the com.ibm.wsspi.webcontainer.servlet.IServletRequest interface, which has one method, the public Object clone method, which creates the CloneNotSupportedException.

Unwrapping occurs until a request wrapper that implements this interface is found. Non-implementing wrappers are lost; however, a servlet filter configured for the include can rewrap the response.

Changes made to the ServletRequest are not propagated back to the top level servlet unless transferState on the AsyncRequestDispatcherConfig is enabled and insertFragmentBlocking is called.

ServletResponse

A wrapped response extending com.ibm.websphere.servlet.response.StoredResponse is created by ARD and sent to the includes because the response output must be retrievable beyond the lifecycle of the original response.

Internal headers set in asynchronous includes are not supported due to lifecycle restrictions unless transferState on the AsyncRequestDispatcher config is enabled and insertFragmentBlocking is called. Normal headers are not supported in a synchronous include as specified by the servlet specification.

Include filters can rewrap the new response and must flush upon completion.

ServletInputStream
An application reading parameters using getParameter is not problematic.Parsing of parameters is forced before the first asynchronous include to prevent concurrent access to the input stream.

HttpSession
Initial getSession calls that result in a Set-Cookie header must be called from the top level servlet because it is unpredictable when the includes are started and if the headers have already been flushed. The exception is when transferState on the AsyncRequestDispatcherConfig is enabled and an insertFragmentBlocking is called. This normally creates an exception when you add the header.

Filters If there is a filter for an include, the filter is issued on the asynchronous thread.

Nested asynchronous includes
Nested asynchronous includes are not supported because they complicate aggregation. However, an asynchronous include can have nested synchronous includes. Any attempt to perform a nested asynchronous include reverts back to a synchronous include.

Transactions

Every asynchronous bean method is called using its own transaction, much like container-managed transactions in typical enterprise beans. The runtime starts a local transaction before invoking the method. The asynchronous bean method can start its own global transaction if this transaction is possible for the calling J2EE component.

If the asynchronous bean method creates an exception, any local transactions are rolled back. If the method returns normally, any incomplete local transactions are completed according to the unresolved action policy configured for the bean. If the asynchronous bean method starts its own global transaction and does not commit this global transaction, the transaction is rolled back when the method returns.

Connection management

An asynchronous bean method can use the connections that its creating servlet obtained using java:comp resource references. However, the bean method must access those connections using a get, use or close pattern. There is no connection caching between method calls on an asynchronous bean. The connection factories or data sources can be cached, but the connections must be retrieved on every method call, used, and then closed. While the asynchronous bean method can look up connection factories using a global Java Naming and Directory Interface (JNDI) name, this is not recommended for the following reasons:

- The JNDI name is hard coded in the application, for example, as a property or string literal.
- The connection factories are not shared because there is no way to specify a sharing scope.

Evaluate high load scenarios because asynchronous includes might increase the number of threads waiting on the connection.

Performance

Because includes are completed asynchronously, the total performance data for a request must take into consideration the performance of the asynchronous includes. The total time of the request could previously be understood by the time for the top level servlet to complete, but now that servlet is exiting before the includes are completed. The top level servlet still accounts for much of the additional setup time required for each include.

Therefore, a new ARD performance metric was added to the Performance Monitoring Infrastructure to measure the time for a complete request through the ARD channel. The granularity of these metrics is at the request URI level.

Since ARD is an optional feature that has to be enabled, no performance decline is seen when not utilizing ARD. However, non-ARD applications that reside on an ARD-enabled application server would suffer from the extra layer of the ARDChannel. The channel layer does not know to which application it is going so it is either on or off for all applications in a channel chain. These are defined per virtual host.

Security

Security is not invoked on synchronous include dispatches according to the servlet specification. However, security context is passed along through AsynchBeans to support programmatic usage of the isUserInRole and getUserPrincipal methods on the ServletRequest. This security context can also be propagated across to a remote request dispatch utilizing Web services security.

Related concepts

“Asynchronous request dispatcher” on page 2
Asynchronous request dispatcher (ARD) can improve Servlet response time when slow operations can be logically separated and performed concurrently with other operations required to complete the response. ARD enables Java™ servlet programmers to perform standard javax.servlet.RequestDispatcher include calls for the same request concurrently on separate threads. These javax.servlet.RequestDispatcher include calls are completed sequentially on the same thread. ARD is also useful in low CPU, long wait situations like waiting for a database connection.

Related tasks

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Web Container Settings** → **Web container** → **Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. Aggregation type is configurable at the application level.

Allow Asynchronous Request Dispatching

Enables applications installed on this server to use asynchronous request dispatching.

Asynchronous include timeout
Specifies the default timeout in milliseconds to complete asynchronous includes.

Data type	Integer
Units	Milliseconds
Default	60000
Range	

Maximum expired requests per minute
Specifies the maximum percentage of expired response versus total response in one minute before switching to synchronous requests.

Data type	Integer
Units	Percentage
Default	15
Range	

Maximum memory size of results store
Specifies the maximum size of store for client side requests.

Data type	Integer
Units	Megabytes
Default	100
Range	

Task overview: Managing HTTP sessions

IBM® WebSphere Application Server provides a service for managing HTTP sessions, Session Manager. The key activities for session management are summarized in this topic.

About this task

Before you begin these steps, make sure you are familiar with the programming model for accessing HTTP session support in the applications following the Servlet 2.5 API.

1. Plan your approach to session management, which could include session tracking, session recovery, and session clustering.
2. Create or modify your own applications to use session support to maintain sessions on behalf of Web applications.
3. Assemble your application.
4. Deploy your application.
5. Ensure the administrator appropriately configures session management in the administrative domain.
6. Adjust configuration settings and perform other tuning activities for optimal use of sessions in your environment.

Sessions

A session is a series of requests to a servlet, originating from the same user at the same browser.

Sessions allow applications running in a Web container to keep track of individual users.

For example, a servlet might use sessions to provide ″shopping carts″ to online shoppers. Suppose the servlet is designed to record the items each shopper indicates he or she wants to purchase from the Web

site. It is important that the servlet be able to associate incoming requests with particular shoppers. Otherwise, the servlet might mistakenly add Shopper_1's choices to the cart of Shopper_2.

A servlet distinguishes users by their unique session IDs. The session ID arrives with each request. If the user's browser is cookie-enabled, the session ID is stored as a cookie. As an alternative, the session ID can be conveyed to the servlet by URL rewriting, in which the session ID is appended to the URL of the servlet or JavaServer Pages (JSP) file from which the user is making requests. For requests over HTTPS or Secure Sockets Layer (SSL), another alternative is to use SSL information to identify the session. Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting.

HTTP session migration

There are no programmatic changes required to migrate from version 5.x to version 6.x. This article describes features that are available after migration.

Migration from Version 5.x

Note: In Version 5 and later, default write frequency mode is TIME_BASED_WRITES, which is different from Version 4.0.x default mode of END_OF_SERVICE.

Session security support

You can integrate HTTP sessions and security in WebSphere Application Server. When security integration is enabled in the session management facility and a session is accessed in a protected resource, you can access that session only in protected resources from then on.

You cannot mix secured and unsecured resources accessing sessions when security integration is turned on. Security integration in the session management facility is not supported in form-based login with SWAM.

Note: SWAM is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release.

Security integration rules for HTTP sessions

Only authenticated users can access sessions created in secured pages and are created under the identity of the authenticated user. Only this authenticated user can access these sessions in other secured pages. To protect these sessions from unauthorized users, you cannot access them from an unsecured page.

Programmatic details and scenarios

WebSphere Application Server maintains the security of individual sessions.

An identity or user name, readable by the com.ibm.websphere.servlet.session.IBMSession interface, is associated with a session. An unauthenticated identity is denoted by the user name `anonymous`. WebSphere Application Server includes the com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException class, which is used when a session is requested without the necessary credentials.

The session management facility uses the WebSphere Application Server security infrastructure to determine the authenticated identity associated with a client HTTP request that either retrieves or creates a session. WebSphere Application Server security determines identity using certificates, LPTA, and other methods.

After obtaining the identity of the current request, the session management facility determines whether to return the session requested using a getSession call.

The following table lists possible scenarios in which security integration is enabled with outcomes dependent on whether the HTTP request is authenticated and whether a valid session ID and user name was passed to the session management facility.

	Unauthenticated HTTP request is used to retrieve a session	**HTTP request is authenticated, with an identity of ″FRED″ used to retrieve a session**
No session ID was passed in for this request, or the ID is for a session that is no longer valid	A new session is created. The user name is `anonymous`	A new session is created. The user name is `FRED`
A session ID for a valid session is passed in. The current session user name is ″anonymous″	The session is returned.	The session is returned. session management changes the user name to `FRED`
A session ID for a valid session is passed in. The current session user name is `FRED`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is returned.
A session ID for a valid session is passed in. The current session user name is `BOB`	The session is not returned. An UnauthorizedSessionRequestException error is created*	The session is not returned. An UnauthorizedSessionRequestException error is created*

* A com.ibm.websphere.servlet.session.UnauthorizedSessionRequestException error is created to the servlet.

Session management support

WebSphere Application Server provides facilities, grouped under the heading *Session Management*, that support the javax.servlet.http.HttpSession interface described in the Servlet API specification.

In accordance with the Servlet 2.3 API specification, the session management facility supports session scoping by Web modules. Only servlets in the same Web module can access the data associated with a particular session. Multiple requests from the same browser, each specifying a unique Web application, result in multiple sessions with a shared session ID. You can invalidate any of the sessions that share a session ID without affecting the other sessions.

You can configure a session timeout for each Web application. A Web application timeout value of 0 (the default value) means that the invalidation timeout value from the session management facility is used.

When an HTTP client interacts with a servlet, the state information associated with a series of client requests is represented as an HTTP session and identified by a session ID. Session management is responsible for managing HTTP sessions, providing storage for session data, allocating session IDs, and tracking the session ID associated with each client request through the use of cookies or URL rewriting techniques. Session management can store session-related information in several ways:

- In application server memory (the default). This information cannot be shared with other application servers.
- In a database. This storage option is known as *database persistent sessions*.

The last two options are referred to as *distributed sessions*. Distributed sessions are essential for using HTTP sessions for the failover facility. When an application server receives a request associated with a session ID that it currently does not have in memory, it can obtain the required session state by accessing the external store (database or memory-to-memory). If distributed session support is not enabled, an application server cannot access session information for HTTP requests that are sent to servers other than

the one where the session was originally created. Session management implements caching optimizations to minimize the overhead of accessing the external store, especially when consecutive requests are routed to the same application server.

Storing session states in an external store also provides a degree of fault tolerance. If an application server goes offline, the state of its current sessions is still available in the external store. This availability enables other application servers to continue processing subsequent client requests associated with that session.

Saving session states to an external location does not completely guarantee their preservation in case of a server failure. For example, if a server fails while it is modifying the state of a session, some information is lost and subsequent processing using that session can be affected. However, this situation represents a very small period of time when there is a risk of losing session information.

The drawback to saving session states in an external store is that accessing the session state in an external location can use valuable system resources. session management can improve system performance by caching the session data at the server level. Multiple consecutive requests that are directed to the same server can find the required state data in the cache, reducing the number of times that the actual session state is accessed in external store and consequently reducing the overhead associated with external location access.

Session tracking options

HTTP session support also involves session tracking. You can use cookies, URL rewriting, or Secure Sockets Layer (SSL) information for session tracking.

the following tracking methods are available:
- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies

Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting

An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

If both cookies and URL rewriting are enabled and the response.encodeURL method or encodeRedirectURL method is called, the URL is encoded, even if the browser making the HTTP request processed the session cookie.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information (Deprecated)

Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or URL rewriting.

No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the Web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web servers only. You can control the lifetime of an SSL session ID by configuring options in the Web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some Web browsers might have their own timers that affect the lifetime of the SSL session ID. These Web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the Web server to properly route a session back to the same server for each request.

Distributed sessions

In a distributed environment, you can save sessions in a database using database session persistence or you can store sessions in multiple WebSphere Application Server instances using memory-to-memory session replication.

WebSphere Application Server provides the following session mechanisms in a distributed environment:

- **Database session persistence**, where sessions are stored in the database specified.
- **Memory-to-memory session replication**, where sessions are stored in one or more specified WebSphere Application Server instances or profiles.

When a session contains attributes that implement HttpSessionActivationListener, notification occurs anytime the session is activated (that is, session is read to the memory cache) or passivated (that is, session leaves the memory cache). Passivation can occur because of a server shutdown or when the session memory cache is full and an older session is removed from the memory cache to make room for a newer session. It is not guaranteed that a session is passivated in one application server prior to activation in another application.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions and memory-to-memory replication. You can use session recovery support when the user's session data must be maintained across a server restart or when the user's session data is too valuable to lose through an unexpected server failure.

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the Web site grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Distributed environment settings

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page at the Web container level, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings**.

Note that the distributed environment settings can be overridden at the application level.

Distributed sessions:

Specifies the type of distributed environment to be used for saving sessions.

None	Specifies that the session management facility discards the session data when the server shuts down.
Database	Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click **Database** to change these data source settings.

Memory-to-memory replication	Specifies that the session management facility stores the session information in a data source in memory. The session information is copied to other session management facilities for failure recovery. Click **Memory-to-memory replication** to change these data source settings.

Memory-to-memory replication

Memory-to-memory session replication is the session replication to another WebSphere Application Server. In this mode, sessions can replicate to one or more Application Servers to address HTTP Session single point of failure (SPOF).

The WebSphere Application Server instance in which the session is currently processed is referred to as the *owner of the session*. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. In a peer-to-peer cluster, the hot failover feature causes the plug-in to failover to a server that already contains the backup copy of the session, avoiding the overhead of session retrieval from another server containing the backup. In a client/server cluster, the server retrieves the session from a server that has the backup copy of the session. The server now becomes the owner of the session and affinity is now maintained to this server.

There are three possible modes to run in:
- **Server mode:** Only store backup copies of other WebSphere Application Server sessions and not to send out copies of any session created in that particular server
- **Client mode:** Only broadcast or send out copies of the sessions it owns and not to receive backup copies of sessions from other servers
- **Both mode:** Simultaneously broadcast or send out copies of the sessions it owns and act as a backup table for sessions owned by other WebSphere Application Server instances.

You can select the replication mode of server, client, or both when configuring the session management facility for memory-to-memory replication. The default is both. This storage option is controlled by the mode parameter.

The memory-to-memory replication function is accomplished by the creation of a data replication service instance in an application server that talks to other data replication service instances in remote application servers. You must configure this data replication service instance as a part of a replication domain. Data replication service instances on disparate application servers that replicate to one another must be configured as a part of the same domain. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. For example, a server only data replication service instance and a both client and server data replication service instance cannot exist in the same replication domain. Multiple data replication service instances that exist on the same application server due to session manager memory-to-memory configuration at various levels that are configured to be part of the same domain must have the same mode.

With respect to mode, the following are the primary examples of memory-to-memory replication configuration:
- Peer-to-peer replication
- Client/server replication

Although the administrative console allows flexibility and additional possibilities for memory-to-memory replication configuration, only the configurations provided above are officially supported.

There is a single replica in a cluster by default. You can modify the number of replicas through the replication domain.

HTTP session replication in the controller

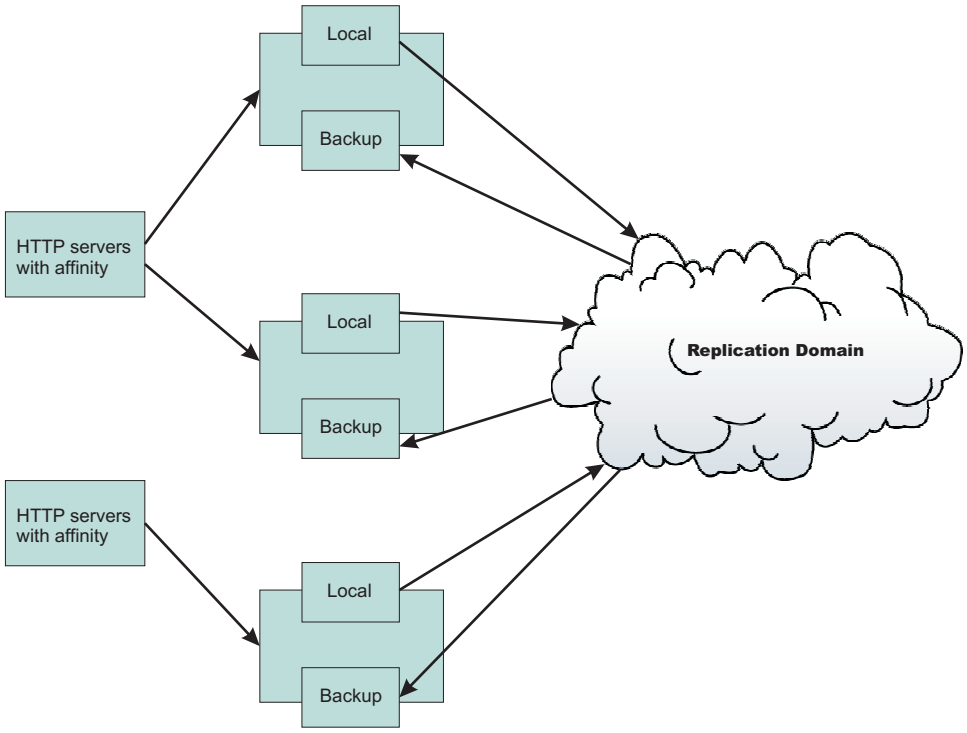
WebSphere Application Servers on z/OS that are enabled for HTTP session memory-to-memory replication can store replicated HTTP session data in the controller and replicate data to other WebSphere Application Servers. HTTP session data that is stored in a controller is retrievable by any of the servants of that controller. HTTP session affinity is still associated to a particular servant; however, if that servant should fail, any of the other servants can retrieve the HTTP session data stored in the controller and establish a new affinity.

The capability of storing HTTP sessions in the controller can also be enabled in unmanaged application servers on z/OS. When this capability is enabled, servants store the HTTP session data in the controller for retrieval when a servant fails which is similar to managed servers. HTTP session data stored in the controller of an unmanaged application server is not retrievable by other application servers and is not replicated to other application servers.

The capability to store HTTP session data in the controller in an unmanaged application server is enabled by setting the JVM custom property HttpSessionEnableUnmanagedServerReplication to true. You can set this property at **Servers > Application servers >** *server_name*. Then, under Server Infrastructure, click **Java and Process Management > Process Definition > Servant > Java Virtual Machine > Custom Properties**.

Memory-to-memory topology: Peer-to-peer function

The basic peer-to-peer (both client and server function, or both mode) topology is the default configuration and has a single replica. However, you can also add additional replicas by configuring the replication domain.



In this basic peer-to-peer topology, each server Java Virtual Machine (JVM) can:

- Host the Web application leveraging the HTTP session
- Send out changes to the HTTP session that it owns
- Receive backup copies of the HTTP session from all of the other servers in the cluster

This configuration represents the most consolidated topology, where the various system parts are collocated and requires the fewest server processes. When using this configuration, the most stable implementation is achieved when each node has equal capabilities (CPU, memory, and so on), and each handles the same amount of work.

It is also important to note that when using the peer-to-peer topology, that one session replication backup must run at all times for invalidation to occur. For example, if you have a cluster of 2 application servers, server1 and server2, that are both configured in the peer-to-peer mode and server2 goes down. All of backup information for server1 is lost and those sessions are no longer invalidated properly.

Session hot failover

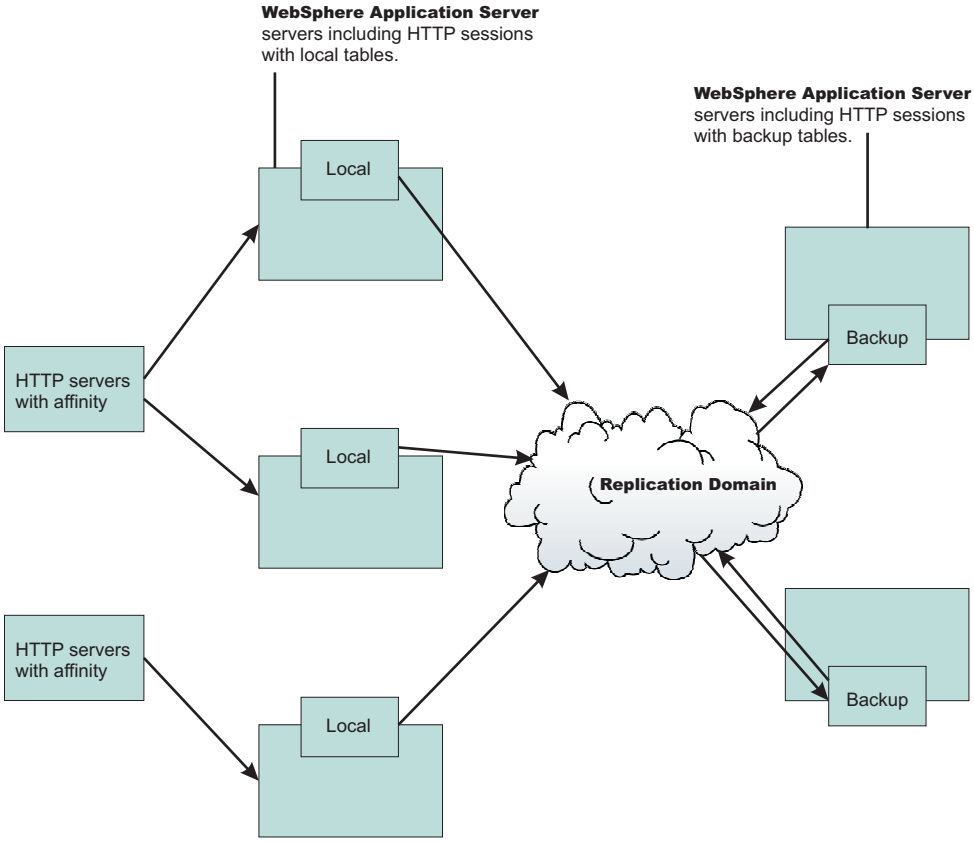
A new feature called session hot failover has been added to this release. This feature is only applicable to the peer-to-peer mode. In a clustered environment, session affinity in the WebSphere Application Server plug-in routes the requests for a given session to the same server. If the current owner server instance of the session fails, then the WebSphere Application Server plug-in routes the requests to another appropriate server in the cluster. For a cluster configured to run in the peer-to-peer mode this feature causes the plug-in to failover to a server that already contains the backup copy of the session, therefore avoiding the overhead of session retrieval from another server containing the backup. However, hot failover is specifically for servant region failures. When an entire server, meaning both controller and server fail, sessions may have to be retrieved over the network.

You must upgrade all WebSphere Application Server plug-in instances that front the Application Server cluster to version 6.0 to ensure session affinity when using the peer-to-peer mode.

Memory-to-memory topology: Client/server function

The client/server configuration, used to attain session affinity, consists of a cluster of servers that are configured as client only and server only. Using the client/server configuration has benefits such as isolating the handling of backup data from local data, recycling backup servers without affecting the servers running the application, and removing the need for a one-to-one correspondence between servers to attain session affinity.

The following figure depicts the client/server mode. There is a tier of applications servers that host Web applications using HTTP sessions, and these sessions are replicated out as they are created and updated. There is a second tier of servers without a Web application installed, where the session manager receives updates from the replication clients.



Benefits of the client/server configuration include:

Isolation for failure recovery

In this case we are isolating the handling of backup data from local data; aside from isolating the moving parts in case of a catastrophic failure in one of them, you again free up memory and processing in the servers processing the Web application.

Isolation for stopping and starting

You can recycle a backup server without affecting the servers running the application (when there are two or more backups, failure recovery is possible), and conversely recycle an application JVM without potentially losing that backup data for someone.

Consolidation

There is most likely no need to have a one-to-one correspondence between servers handling backups and those processing the applications; hence, you are again reducing the number of places to which you transfer the data.

Disparate hardware:

While you run your Web applications on cheaper hardware, you may have one or two more powerful computers in the back end of your enterprise that have the capacity to run a couple of session managers in replication server mode; allowing you to free up your cheaper Web application hardware to process the Web application.

Timing consideration: Start the backup application servers first to avoid unexpected timing windows. The clients attempt to replicate information and HTTP sessions to the backup servers as soon as they come up. As a result, HTTP sessions that are created prior to the time at which the servers come up might not replicate successfully.

Memory-to-memory session partitioning

Session partitioning gives the administrator the ability to filter or reduce the number of destinations that the session object gets sent to by the replication service. You can also configure session partitioning by specifying the number of replicas on the replication domain. The Single replica option is chosen by default. Since the number of replicas is global for the entire replication domain, all the session managers connected to the replication domain use the same setting.

Single replica

You can replicate a session to only one other server, creating a single replica. When this option is chosen, a session manager picks another session manager that is connected to the same replication domain to replicate the HTTP session to during session creation. All updates to the session are only replicated to that single server. This option is set at the replication domain level. When this option is set, every session manager connected to this replication domain creates a single backup copy of HTTP session state information on a backup server.

Full group replica

Each object is replicated to every application server that is configured as a consumer of the replication domain. However, in the peer-to-peer mode, this topology is the most redundant because everyone replicates to everyone and as you add servers, more overhead (both CPU and memory) is needed to deal with replication. This mode is most useful for dynamic caching replication. Redundancy does not affect the client/server mode because clients only replicate to servers that are set to server mode.

Specific number of replicas

You can specify a specific number of replicas for any entry that is created in the replication domain. The number of replicas is the number of application servers that the user wants to use to replicate in the domain. This option eliminates redundancy that occurs in a full group replica and also provides additional backup than a single replica. In peer-to-peer mode, the number of replicas cannot exceed the total number of application servers in the cluster. In the client/server mode, the number of replicas cannot exceed the total number of application servers in the cluster that are set to server mode.

Clustered session support

A clustered environment supports load balancing, where the workload is distributed among the application servers that compose the cluster.

In a cluster environment, the same Web application must exist on each of the servers that can access the session. You can accomplish this setup by installing an application onto a cluster definition. Each of the servers in the group can then access the Web application

In a clustered environment, the session management facility requires an affinity mechanism so that all requests for a particular session are directed to the same application server instance in the cluster. This requirement conforms to the Servlet 2.3 specification in that multiple requests for a session cannot coexist in multiple application servers. One such solution provided by IBM WebSphere Application Server is *session affinity* in a cluster; this solution is available as part of the WebSphere Application Server plug-ins

for Web servers. It also provides for better performance because the sessions are cached in memory. In clustered environments other than WebSphere Application Server clusters, you must use an affinity mechanism (for example, IBM WebSphere Edge Server affinity).

If one of the servers in the cluster fails, it is possible for the request to reroute to another server in the cluster. If distributed sessions support is enabled, the new server can access session data from the database or another WebSphere Application Server instance. You can retrieve the session data only if a new server has access to an external location from which it can retrieve the session.

Session management tuning

WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

The following table summarizes the features, including whether they apply to sessions tracked in memory, in a database, with memory-to-memory replication, or all. Some features are easily manipulated using administrative settings; others require code or database changes.

Feature or option	Goal	Applies to sessions in memory, database, or memory-to-memory
Write frequency	Minimize database write operations.	Database and Memory-to-Memory
Session affinity	Access the session in the same application server instance.	All
Multirow schema	Fully utilize database capacities.	Database
Base in-memory session pool size	Fully utilize system capacity without overburdening system.	All
Write contents	Allow flexibility in determining what session data to write	Database and Memory-to-Memory
Scheduled invalidation	Minimize contention between session requests and invalidation of sessions by the Session Management facility. Minimize write operations to database for updates to last access time only.	Database and Memory-to-Memory
Tablespace and row size	Increase efficiency of write operations to database.	Database (DB2® only)

HTTP sessions: Resources for learning

Use the following links to find relevant supplemental information about HTTP sessions. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks® that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Scheduled invalidation
Instead of relying on the periodic invalidation timer that runs on an interval based on the session timeout parameter, you can set specific times for the session management facility to scan for invalidated sessions in a distributed environment.

When used with distributed sessions, this feature has the following benefits:
- You can schedule the scan for invalidated sessions for times of low application server activity, avoiding contention between invalidation scans of database or another WebSphere Application Server instance and read and write operations to service HTTP session requests.
- Significantly fewer external write operations can occur when running with the End of Service Method Write mode because the last access time of the session does not need to be written out on each HTTP request. (Manual Update options and Time Based Write options already minimize the writing of the last access time.)

Usage considerations
- The session manager invalidates sessions only at the scheduled time, therefore sessions are available to an application if they are requested before the session is invalidated.
- With scheduled invalidation configured, HttpSession timeouts are not strictly enforced. Instead, all invalidation processing is handled at the configured invalidation times.
- HttpSessionBindingListener processing is handled at the configured invalidation times unless the HttpSession.invalidate method is explicitly called.
- The HttpSession.invalidate method immediately invalidates the session from both the session cache and the external store.
- The periodic invalidation thread still runs with scheduled invalidation. If the current hour of the day does not match one of the configured hours, sessions that have exceeded the invalidation interval are removed from cache, but not from the external store. Another request for that session results in returning that session back into the cache.
- When the periodic invalidation thread runs during one of the configured hours, all sessions that have exceeded the invalidation interval are invalidated by removal from both the cache and the external store.
- The periodic invalidation thread can run more than once during an hour and does not necessarily run exactly at the top of the hour.
- If you specify the interval for the periodic invalidation thread using the HttpSessionReaperPollInterval custom property, do not specify a value of more than 3600 seconds (1 hour) to ensure that invalidation processing happens at least once during each hour.

Base in-memory session pool size
The base in-memory session pool size number depends on the session support configuration.
- With in-memory sessions, session access is optimized for up to this number of sessions.
- With distributed sessions, when sessions are stored in a database or in another WebSphere Application Server instance,; the pool size also specifies the cache size and the number of last access time updates saved in manual update mode.

For distributed sessions, when the session cache has reached its maximum size and a new session is requested, the Session Management facility removes the least recently used session from the cache to make room for the new one.

General memory requirements for the hardware system, and the usage characteristics of the e-business site, determines the optimum value.

Note that increasing the base in-memory session pool size can necessitate increasing the heap sizes of the Java processes for the corresponding WebSphere Application Servers.

Overflow in non-distributed sessions

By default, the number of sessions maintained in memory is specified by base in-memory session pool size. If you do not wish to place a limit on the number of sessions maintained in memory and allow overflow, set overflow to *true*.

Allowing an unlimited amount of sessions can potentially exhaust system memory and even allow for system sabotage. Someone could write a malicious program that continually hits your site and creates sessions, but ignores any cookies or encoded URLs and never utilizes the same session from one HTTP request to the next.

When overflow is disallowed, the Session Management facility still returns a session with the HttpServletRequest getSession(true) method when the memory limit is reached, and this is an invalid session that is not saved.

With the WebSphere Application Server extension to HttpSession, com.ibm.websphere.servlet.session.IBMSession, an isOverflow method returns *true* if the session is such an invalid session. An application can check this status and react accordingly.

HTTP session invalidation

HTTP sessions are invalidated by calling the invalidate method on the session object or by specifying a specific time interval using the MaxInactiveInterval property.

Sessions that are invalidated explicitly by application code are invalidated immediately. Sessions that are not invalidated by application code are invalidated by the session manager. Session invalidation occurs regardless of session persistence configuration.

A session is a candidate for invalidation if it has not been accessed for a period that is longer than the specified session timeout, specified by the MaxInactiveInterval value. The session manager has an invalidation process thread that runs every X seconds to invalidate sessions that are eligible for invalidation.

The session manager uses a formula to determine the value of X, specified by the ReaperInterval property. The value of X is calculated based on the MaxInactiveInterval value that is specified in the session manager.

For example, for a maximum inactive interval less than 15 minutes, the ReaperInterval value is approximately 60 to 90 seconds. For a maximum inactive interval greater than 15 minutes, the ReaperInterval value is approximately 300 to 360 seconds.

A session is invalidated when the MaxInactiveInterval is exceeded and the ReaperInterval passes. After a session is eligible for invalidation, the invalidation thread must run for the session to be invalidated. Therefore, a session might not be invalidated for the sum of the MaxInactiveInterval and ReaperInterval value in seconds.

A session that has exceeded the MaxInactiveInterval but is not yet removed by the invalidation thread is still available for use. If that session is requested then it is returned to the client.

You can specify whether the session is invalidated immediately or after a specified time interval. For immediate invalidation the application should call the invalidate method. To invalidate a session at a specific time, you can set the ReaperInterval Web container custom property in seconds to specify the frequency of the invalidation thread.

Write operations

You can manually control when modified session data is written out to the database or to another WebSphere Application Server instance by using the sync method in the com.ibm.websphere.servlet.session.IBMSession interface. The manual update, end of service servlet and the time based write frequency modes are available to tune write frequency of session data.

This interface extends the javax.servlet.http.HttpSession interface. By calling the sync method from the service method of a servlet, you send any changes in the session to the external location. When manual update is selected as the write frequency mode, session data changes are written to an external location only if the application calls the sync method. If the sync method is not called, session data changes are lost when a session object leaves the server cache. When end of service servlet or time based is the write frequency mode, the session data changes are written out whenever the sync method is called. If the sync method is not called, changes are written out at the end of service method or on a time interval basis based on the write frequency mode that is selected.

```
IBMSession iSession = (IBMSession) request.getSession();
iSession.setAttribute("name", "Bob");

//force write to external store
iSession.sync( )
```

If the database is down or is having difficulty connecting during an update to session values, the sync method always makes three attempts before it finally creates a BackedHashtable.getConnectionError error. For each connection attempt that fails, the BackedHashtable.StaleConnectionException is created and can be found in the sync method. If the database opens during any of these three attempts, the session data in the memory is then persisted and committed to the database.

However, if the database is still not up after the three attempts, then the session data in the memory is persisted only after the next check for session invalidation. Session invalidation is checked by a separate thread that is triggered every five minutes. The data in memory is consistent unless a request for session data is issued to the server between these events. For example, if the request for session data is issued within five minutes, then the previous persisted session data is sent.

Sessions are not transactional resources. Because the sync method is associated with a separate thread than the client, the exception that is created does not propagate to the client, which is running on the primary thread. Transactional integrity of data can be maintained through resources such as enterprise beans.

Related reference

“Session management tuning” on page 20
WebSphere Application Server session support has features for tuning session performance and operating characteristics, particularly when sessions are configured in a distributed environment. These options support the administrator flexibility in determining the performance and failover characteristics for their environment.

Tuning parameter settings

Use this page to set tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings** → **Custom tuning parameters**.

Tuning level
Specifies that the session management facility provides certain predefined settings that affect performance.

Select one of these predefined settings or customize a setting. To customize a setting, select one of the predefined settings that comes closest to the setting desired, click **Custom settings**, make your changes, and then click **OK**.

Very high (optimize for performance)

Write frequency	Time based
Write interval	300 seconds
Write contents	Only updated attributes
Schedule sessions cleanup	true
First time of day default	0
Second time of day default	2

High

Write frequency	Time based
Write interval	300 seconds
Write contents	All session attributes
Schedule sessions cleanup	false

Medium

Write frequency	End of servlet service
Write contents	Only updated attributes
Schedule sessions cleanup	false

Low (optimize for failover)

Write frequency	End of servlet service
Write contents	All session attributes
Schedule sessions cleanup	false

Custom settings

Write frequency default	Time based
Write interval default	10 seconds
Write contents default	All session attributes
Schedule sessions cleanup default	false

Tuning parameter custom settings
Use this page to customize tuning parameters for distributed sessions.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Session management** → **Distributed environment settings** → **Custom tuning parameters** → **Custom settings**.

Write frequency
Specifies when the session is written to the persistent store.

End of servlet service
A session writes to a database or another WebSphere Application Server instance after the servlet completes execution.

Manual update
A programmatic sync on the IBMSession object is required to write the session data to the database or another WebSphere Application Server instance.

Time based
Session data writes to the database or another WebSphere Application Server instance based on the specified Write interval value. Default: 10 seconds

Write contents
Specifies whether updated attributes are only written to the external location or all of the session attributes are written to the external location, regardless of whether or not they changed. The external location can be either a database or another application server instance.

Only updated attributes
Only updated attributes are written to the persistent store.

All session attribute
All attributes are written to the persistent store.

Schedule sessions cleanup
Specifies when to clean the invalid sessions from a database or another application server instance.

Specify distributed sessions cleanup schedule
Enables the scheduled invalidation process for cleaning up the invalidated HTTP sessions from the external location. Enable this option to reduce the number of updates to a database or another application server instance required to keep the HTTP sessions alive. When this option is not enabled, the invalidator process runs every few minutes to remove invalidated HTTP sessions.

When this option is enabled, specify the two hours of a day for the process to clean up the invalidated sessions in the external location. Specify the times when there is the least activity in the application servers. An external location can be either a database or another application server instance.

First Time of Day (0 - 23)
Indicates the first hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Second Time of Day (0 - 23)
Indicates the second hour during which the invalidated sessions are cleared from the external location. Specify this value as a positive integer between 0 and 23. This value is valid only when schedule invalidation is enabled.

Best practices for using HTTP sessions
This topic presents best practices for the implementation of HTTP sessions.

Note: Browse the following recommendations for implementing HTTP sessions.

- **Enable Security integration for securing HTTP sessions**

  HTTP sessions are identified by session IDs. A session ID is a pseudo-random number generated at the runtime. Session hijacking is a known attack HTTP sessions and can be prevented if all the requests going over the network are enforced to be over a secure connection (meaning, HTTPS). But not every configuration in a customer environment enforces this constraint because of the performance impact of SSL connections. Due to this relaxed mode, HTTP session is vulnerable to hijacking and because of this vulnerability, WebSphere Application Server has the option to tightly integrate HTTP sessions and

WebSphere Application Server security. Enable security in WebSphere Application Server so that the sessions are protected in a manner that only users who created the sessions are allowed to access them.

- **Release HttpSession objects using `javax.servlet.http.HttpSession.invalidate()` when finished.**

  HttpSession objects live inside the Web container until:
  - The application explicitly and programmatically releases it using the javax.servlet.http.HttpSession.invalidate method; quite often, programmatic invalidation is part of an application logout function.
  - WebSphere Application Server destroys the allocated HttpSession when it expires (default = 1800 seconds or 30 minutes). The WebSphere Application Server can only maintain a certain number of HTTP sessions in memory based on session management settings. In case of distributed sessions, when maximum cache limit is reached in memory, the session management facility removes the least recently used (LRU) one from cache to make room for a session.

  .
- **Avoid trying to save and reuse the HttpSession object outside of each servlet or JSP file.**

  The HttpSession object is a function of the HttpRequest (you can get it only through the req.getSession method), and a copy of it is valid only for the life of the service method of the servlet or JSP file. You *cannot* cache the HttpSession object and refer to it outside the scope of a servlet or JSP file.
- **Implement the java.io.Serializable interface when developing new objects to be stored in the HTTP session.**

  Serializability of a class is enabled by the class implementing the java.io.Serializable interface. Implementing the java.io.Serializable interface allows the object to properly serialize when using distributed sessions. Classes that do not implement this interface will not have their states serialized or deserialized. Therefore, if a class does not implement the Serializable interface, the JVM cannot persist its state into a database or into another JVM. All subtypes of a serializable class are serializable. An example of this follows:

  ```
  public class MyObject implements java.io.Serializable {...}
  ```

  Make sure all instance variable objects that are not marked transient are serializable. You cannot cache a non-serializable object.

  In compliance with the Java Servlet specification, the distributed servlet container must create an IllegalArgumentException for objects when the container cannot support the mechanism necessary for migration of the session storing them. An exception is created only when you have selected distributable.
- **The HTTPSession API does not dictate transactional behavior for sessions.**

  Distributed HTTPSession support does not guarantee transactional integrity of an attribute in a failover scenario or when session affinity is broken. Use transactional aware resources like enterprise Java beans to guarantee the transaction integrity required by your application.
- **Ensure the Java objects you add to a session are in the correct class path.**

  If you add Java objects to a session, place the class files for those objects in the correct class path (the application class path if utilizing sharing across Web modules in an enterprise application, or the Web module class path if using the Servlet 2.2-complaint session sharing) or in the directory containing other servlets used in WebSphere Application Server. In the case of session clustering, this action applies to every node in the cluster.

  Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.
- **Avoid storing large object graphs in the HttpSession object.**

  In most applications each servlet only requires a fraction of the total session data. However, by storing the data in the HttpSession object as one large object, an application forces WebSphere Application Server to process all of it each time.
- **Utilize Session Affinity to help achieve higher cache hits in the WebSphere Application Server.**

  WebSphere Application Server has functionality in the HTTP Server plug-in to help with session affinity. The plug-in reads the cookie data (or encoded URL) from the browser and helps direct the request to

the appropriate application or clone based on the assigned session key. This functionality increases use of the in-memory cache and reduces hits to the database or another WebSphere Application Server instance

- **Maximize use of session affinity and avoid breaking affinity.**

  Using session affinity properly can enhance the performance of the WebSphere Application Server. Session affinity in the WebSphere Application Server environment is a way to maximize the in-memory cache of session objects and reduce the amount of reads to the database or another WebSphere Application Server instance. Session affinity works by caching the session objects in the server instance of the application with which a user is interacting. If the application is deployed in multiple servers of a server group, the application can direct the user to any one of the servers. If the users starts on server1 and then comes in on server2 a little later, the server must write all of the session information to the external location so that the server instance in which server2 is running can read the database. You can avoid this database read using session affinity. With session affinity, the user starts on server1 for the first request; then for every successive request, the user is directed back to server1. Server1 has to look only at the cache to get the session information; server1 never has to make a call to the session database to get the information.

  You can improve performance by not breaking session affinity. Some suggestions to help avoid breaking session affinity are:
  - Combine all Web applications into a single application server instance, if possible, and use modeling or cloning to provide failover support.
  - Create the session for the frame page, but do not create sessions for the pages within the frame when using multi-frame JSP files. (See discussion later in this topic.)
- **When using multi-framed pages, follow these guidelines:**
  - Create a session in only one frame or before accessing any frame sets. For example, assuming there is no session already associated with the browser and a user accesses a multi-framed JSP file, the browser issues concurrent requests for the JSP files. Because the requests are not part of any session, the JSP files end up creating multiple sessions and all of the cookies are sent back to the browser. The browser honors only the last cookie that arrives. Therefore, only the client can retrieve the session associated with the last cookie. Creating a session before accessing multi-framed pages that utilize JSP files is recommended.
  - By default, JSP files get a HTTPSession using `request.getSession(true)` method. So by default JSP files create a new session if none exists for the client. Each JSP page in the browser is requesting a new session, but only one session is used per browser instance. A developer can use `<% @ page session="false" %>` to turn off the automatic session creation from the JSP files that do not access the session. Then if the page needs access to the session information, the developer can use `<%HttpSession session = javax.servlet.http.HttpServletRequest.getSession(false); %>` to get the already existing session that was created by the original session creating JSP file. This action helps prevent breaking session affinity on the initial loading of the frame pages.
  - Update session data using only one frame. When using framesets, requests come into the HTTP server concurrently. Modifying session data within only one frame so that session changes are not overwritten by session changes in concurrent frameset is recommended.
  - Avoid using multi-framed JSP files where the frames point to different Web applications. This action results in losing the session created by another Web application because the JSESSIONID cookie from the first Web application gets overwritten by the JSESSIONID created by the second Web application.
- **Secure all of the pages (not just some) when applying security to servlets or JSP files that use sessions with security integration enabled, .**

  When it comes to security and sessions, it is all or nothing. It does not make sense to protect access to session state only part of the time. When security integration is enabled in the session management facility, all resources from which a session is created or accessed must be either secured or unsecured. You cannot mix secured and unsecured resources.

  The problem with securing only a couple of pages is that sessions created in secured pages are created under the identity of the authenticated user. Only the same user can access sessions in other secured pages. To protect these sessions from use by unauthorized users, you cannot access these

sessions from an unsecured page. When a request from an unsecured page occurs, access is denied and an `UnauthorizedSessionRequestException` error is created. (`UnauthorizedSessionRequestException` is a runtime exception; it is logged for you.)

- **Use manual update and either the sync() method or time-based write in applications that read session data, and update infrequently.**

  With END_OF_SERVICE as write frequency, when an application uses sessions and anytime data is read from or written to that session, the LastAccess time field updates. If database sessions are used, a new write to the database is produced. This activity is a performance hit that you can avoid using the Manual Update option and having the record written back to the database only when data values update, not on every read or write of the record.

  To use manual update, turn it on in the session management service. (See the tables above for location information.) Additionally, the application code must use the `com.ibm.websphere.servlet.session.IBMSession` class instead of the generic HttpSession. Within the IBMSession object there is a sync method. This method tells the WebSphere Application Server to write the data in the session object to the database. This activity helps the developer to improve overall performance by having the session information persist only when necessary.

  Note: An alternative to using the manual updates is to utilize the timed updates to persist data at different time intervals. This action provides similar results as the manual update scheme.
- Implement the following suggestions to achieve high performance:
  - If your applications do not change the session data frequently, use Manual Update and the sync function (or timed interval update) to efficiently persist session information.
  - Keep the amount of data stored in the session as small as possible. With the ease of using sessions to hold data, sometimes too much data is stored in the session objects. Determine a proper balance of data storage and performance to effectively use sessions.
  - If using database sessions, use a dedicated database for the session database. Avoid using the application database. This helps to avoid contention for JDBC connections and allows for better database performance.
  - If using memory-to-memory sessions, employ partitioning (either group or single replica) as your clusters grow in size and scaling decreases.
  - Verify that you have the latest fix packs for the WebSphere Application Server.
- Utilize the following tools to help monitor session performance.
  - Run the com.ibm.servlet.personalization.sessiontracking.IBMTrackerDebug servlet. - To run this servlet, you must have the servlet invoker running in the Web application you want to run this from. Or, you can explicitly configure this servlet in the application you want to run.
  - Use the WebSphere Application Server Resource Analyzer which comes with WebSphere Application Server to monitor active sessions and statistics for the WebSphere Application Server environment.
  - Use database tracking tools such as ″Monitoring″ in DB2. (See the respective documentation for the database system used.)

HTTP session manager troubleshooting tips

This article provides troubleshooting tips for problems creating or using HTTP sessions with your Web application hosted by WebSphere Application Server.

Here are some steps to take:

- View the logs for the application server which hosts the problem application:
  - first, look at messages written while each application is starting. They will be written between the following two messages:

    ```
    Starting application: application
    ......................
    Application started: application
    ```
  - Within this block, look for any errors or exceptions containing a package name of com.ibm.ws.webcontainer.httpsession. If none are found, this is an indication that the session manager started successfully.

  - Error ″**SRVE0054E: An error occurred while loading session context and Web application**″ indicates that SessionManager didn't start properly for a given application.
  - Look within the logs for any Session Manager related messages. These messages will be in the format SESNxxxxE and SESNxxxxW for errors and warnings, respectively, where xxxx is a number identifying the precise error. Look up the extended error definitions in the Session Manager message table.
- See the Best practices for using HTTP Sessions section in the *Developing and deploying applications* PDF books for more details.
- Alternatively, a special servlet can be invoked that displays the current configuration and statistics related to session tracking.
  - Servlet name: **com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - It can be invoked from any Web module which is enabled to serve by class name. For example, using default_app, **http://localhost:9080/servlet/com.ibm.ws.webcontainer.httpsession.IBMTrackerDebug**.
  - If you are viewing the module via the serve-by-class-name feature, be aware that it may be viewable by anyone who can view the application. You may wish to map a specific, secured URL to the servlet instead and disable the serve-servlets-by-classname feature.
- If you are using **database-based persistent sessions**, look for problems related to the **data source** the Session Manager relies on to keep session state information. For details on diagnosing database related problems see the Errors accessing a datasource or connection pool in the *Administering applications and their environment* PDF book

Error message `SRVE0079E Servlet host not found` after you define a port

Error message SRVE0079E can occur after you define the port in WebContainer > HTTP Transports for a server, indicating that you do not have the port defined in your virtual host definitions. To define the port,

1. On the administrative console, go to Environment > Virtual Hosts > default_host> Host Aliases> New
2. Define the new port on host ″*″

The application server gets EC3 - 04130007 ABENDs

To prevent an EC3 - 04130007 abend from occuring on the application server, change the HTTP Output timeout value. The custom property *ConnectionResponseTimeout* specifies the maximum number of seconds the HTTP port for an individual server can wait when trying to read or write data. For instructions on how to set *ConnectionResponseTimeout*, see HTTP transport custom properties section of the *Administering applications and their environment* PDF book.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, technotes, and fixes). If you don't find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

HTTP session problems

This article provides troubleshooting information related to creating or using Hypertext Transfer Protocol (HTTP) sessions.

To view and update the session manager settings discussed here, use the administrative console. Select the application server that hosts the problem application, then under **Additional properties**, select **Web Container**, then **Session manager**.

What kind of problem are you having?
- HTTP Sessions are not getting created, or are lost between requests.
- HTTP Sessions are not persistent (session data lost when application server restarts, or not shared across cluster).
- Session is shared across multiple browsers on same client machine.
- Session is not getting invalidated immediately after specified session timeout interval.
- Unwanted sessions are being created by JavaServer Pages.
- Session data intended for one client is seen by another client.
- A ClassCastException error occurs during failover of a session that contains an Enterprise JavaBeans™ (EJB) reference.
- Users are not logged out after HTTP session timer expires

HTTP sessions are not getting created, or are lost between requests

By default, the session manager uses cookies to store the session ID on the client between requests. Unless you intend to avoid cookie-based session tracking, ensure that cookies are flowing between WebSphere Application Server and the browser:
- Make sure the **Enable cookies** check box is checked under the **Session tracking Mechanism** property.
- Make sure cookies are enabled on the browser you are testing from or from which your users are accessing the application.
- Check the Cookie domain specified on the SessionManager (to view the or update the cookie settings, in the **Session tracking mechanism->enable cookies** property, click **Modify**).
  - For example, if the cookie domain is set as ″.myCom.com″, resources should be accessed using that domain name. Example: http://www.myCom.com/myapp/servlet/sessionservlet.
  - If the domain property is set, make sure it begins with a dot (.). Certain versions of Netscape do not accept cookies if domain name doesn't start with a dot. Internet Explorer honors the domain with or without a dot. For example, if the domain name is set to *mycom.com*, change it to *.mycom.com* so that both Netscape and Internet Explorer honor the cookie.

    Note: When the servers are on different hosts, ensure that session cookies flow to all the servers by configuring a front-end router such as a Web server with the plug-in or setting the Cookie domain.
- Check the **Cookie path** specified on the SessionManager. Check whether the problem URL is hierarchically below the Cookie path specified. If not correct the Cookie path.
- If the `Cookie maximum age` property is set, ensure that the client (browser) machine's date and time is the same as the server's, including the time zone. If the client and the server time difference is over the ″Cookie maximum age″ then every access would be a new session, since the cookie expires after the access.
- If you have multiple Web modules within an enterprise application that track sessions:
  - If you want to have different session settings among Web modules in an enterprise application, ensure that each Web module specifies a different cookie name or path, or
  - If Web modules within an enterprise application use a common cookie name and path, ensure that the HTTP session settings, such as Cookie maximum age, are the same for all Web modules. Otherwise cookie behavior is unpredictable, and depends upon which application creates the session. Note that this does not affect session data, which is maintained separately by Web module.
- Check the cookie flow between browser and server:
  1. On the browser, enable ″cookie prompt″. Hit the servlet and make sure cookie is being prompted.
  2. Access the session servlet from the browser.
  3. The browser prompts for the cookie; note the jsessionid.
  4. Reload the servlet, note down the cookie if a new cookie is sent.
  5. Check the session trace and look for the session ID and trace the request by the thread. Verify that the session is stable across Web requests:
     - Look for **getIHttpsession(...)** which is start of session request.
     - Look for **releaseSession(..)** which is end of servlet request.
- If you are using URL rewriting instead of cookies:

  – Ensure there are no static HTML pages on your application's navigation path.
•

  Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting.

  If you are using SSL as your session tracking mechanism:
  – Ensure that you have SSL enabled on your IBM HTTP Server or iPlanet HTTP server.
- If you are in a clustered (multiple node) environment, ensure that you have session persistence enabled.

HTTP Sessions are not persistent

If your HTTP sessions are not persistent, that is session data is lost when the application server restarts or is not shared across the cluster:
- Check the data source.
- Check the session manager's persistence settings properties:
  – If you intend to take advantage of session persistence, verify that Persistence is set to **Database**.
  – If you are using **Database-based persistence**:
    - Check the JNDI name of the data source specified correctly on SessionManager.
    - Specify correct userid and password for accessing the database.

      Note that these settings have to be checked against the properties of an existing data source in the administrative console. The session manager does not automatically create a session database for you.
    - The data source should be non-JTA, for example, non XA enabled.
    - Check the logs for appropriate database error messages.
    - With DB2, for row sizes other than 4k make sure specified row size matches the DB2 page size. Make sure tablespace name is specified correctly.
  – If you are using **memory-based persistence** (available only in a network deployment environment):
    - Review the Memory-to-memory replication section of the *Developing and deploying applications* PDF book.
    - Review the **Internal Replication Domains properties** of your session manager.

Session is shared across multiple browsers on same client machine

This behavior is browser-dependent. It varies between browser vendors, and also may change according to whether a browser is launched as a new process or as a subprocess of an existing browser session (for example by hitting Ctl-N on Windows®).

The Cookie maximum age property of the session manager also affects this behavior, if cookies are used as the session-tracking mechanism. If the maximum age is set to some positive value, all browser instances share the cookies, which are persisted to file on the client for the specified maximum age time.

Session is not getting invalidated immediately after specified session timeout interval

The SessionManager invalidation process thread runs every *x* seconds to invalidate any invalid sessions, where x is determined based on the session timeout interval specified in the session manager properties. For the default value of 30 minutes , *x* is around 300 seconds. In this case, it could take up to 5 minutes (300 seconds) beyond the timeout threshold of 30 minutes for a particular session to become invalidated.

Unwanted sessions are being created by JavaServer Pages

As required by the JavaServer Pages (JSP) specification, JSP pages by default perform a request.getSession(true), so that a session is created if none exists for the client. To prevent JSP pages from creating a new session, set the session scope to **false** in the .jsp file using the page directive as follows:

```
<% @page session="false" %>
```

Users are not logged out after the HTTP session timer expires

If users of WebSphere Application Server log onto an application and sit idle longer than the specified HTTP session timeout value, the user information is not invalidated and user credentials stay active until LTPA token timeout occurs.

After you apply PK25740, complete the following steps to log out users from the application after the HTTP session has expired.

1. In the administrative console, click **Security > Global security**.
2. Under Custom properties, click **New**.
3. In the Name field, enter com.ibm.ws.security.web.logoutOnHTTPSessionExpire.
4. In the Values field, enter true.
5. Click Apply and Save to save the changes to your configuration.
6. Resynchronize and restart the server.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/software/webservers/appserv/zos_os390/support/

Developing session management in servlets

About this task

This information, combined with the coding example SessionSample.java, provides a programming model for implementing sessions in your own servlets.

1. Get the HttpSession object.

   To obtain a session, use the getSession method of the javax.servlet.http.HttpServletRequest object in the Java Servlet 2.3 API.

   When you first obtain the HttpSession object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

   Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting

   Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

   In Step 1 of the code sample, the Boolean(create) is set to `true` so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to `true` and creates a session if one does not already exist for this user.)
2. Store and retrieve user-defined data in the session.

   After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.
4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a Web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that Web page during the session.
5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.
6. End the session. You can end a session:
   - Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
   - By coding the servlet to call the invalidate() method on the session object.

Example

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample  extends HttpServlet {
  public void doGet (HttpServletRequest request, HttpServletResponse response)
       throws ServletException, IOException {

   // Step 1: Get the Session object

      boolean create = true;
      HttpSession session = request.getSession(create);

   // Step 2: Get the session data value

      Integer ival = (Integer)
      session.getAttribute ("sessiontest.counter");
      if (ival == null) ival = new Integer (1);
      else ival = new Integer (ival.intValue () + 1);
      session.setAttribute ("sessiontest.counter", ival);

   // Step 3: Output the page

      response.setContentType("text/html");
      PrintWriter out = response.getWriter();
      out.println("<html>");
      out.println("<head><title>Session Tracking Test</title></head>");
      out.println("<body>");
      out.println("<h1>Session Tracking Test</h1>");
      out.println ("You have hit this page " + ival + " times" + "<br>");
      out.println ("Your " + request.getHeader("Cookie"));
      out.println("</body></html>");
   }
}
```

Assembling so that session data can be shared

By default, the Session Management facility supports session scoping by Web module in accordance with the Servlet 2.3 API specification. Only servlets in the same Web module can access the data associated with a particular session. However, you can use the IBMApplicationSession object or the IBM extension, shared session context, to share data outside of the Web module scope.

About this task

Note: The IBMApplicationSession object is the recommended method for sharing session attributes. The IBM extension, shared session context, is deprecated.

The IBMApplicationSession object is a parent session object that can be retrieved by a Web module's session and can share session attributes across all of the Web modules in a business-level application. The default scope of the business-level application is the enterprise application. The shared session context option extends the scope of the session attributes as well. Using the shared session context extension, there is only one session object for the entire business-level application or for the default enterprise application.

If you are using a shared session for a business-level application, then the class files for all objects placed in the session must exist in an isolated shared library and be common among all applications.

The benefit to using the IBMApplicationSession method is that each Web module can maintain its own session as well as have a reference to the shared session.

If you're migrating an application from a previous version of the product, the IBMApplicationSession method requires a change to the application logic of the application.

Restriction: To use a shared session, you must install all applications within a business-level application on a given server. You cannot split up the enterprise application by servers. For example, you cannot use this option when one enterprise application in "BLA1" is installed on one server and a second enterprise application also in "BLA1" is installed on a different server. In such split installations, applications might share session attributes across Web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different Web modules. It also severely restricts use of some Session Management features, like TIME_BASED_WRITES.

For enterprise applications on which this shared session context extension is enabled, the Session Management configuration on the Web module inside the enterprise application is ignored. Then Session Management configuration defined on enterprise application is used if Session Management is overwritten at the enterprise application level. Otherwise, the Session Management configuration on the Web container is used. If using multiple enterprise applications within a business-level application, the session management configuration must be common among all applications and Web modules within this business-level application.

Note: HttpSession listeners defined in all the Web modules inside the business-level application or enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Do the following to share session data across the business-level application.

1. Do the following to share session data using the IBMApplicationSession object within the application code.
   a. Retrieve the session object
      ```
      HttpSession session = request.getSession();
      ```
   b. Cast this object to an IBMSession object and call the getIBMApplicationSession method.
      ```
      IBMApplicationSession appSession = ((IBMSession)session).getIBMApplicationSession();
      ```

c. Use the appSession like a normal session object.

2. Do the following to share session data using the Shared session context extension.
   a. Start an assembly tool.
   b. In the assembly tool, right-click the application (EAR file) that you want to share and click **Open With > Deployment Descriptor Editor**.
   c. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under **WebSphere Extensions**. Make sure the class definition of attributes put into session are available to all Web modules in the enterprise application. The shared session context does not fully meet the requirements of the specifications.
   d. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Developing servlets with WebSphere Application Server extensions

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

1. Review the supported specifications.

   Create Java components, referring to the Servlet specifications from Sun Microsystems.

   The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the API documentation for the application server APIs in the `install_root\web\apidocs` directory for the default installation. All of the public Application Server APIs are located in the `com.ibm.websphere` packages, however, com.ibm.websphere.servlet package is specific to the product servlet APIs.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a Web module using assembly tools as a prerequisite to deploying the code to the application server.

Configuring page list servlet client configurations

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the Web applications archive (WAR) file by an assembly tool.

About this task

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

To configure and implement page lists:

1. To configure page list information, use the Add Markup Language entry dialog of an assembly tool. On the **Servlets** tab of a Web deployment descriptor editor, select a servlet and click **Add** under **WebSphere Extensions**.

2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

   The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:

   - `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`

     where the method arguments are:

     pageName
     A page name defined in the PageListServlet configuration

     request
     The HttpServletRequest object

     response
     The HttpServletResponse object

   - `callPage(String mlName, String pageName, HttpServletRequest request, HttpServletResponse response)`

     where the method arguments are:

     mlName A markup language type

     pageName
     A page name defined in the PageListServlet configuration

     request
     The HttpServletRequest object

     response
     The HttpServletResponse object

3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Extending PageListServlet

The following example shows how a servlet extends the PageListServlet class and determines the markup-language type required by the client. The servlet then uses the callPage method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
     /*
     * doGet -- Process incoming HTTP GET requests
     */
    public  void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException
    {
       // This is the name of the page to be called:
       String pageName = "Hello.page";

       // First check if the servlet was invoked with a queryString that contains
    // a markup-language value.
       // For example, if this is how the  servlet is invoked:
       //  http://localhost/servlets/HeloPervasive?mlname=VXML
       //  then use the following method:
       String mlname= getMLNameFromRequest(request);

        // If no markup language type is provided in the queryString,
        // then try to determine the client
        // Type from the request, and use the markup-language name configured in
        // the client_types.xml file.
        if (mlName == null)
        {
          mlName = getMLTypeFromRequest(request);
         }
         try
         {
```

```
            // Serve the request page.
            callPage(mlName, pageName, request, response);
           }
           catch (Exception e)
           {
             handleError(mlName, request, response, e);
            }
       }
}
```

Page lists

Page lists allow you to avoid hard-coding Uniform Resource Locators (URLs) in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following list of classes are deprecated:

- com.ibm.servlet.ClientList
- com.ibm.servlet.ClientListElement
- com.ibm.servlet.MLNotFoundException
- com.ibm.servlet.PageListServlet
- com.ibm.servlet.PageNotFoundException

WebSphere Application Server supplies the PageListServlet servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a Web module. This support allows you to access multiple URLs without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the PageListServlet servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the PageListServlet servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support

In addition to providing the page list mapping capability, the PageListServlet also provides *Client Type Detection* support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the PageListServlet, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the `callPage` method, which calls a JSP file based on the markup-language type of the request.

The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

client_types.xml

The client_types.xml file provides client type detection support for servlets extending PageListServlet. Using the configuration data in the client_types.xml file, servlets can determine the language type that calling clients require for the response.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 7.0 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the callPage method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the callPage method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
                  HttpServletResponse response)
```

where the arguments are:
- mlName - a markup language type
- pageName - a page name defined in the PageListServlet configuration
- request - the HttpServletRequest object
- response - the HttpServletResponse object

Review the Extending the PageListServlet code example in Extending the PageListServlet to see how the callPage method is invoked by a servlet.

In the example, the client type detection method, getMLTypeFromRequest(HttpServletRequestrequest), provided by the PageListServlet, inspects the HttpServletRequest object request headers, and searches for a match in the client_types.xml file.

The client type detection method does the following:
- Uses the input HttpServletRequest and the client_types.xml file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the <client-type> element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first <client-type> element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the PageListServlet configuration.

Location

The client_types.xml file is located in the *install_root*/properties directory.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  No
- If so, what triggers its update?

  This file is created and updated manually by users.
- How and when are the contents of this file used?

  Servlets that extending the PageListServlet servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
      <client-type>
      <description>IBM Speech Client</description>
      <markup-language>VXML</markup-language>
      <request-header>
           <name>user-agent</name>
           <value>IBM VoiceXML pre-release version 000303</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vxml</value>
      </request-header>
      </client-type>
      <client-type>
           <description>WML Browser</description>
           <markup-language>WML</markup-language>
      <request-header>
           <name>accept</name>
           <value>text/x-wap.wml</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vnd.wap.xml</value>
      </request-header>
    </client-type>
</clients>
```

autoRequestEncoding and autoResponseEncoding

Starting with WebSphere Application Server Version 5, the Web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 Specification or later. If programmers choose not to use the character encoding methods, they can specify the `autoRequestEncoding` and `autoResponseEncoding` extensions, which enable the application server to set the encoding values and content type.

The values of the `autoRequestEncoding` and `autoResponseEncoding` extensions are either `true` or `false`. The default value for both extensions is `false`. If the value is `false` for both `autoRequestEncoding` and `autoResponseEncoding`, then the request and response character encoding is set to the Servlet 2.3 Specification default, which is ISO-8859-1. Also, if the value is set to `false` for a response, the Web container cannot set a response content type. Different character encodings are possible if the client defines character encoding in the request header, or if the code includes the `setCharacterEncoding(String encoding)` method.

If the `autoRequestEncoding` value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the `setCharacterEncoding(String encoding)` method, the Web container tries to determine the correct character encoding for the request parameters and data.

Use an assembly tool to change the default values for the `autoRequestEncoding` and `autoResponseEncoding` extensions.

The Web container performs each step in the following list until a match is found:

- Looks at the character set (charset) in the *Content-Type* header.

- Attempts to map the servers locale to a character set using defined properties.
- Attempts to use the DEFAULT_CLIENT_ENCODING system property, if one is set.
- Uses the ISO-8859-1 character encoding as the default.

If the autoResponsetEncoding value is set to true, and the client did not specify character encoding in the request header, and the code does not include the setCharacterEncoding(String encoding) method, the Web container does the following:
- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

Initial parameters for servlets settings

Use this page to specify initial parameters that are passed to the init method of Web module servlet filters. You can specify initial parameter values for servlets in Web modules during or after installation of an application onto a WebSphere Application Server deployment target. The <param-value> values specified in <init-param> statements in the web.xml file of Web modules are used by default.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Init parameters for servlets**. This page is the same as the Init parameters for servlets in each Web module panel on the application installation and update wizards.

Module

Specifies the name of a module in the application that you are installing or that you are viewing after installation.

URI

Specifies the location of the module relative to the root of the application (EAR file).

Servlet

Specifies a unique name for the servlet within the application.

A *servlet* is a Java program that uses the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or Web module for deployment to an application server. Servlets run on a Java-enabled Web server and extend the capabilities of a Web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Name

Specifies the name of the initial parameter passed to the init method of the Web module servlet filter.

The following example servlet filter statement in a web.xml file specifies an initial parameter name of attribute:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Value

Specifies the value assigned to an initial parameter passed to the init method of the Web module servlet filter.

The following example servlet filter statement in a web.xml file specifies an initial parameter value of tests.Filter.DoFilter_Filter.SERVLET_MAPPED for the init parameter attribute:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Description
Specifies information on the initial parameter.

Servlet filtering
Servlet filtering provides a new type of object called a *filter* that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their life cycle is very similar.

Filters are handled in the following manner:

1. The Web container determines whether it needs to construct a `FilterChain` containing the `LoggingFilter` for the requested resource.

   The `FilterChain` begins with the invocation of the `LoggingFilter` and ends with the invocation of the requested resource.
2. If other filters need to go in the chain, the Web container places them after the`LoggingFilter` and before the requested resource.
3. The Web container then instantiates and initializes the `LoggingFilter` (if it was not done previously) and invokes its `doFilter(FilterConfig)` method to start the chain.
4. The `LoggingFilter` preprocesses the request and response objects and then invokes the filter chain `doFilter(ServletRequest, ServletResponse)` method.

   This method passes the processing to the next resource in the chain, the requested resource.
5. Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

Note: Java Specification 2.4 allows you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as REQUEST, FORWARD, INCLUDE, ERROR, instead of invoking filters with RequestDispatcher.

For example:

```
<filter-mapping>
<filter-name>Logging Filter</filter-name>
<url-pattern>/products/*</url-pattern>
<dispatcher>FORWARD</dispatcher>
<dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

This indicates that the filter should be applied to requests directly from the client as well as forward requests. Adding the INCLUDE and ERROR values also indicates that the filter should additionally be applied for included requests and `<error-page>` requests. If you do not specify any <dispatcher> elements, then the default is REQUEST.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the javax.servlet package:
- Filter interface - methods: doFilter, getFilterConfig, setFilterConfig
- FilterChain interface - methods: doFilter
- FilterConfig interface - methods: getFilterName, getInitParameter, getInitParameterNames, getServletContext

The following classes are defined as part of the javax.servlet.http package:
- HttpServletRequestWrapper - methods: See the Servlet 2.4 Specification
- HttpServletResponseWrapper - methods: See the Servlet 2.4 Specification

Application life cycle listeners and events

With application life cycle listeners and events, which are now part of the Servlet API, you can notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The life cycle listeners give the application developer greater control over interactions with ServletContext and HttpSession objects. Servlet context listeners manage resources at an application level. Session listeners manage resources that are associated with a series of requests from a single client. Listeners are available for life cycle events and for attribute modification events. The listener developer creates a class that implements the javax listener interface, corresponding to the listener functionality that you want.

At application startup time, the container uses *introspection* to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the contextInitialized method of your listener class is invoked, which creates the database connection for the servlets in your application to use if this context is for your application. All servlet context listeners are notified of context initialization before any servlet in the Web application is initialized.

When the servlet context is destroyed, your contextDestroyed method is invoked, which releases the database connection, if this context is for your application. You must destroy all servlets before any servlet context listeners are notified of context destruction.

Notifications to session listeners precede notifications to context listeners.

Listener classes for servlet context and session changes

The following methods are defined as part of the javax.servlet.ServletContextListener interface:
- void contextInitialized(ServletContextEvent)

  Notification that the Web application is ready to process requests. Place code in this method to see if the created context is for your Web application and if it is, allocate a database connection and store the connection in the servlet context.
- void contextDestroyed(ServletContextEvent)

  Notification that the servlet context is about to shut down. Place code in this method to see if the created context is for your Web application and if it is, close the database connection stored in the servlet context.

The following methods are defined as part of the `javax.servlet.ServletRequestListener` interface:
- `public void requestInitialized(ServletRequestEvent re)`
  - Notification that the request is about to come into scope

    A request is defined as coming into scope when it is about to enter the first filter in the filter chain that processes the request.
- `public void requestDestroyed(ServletRequestEvent re)`
  - Notification that the request is about to go out of scope

    A request is defined as going out of scope when it exits the last filter in its filter chain.

The following listener interfaces are defined as part of the javax.servlet package:
- ServletContextListener
- ServletContextAttributeListener

The following filter interface is defined as part of the javax.servlet package:
- FilterChain interface - methods: doFilter()

The following event classes are defined as part of the javax.servlet package:
- ServletContextEvent
- ServletContextAttributeEvent

The following interfaces are defined as part of the javax.servlet.http package:
- HttpSessionListener
- HttpSessionAttributeListener
- HttpSessionActivationListener

The following event class is defined as part of the javax.servlet.http package:
- HttpSessionEvent

Example: Creating a servlet context listener with com.ibm.websphere.DBConnectionListener.java

The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
     // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

     // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

Configuring JSP engine parameters

About this task

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the Administrative Console or through administrative scripting.

To add, change or delete JSP engine configuration parameters, complete the following steps:

1. Open the `WEB-INF/ibm-web-ext.xmi` file.

   JSP engine configuration parameters are stored in a web module's configuration directory or in a web modules's binaries directory in the `WEB-INF/ibm-web-ext.xmi` file. Open the `WEB-INF/ibm-web-ext.xmi` file from:

   - The configuration directory, as in the following example: `{WAS_ROOT}/profiles/`*`profilename`*`/config/cells/`*`cellname`*`/applications/`*`enterpriseappname`*`/ deployments/`*`deployedname`*`/`*`webmodulename`*
   - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: `{WAS_ROOT}/profiles/`*`profilename`*`/installedApps/`*`nodename`*`/`*`EnterpriseAppName`*`/`*`WebModuleName`*`/`
2. Edit the `WEB-INF/ibm-web-ext.xmi` file.
   - To add configuration parameters, use the following format: `xmi:id="JSPAttribute_6" name="parametername" value="parametervalue"/>`

- To delete configuration parameters, either delete the line from the file, or enclose the statement with <!-- --> tags.

3. Save the file.
4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the Web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a Web module. The batch compiler uses the JSP engine configuration parameters that you have set in the `ibm-web-ext.xmi` file, unless you specifically override them. The topic JSP engine configuration parameters″ identifies the parameters that affect the generated Java source.

Example

The following is a sample of the `WEB-INF/ibm-web-ext.xmi` file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<webappext:WebAppExtension xmi:version="2.0" xmlns:xmi=http://www.omg.org/XMI
   xmlns:webappext="webappext.xmi" xmlns:webapplication="webapplication.xmi" xmi:id="WebAppExtension_1"
   reloadInterval="9" reloadingEnabled="true" defaultErrorPage="error.jsp" additionalClassPath=""
   fileServingEnabled="true" directoryBrowsingEnabled="false" serveServletsByClassnameEnabled="true"
   autoRequestEncoding="true" autoResponseEncoding="false"
   <webApp href="WEB-INF/web.xml#WebApp_1"/>
   <jspAttributes xmi:id="JSPAttribute_1" name="useThreadTagPool" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_2" name="verbose" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_3" name="deprecation" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_4" name="reloadEnabled" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_5" name="reloadInterval" value="5"/>
   <jspAttributes xmi:id="JSPAttribute_6" name="keepgenerated" value="true"/>
   <!--<jspAttributes xmi:id="JSPAttribute_7" name="trackDependencies" value="true"/> -->

</webappext:WebAppExtension>
```

Note: The integer **n** in **JSPattribute_n** has to be unique within the file.

JSP engine

The WebSphere Application Server JavaServer Pages (JSP) engine is the implementation of the JavaServer Pages Specification.

WebSphere Application Server Version 7.0 supports the JSP 2.1 specification.

The JSP engine

- Validates JSP source, both classic and XML styles
- Translates JSP source to Java classes
- Compiles Java classes, reporting any errors
- Generates Java classes for any tag files that are used by the JSP
- Interfaces with the Web container to load JSP class files
- Supports JSP batch compilation, JSP compilation during application installation, and JSP compilation during the build process of customer applications, through an Ant task.
- Loads class files, and manage life-cycle (reloading, unloading as necessary)
- Supports debugging of JavaServer Pages files through support for JSR 45 (Debugging Support for Other Languages)

JSP engine configuration parameters

In WebSphere Application Server, you can configure the JavaServer Pages (JSP) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSP engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value. Some parameters affect the Java source that is generated for a JSP or tag file. These parameters are identified by the statement ″This parameter requires regeneration of Java source.″ This statement indicates that if the configuration parameter is modified, the new value for the parameter does not have any effect until the JSP files are retranslated and the Java sources are recompiled.

compileWithAssert

Specifies whether the generated Java classes should contain support for the Developer Kit, Java Technology Edition 1.4 Assertion facility. The effect of setting this parameter to true is that the –source 1.4 option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

classdebuginfo

Indicates whether the compiler includes debugging information in the generated class file. When you set this parameter to true, the –g option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

convertAttrValueToString

Specifies whether to convert start and end attributes of the repeat tag to strings before they are used. The default for this parameter is `false`. This parameter requires regeneration of Java source.

deprecation

Specifies whether the compiler generates deprecation warnings when compiling the generated Java source. When you set this parameter to true, the -deprecation option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

disableElCache

Set the com.ibm.wsspi.jsp.disableElCache Web container custom property to `true` to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator. The default for this parameter is `false`.

disableJspRuntimeCompilation

If this option is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. When this option is set to true, you can install an application without JSP source, but the application must have precompiled class files. There is a Web container custom property with the same name that is used to determine the behavior of all Web modules installed in a server. If both the Web container custom property and the JSP engine option are set, the JSP engine option takes precedence. The default for this parameter is `false`.

evalQuotedAndEscapedExpression

Set this option to true to handle escape characters and quotations properly when determining whether to evaluate an expression.

During the translation phase of a JSP compile, expressions are evaluated by the JSP engine. Characters, such as the escape character (\) or nested quotations, single or double, causes the JSP file translation to fail. For example, when you use functions that contain an expression such as

```
<input type="text" value="${fn:substring('1234567', 0,4)}"/>
```

Because of the double quote directly before the fn:substring statement, the JSP file fails to compile because the translator did not add the function mapper to the generated Java class. Also, if a dollar sign ($) was escaped using the backslash (\$), the translator still attempts to evaluate the expression instead of treating it as a literal string. To handle escape characters and quotations properly, you must set evalQuotedAndEscapedExpression to `true` in the ibm-web-ext.xmi file of the failing application.. An example entry follows:

```
<jspAttributes xmi:id="JSPAttribute_1"
name="evalQuotedAndEscapedExpression" value="true"/>
```

To apply this behavior globally across all Web applications, you can set the com.ibm.wsspi.jsp.evalQuotedAndEscapedExpression Web container custom property to true.

extendedDocumentRoot

To share a JSP file resource across Web application archives, specify a comma delimited list of directories or Java Archive (JAR) files or both as search paths to be used if the requested resource is not located in the public document tree of the Web application archive. If the request is a valid partial request for a welcome file, a 404 error is returned. If the JSP file is located inside a JAR file and reloadEnabled is true, the timestamp of the JAR file is used for isOutDated checks for recompile purposes. The default for this parameter is null.

ieClassID

Indicates the Java plug-in COM class ID for Internet Explorer.

The `<jsp:plugin>` tags use this value. The default classid is `clsid:8AD9C840-044E-11D1-B3E9-00805F499D93`

javaEncoding

Specifies the encoding that is used when the `.java` file is generated, and when it is compiled by the Java compiler. Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible. When javaEncoding is set, the encoding is passed to the Java compiler through the -encoding argument. Note that encoding is not supported by Jikes. The default is UTF-8. This parameter requires regeneration of Java source.

jdkSourceLevel

This is a new JSP engine parameter which was introduced in WebSphere Application Server version 6.1 to support JDK 5. This parameter should be used instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

The default value for this parameter is 13. This parameter requires regeneration of Java source. The following are jdkSourceLevel paramater values:

- **13 (default)** - This value will disable all new language features of JDK 1.4 and JDK 5.0.
- **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0.
- **15** - This value will enable the use of the assertion facility and all new language features of JDK 5.0.

jsp.file.extensions

For JSP files with extensions other than the four standard extensions, *.jsp, *.jspx, *.jsw, and *.jsv, you can configure this the extensions using this parameter. These extensions are added to the standard extensions.

The preferred method for doing this is to create a `<jsp-property-group>`in web.xml, and add a `<url-pattern>` tag for each extension.

The JSP engine can handle a list of file extensions that is separated by a colon or semi-colon. For example, *.ext1;*.ext2:*.extn

keepgenerated
Indicates that the Java files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `false`. This parameter requires regeneration of Java source.

keepGeneratedclassfiles
Indicates that the class files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `true`. This parameter requires regeneration of Java source.

modifyPageContextVariable
During the translation phase of a tag file that is compiled, the JSP container implicitly uses the pageContext variable for the PageContext object. The use of the pageContext variable as an implicit variable name in tag files does not comply with the JSP Specification. If compilation errors occur for applications that use a local pageContext variable in their tag file, set the modifyPageContextVariable attribute to`true` to remove the use of the pageContext variable name in the generated Java code for tag files.

recompileJspOnRestart
Determines whether a JSP file is retranslated and recompiled after application startup for the first time the file is requested. If recompileJspOnRestart is false, a JSP file is still compiled, if necessary, on the first request to that JSP file unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is false.

reloadEnabled
Determines whether or not a JSP file is translated and compiled at runtime if the JSP file or its dependencies (see trackDependencies) are modified.

If reloadEnabled is false, a JSP file is still compiled, if necessary, on the first request to it unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is `false`.

If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is true. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

reloadInterval
If reloading is enabled, reloadInterval determines the delay between checks to see if a JSP file is outdated.

For example, if reloadInterval is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than 5 seconds prior to the current request for the JSP file. The larger the reloadInterval, the less frequently the JSP engine checks for the need to reload a JSP file. If this JSP engine parameter is not specified, the equivalent Web container parameter for Web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is 5 seconds. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

scratchdir
Specifies the directory where the generated class files are created.

The system property com.ibm.websphere.servlet.temp.dir is used to set the scratchdir option on a server-wide basis. The JSP engine scratchdir parameter takes precedence over the system property com.ibm.websphere.servlet.temp.dir. The default for this parameter is *profile_root*/`temp`. This parameter requires regeneration of Java source.

trackDependencies
If reloading is enabled, trackDependencies determines whether the JSP engine tracks modifications to the requested JavaServer Pages files dependencies as well as to the JSP file itself.

The dependencies tracked by the JSP engine are :

1. files statically included in the JSP file
2. tag files referenced in the JSP file (excluding tag files that are in JARs)
3. TLD files referenced in the JSP file (excluding TLDs that are in JARs)

The default is `false`.

useFullPackageNames
If useFullPackageNames is true, the JSP engine generates and loads JSP classes using full package names.

The default is to generate all JSP classes in the same package. (For more information, see Packages and directories for generated .java and .class files). The JSP engine's class loader knows how to load JSP classes when they are all in the same package.

The default method of generating all JSP classes in the same package has the benefit of generating smaller file-system paths. Full package names has the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without the use of the jsp-file attribute, resulting in a single class loader, the Web application's class loader, that is used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes useFullPackageNames and disableJspRuntimeCompilation are both true, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

When useFullPackageNames is set to true, the batch compiler generates a file called `generated_web.xml` in the Web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP file that was successfully translated and compiled. The information can optionally be copied into the Web module's `web.xml` file so that the JSP files are loaded as servlets by the Web container. Note that if a JSP file is configured as a servlet in this way, no reloading of the JSP file is done at runtime if the JSP file is modified. This is because the JSP file is treated as a regular servlet and requests for it do not pass through the JSP engine. This parameter requires regeneration of Java source.

useImplicitTagLibs
The JSP engine implicitly recognizes tsx and jsx as tag library prefixes for tag libraries supplied by the JSP engine. If tsx or jsx are used as prefixes for a customer's tag library, the customer's tag library overrides the implicit tag library. However, the implicit tag library is still cached by the JSP engine. Explicitly setting this parameter to false tells the engine not to cache the implicit tag library, and save resources. The default for this parameter is `true`.

useInMemory
Specifies that the JSP engine translate and compile Java code in the system memory.

When this option is not set, the JSP engine must perform the following steps:

1. Write the translated Java file to the file system
2. Load the Java file from the file system
3. Compile the code into a class file
4. Write the class to the file system
5. Load the class file into a classloader.

Note: No .class file or .java file will be written to the system disk. For debugging or creating a JAR file from precompiled JSP code, you will need to disable this option.

useJikes
Specifies whether Jikes is used for compiling Java sources.

NOTE: Jikes is not shipped with WebSphere Application Server. The default for this parameter is `false`. This parameter requires regeneration of Java source.

usePageTagPool
*Enables or disables the reuse of custom tag handlers on an individual JavaServer Pages basis. The default for this parameter is `false`. This parameter requires regeneration of Java source.

useThreadTagPool
When thread-level tag handler pooling is used, tag handlers may be reused among separate occurrences of a custom action across all JSP pages in a single Web module across separate requests. The default for this parameter is `false`. This parameter requires regeneration of Java source.

Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

verbose
Indicates that the compiler generates verbose output when compiling the generated Java source code. The effect of setting this parameter to true is that the -verbose option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

JavaServer Pages troubleshooting tips
Use this tips to troubleshoot problems with JavaServer Pages.

JavaServer Pages source code shown by the Web server

If you share the document root of the WebSphere Application Server with the Web server document root, a security exposure can result as the Web server might display the JavaServer Pages (JSP) source file as plain text.

Problem

You can use the WebSphere Web server plug-in set of rules to determine whether a given request will be handled by the WebSphere Application Server. When an incoming request fails to match those rules, the Web server plug-in returns control to the Web server so that the Web server can fulfill the request. In this case, the unknown host header causes the Web server plug-in to return control to the Web server because the rules do not indicate that the WebSphere Application Server should handle it. Therefore, the Web server looks for the request in the Web server document root. Since the JSP source file is stored in the document root of the Web server, the Web server finds the file and displays it as plain text.

Suggested solution

Move the WebSphere Application Server JSP source file outside of the Web server document root. Then, when this request comes in with the unknown host header, the plug-in returns control to the Web server and the JSP source file is not found in the document root. Therefore, the Web server returns a `404 File Not Found` error rather than the JSP source file.

Problems displaying double-byte character set (DBCS) characters when using the @include directive

JavaServer Pages files that use the @include directive might experience problems when displaying double-byte character set (DBCS) characters. Some applications that are migrated to WebSphere Application Server Version 6.0 and above might need to be modified to comply with the JSP 2.0 specification as a result of backwards compatibility issues. The JSP 2.0 specification requires that each statically included resource must set a page encoding or content type because the character encoding for each file is determined separately, even if one file includes another using the include directive.

Problems using the JavaServer Pages (JSP) engine

If you are having difficulty using the JavaServer Pages (JSP) engine, try these steps:

1. Determine whether other resources such as `.html` files or servlets are being requested and displayed correctly. If they are not, the problem probably lies at a deeper level, such as with the HTTP server.
2. If other resources are being displayed correctly, determine whether the JSP processor has started normally:
   - Browse the logs of the server hosting the JSP files you are trying to access. The following messages indicate that the JSP processor has started normally:

     ```
     Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
     was initialized successfully.
     Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
     has been associated with patterns [*.jsp *.jspx *.jsw *.jsv ].
     ```

     If the JSP processor fails to load, you will see a message such as

     ```
     No Extension Processor found for handling JSPs.
     JSP Processor not defined. Skipping : jspfilename.
     ```

     in the server log files.
3. If the JSP engine has started normally, the problem may be with the JSP file itself.
   - The JSP may have invalid JSP syntax and could not be processed by the JSP Processor. Examine the server log files of the target application for invalid JSP directive syntax messages. Errors similar to the following in a browser indicate this kind of problem:

     ```
     Message: /filename.jsp(2,1)JSPG0076E: Missing required attribute page for jsp
                 element jsp:include
     ```

     This example indicates that line 2, column 1 of the named JavaServer Pages file is missing a mandatory attribute for the jsp:include action. Similar messages are displayed for other syntax errors.
   - Examine the target application server's `SystemErr.log` files for problems with invalid Java syntax. Errors similar to **`Message: Unable to compile class for JSP`** in a browser indicate this kind of problem.

     The error message output from the Javac compiler will be found in the `SystemErr.log`. It might look like:

     ```
     JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
     JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
     test.war\_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
     int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
     int myInt=121;
              ^  1 error
     ```

     Correct the error in the JSP file and retry the file.
   - Examine the target application server's server log files files for problems with invalid Java syntax. Errors similar to **`Message: Unable to compile class for JSP`** in a browser indicate this kind of problem.

     The error message output from the Javac compiler will be found in the server log files. It might look like:

```
JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
test.war\_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
int myInt=121;
         ^  1 error
```

Correct the error in the JSP file and retry the file.

JavaServer Pages fail to compile when using precompile

Symptom

JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected.

```
SystemErr R com.ibm.websphere.management.exception.AdminException:
ADMA0021E: Error in compiling jsps - xyz.war (rc=1)
```

Problem

JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected when there is a dependency on another Java archive (JAR) file that is not available on any class path.

Suggested solution

You may use wsadmin scripting to precompile JSP files during enterprise application deployment. However if you want to use the administrative console, then compile all JSP files before packaging the application.

1. Add the dependent JAR to the deployment manager in a cell environment.
   a. Click **System Administration > Deployment manager > Java and Process Management > Process Definition > Java Virtual Machine** in the console navigation.
   b. Add fully qualified dependent JAR in class path field.
   c. Click OK.
   d. Restart deployment manager.

JSPG0089E: Mismatch found between page directive encoding Shift_JIS and xml prolog encoding UTF-8

Symptom

The following error appears:

```
JSP Processing Error

HTTP Error Code: 500

Error Message: /test.jsp(2,1) /test.jsp(2,1) JSPG0089E: Mismatch found between
page directive encoding Shift_JIS and xml prolog encoding UTF-8
```

Problem

The pageEncoding attribute in the jsp:directive.page element is not UTF-8.

Suggested solution

JavaServer Pages must specify a prolog that matches the encoding specified in the page directive. For example,

```
<?xml version="1.0" encoding="Shift_JIS"?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.0">
<jsp:directive.page language="java" contentType="text/html";
 charset=Shift_JIS" pageEncoding="Shift_JIS"/>
<jsp:text>XXXXXjsp:text>XXXXX>
</jsp:root>
```

For additional information, see section JSP.4.1, Page Character Encoding, in the JavaServer Pages specification and section 4.3.3 and appendix F.1 of the Extensible Markup Language (XML) specification

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. The IBM Support page contains documents that can save you time gathering information needed to resolve this problem.

Developing Web applications

Before you begin

Design a Web application and the required components.

About this task

There are two basic approaches to selecting tools for developing Web applications:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the Web application components.
- If you decide to develop Web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java SE Development Kit 6 and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.

1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the Web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product directory:
   - *<install_root>*`\lib`

   To compile that same servlet on the Windows NT® version of WebSphere Network Deployment, specify:

   ```
   javac -classpath D:\Program Files\WebSphere\DeploymentManager\lib\j2ee.jar MyServlet.java
   ```
3. **(Optional)** Disable JavaServer Pages (JSP) runtime compilation, if necessary.

What to do next

Assemble the application components in one or more Web modules.

JavaServer Faces

JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java based Web applications. WebSphere Application Server version 7.0 supports JavaServer Faces 1.2 at a runtime level, therefore using JSF reduces the size of the Web application since runtime binaries no longer need to be included in your Web application.

The JSF runtime also :

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface
- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Supports custom user interface components to be easily build and reused

Both the SUN Reference Implementation and Apache MyFaces implementation are shipped with the product.

The Sun JSF Reference Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. However, some dependencies on Jakarta APIs have been removed and replaced with Application Server specific solutions as a result of potential problems that may occur when open source APIs are included in the Application Server runtime. For example, when included in the Application Server runtime, these open source APIs are made available to all applications installed within the Application Server, therefore bringing versioning, support and legal issues. The version of the JSF runtime provided by the Application Server resides in the normal runtime library location and is available to all Web applications that leverage JSF APIs. The loading of the JSF servlet works in the same manner as if the runtime was packaged with the Web application.

The following open source dependencies are replaced with other APIs or in-house versions:

- Jakarta Commons BeanUtils
- Jakarta Commons Collections
- Jakarta Commons Digester
- Jakarta Commons Logging
- Mozilla Assert API

The JSF Specification requires JavaServer Pages Standard Tag Library (JSTL) as a dependency, therefore the required version of the JSTL from Jakarta is made available in the Application Server runtime.

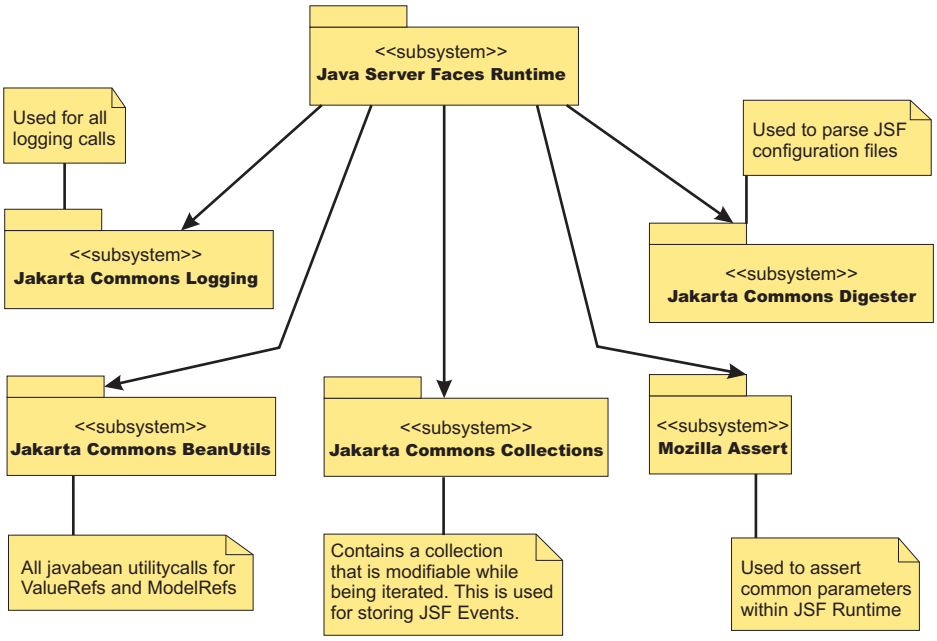

Figure 1. Current external API dependencies from the Sun based JSF runtime

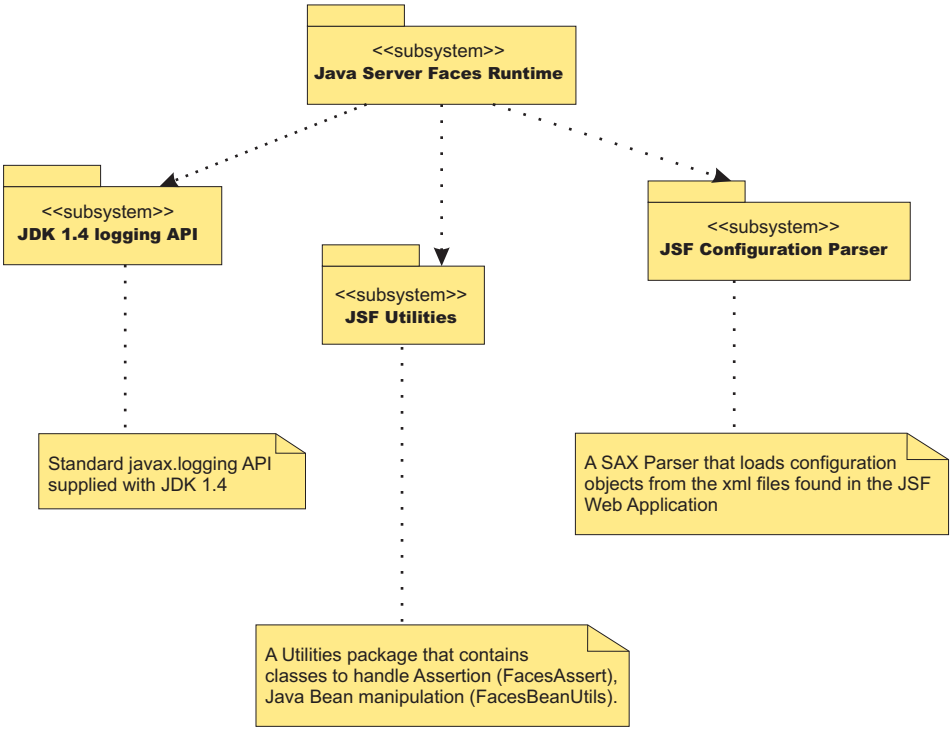
Figure 2. Replacement APIs



The specification related classes (javax.faces.*) for JSF and the IBM modified version of the JSF Sun reference implementation are packaged in the Application Server runtime.

Typically, Web applications that leverage this API/Framework embed the JSF API and implementation Java archive (JAR) files within their Web archive (WAR) file. This is not required when these Web applications are deployed and run within WebSphere Application Server. Only the removal of these JAR files along with any JSTL JAR files from the WAR file is required. However, because JavaServer Faces 1.2 is a part of the Java Platform, Enterprise Edition (Java EE) platform, a Web application does not need to bundle a JavaServer Faces implementation when it runs on a Web container that is Java EE technology compliant. If a JavaServer Faces implementation is bundled with a Web application, it is ignored as the JavaServer Faces implementation provided by the platform always takes precedence.

The JSF runtime for WebSphere Application Server does not support the use of a single class loader for the entire application. This support is not available when the application contains multiple Web modules and one of those modules is a JSF module. A single class loader for the entire application is not supported because the FacesConfig initialization requires a single class loader for each JSF module to perform the initialization. Therefore, you must use multiple class loaders when the application contains multiple Web modules and at least one JSF module.

For using different implementations of JSF, the WAS JSF engine determines if the SUN RI or Apache MyFaces is used from the application server runtime. After the JSF engine determines the implementation that is used, the correct listener class is registered with the Web container. You not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your web.xml file.

If you want to use a third party JSF implementation that is not shipped with the product, leave the configuration set to the SUN RI, add the third party listener to the web.xml file that is required and add the third party implementation JAR files to the application as an isolated shared library. Using an isolated shared library, the Web application version of the JSF or JSTL classes load before the Application Server.

FacesBeanUtils class

The FacesBeanUtils class provides static method replacements for methods used in the Jakarta Commons BeanUtils API. The FacesBeanUtils class has no life cycle.

FacesBeanUtils
+ getProperty ([in] bean : Object , [in] property : String) : Object
+ getPropertyType ([in] bean : Object , [in] property : String) : Class
+ getSimpleProperty ([in] bean : Object, [in] property : String , [in] value : Object)
+ getProperty ([in] bean : Object , [in] property : String , [in] value : Object)
+ convertFromString ([in] value : String, [in] valueClass : Class) : Object
+ convert ([in] targetType : Class , [in] bean : String) : Object

JavaServer Faces widget library (JWL)

JavaServer Faces widget library (JWL) is a IBM JSF-based Web widget library that integrates widgets from a number of sources. The IBM JSF-based Web widget library is deprecated, however, you can obtain the latest version from Rational® Application Developer version 6 (RAD) to work with JSF 1.2.

JWL includes the JSF components from Rational Application Developer with the exception of the base JSF components, which are included in the Application Server runtime. This includes the IBM extended JSF components and the extended FacesClient Component. JWL also extends JSF with client-side features for rich browser-based experiences in the form of the FacesClient Component.

JWL Java archive files

JWL is packaged into two Java archive (JAR) files, odc-jsf.jar and jsf-ibm.jar, which are located in the ${WAS_HOME}\optionalLibraries\IBM\jwl\2.0 directory.

To include JWL in your application, you can use the JWL shared library named JWLLib, which is created at install time. To assign the library to an application, see the topic, Using installed optional packages.

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use the Apache MyFaces or the SUN Reference Implementation of JSF 1.2 or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific web.xml context parameters for the implementation that you have chosen.

About this task

The Application Server JSF engine determines if the SUN Reference Implementation 1.2 or Apache MyFaces 1.2 is used from the Application Server runtime. If either is used, the correct listener class is registered with the Web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your web.xml file.

If the you want to use a third party JSF implementation that is not shipped with the product, keep the configuration set to the SUN RI, add the third party listener to the web.xml file that is required and add the third party implementation Java archive (JAR) files to the application as an isolated shared library.

You can also configure the JSF implementation on the **Provide JSP reloading options for Web modules** panel for application installation and update wizards.

1. In the administrative console panel, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **JSP and JSF options**. Select one of the following implementations:

Option	Description
Sun Reference Implementation 1.2	Select this option to use the Sun Reference Implementation 1.2 JSF implementation. This is the default JSF implementation.
MyFaces 1.2	Select this option to use the MyFaces 1.2 JSF implementation.

2. To use your own JSF implementation, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **JSP and JSF options** in the administrative console.
   a. Select Sun Reference Implementation 1.2 as the JSF implementation.
   b. Add your implementation as an isolated shared library. See Creating shared libraries for details.
   c. Associate the isolated shared library to the Web module class loader in the application.
3. Click **Ok**.
4. Recompile the JSP files that contain the JSF implementation. You can set the JSF engine configuration paramater, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

Results

If MyFaces is selected, then the MyFaces implementation is added to the application through an isolated shared library and the entire application uses the MyFaces implementation. Using both the SUN Reference Implementation and the MyFaces implementation within the same application is not supported.

What to do next

Configure JSF engine parameters as necessary.

Related concepts

"JavaServer Faces" on page 52
JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java based Web applications. WebSphere Application Server version 7.0 supports JavaServer Faces 1.2 at a runtime level, therefore using JSF reduces the size of the Web application since runtime binaries no longer need to be included in your Web application.

"JSF engine configuration parameters" on page 58
In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

Configuring JSF engine parameters

About this task

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the administrative console or through administrative scripting.

To add, change or delete JSF engine configuration parameters, complete the following steps:

1. Open the `WEB-INF/web.xml` file.

   JSP engine configuration parameters are stored in a Web module's configuration directory or in a Web modules's binaries directory in the `WEB-INF/web.xml` file. Open the `WEB-INF/web.xml` file from:

   - The configuration directory, as in the following example: `{WAS_ROOT}/profiles/`*`profilename`*`/config/cells/`*`cellname`*`/applications/`*`enterpriseappname`*`/ deployments/`*`deployedname`*`/`*`webmodulename`*
   - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: `{WAS_ROOT}/profiles/`*`profilename`*`/installedApps/`*`nodename`*`/`*`EnterpriseAppName`*`/`*`WebModuleName`*`/`
2. Edit the `WEB-INF/web.xml` file.
   - To add configuration parameters, use the following format:

     ```
     <context-param>
       <description>descriptive text</description>
       <param-name>parameter name</param-name>
       <param-value>parameter value</param-value>
     </context-param>
     ```
   - To delete configuration parameters, either delete the line from the file, or enclose the statement with `<!-- -->` tags.
3. Save the file.
4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the Web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a Web module. The batch compiler uses the JSP engine configuration parameters that you have set in the `web.xml` file, unless you specifically override them. The topic JSP engine configuration parameters" identifies the parameters that affect the generated Java source.

Example

The following is a sample of the WEB-INF/web.xml file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<webappext:WebAppExtension xmi:version="2.0" xmlns:xmi=http://www.omg.org/XMI
   xmlns:webappext="webappext.xmi" xmlns:webapplication="webapplication.xmi" xmi:id="WebAppExtension_1"
   reloadInterval="9" reloadingEnabled="true" defaultErrorPage="error.jsp" additionalClassPath=""
   fileServingEnabled="true" directoryBrowsingEnabled="false" serveServletsByClassnameEnabled="true"
   autoRequestEncoding="true" autoResponseEncoding="false"
   <webApp href="WEB-INF/web.xml#WebApp_1"/>
   <jspAttributes xmi:id="JSPAttribute_1" name="useThreadTagPool" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_2" name="verbose" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_3" name="deprecation" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_4" name="reloadEnabled" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_5" name="reloadInterval" value="5"/>
   <jspAttributes xmi:id="JSPAttribute_6" name="keepgenerated" value="true"/>
   <!--<jspAttributes xmi:id="JSPAttribute_7" name="trackDependencies" value="true"/> -->

</webappext:WebAppExtension>
```

JSF engine configuration parameters:

In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSF engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value.

JSF options using SUN RI

- **com.sun.faces.numberOfViewsInSession**

  Specifies the number of views that are stored in the session when Server-Side State Saving is used. If set to true while client-side state saving is being used, reduces the number of bytes sent to the client by compressing the state before it is encoded and written as a hidden field. The default for this parameter is 15.
- **com.sun.faces.numberOfLogicalViews**

  Specifies the number of logical views that are stored in the session when Server-Side State Saving is used. The default for this parameter is 15.
- **com.sun.faces.enableHighAvailability**

  If set to true while server-side state saving is used, a serialized representation of the view is stored on the server. This provides failover and sever clustering support. The default for this parameter is false.
- **com.sun.faces.injectionProvider**

  Defines an injection provider that is used for JSF annotations.
- **com.sun.faces.serializationProvider**

  Defines a serialization provider that is used for serializing JSF objects into session.
- **com.sun.faces.responseBufferSize**

  Define the size of the response buffer for a JSF response. The default for this parameter is 1048.
- **com.sun.faces.clientStateWriteBufferSize**

  The default for this parameter is 8192.
- **com.sun.faces.expressionFactory**

  Specifies the default EL Expression Factory to use. The default for this parameter is org.apache.el.ExpressionFactoryImpl.
- **com.sun.faces.clientStateTimeout**

  The timeout value used for client side state saving. Once the value set has been reached then the state is lost. Default is infinite.

- **com.sun.faces.displayConfiguration**

  The default for this parameter is `false`.
- **com.sun.faces.validateXml**

  The default for this parameter is `false`.
- **com.sun.faces.verifyObjects**

  The default for this parameter is `false`.
- **com.sun.faces.forceLoadConfiguration**

  The default for this parameter is `false`.
- **com.sun.faces.diableVersionTracking**

  The default for this parameter is `false`.
- **com.sun.faces.enableHtmTagLibValidator**

  The default for this parameter is `false`.
- **com.sun.faces.prerefXHTML**

  The default for this parameter is `false`.
- **com.sun.faces.compressViewState**

  The default for this parameter is `true`.
- **com.sun.faces.compressJavaScipt**

  The default for this parameter is `true`.
- **com.sun.faces.sendPoweredByHeader**

  The default for this parameter is `true`.
- **com.sun.faces.enableJSStyleHiding**

  The default for this parameter is `false`.
- **com.sun.faces.writeStateAtFormEnd**

  The default for this parameter is `true`.
- **com.sun.faces.enableLazyBeanValidation**

  The default for this parameter is `ture`.
- **com.sun.faces.enableLoadBundle11Compatibility**

  The default for this parameter is `false`.
- **com.sun.faces.enableRestoreView11Compatibilty**

  The default for this parameter is `false`.
- **com.sun.face.serializeServerState**

  The default for this parameter is `false`.

JSF options for MyFaces

- **org.apache.myfaces.RESOURCE_VIRTUAL_PATH**

  The default for this parameter is `/faces/myFacesExtensionResource`.
- **org.apache.myfaces.PRETTY_HTML**

  The default for this parameter is `true`.
- **org.apache.myfaces.ALLOW_JAVASCRIPT**

  The default for this parameter is `true`.
- **org.apache.myfaces.DETECT_JAVASCRIPT**

  The default for this parameter is `false`.
- **org.apache.myfaces.AUTO_SCROLL**

  The default for this parameter is `false`.
- **org.apache.myfaces.ADD_RESOURCE_CLASS**

  The default for this parameter is `org.apache.myfaces.renderkit.html.util.DefaultAddResource`.
- **org.apache.myfaces.CHECK_EXTENSIONS_FILTER**

  The default for this parameter is `true`.
- **org.apache.myfaces.READONY_AS_DISABLED_FOR_SELECTS**

  The default for this parameter is `true`.

- **org.apache.myfaces.SERIALIZE_STATE_IN_SESSION**

  Set this option to `true` to serialize the state to a byte stream before it is written to the session. If this option is set to `false`, the state is not serialized to a byte stream. This option is only applicable if the state saving method is set to server. The default for this parameter is `true`.
- **org.apache.myfaces.COMPRESS_STATE_IN_SESSION**

  Set this option to `true` to compress the serialized state before it is written to the session. If this option is set to `false`, the state is not compressed. This option is only applicable if the state saving method is set to server and if org.apache.myfaces.SERIALIZE_STATE_IN_SESSION is set to `true`. The default for this parameter is `true`.
- **org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION**

  Defines the number of the latest views that are stored in session. This option is only applicable if the state saving method is set to server. The default for this parameter is `20`.

JSF options using SUN RI or MyFaces

The following options are valid for both the SUN RI and the MyFaces implementations.
- **javax.faces.STATE_SAVING_METHOD**

  Specifies the location where state information is saved. Valid values are 'server', which is saved in HttpSession, and 'client', which is saved as a hidden field in the form. The default for this parameter is `server`.
- **javax.faces.CONFIG_FILES**

  Use this parameter to specify a comma-delimited list of context-relative resource paths under which the JSF implementation looks for application configuration resources before loading a configuration resource named /WEB-INF/facesconfig.xml, if a resource exists.
- **javax.faces.DEFAULT_SUFFIX**

  Specifies the default suffix for extension-mapped resources that contain JSF components. The default for this parameter is `.jsp`.
- **javax.faces.LIFECYCLE_ID**

  Use this parameter to configure an alternate lifecycle ID.
- **com.ibm.ws.jsf.JSF_IMPL_CHECK**

  Specifies that the JSP files in a Web module must be recompiled when the application is restarted because the implementation of JSF that is used has changed. After the application is restarted, the next time a JSP files is accessed for this module the JSP is recompiled against the selected implementation of JSF specified in the administration console. Subsequent calls to the JSP do not cause a recompile. The default setting for this option is false. Use this option for development and not in a production environment.

IBM options for JSF runtime
- **com.ibm.ws.jsf.JSP_UPDATE_CHECK**

  This parameter monitors Faces JaaverServer Pages (JSP) files for modifications and synchronizes a running server with the changes without restarting the server. If this parameter is set to false or removed from the deployment descriptor, any changes made to Faces JSP files might not be seen by the server until it is restarted. Set this parameter to true while developing and debugging the Faces JSP files to improve the performance of the development environment.
- **com.ibm.ws.jsf.LOAD_FACES_CONFIG_AT_STARTUP**

  Specifies to load the JSF runtime when the application server starts up. If this parameter is set to false or removed, JSF runtime is loaded and initialized when the first JSF request is processed. This might disable custom JSF extensions such as factories defined in the project.
- **com.ibm.ws.jsf.JSF_IMPL_CHECK**

  Set the com.ibm.ws.jsf.JSF_IMPL_CHECK parameter to true to check at application restart if the SUN RI and MyFaces implementations were switched. If the implementation has switched, then the runtime removes any generated JSP files from the temp directory and the JSP file is retranslated the next time it is requested.

JavaServer Faces custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond what is available in the administrative console. The following is a list of the available JavaServer Faces custom properties.

com.ibm.ws.jsf.disableStylePassthroughForCheckboxList:

This custom property prevents passing the style information into the items in the check box list. This property defaults to false to maintain the current behavior. Define and set the com.ibm.ws.jsf.disableStylePassthroughForCheckboxList context parameter to `true` in the web.xml file prevent passing style information into items in the check box list. Use the following code as an example.

```
<context-param>
<description>
Set to true if style information should not be passed into items of check box list
</description>
<param-name>com.ibm.ws.jsf.disableStylePassthroughForCheckboxList</param-name>
<param-value>true</param-value>
</context-param>
```

com.ibm.ws.jsf.associateLabelWithId:

The com.ibm.ws.jsf.associateLabelWithId custom property changes the rendering behavior for both the <h:selectOneRadio> and <h:selectManyCheckbox> components. The label no longer wraps the input element. Instead, each input element has a unique ID and the label is associated with that ID used for that attribute. Define and set the com.ibm.ws.jsf.associateLabelWithId context parameter to `true` in the web.xml file. Use the following code as an example.

```
<context-param>
<description>
Set to true to explicitly associate labels with their input elements for select one radio buttons
and select many check box lists.
</description>
<param-name>com.ibm.ws.jsf.associateLabelWithId</param-name>
<param-value>true</param-value>
</context-param>
```

enableRestoreView11Compatibility:

Because JSF 1.2 is supported, a JSF 1.2 application, might create the ViewExpiredException exception under load. If your view is not found in session, you can use a compatibility mode in JSF to create a new view. This can have adverse behaviors because it is a new view, and items that are usually in the view, such as state, are no longer be there. Use the following code as an example to add the com.sun.faces.enableRestoreView11Compatibility context parameter to `true` in the web.xml file.

```
<context-param>
   <param-name>com.sun.faces.enableRestoreView11Compatibility</param-name>
   <param-value>true</param-value>
</context-param>
```

com.ibm.ws.jsf.loadExternalDtd:

When parsing the faces-config.xml file from included libraries, the Faces configuration parser attempts to load the DTD even when validation is disabled. The Faces configuration parser uses a SAXParser to read the faces-config.xml. The default behavior of the SAXParser parser is to always load the DTD even if validation is disabled. This behavior can lead to errors initializing the Faces Servlet on systems isolated from the internet.

In your web.xml file, set the com.ibm.ws.jsf.loadExternalDtd context paramater to `false` to have the Faces configuration parser set the ″http://apache.org/xml/features/nonvalidating/load-external-dtd″ feature to false.

```
<context-param>
<description>
When set to false, this property sets a feature on the SAX parser to prevent loading the external DTD.
</description>
<param-name>com.ibm.ws.jsf.loadExternalDtd</param-name>
<param-value>false</param-value>
</context-param>
```

Assembling Web applications

Assemble a Web module to contain servlets, JavaServer page (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a Web module, you can install it as a standalone application or combine it with other modules into an enterprise application.

Before you begin

This topic assumes that you have created and unit tested Servlets, JavaServer Pages (JSP) files and other Web components that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Use an assembly tool to assemble a Web module in any of the following ways:
- Import an existing Web module (WAR file).
- Create a new Web module.
- Copy code artifacts (such as servlets) from one Web module into a new Web module.

Although you can input various properties for Web archives, available properties are specific to the Servlet, JSP, and Java Platform, Enterprise Edition (Java EE) specification level.

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new Web module.
5. Copy code artifacts (such as servlets) from one Web module into a new Web module.

Results

A Web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

What to do next

You can now deploy your Web project to an application server.

Web component security

A Web module consists of servlets, JavaServer Pages (JSP) files, server-side utility classes, static Web content, which includes HTML, images, sound files, cascading style sheets (CSS), and client-side classes or applets. You can use development tools such as Rational Application Developer to develop a Web module and enforce security at the method level of each Web resource.

You can identify a Web resource by its URI pattern. A Web resource method can be any HTTP method (GET, POST, DELETE, PUT, for example). You can group a set of URI patterns and a set of HTTP

methods together and assign this grouping a set of roles. When a Web resource method is secured by associating a set of roles, grant a user at least one role in that set to access that method. You can exclude anyone from accessing a set of Web resources by assigning an empty set of roles. A servlet or a JavaServer Pages (JSP) file can run as different identities before invoking another enterprise bean component. All the secured Web resources require the user to log in by using a configured login mechanism. Three types of Web login authentication mechanisms are available: basic authentication, form-based authentication and client certificate-based authentication.

In WebSphere Application Server Version 6.1, a portlet resource that is part of a web module can also be protected when it is accessed directly through URL. The protection is similar to other Web based resources. For more information, see “Portlet URL security” on page 96.

For more detailed information on Web security, see the product architectural overview article.

Securing Web applications using an assembly tool

You can use three types of Web login authentication mechanisms to configure a Web application: basic authentication, form-based authentication and client certificate-based authentication. Protect Web resources in a Web application by assigning security roles to those resources.

About this task

To secure Web applications, determine the Web resources that need protecting and determine how to protect them.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

The following steps detail securing a Web application using an assembly tool:

1. In an assembly tool, import your Web archive (WAR) file or an application archive (EAR) file that contains one or more Web modules.
2. In the Project Explorer folder, locate your Web application.
3. Right-click the deployment descriptor and click **Open With > Deployment Descriptor Editor**. The Deployment Descriptor window opens. To see online information about the editor, press F1 and click the editor name. If you select a Web archive (WAR) file, a Web deployment descriptor editor opens. If you select an enterprise application (EAR) file, an application deployment descriptor editor opens.
4. Create security roles either at the application level or at the Web module level. If a security role is created at the Web module level, the role also displays in the application level. If a security role is created at the application level, the role does not display in all of the Web modules. You can copy and paste a security role at the application level to one or more Web module security roles.
   - Create a role at a Web-module level. In a Web deployment descriptor editor, click the Security tab. Under **Security Roles**, click **Add.**. Enter the security role name, describe the security role, and click **Finish**.
   - Create a role at the application level. In an application deployment descriptor editor, click the Security tab. Under the list of security roles, click **Add**. In the Add Security Role wizard, name and describe the security role and then click **Finish**.
5. Create security constraints. Security constraints are a mapping of one or more Web resources to a set of roles.
   a. On the Security tab of a Web deployment descriptor editor, click **Security Constraints**. On the Security Constraints tab, you can do the following actions:
      - Add or remove security constraints for specific security roles.
      - Add or remove Web resources and their HTTP methods.
      - Define which security roles are authorized to access the Web resources.

- Specify None, Integral, or Confidential constraints on user data.
  None The application does not require transport guarantees.
  Integral
  Data cannot be changed in transit between the client and the server.
  Confidential
  Data content cannot be observed while it is in transit.
  Integral and Confidential usually require the use of SSL. When deploying applications that are available over public networks, specify Confidential for your Web Applications constraints

b. Under Security Constraints, click **Add**.

c. Under Constraint name, specify a display name for the security constraint and click **Next**.

d. Type a name and description for the Web resource collection.

e. Select one or more HTTP methods. The HTTP method options are: GET, PUT, HEAD, TRACE, POST, DELETE, and OPTIONS.

f. Beside the Patterns field, click **Add**.

g. Specify a URL Pattern. For example, type - `/*, *.jsp, /hello`. Consult the Servlet specification Version 2.4 for instructions on mapping URL patterns to servlets. The security runtime uses the exact match first to map the incoming URL with URL patterns. If the exact match is not present, the security runtime uses the longest match. The wild card (`*.,*.jsp`) URL pattern matching is used last.

h. Click **Finish**.

i. Repeat these steps to create multiple security constraints.

6. Map security-role-ref and role-name elements to the role-link element. During the development of a Web application, you can create the security-role-ref element. The security-role-ref element contains only the role-name field. The role-name field contains the name of the role that is referenced in the servlet or JavaServer Pages (JSP) code to determine if the caller is in a specified role. Because security roles are created during the assembly stage, the developer uses a logical role name in the Role-name field and provides enough description in the Description field for the assembler to map the role actual. The Security-role-ref element is at the servlet level. A servlet or JavaServer Pages (JSP) file can have zero or more security-role-ref elements.

   a. Go to the References tab of a Web deployment descriptor editor. On the References tab, you can add or remove the name of an enterprise bean reference to the deployment descriptor. You can define five types of references on this tab:
      - EJB reference
      - Service reference
      - Resource reference
      - Message destination reference
      - Security role reference
      - Resource environment reference

   b. Under the list of Enterprise JavaBeans (EJB) references, click **Add**.

   c. Specify a name and a type for the reference in the **Name** and **Ref Type** fields.

   d. Select either **Enterprise Beans in the workplace** or **Enterprise Beans not in the workplace**.

   e. Optional: If you select **Enterprise Beans not in the workplace**, select the type of enterprise bean in the **Type** field. You can specify either an entity bean or a session bean.

   f. Optional: Click **Browse** to specify values for the local home and local interface in the **Local home** and **Local** fields before you click **Next**.

   g. Map every role-name that is used during development to the role using the previous steps. Every role name that is used during development maps to the actual role.

7. Specify the RunAs identity for servlets and JSP files. The RunAs identity of a servlet is used to invoke enterprise beans from within the servlet code. When enterprise beans are invoked, the RunAs identity

is passed to the enterprise bean for performing an authorization check on the enterprise beans. If the RunAs identity is not specified, the client identity is propagated to the enterprise beans. The RunAs identity is assigned at the servlet level.

a. On the Servlets tab of a Web deployment descriptor editor, under **Servlets and JSP**, click **Add**. The Add Servlet or JSP wizard opens.
b. Specify the servlet or JavaServer Pages (JSP) file settings, including the name, initialization parameters, and URL mappings and click **Next**.
c. Specify the class file destination.
d. Click **Next** to specify additional settings or click **Finish**.
e. Click **Run As** on the **Servlets** tab, select the security role and describe the role.
f. Specify a RunAs identity for each servlet and JSP file that is used by your Web application.

8. Configure the login mechanism for the Web module. This configured login mechanism applies to all the servlets, JavaServer Pages (JSP) files and HTML resources in the Web module.
   a. Click the **Pages** tab of a Web deployment descriptor editor and click **Login**. Select the required authentication method. Available method values include: Unspecified, Basic, Digest, Form, and Client-Cert.
   b. Specify a realm name.
   c. If you select the Form authentication method, select a login page and an error page Web address. For example, you might use `/login.jsp` or `/error.jsp`. The specified login and error pages are present in the `.war` file.
   d. Install the client certificate on the browser Web Client and place the client certificate in the server trust keyring file, if ClientCert certificate is selected. The public certificate of the clients certificate authority must be placed in the servers RACF® keyring. If the registry is a local OS registry, use the RACDCERT MAP or the equivalent System Authorization Facility (SAF) command to enable an MVS™ identity creation using the client certificate.
9. Close the deployment descriptor editor and, when prompted, click **Yes** to save the changes.

Results

After securing a Web application, the resulting Web archive (WAR) file contains security information in its deployment descriptor. The Web module security information is stored in the `web.xml` file. When you work in the Web deployment descriptor editor, you also can edit other deployment descriptors in the Web project, including information on bindings and IBM extensions in the `ibm-web-bnd.xmi` and `ibm-web-ext.xmi` files.

What to do next

After using an assembly tool to secure a Web application, you can install the Web application using the administrative console. During the Web application installation, complete the steps in Deploying secured applications to finish securing the Web application.

Security constraints

Security constraints determine how Web content is to be protected.

These properties associate security constraints with one or more Web resource collections. A constraint consists of a Web resource collection, an authorization constraint and a user data constraint.

- A Web resource collection is a set of resources (URL patterns) and HTTP methods on those resources. All requests that contain a request path that matches the URL pattern described in the Web resource collection are subject to the constraint. If no HTTP methods are specified, then the security constraint applies to all HTTP methods.

- An authorization constraint is a set of roles that users must be granted in order to access the resources described by the Web resource collection. If a user who requests access to a specified Uniform Resource Identifier (URI) is not granted at least one of the roles specified in the authorization constraint, the user is denied access to that resource.

  Previously the http-methodType schema limited HTTP methods to DELETE, GET, HEAD, OPTIONS, POST, PUT and TRACE. The http-methodType schema has changed. The http-methodType schema has been changed as follows:

  ```
  <xsd:simpleType name="http-methodType">
  <xsd:annotation>
  <xsd:documentation>
  A HTTP method type as defined in HTTP 1.1 section 2.2.
  </xsd:documentation>
  </xsd:annotation>
  <xsd:restriction base="xsd:token">
  <xsd:pattern value="[\p{L}-[\p{Cc}\p{Z}]]+"/>
  </xsd:restriction>
  </xsd:simpleType>
  ```

  This requires elements to be a token. Based upon the pattern value, tokens can contain any character except for control characters and separators.
- A user data constraint indicates that the transport layer of the client or server communications process must satisfy the requirement of either guaranteeing content integrity (preventing tampering in transit) or guaranteeing confidentiality (preventing reading while in transit).

Security settings

Use the administrative console to modify the security settings for all applications.

You can enable security for applications by selecting the **Enable application security** option on the Global security panel.

The default settings are used as a template or starting point for configuring individual applications. The administrator should still explicitly configure security settings for each application.

The following security settings are specified during application assembly:

Security role settings

When using the Assembly Toolkit at an application level (Enterprise Archive (EAR) file), security roles are synchronized with the security roles defined for the embedded modules of the application.

If a security role is manually added to the EAR file, it can be automatically removed when the file is saved if an embedded module does not reference the role, or the role is in conflict with an existing role. In this case, remove the manually added role, but then all roles with the same name are removed.

The role is automatically added again when the file is saved if it is still referenced in an embedded module file. If a duplicate role is added in an embedded module file, delete all roles with the same name and manually read the correct role.

Security constraints

Security constraints declare how to protect Web content. These properties associate security constraints with one or more Web resource collections. A *constraint* consists of a Web resource collection, an authorization constraint, and a user data constraint.

Security constraints are set when configuring a Web application in the Assembly Toolkit.

Security role references

Web application developers or Enterprise JavaBeans (EJB) providers must use a role-name in the code when using the available programmatic security Java Platform, Enterprise Edition (Java EE) application programming interfaces (APIs) isUserInRole(String roleName) and isCallerInRole(String roleName).

The roles used in the deployed run-time environment might not be known until the Web application and EJB components (for example, Web archive (WAR) files and `ejb-jar.xml` files) are assembled into an enterprise archive (EAR) file. Therefore, the role names used in the Web application or EJB component code are logical role names which the application assembler maps to the actual run-time environment roles during application assembly. The security role references provide a level of indirection that insulate Web application component and EJB developers from having to know the actual roles in the run-time environment.

The definition of the logical roles and the mapping to the actual run-time environment roles are specified in the security-role-ref element of both the Web application and the EJB JAR file deployment descriptors, `web.xml` and `ejb-jar.xml` respectively. Use the assembly tools to define the role names and map them to the actual run-time roles in the environment with the role-link element.

The following code sample is an example of a security-role-ref from an EJB `ejb-jar.xml` deployment descriptor.

```
... <enterprise-beans>
... <entity>
<ejb-name>AardvarkPayroll</ejb-name>
<ejb-class>com.aardvark.payroll.PayrollBean</ejb-class>
...
<security-role-ref>
<description>
```

This role should be assigned to the employees of the payroll department. Members of this role have access to the payroll record of everyone. The role has been linked to the payroll-department role. This role should be assigned to the employees of the payroll department. Members of this role have access to all payroll records. The role has been linked to the payroll-department role.

```
</description> <role-name>payroll</role-name>
<role-link>payroll-department</role-link>
</security-role-ref>
 ...
</entity>
 ...
</enterprise-beans>
```

In the previous example, the string `payroll`, which appears in the <role-name> element, is what the EJB provider uses as the argument to the isCallerInRole() API. The <role-link> element is what ties the logical role to the actual role used in the run-time environment.

Note that for enterprise beans, the security-role-ref element must appear in the deployment descriptor even if the logical role name is the same as the actual role name in the environment.

The rules Web application components are slightly different. If no security-role-ref element matching a security-role element is declared, the container must default to checking the role-name element argument against the list of security-role elements for the Web application. The isUserInRole method references the list to determine whether the caller is mapped to a security role. The developer must be aware that the use of this default mechanism can limit the flexibility in changing role names in the application without having to recompile the servlet making the call.

See the EJB Version 2.0 and Servlet Version 2.3 specification in the Security: Resources for Learning article for complete details on this specification.

File serving

In file serving, Web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

The file-serving behavior is implemented by setting the fileservingenabled property to true when configuring the Web module.

Example attributes:

bufferSize
Sets buffer size that is used for serving static files.

extendedDocumentRoot
Path that specifies the directory where static files are sent. Use this attribute in addition to the contextRoot attribute.

file.serving.patterns.allow
Specifies that only files matching the specified pattern are served.

file.serving.patterns.deny
Specifies that files that match the specified file pattern are denied

Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

Before you begin

You must have an extensible application to define an extension for the registry filter.

About this task

Complete the following steps to filter out extensions for an application.

1. Define an extension for the registry filter extension point for a named registry instance in the plugin.xml file.

```
<extension point="org.eclipse.extensionregistry.RegistryFilter">
 <filter name="AdminConsole*"
   class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
 </extension>
```

2. Add the filter implementation to the application by creating a class to implement the com.ibm.workplace.extension.IExtensionRegistryFilter interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
        :
}
```

3. The extensible application declares the registry name by defining an extension for the RegistryInstance extension point. This way, the registry can prepare an IExtensionRegistry instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>

</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup( lookupName );
```

Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications are extensible when they contain a defined extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible J2EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the J2EE application using a deployment tool that is based upon standard J2EE and portal Web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the plugin.xml file. The plugin.xml manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

You can find additional information about the Eclipse Plug-in Architecture at http://www.eclipse.org/articles/Article-Plug-in-architecture/plugin_architecture.html.

WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (J2EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.1.
- The identical plugin.xml syntax, however, some attributes are not used, for example, <runtime>.
- The discovery and addition of plug-ins to the registry, when the containing J2EE module starts, and plug-ins are dismissed and removed from the registry when the containing J2EE module stops.
- Access to an IExtensionRegistry object is through the Java Naming and Directory Interface (JNDI), instead of by using the Platform.getExtensionRegistry method in the Eclipse Workbench.
- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the developer API documentation for the IExtensionRegistryFilter interface for more details.

Available Eclipse 3.1 interfaces

The following Eclipse 3.1 interfaces are available on WebSphere Application Server:

- Extension registry API
- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:

- Executable extension API
- Executable extension factory API

Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

Registry filter API

Supported arguments include:

org.eclipse.core.runtime.IExtension[]
doFilter(org.eclipse.core.runtime.IExtension[] extensions)

This code returns an array of IExtension objects that are included in the valid extension list.

Registry instance extension point

The extension registry exposes the *RegistryInstance* . The instance name is declared in the application's plugin.xml file, and the application requests an registry instance for that name at runtime.

plugin.xml file

A plug-in is described in an XML manifest file, called plugin.xml, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server plugin.xml closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

Location

The `plugin.xml` file must reside in the WEB-INF directory under the context of the hierarchy of directories that exist for a Web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the`plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  ???
- If so, what triggers its update?

  Rational Application Developer updates the `web.xml` file when you assemble Web components into a Web module, or when you modify the properties of the Web components or the Web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of Web application development.

- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

```
SimpleToken := sequence of characters from ('a-z','A-Z','0-9')
ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)
PlugInId := ComposedToken
PlugInPrereq := PlugInId
ExtensionId := SimpleToken
ExtensionPointId := SimpleToken
ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)
```

Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule element* means zero or more occurrences of the element; element? means zero or one occurrence of the element; and element+ means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
>
<!ELEMENT requires (import+)>
<!ELEMENT import EMPTY>
<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>
```

WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

The `plugin` element

The plugin element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the plugin element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

The `import` element

The requires element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the match attribute has an option for a greater than or equal to match for versions (greaterOrEqual).

The `extension-point` element

The extension-point element has the name attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (linkExtensionPoint) and an extension to this extension point (linkExtension). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the <extension> and </extension> tags in its manifest.

```
<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
   id="com.ibm.ws.console.core"
   version="1.0.0"
   provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
 <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>
 </requires>

 <!--declaration of link extension point -->
 <extension-point
    id="linkExtensionPoint"
    schema="/schemas/linkSchema.xsd"/>

 <!--declaration of an extension to the link extension point -->
 <extension
    point="com.ibm.ws.console.core.linkExtensionPoint"
    id="linkExtension">

   <link
     label="Example.displayName"
     actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
        forwardName=example.config.view&
        lastPage=ApplicationServer.config.view">
   </link>
 </extension>
</plugin>
```

Task overview: Assembling applications using remote request dispatcher

Remote request dispatcher (RRD) is a pluggable extension to the Web container which allows application frameworks, servlets and JavaServer Pages (JSP) to include content from outside the currently executing resource's Java Virtual Machine (JVM) as part of the response sent to the client.

Before you begin

You must have WebSphere Application Server Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, "Remote request dispatcher considerations" on page 78 for details.

1. Installing enterprise application files with the console
2. Configure the sending of include requests between the application and remote resources.

- “Configuring Web applications to dispatch remote includes” on page 76
- “Configuring Web applications to service remote includes” on page 76

3. Optional: Modify your application to locate resources located in two different contexts using the servlet programming model.

   The Servlet Programming Model for including resources remotely does not require you to use any non-Java 2 Platform, Enterprise Edition (J2EE) Servlet Application Programming Interfaces (APIs). The remote request dispatcher (RRD) component follows the same rules to obtain a ServletContext and a remote resource. By using JavaServer Pages standard tag library (JSTL), your application is further removed from obtaining a ServletContext object or RequestDispatcher that is required in the framework example in the following step because the JSTL custom tag does this implicitly. Study the following example of a sample JavaServer Pages application to learn how to locate resources that are in two different contexts, investments and banking.

```
<HEAD>
<%@ page
language="java"
contentType="text/html; charset=ISO-8859-1"
pageEncoding="ISO-8059-1"
isELIgnored="false"
%>
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" $>
</HEAD>
<BODY>

<%--

Programming example using JavaServer Pages and JavaSever Pages
Standard Tag Library (JSTL).
JSTL provides a custom tag to import contents (in servlet and JSP
terms include) in the scope of the same request from outside of
the current Web module context by specifying a context parameter.

JSTL restriction: The Web module that is imported
must run inside of the same JVM as the calling resource
if imported URL is not fully qualified.

RRD extends this functionality by permitting the Web module to
be located within the scope of the current WebSphere Application
Server core group versus the scope of the JVM.
--%>

<hr size="5"/>
<%--  Include resource investmentSummary.jsp located in the
  Web application with context root of /investments. --%>

<c:import url="investmentSummary.jsp" context="/investments"/>

<hr size="5"/>
<%--  Include resource accountSummary.jsp located in the
  Web application with context root of /banking. --%>

<c:import url="accountSummary.jsp" context="/banking"/>

<hr size="5"/>

</BODY>
</HTML>
```

4. Optional: Modify your application to locate resources located in two different contexts using the framework programming model.

   The Framework Programming Model for including resources remotely does not require you to use any non-Java 2 Platform, Enterprise Edition (J2EE) Servlet Application Programming Interfaces (APIs). When a request is initiated for a ServletContext name that is not presently running inside of the current

Web container, the remote request dispatcher (RRD) component returns a ServletContext object that can locate a resource that exists anywhere inside a WebSphere Application Sever Network Deployment environment provided that the resource exists and RRD is enabled for that ServletContext object. Study the following sample framework snippet that demonstrates how to locate resources located in two different contexts, investments and banking.

```
/*
Programming example using a generic framework.
Servlet Specification provides an API to obtain
a servlet context in the scope of the same request
different from the current Web module context by
specifying a context parameter.

Servlet Specification restriction: The Web module that obtain
must run inside of the same JVM as the calling resource.

RRD extends this functionality by permitting the Web module to be located
within the scope of the current WebSphere Application Server core group
versus the scope of the JVM.

*/

protected void frameworkCall (ServletContext context, HttpServletRequest request, HttpServletResponse response)
       throws ServletException, IOException(

   PrintWriter writer = response.getWriter();

   writer.write("<HTML>");
   writer.write("<HEAD>");
   writer.write("</HEAD>");
   writer.write("<BODY>");
   writer.write("<hr size=\"5/">);

   //Include resource investmentSummary.jsp located in Web application
   //with context root of /investments.
   RequestDispatcher rd = getRequestDispatcher ( context, "/investments", "/investmentSummary.jsp");
   rd.include(request, response);

   writer.write("<hr size=\"5/">);

   //Include resource accountSummary.jsp located in Web application
   //with context root of /banking.
   rd = getRequestDispatcher ( context, "/banking", "/accountSummary.jsp");
   rd.include(request, response);

   writer.write("</BODY>");
   writer.write("</HTML>");
}
private RequestDispatcher getRequestDispatcher (ServletContext context, String contextName, String resource) {
   return context.getContext(contexName).getRequestDispatcher(resource);
}
```

Results

After enabling at least one enterprise application to dispatch remote includes and at least one enterprise application to service remote includes, RRD is now enabled.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable RRD on each application.

Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the Web container that allows application frameworks, servlets and JavaServer Pages to include content from outside of the current executing resource's Java virtual machine (JVM) as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure to allow other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard J2EE `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using Web services to communicate between machines within a Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also leverage SSL for secure communications and WS-Security security context propagation between servers. See rrdSecurity.props file for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container to allow invocation of portlets outside of the current executing resource's JVM.

By utilizing the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are invoked as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and OutputStream

  Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to WebSphere Application Server's plugin
  - Method calls return the state as if they are on local server. For example, getServer returns the local server name or isSecure returns whether the request to the 'local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.
  - Sessions in local and remote servers use the same cookie or session id for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is a exception on the remote server, the server returns an RRD specific Web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD specific ServletException is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache

  When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

You can use SSL to encrypt RRD messages between application servers. This is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD leverages WS-Security to pass this information, but this security context propagation is disabled by default. See the topic, rrdSecurity.props file, for additional information.

Configuring Web applications to dispatch remote includes

You can configure Web modules in an application as remote request dispatcher clients to dispatch include requests to resources across Web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

Before you begin

You must have WebSphere Application Server for Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, “Remote request dispatcher considerations” on page 78 for details.

About this task

You can also configure this property when you install the application installation. See Installing enterprise application files with the console

1. In the administrative console, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Request dispatcher properties**.
2. Select **Allow dispatching includes to remote resources**.

Results

Web modules included in this application are enabled as remote request dispatcher clients that can dispatch remote includes.

What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the remote server that includes the resource that you want to include, see article, “Configuring Web applications to service remote includes.”

Configuring Web applications to service remote includes

You can configure Web modules in an application as remote request dispatcher servers that are remotely included by other Web applications.

Before you begin

You must have WebSphere Application Server Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, “Remote request dispatcher considerations” on page 78 for details.

About this task

The purpose of this task is to specify whether an application can service an include request from another application. You can also configure this property when you install the application installation. Some statement about the process used to arrive here. See Installing enterprise application files with the console

1. In the administrative console, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Request dispatcher properties**.

2. Select **Allow servicing includes from remote resources**.

Results

Web modules included in this application are enabled as remote request dispatcher servers that are resolved to service remote includes from another application.

What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the local server to include a remote resource, see article, “Configuring Web applications to dispatch remote includes” on page 76.

Configuring remote request dispatcher caching

The creation and handling of the remote request dispatcher (RRD) message and the transfer of this data across a network creates substantial overhead. To improve performance, the local machine can receive the cache rules of the remote server and know when to cache the response locally to prevent the RRD call altogether.

About this task

Unsupported rules are cached remotely. However, remote request dispatcher does not support the entire set of rules of the cachespec.xml file for local caching. The following rules for the cachespec.xml file are supported for local caching.

parameters
Retrieves the named parameter value.

cookie
Retrieves the named cookie value.

header
Retrieves the named request header.

locale
Retrieves the request locale.

requestType
Retrieves the HTTP request method from the request.

Complete the following steps to enable RRD dynamic cache support.

1. Enable servlet caching on the local server See Configuring servlet caching for more information
2. Construct and install an application with a valid `cachespec.xml file` policy with RRD supported rules. See the article, Configuring cacheable objects with the cachespec.xml file, for additional information.
3. Enable servlet caching on the remote server. See Configuring servlet caching for more information
4. Restart WebSphere Application Server. See Managing application servers for more information.

Results

To verify that dynamic cache is enabled locally, you can enable RRD trace and verify that there is a CACHE HIT printed out for multiple requests to a resource that has an appropriate cache policy. You also have the option to use CacheMonior instead of turning on tracing. If the CacheMonitor on the remote machine is not receiving cache hits, then the response is cached locally. The local CacheMonitor will not receive hits because RRD uses its own custom cache.

Remote dispatcher property settings

Use this page to configure the sending of include requests between the application and remote resources.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → ***application_name*** → **Request dispatcher properties**.

Allow dispatching includes to remote resources

Specifies whether an application can dispatch include requests to resources across Web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

Data type	Boolean
Default	false

Allow servicing includes from remote resources

Specifies whether an application can service an include request from another application.

Data type	Boolean
Default	false

Asynchronous request dispatching type

Changes the behavior of the servlet request dispatcher to support cross-JVM dispatching and asynchronous dispatching.

Disabled	Specifies that asynchronous request dispatching is not supported for this application
Server side	Specifies that the response content is aggregated on the server
Client side	Specifies that the response content is aggregated on the client/browser

Remote request dispatcher considerations

This topic presents some considerations of which you need to be aware when using remote request dispatcher.

- If an application expects parameters in certain encoding, the application should set character encoding, as in a normal include, before the remote request dispatch (RRD) occurs.
  - ServletInputStream data of local server is not available to remote server. The local server parses POST data prior to sending the RRD request to the remote server and include parameters as request parameters. Multipart form data is inaccessible to remote server. An UnsupportedOperationException is created if the remote server attempts to obtain inputstream from the request.
  - No access to original request reference on the remote server.
  - Request and response wrappers created in the local server are not available in remote server. This cannot be done due to ServletRequestWrappers and WebSphere internal ServletRequest objects not implementing Serializable.
- Request attributes need to be serializable.
  - Class definition of attributes need to be available in both local and remote servers.
  - Request attributes are propagated to the remote server and back to the local server.
- HTTP Sessions
  - You cannot have cross session access between different Web applications when Web applications are remote.

  - When all Web applications are in a local server, an application can share sessions across Web applications by storing the session in a table that is accessible to multiple Web applications. This is not possible with RRD and not recommended in local case either.
  - Servlet Programming Model: You cannot access sessions in different Web applications.
  - Normal programming model in local case as well as remote case.
  - In local mode, application can cache away reference and share the session across the Web applications, which is not feasible in RRD case.
  - A session object that is stored as request attribute is not available on remote server as the Session class does not implement Serializable.
- Thread local variables that are set on the local server are not available on the remote server.
- Not all methods defined on ServletContext object are available for the RRD ServletContext object. See the SPI documentation for com.ibm.wsspi.rrd.context.RemoteServletContext for details.
- The remote server does not have access to output of local server when using RRD.
- Cookies and ServletRequestWrappers

  If customer application wrappers the HttpServletRequest.getCookies method and returns additional cookies or removes cookies, the modified cookies are not sent to the remote server because javax.servlet.http.Cookie does not implement Serializable. Cookies from the original request headers are sent to the remote server.

Servlet extension interfaces

You can use extension generators and handlers to add content to the remote message for servlet and portlets calls. The servlet extension can also modify existing behavior by leveraging the filter concept. The Remote Request Dispatcher (RRD) extension framework relies on extension generators, which attach arbitrary data to an outbound RRD request, and extension handlers, which consume the data and perform actions based on the data received.

- " Extension generators"
- "Extension handlers" on page 80
- "Extension delegators" on page 81
- "Custom EMF packages" on page 81

For more information on the `com.ibm.wsspi.rrd.extension` package, see Additional Application Programming Interfaces (APIs) for administrators.

Extension generators

Extension generators, which are part of an extension generator chain, are invoked prior to initiating an RRD request. This extension generator chain is defined in the com.ibm.wsspi.rrd.generators extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local Web application.

Each extension generator is defined by a generator element, which contains an id attribute, which is used to assign a unique identifier to the extension generator such that any extension generator can be targeted by extensions added to RRD response data. The class attribute is used to specify the class name of the extension generator, which must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface. Each extension generator can also have an execution order associated with it via the order attribute, which is useful for enforcing extension generator execution order in an environment where multiple extension generator descriptor files are present. Additionally, a generator has a mandatory attribute called type that defines the type of the generator. For servlet RRD, the value is "servlet" and the class must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface.

Additionally, each extension generator may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the generator element. An example extension generator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.generators">
  <generator id="int1"
        class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
        order="1"
        type="servlet">
    <init-param>
            <param-name>intValue</param-name>
            <param-value>100</param-value>
    </init-param>
   </generator>
   <generator id="string1"
        class="com.ibm.ws.rrd.example.extension.StringExtensionGenerator"
        order="2"
        type="servlet">
      <init-param>
            <param-name>stringValue</param-name>
            <param-value>This is an example string</param-value>
      </init-param>
   </generator>
   <generator id="int2"
        class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
        order="3"
        type="servlet">
      <init-param>
            <param-name>intValue</param-name>
            <param-value>200</param-value>
      </init-param>
   </generator>
</extension>
```

For more information on the `com.ibm.wsspi.rrd.extension.generator` package, see Additional Application Programming Interfaces (APIs) for administrators.

Extension handlers

Extension handlers, which are part of an extension handler chain, are invoked after an RRD request has been received. This extension handler chain is defined in the `com.ibm.wsspi.rrd.handlers` extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local Web application.

Each extension handler is defined by a handler element, which contains namespaceURI and localName attributes, the combination of which defines the qualified name of the extension data that the extension handler can process. Each extension handler additionally requires a unique identifier, specified by the id attribute. The value specified by this attribute must correspond to an extension generator, which generates extension data of a matching qualified name and identifier. The class attribute is used to specify the class name of the extension handler, which must implement the com.ibm.wsspi.extension.handler.ExtensionHandler interface. Additionally a handler has a mandatory attribute called type that defines the type of the handler. The value is “servlet” and the class must implement the com.ibm.wsspi.rrd.extension.handler.ExtensionHandler interface.

Additionally, each extension handler may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the handler element. An example extension handler declaration follows:

```
  <extension point="com.ibm.wsspi.rrd.handlers">
      <handler id="int1"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="1"
               type="servlet"/>
      <handler id="string1"
               class="com.ibm.ws.rrd.example.extension.StringExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="2"
               type="servlet"/>
      <handler id="int2"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="3"
               type="servlet"/>
</extension>
```

For more information on the `com.ibm.wsspi.rrd.extension.handler` package, see Additional Application Programming Interfaces (APIs) for administrators.

Extension delegators

An extension delegator enables RRD to handle arbitrary servlet containers by allowing users to specify the specific extension generator and handler chain instances that are to be used during an RRD call. RRD maintains a user-extendable list of extension delegators and selects an appropriate delegator at runtime based on the type of servlet request being issued.

Custom extension delegators may be defined in the `com.ibm.wsspi.rrd.rrd-extension-delegator` extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the WEB-INF directory of an RRD-enabled local Web application.

Each extension delegator is defined by an `ExtensionDelegator` element, which contains a priority attribute for defining the relative order in which an extension delegator is initiated, and a classname attribute that defines the implementing class for a particular extension delegator, which must implement the `com.ibm.wsspi.rrd.extension.factory.ExtensionDelegator` interface. Note that the execution order of two or more extension delegators with the same priority is not predictable. An example extension delegator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-extension-delegator">
  <ExtensionDelegatorRegistration>
    <ExtensionDelegator priority="1" classname="com.ibm.ws.rrd.extension.PortletExtensionDelegator"/>
    <ExtensionDelegator priority="2" classname="com.ibm.ws.rrd.extension.ServletExtensionDelegator"/>
  </ExtensionDelegatorRegistration>
</extension>
```

Custom EMF packages

Extension data produced by an extension generator and consumed by an extension handler is serialized using the Eclipse Modeling Framework (EMF). Users intending to use custom extension data should utilize the `com.ibm.wsspi.rrd.rrd-emf-packages` extension point in order to ensure that the proper EMF packages are initialized prior to use by RRD. This extension point is part of the plugin.xml file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local Web application.

Each EMF package is defined by an `emfPackage` element, which contains a className element that must point to the generated EMF factory implementation class for a particular EMF package (the generated model class which implements `org.eclipse.emf.ecore.impl.EFactoryImpl`). An example EMF package declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-emf-packages">
  <emfPackages>
    <emfPackage className="com.ibm.ws.rrd.webservices.types.emf.impl.TypesFactoryImpl" />
  </emfPackages>
</extension>
```

Note: If the same generated EMF model code is shared among multiple Web applications that the EMF model code must be part of a shared server library, but only in the case that all Web applications are running in the same application server. In production, this is usually not the case, and common EMF model code may exist at the Web application level.

Related tasks

"Task overview: Assembling applications using remote request dispatcher" on page 72
Remote request dispatcher (RRD) is a pluggable extension to the Web container which allows application frameworks, servlets and JavaServer Pages (JSP) to include content from outside the currently executing resource's Java Virtual Machine (JVM) as part of the response sent to the client.

Chapter 2. Portlet applications

Task overview: Managing portlets

You can use this task to manage deployed portlet applications.

Before you begin

Before you begin this task, you must have a portlet application installed. See Installing enterprise application files for additional information.

About this task

You can complete the following steps to manage portlets.

- Render a portlet.
  - Access a single portlet using “Portlet Uniform Resource Locator (URL) addressability” on page 90.
  - Access multiple portlets using “Portlet aggregation using JavaServer Pages” on page 84.
  - Access portlets using “Remote request dispatcher” on page 75.
- Change the location of “Portlet preferences” on page 92. By default, portlet preferences for each portlet window are stored in a cookie. However, you can change the location of where to store portlet preferences.
- Disable URL addressability. By default, you can access a portlet through an Uniform Resource Locator (URL), however, you can disable this feature.
- Enable portlet fragment caching. Portlet fragment caching is disabled by default.

Portlets

Portlets are reusable Web modules that provide access to Web-based content, applications, and other resources. Portlets can run on WebSphere Application Server because it has an embedded JSR 286 Portlet container. The JSR 286 API provides backwards compatibility. You can assemble portlets into a larger portal page, with multiple instances of the same portlet displaying different data for each user.

From a user’s perspective, a portlet is a window on a portal site that provides a specific service or information, for example, a calendar or news feed. From an application development perspective, portlets are pluggable Web modules that are designed to run inside a portlet container of any portal framework. You can either create your own portlets or select portlets from a catalog of third-party portlets.

Each portlet on the page is responsible for providing its output in the form of markup fragments to be integrated into the portal page. The portal is responsible for providing the markup surrounding each portlet. In HTML, for example, the portal can provide markup that gives each portlet a title bar with minimize, maximize, help, and edit icons.

You can also include portlets as fragments into servlets or JavaServer Pages files. This provides better communication between portlets and the Java Platform, Enterprise Edition (Java EE) Web technologies provided by the application server.

If you use Rational Application Developer version 6 (RAD) to create your portlets, you must remove the following reference to the std-portlet.tld from the web.xml file to run the portlets outside of RAD:

```
<taglib id="PortletTLD">
 <taglib-uri>http://java.sun.com/portlet</taglib-uri>
 <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

Also if you use RAD version 6 to create portlets, note that portlets created by using the Struts Portlet Framework are not supported on WebSphere Application Server.

Portlet applications

If the portlet application is a valid Web application written to the Java Portlet API, the portlet application can operate on both the Portal Server and the WebSphere Application Server without requiring any changes. JSR 168 and JSR 286 compliant portlet applications must not use extended services provided by WebSphere Portal to operate on the WebSphere Application Server.

Portlet container

The *portlet container* is the runtime environment for portlets using the JSR 286 Portlet specification, in which portlets are instantiated, used, and finally destroyed. The JSR 286 Portlet API provides standard interfaces for portlets and backwards compatibility for JSR 168 portlets. Portlets based on this JSR 286 Portlet Specification are referred to as standard portlets.

A simple portal framework is provided by the PortletServingServlet servlet. The PortletServingServlet servlet registers itself for each Web application that contains portlets. You can use the PortletServingServlet servlet to directly render a portlet into a full browser page by a URL request and invoke each portlet by its context root and name. See “Portlet Uniform Resource Locator (URL) addressability” on page 90 for additional information. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article “Portlet aggregation using JavaServer Pages” for additional information. The PortletServingServlet servlet can be disabled in an extended portlet deployment descriptor called the ibm-portlet-ext.xmi file.

Remote request dispatcher support for portlets

The remote request dispatcher (RRD) support allows the invocation of portlets outside of the current Java virtual machine (JVM) within an Network Deployment single core group environment. The request related data is passed to the remote JVM where the portlet is invoked. The response is transmitted back and processed on the local JVM. Thus it guarantees that URLs contained in the portlet markup are created according to the local portal context. The remote request dispatcher support is only provided for JSR 168 compliant portlets.

Portlet container settings

Use this page to configure and manage the portlet container of this application server.

To view this administrative console page, click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Portlet Container Settings** → **Portlet container**.

Enable portlet fragment cache

Specifies whether to create a cached entry when a portlet is invoked, similar to servlet caching of the Web container settings.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Portlet aggregation using JavaServer Pages

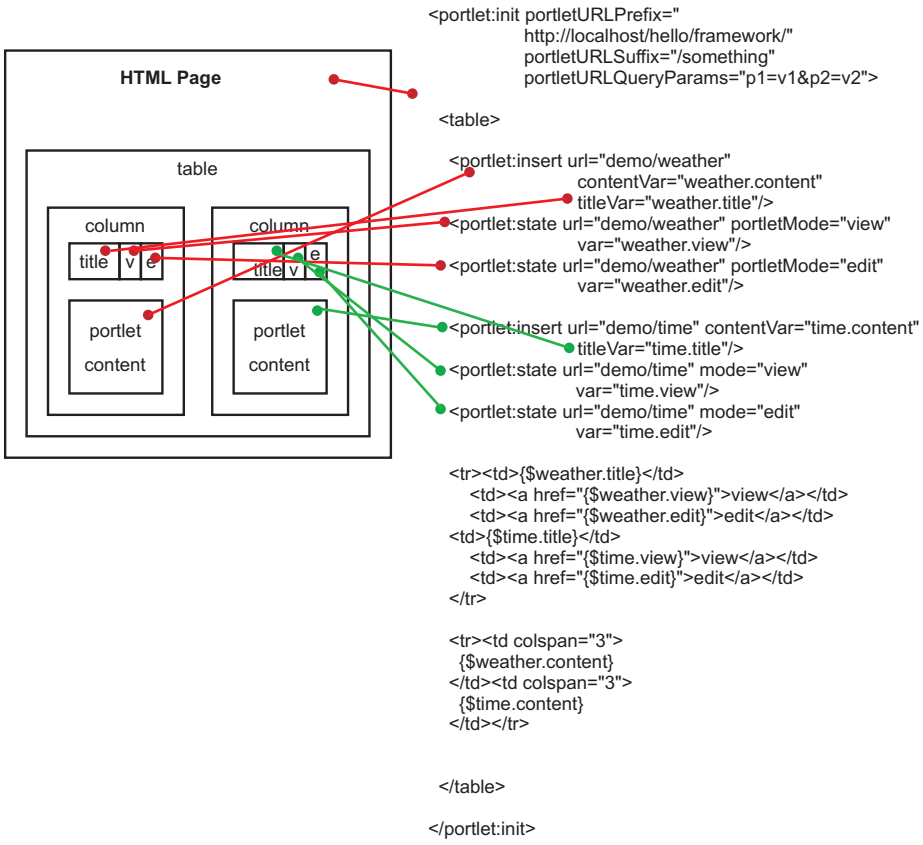
The aggregation tag library generates a portlet aggregation framework to address one or more portlets on one page If you write JavaServer Pages, you can aggregate multiple portlets on one page using the aggregation tag library. This tag library does not provide full featured portal aggregation implementation, but provides a good migration scenario if you already have aggregating servlets and JavaServer Pages and want to switch to portlets.

To allow the customer to create a simple portal aggregation, the aggregation tag library also provides the following features.

- Invoke a portlet's action method
- Render multiple portlets on one page
- Provide links to change the portlet's mode or window state
- Display the portlet's title
- Retain the portlet cookie state

The aggregation tag library and JavaServer Pages that use the aggregation tag library will only work with the WebSphere Application Server portlet container implementation because the protocol between the tags and the container is not standardized.

The following diagram depicts how an HTML page would look like and what tags are used in order to create the page. See "Aggregation tag library attributes" on page 86 for information on the aggregation tag library attributes.



When you use the aggregation tag library, you must set the portletUrlPrefix attribute of the init tag to the aggregating application. You need to:

- Ensure that the portletUrlPrefix attribute is set to the following in the aggregator page.

  `"http://" + <server_address> + ":" + <server_port> + "/" + <aggregator context> + "/" <aggregator mapping>`
- Reference the aggregation JSP page within the web.xml file through a servlet mapping ending with `/*`. For example, `/aggregation/*`

When aggregating multiple portlets on a single page, special care must be used with the naming conventions of form attribute names in your portlets. Because your portlets are all on the same page, they all share the same HttpServletRequest. When one portlet is viewed the entire page is refreshed and form

data is re-posted. Therefore, if there are multiple portlets that are aggregated on a single page with the same form attribute names, there could be logic corruption when form data is re-posted.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the init tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The state and insert tags are sub-tags of the init tag.

The init tag has the following attributes:

- portletURLPrefix = ”<any string>”

  This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is a required attribute.
- portletURLSuffix = ”<any string>”

  This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is attribute optional.
- portletURLQueryParams = ”<any string>”

  This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet’s render method, which is called by using the insert tag. This is attribute optional.

scope, portlet

The scope tag and portlet tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, /context1/context2. These tags add a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- context = ″/<context1>/<context2>″

  Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.
- portletname = ″<portlet-name>″

  Specifies the portlet-name. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the scope and portlet tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
         <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/ ">
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This

tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = ”<context>/<portlet-name>”

  Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the portlet URL created by this tag. This is attribute optional.
- var = ”<any string>”

  If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.
- scope = ”page|request|session|application”

  This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.
- portletMode = ”view|help|edit|<custom>”

  This attribute sets the portlet mode.
- portletWindowState = ”maximized|minimized|normal|<custom>”

  This attribute sets the window state.
- action = ”true/false”

  This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = ”<any string>”

  Indicates the name of the parameter. This is attribute required.
- value = ”<any string>”

  Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = ”<context>/<portlet-name>” (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet

  This is attribute required.
- windowId = ”<any string>”

  Defines the window ID of the portlet. This is attribute optional.
- contentVar = ”<any string>”

  If defined, the portlet’s content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = ”page|request|session|application”

  This attribute is only valid if the contentVar tag is used. If defined, the portlet’s content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.
- titleVar = ”<any string>”

If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.

- titleScope = "page|request|session|application"

  This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">

   <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
       portletWindowState="maximized">
        <portlet:urlParam name="namea" value="valuea"/>
        <portlet:urlParam name="nameb" value="valueb"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
       portletWindowState="minimized">
        <portlet:urlParam name="namemin" value="valuemin"/>
        <portlet:urlParam name="namemin" value="valuemin"/>
    </portlet:state>

    <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
  portletWindowState="maximized">
        <portlet:urlParam name="name3" value="value3"/>
        <portlet:urlParam name="name4" value="value4"/>
        <portlet:urlParam name="name5" value="value5"/>
        <portlet:urlParam name="name5" value="value5a"/>
        <portlet:urlParam name="name5" value="value5b"/>
        <portlet:urlParam name="name5" value="value5c"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
  action="true" portletWindowState="normal">
        <portlet:urlParam name="name6" value="value6"/>
        <portlet:urlParam name="name6" value="value6z"/>
            </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
  portletWindowState="minimized">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>

    <portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
    <portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
    <portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>
```

```
<!--  This table is the outtermost table for creating two-column portal layout  -->
<TABLE border="0" CELLPADDING="3" CELLSPACING="8" WIDTH="100%">
<TR>

You can include the following formatting to the previous example JSP file immediately after declaring the tag library.

```
<STYLE TYPE="TEXT/CSS">
BODY {
    font-family:Verdana,sans-serif; font-size:70%
}
.portletTitle {
    text-align: left;border-top: #000000 1px solid; border-bottom: #000000 1px solid; FONT-SIZE: 60.0%;
    COLOR: #ffffff; FONT-FAMILY: Verdana, Arial, Helvetica, sans-serif; BACKGROUND-COLOR: #5495d5;
}
.portletTitleControls {
    text-align: right;border-top: #000000 1px solid; border-right: #000000 1px solid; border-bottom: #000000
    1px solid; FONT-SIZE: 60.0%; COLOR: #ffffff; FONT-FAMILY: Verdana, Arial, Helvetica, sans-serif;
    BACKGROUND-COLOR: #5495d5;
}
.portletTitleControls A {
    COLOR: #ffffff; text-decoration:none; border:#5495d5 1px solid;border-left:white 1px solid;
    padding-left:0.5em; padding-right:0.5em;
}
.portletTitleControls A:hover {
    COLOR: #ffffff; text-decoration:none; border-top:white 1px solid;
   border-bottom:white 1px solid;border-right:white 1px solid;
}
.minimizeControl {
    font-weight:bold; font-size:100%;
}
.portletTable {
    border-left: gray 1px solid;
    border-bottom: gray 1px solid;
    border-right: gray 1px solid;
}
.portletBody {
    font-family:Verdana,sans-serif; font-size:70%
}

</STYLE>
```

Portlet Uniform Resource Locator (URL) addressability

You can request a portlet directly through a Uniform Resource Locator (URL) to display its content without portal aggregation. The PortletServingServlet servlet registers each Web application that contains portlets. It is similar to the FileServingServlet servlet of the Web container that serves resources. The PortletServingServlet servlet supports direct rendering of portlets into a full browser page by a URL request.

You can invoke each portlet by its context root and name with the URL mapping /<portlet-name> that is created for each portlet. The context root and name has the following format:

```
http://<host>:<port>/<context-root>/<portlet-name> For example,
 http://localhost:9080/portlets/TestPortlet1
```

The context root identifies the Web archive (WAR) file that contains the portlet. The portlet name uniquely identifies the portlet with a portlet application of a WAR file. The DefaultDocumentFilter servlet only supports HTML, UTF8 encoding and an extended URL form based on the basic URL form as shown above.

You can only display one portlet at a time using the PortletServingServlet servlet. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. See the article “Portlet aggregation using JavaServer Pages” on page 84 for additional information.

Because a portlet only delivers fragment output whereas a servlet usually delivers document output, a mechanism is introduced to convert the fragment into a document, called the PortletDocumentFilter filter. By default, the PortletDocumentFilter filter only supports converting HTML. The conversion is implemented using a servlet filter before the PortletServingServlet servlet is initiated to return the portlet‘s content inside of a document. This default document servlet filter only applies to URL requests, not for includes or forwards using the RequestDispatcher method. You can create servlet filters to support other markups additional document servlet filters. See the article, Converting portlet fragments to an HTML document, for additional information.

The PortletServingServlet servlet does not persist portlet preferences in a XML file or database. It places the portlet preferences directly into a cookie to store the preferences persistently. See the article, “Portlet preferences” on page 92, for additional information on how to change this behavior.

Portlet URL syntax

You can add additional portal context such as portlet mode or window state. You can access the PortletServingServlet servlet by using a URL mapping that has the following structure:

```
http://host:port/context/portlet-name [/portletwindow[/ver [/action |
 /resource[/id=custom-id][/cacheability]] [/mode] [/state] [rparam][/?name]]]
```

Any differing URL structure results in a com.ibm.wsspi.portletcontainer.InvalidURLException exception. Empty strings are not permitted as parameter values and creates an InvalidURLException exception. The following is a list of valid parameters:

http:// host:port/context/*portlet-name*
: This is the minimum URL required to access a portlet. A default portlet window called ‘default’ is created. The *portlet-name* variable is case-sensitive.

/*portletwindow*
: This parameter identifies the portlet window. You must set this parameter if you choose to add more portal context information to the URL.

/ver=*major.minor*
: This optional parameter is used to define the version of the portlet API that is used. You must set this parameter if you choose to add more portal context information to the URL. Only versions ’1.0’ and ’2.0’ are supported. Any other version creates an InvalidURLException exception.

/action
: This is a required parameter if you call the action method of the portlet. The action parameter causes the action process of the portlet to be called. After the action has been completed, a redirect is automatically issued to call the render process. To control the subsequent render process, a document servlet filter can set a request attribute with name ’com.ibm.websphere.portlet.action’ and value ’redirect’ to specify that the portlet serving servlet directly returns after action without calling the render process.

/mode=view | edit | help | *custom-mode*
: This optional parameter defines the portlet mode that is used to render the portlet. The default mode is ‘view’. The value is not case-sensitive. For example, ‘View’, ‘view’ or ‘VIEW’ results in the same mode.

/state=normal | maximized | minimized | *custom-state*
: This optional parameter defines the window state that is used to render the portlet. The default state is ‘normal’. The value is not case-sensitive, for example, ‘Normal’, ‘normal’, or ‘NORMAL’ results in the same state.

*** [/rparam=***name* ***[=***value***]]**
This optional parameter specifies render parameters for the portlet. Repeat this parameter chain to provide more than one render parameter. For example, /rparam=invitation/ rparam=days=Monday=Tuesday.

?name=*value***&***name2***=***value2* **...**
Query parameters may follow optionally. They are not explicitly supported by the portlet container, but they do not invalidate the URL format.

/action | /resource
This parameter defines the methods of the portlet that is called. Valid values are no, action or resource parameter. No specific method defined calls the render method. The resource parameter is only supported for JSR 286 portlets.

/resource [/id=custom-id] [/cacheability=cacheLevelFull | cacheLevelPortlet | cacheLevelPage]
Set this parameter to define the method of the portlet to be called. No redirection occurs. No other method of the portlet is called. To control the resource parameter, you can add an additional ID parameter to provide a resource serving identifier that is passed through to the portlet. The cacheability parameter defines the cache level of this resource URL. This parameter is only supported with JSR 286 portlets .

The following list includes examples of valid JSR 168 and JSR 286 URLs:

- http:// localhost:9080/sample/WorldClock
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/mode=edit/rparam=timezone=UTC
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/action/state=maximized?timezone=UTC
- http://localhost:9080/sample/WorldClock/myPortlet/ver=2.0/resource/id=somePicture.jpg

Portlet preferences

Preferences are set by portlets to store customized information. By default, the PortletServingServlet servlet stores the portlet preferences for each portlet window in a cookie. However, you can change the location to store them in either a session, an .xml file, or a database.

Storing portlet preferences in cookies

The attributes of the cookie are defined as follows:

Path
context/*portlet-name*/*portletwindow*

Name:
The name of the cookie has the fixed value of **PortletPreferenceCookie**.

Value
The value of the cookie contains a list of preferences by mapping to the following structure:

```
*['/' pref-name *['=' pref-value]]
```

All preferences start with '/' followed by the name of the preference. If the preference has one or more values, the values follow the name separated by the '=' character. A null value is represented by the string '#*!0_NULL_0!*#'. As an example, the cookie value may look like, /locations=raleigh=boeblingen/ regions=nc=bw

Customizing the portlet preferences storage

You can override how the cookie is handled to store preferences in a session, an .xml file or database. To customize the storage, you must create a filter, servlet or JavaServer Pages file as new entry point that

wraps the request and response before calling the portlet. Examine the following example wrappers to understand how to change the behavior of the PortletServingServlet to store the preferences in a session instead of cookies.

The following is an example of how the main servlet manages the portlet invocation.

```
public class DispatchServlet extends HttpServlet
{
    ...
    public void service(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
    {
 response.setContentType("text/html");

 // create wrappers to change preference storage
 RequestProxy req = new RequestProxy(request);
 ResponseProxy resp = new ResponseProxy(request, response);

 // create url prefix to always return to this servlet
                ...
                req.setAttribute("com.ibm.wsspi.portlet.url.prefix", urlPrefix);

 // prepare portlet url
 String portletPath = request.getPathInfo();
                ...

 // include portlet using wrappers
 RequestDispatcher rd = getServletContext().getRequestDispatcher(modifiedPortletPath);
                rd.include(req, resp);
    }
}
```

In the following example, the request wrapper changes the cookie handling to retrieve the preferences out of the session.

```
public class RequestWrapper extends HttpServletRequestWrapper
{
    ...
    public Cookie[] getCookies() {
        Cookie[] cookies = (Cookie[]) session.getAttribute("SessionPreferences");
        return cookies;
    }
}
```

In the following example, the response wrapper changes the cookie handling to store the preferences in the session:

```
public class ResponseProxy extends HttpServletResponseWrapper
{
   ...
    public void addCookie(Cookie cookie) {
        Cookie[] oldCookies = (Cookie[]) session.getAttribute("SessionPreferences");
        int newPos = (oldCookies == null) ? 0 : oldCookies.length;
        Cookie[] newCookies = new Cookie[newPos+1];
        session.setAttribute("SessionPreferences", newCookies);

        if (oldCookies != null) {
        System.arraycopy(oldCookies, 0, newCookies, 0, oldCookies.length);
        }
        newCookies[newPos] = cookie;
    }
}
```

Example: Configuring the extended portlet deployment descriptor to disable PortletServingServlet

Portlet URL serving supports direct access to all functions and states of a portlet by creating the appropriate URLs. In a production setup where the portlet is served through an enterprise portal application that applies its own access control, is considered a security risk. By setting the portletServingEnabled property to false, an administrator can ensure that a sensitive portlet is never accessed by direct URL serving.

Extensions for the portlet deployment descriptor are defined within a file called ibm-portlet-ext.xmi. This deployment descriptor is an optional descriptor that you can use to configure WebSphere extensions for the portlet application and its portlets. For example, you can disable the PortletServingServlet servlet for the portlet application in the extended portlet deployment descriptor.

The ibm-portlet-ext.xmi extension file is loaded during application startup. If there are no extension files specified with this setting, the default values of the portlet container are used.

The default for the portletServingEnabled attribute is true. The following is an example of how to configure the application so that a PortletServingServlet servlet is not created for any portlet on the portlet application.

```
<?xml version="1.0" encoding="UTF-8"?>
<portletappext:PortletApplicationExtension xmi:version="1.0"
    xmlns:xmi="http://www.omg.org/XMI"
    xmlns:portletappext="portletapplicationext.xmi"
    xmlns:portletapplication="portletapplication.xmi"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmi:id="PortletApp_ID_Ext"
    portletServingEnabled="false">
  <portletappext:portletApplication href="WEB-INF/portlet.xml#myPortletApp"/>
</portletappext:PortletApplicationExtension>
```

Portlet container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of the available Portlet container custom properties.

To specify Portlet container custom properties:

1. In the administrative console click **Servers** → **Server Types** → **WebSphere application servers** → ***server_name*** → **Portlet Container Settings** → **Portlet container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

Following is a list of custom properties provided with the Application Server.

Using short names for Portlet and PortletApplication MBeans

Portlet MBeans are registered by both their short name and full name. To enable the use of short MBean names, create the following name-value pair:

Name	Value
useShortMBeanNames	true

The default is false.

MBeans registered by the full identifiable name, have the following format:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`.

Portlet and PortletApplication MBeans

The MBeans of type portlet and portletapplication provide information about a given portlet application and its portlets. Through the MBean of type portletapplication, you can retrieve a list of names of all portlets that belong to a portlet application. By querying the MBean of type portlet with a given portlet name, you can retrieve portlet specific information from the MBean of type portlet.

Each MBean that corresponds to a portlet or portlet application is uniquely identifiable by its name. Portlet applications are not required to have a name set within the portlet.xml. The MBean name for MBeans of the portletapplication type is the enterprise archive (EAR) file name followed by ″#″ and the Web module name concatenated with the string ″_portlet″. For example, portletapplication type MBeans have the following format:

```
<EarFileName>#<WarFileName>_portlet
```

The name chosen for the MBean of type portlet is the name of the MBean of type portletapplication that the portlet belongs to, concatenated with the portlet name:

```
<EarFileName>#<WarFileName>_portlet.<portletname>
```

The following is an example of the resulting PortletApplication MBean name and portlet names:

```
EarName            SampleEar
WebModule            SampleWar.war

PortletApplication MBean name:   SampleEar#SampleWar_portlet
Portlet:            SampleEar#SampleWar_portlet.BookmarkPortlet
```

The MBean names have been changed compared to version 6.1, because the old naming patterns are not unique and can lead to problems under certain circumstances. If you rely on the old naming pattern, you can set the portlet container custom property, `useShortMBeanNames`, to true to activate the previous known MBean names. Because this is a performance impact, you might not want to activate the old naming pattern if it is not necessary.

A full stop separates the preceding Web module name from the portlet name. Review the Portlet and PortletApplication MBean type API documentation for additional information. The generated API documentation is available in the information center table of contents from the path, **Reference** > **Administrator** > **API documentation** > **MBean interfaces**.

The following code is an example of how to invoke the MBean of type portletapplication for an application with the name, SampleWar.

```
String myPortletApplicationName = "SampleEar#SampleWar_portlet";
This name is composed by the Ear file name followed by "#" and
the Web module name concatenated with the substring "_portlet"

com.ibm.websphere.management.AdminService adminService =
```

```
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=PortletApplication,name=" + myPortletApplicationName + ",*");

Iterator onIter = adminService.queryNames(on, null).iterator();
while(onIter.hasNext())
{
 on = (ObjectName)onIter.next();
}

String ctxRoot = (java.lang.String)adminService.getAttribute(on, "webApplicationContextRoot");
```

In the previous example, the MBeanServer is first queried for an MBean of type portletapplication. If this query is successful, the webApplicationContextRoot attribute is retrieved on that MBean or the first MBean that is found. The result is stored in the ctxRoot variable. This variable now contains the context root of the Web application that contains the portlet application that was searched. The variable is similar to ″/bookmark″.

The next code example demonstrates how to invoke the MBean of type portlet for a portlet with the name, BookmarkPortlet.

```
String myPortletName = "SampleEar#SampleWar_portlet.BookmarkPortlet";
This name is composed by the name of the MBean of type portletapplication and
the portlet name, separated by a full stop because the same portlet name may
be used within different Web modules, but must be unique within the system.

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=Portlet,name=" + myPortletName + ",*");
Iterator iter = adminService.queryNames(on, null).iterator();

while(iter.hasNext())
{
 on = (ObjectName)iter.next;
}

java.util.Locale locale = (java.util.Locale) adminService.getAttribute(on, "defaultLocale");
```

The locale returned by the method getAttribute method for the MBean is the default locale defined for this portlet.

Full names for Portlet and PortletApplication MBeans

MBeans are also registered by the full identifiable name:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`. You can enable the short MBean names by setting the `useShortMBeanNames` portlet container custom property to true.

Portlet URL security

WebSphere Application Server enables direct access to portlet Uniform Resource Locators (URLs), just like servlets. This section describes security considerations when accessing portlets using URLs.

For security purposes, portlets are treated similar to servlets. Most portlet security uses the underlying servlet security mechanism. However, portlet security information resides in the `portlet.xml` file, while the

servlet and JavaServer Pages files reside in the web.xml file. Also, when you make access decisions for portlets, the security information, if any, in the web.xml file is combined with the security information in the portlet.xml file.

Portlet security must support both programmatic security, that is isUserInRole, and declarative security. The programmatic security is exactly the same as for servlets. However, for portlets, the isUserInRole method uses the information from the security-role-ref element in portlet.xml. The other two methods used by programmatic security, getRemoteUser and getUserPrincipal, behave the same way as they do when accessing a servlet. Both of these methods return the authenticated user information accessing the portlet.

The declarative security aspect of the portlets is defined by the security-constraint information in the portlet.xml file. This is similar to the security-constraint information used for the servlets in the web.xml file with the following differences:

- The auth-constraint element, which lists the names of the roles that can access the resources, does not exist in the portlet.xml file. The portlet.xml file contains only the user-data-constraint element, which indicates what type of transport layer security (HTTP or HTTPS) is required to access the portlet.
- The security-constraint information in the portlet.xml file contains the portlet-collection element, while the web.xml file contains the web-resource-collection element. The portlet-collection element contains only a list of simple portlet names, while the web-resource-collection contains the url-patterns as well as the HTTP methods that need protection.

The portlet container does not deal with the user authentication directly. For example, it does not prompt you to collect the credential information. The portlet container must, instead, use the underlying servlet container for the user authentication mechanism. As a result, there is no auth-constraint element in the security-constraint information in the portlet.xml file.

In WebSphere Application Server, when a portlet is accessed using a URL, the user authentication is processed based on the security-constraint information for that portlet in the web.xml file. This implies that to authenticate a user for a portlet, the web.xml file must contain the security-constraint information for that portlet with the relevant auth-constraints contained in it. If a corresponding auth-constraint for the portlet does not exist in the web.xml file, it indicates that the portlet is not required to have authentication. In this case, unauthenticated access is permitted just like a URL pattern for a servlet that does not contain any auth-constraints in the web.xml file. An auth-constraint for a portlet can be specified directly by using the portlet name in the url-pattern element, or indirectly by a url-pattern that implies the portlet.

Note: You cannot have a servlet or JSP with the same name as a portlet for WebSphere Application Server security to work with portlet.

The following examples demonstrate how the security-constraint information contained in the portlet.xml and web.xml files in a portlet application are used to make security decisions for portlets. The security-role-ref element, which is used for isUserInRole calls, is not discussed here because it is used the same way for servlets.

In the examples below (unless otherwise noted), there are four portlets (MyPortlet1, MyPortlet2, MyPortlet3, MyPortlet4) defined in portlet.xml. The portlets are secured by combining the information, if any, in the web.xml file when they are accessed directly through URLs.

All of the examples show the contents of the web.xml and portlet.xml files. Use the correct tools when creating these deployment descriptor files as you normally would when assembling a portlet application.

Example 1: The web.xml file does not contain any security-constraint data

In the following example, the security-constraint information is contained in portlet.xml:

```
<security-constraint>
   <display-name>Secure Portlets</display-name>
   <portlet-collection>
   <portlet-name>MyPortlet1</portlet-name>
   <portlet-name>MyPortlet3</portlet-name>
   </portlet-collection>
   <user-data-constraint>
   <transport-guarantee>CONFIDENTIAL</transport-guarantee>
   </user-data-constraint>
</security-constraint>
```

In this example, when you access anything under MyPortlet1 and MyPortlet3, and these portlets are accessed using the unsecured HTTP protocol, you are redirected through the secure HTTPS protocol. The transport-guarantee is set to use secure connections. For MyPortlet2 and MyPortlet4, unsecured (HTTP) access is permitted because the transport-guarantee is not set. There is no corresponding security-constraint information for all four portlets in the `web.xml` file. Therefore, all of the portlets can be accessed without any user authentication and role authorization. The only security involved in this instance is the transport-layer security using Secure Sockets Layer (SSL) for MyPortlet1 and MyPortlet3.

The following table lists the security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
/MyPortlet1/*	HTTPS	None	None
/MyPortlet2/*	None	None	None
/MyPortlet3/*	HTTPS	None	None
/MyPortlet4/*	None	None	None

Example 2: The `web.xml` file contains portlet specific security-constraint data

In the following example, the security-constraint information that corresponds to the portlet is contained in `web.xml`. The `portlet.xml` file is the same as that shown in the previous example.

```
<security-constraint id="SecurityConstraint_1">
    <web-resource-collection id="WebResourceCollection_1">
      <web-resource-name>Protected Area</web-resource-name>
      <url-pattern>/MyPortlet1/*</url-pattern>
      <url-pattern>/MyPortlet2/*</url-pattern>
      </web-resource-collection>
    <auth-constraint id="AuthConstraint_1">
      <role-name>Employee</role-name>
    </auth-constraint>
</security-constraint>
```

The security-constraint information contained in the `web.xml` file in this example indicates that the user authentication must be performed when accessing anything under the MyPortlet1 and MyPortlet2 portlets. When you attempt to access these portlets directly using URLs, and there is no authentication information available, you are prompted to enter their credentials. After you are authenticated, the authorization check is performed to see if you are listed in the Employee role. The user/group to role mapping is assigned during the portlet application deployment. In the `web.xml` file listed above, note the following:

- Because the `web.xml` file uses url-pattern, the portlet names have been modified slightly. MyPortlet1 is now /MyPortlet1/*, which indicates that everything under the MyPortlet1 URL is protected. This matches the information in the `portlet.xml` file because the security runtime code converts the portlet-name element in the `portlet.xml` file to url-pattern (for example, MyPortlet1 to /MyPortlet1/*), even for the transport-guarantee.
- The http-method element in the `web.xml` file is not used in the example because all HTTP methods must be protected.

The following table lists the new security constraints that are applicable to the individual portlets.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Employee)
MyPortlet2/*	None	Yes	Yes (Employee)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	None	None

Example 3: The `web.xml` file contains generic security-constraint data implying all portlets.

In the following example, the security-constraint information is contained in the `web.xml` file that corresponds to the portlet. The `portlet.xml` file is the same as that shown in the first example.

```
<security-constraint id="SecurityConstraint_1">
    <web-resource-collection id="WebResourceCollection_1">
      <web-resource-name>Protected Area</web-resource-name>
      <url-pattern>/*</url-pattern>
      </web-resource-collection>
    <auth-constraint id="AuthConstraint_1">
      <role-name>Manager</role-name>
    </auth-constraint>
    </security-constraint>
```

In this example, /* implies that all resources that do not contain their own explicit security-constraints should be protected by the Manager role as per the URL pattern matching rules. Because the `portlet.xml` file contains explicit security-constraint information for MyPortlet1 and MyPortlet3, these two portlets are not protected by the Manager role, only by the HTTPS transport. Because the `portlet.xml` file cannot contain the auth-constraint information, any portlets that contain security-contraints in it are rendered unprotected when an implying URL (`/*` for example) is listed in the `web.xml` file because of the URL matching rules.

In the case above, both MyPortlet1 and MyPortlet3 can be accessed without user authentication. However, because MyPortlet2 and MyPortlet4 do not have security-constraints in the `portlet.xml` file, the /* pattern is used to match these portlets and are protected by the Manager role, which requires user authentication.

The following table lists the new security constraints that are applicable to the individual portlets with this setup.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	None	None
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

If in the example above, if you must also protect a portlet contained in the `portlet.xml` file (for example, MyPortlet1), the `web.xml` file should contain an explicit security-constraint entry in addition to `/*` as shown in the following example:

```
<security-constraint id="SecurityConstraint_1">
         <web-resource-collection id="WebResourceCollection_1">
            <web-resource-name>Protected Area</web-resource-name>
            <url-pattern>/*</url-pattern>
            </web-resource-collection>
         <auth-constraint id="AuthConstraint_1">
            <role-name>Manager</role-name>
          </auth-constraint>
```

```
</security-constraint>
<security-constraint id="SecurityConstraint_2">
   <web-resource-collection id="WebResourceCollection_2">
      <web-resource-name>Protection for MyPortlet1</web-resource-name>
      <url-pattern>/MyPortlet1/*</url-pattern>
      </web-resource-collection>
   <auth-constraint id="AuthConstraint_1">
      <role-name>Manager</role-name>
    </auth-constraint>
</security-constraint>
```

In this case, MyPortlet1 is protected by the Manager role and requires authentication. The data-constraint of `CONFIDENTIAL` is also applied to it because the information in the `web.xml` file and the `portlet.xml` file are combined. Because MyPortlet3 is not explicitly listed in the `web.xml` file, it is still not protected by the Manager role and does not require user authentication.

The following table shows the effect of this change.

URL	Transport Protection	User Authentication	Role Based Authorization
MyPortlet1/*	HTTPS	Yes	Yes (Manager)
MyPortlet2/*	None	Yes	Yes (Manager)
MyPortlet3/*	HTTPS	None	None
MyPortlet4/*	None	Yes	Yes (Manager)

Chapter 3. SIP applications

Using Session Initiation Protocol to provide multimedia and interactive services

Follow these procedures for creating SIP applications and configuring the SIP container.

About this task

Session Initiation Protocol (SIP) is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging. A *SIP application* in WebSphere is a Java program that uses at least one Session Initiation Protocol (SIP) servlet. A SIP servlet is a Java-based application component that is managed by a SIP servlet container.

The servlet container is a part of an application server that provides the network services over which requests and responses are received and sent. The servlet container decides which applications to invoke and in what order. A servlet container also contains and manages a servlet through its lifecycle.

SIP servlet containers can employ SIP proxy servers as surrogates to handle load balancing and security issues. For more information about the SIP proxy server, see: Session Initiation Protocol proxy server.

This topic is divided into the following subsections:

- Configure the SIP container: Information and instructions for configuring SIP container properties and timers.
- Developing SIP applications: Reference information for developers.
- Deploying SIP applications: Information for installing, starting, and stopping, your applications.
- Securing SIP applications: Instructions for enabling security providers and setting up a trust association interceptor (TAI).
- Tracing a SIP container: Troubleshoot SIP applications through traces on the SIP container.

SIP in WebSphere Application Server

WebSphere Application Server delivers rich SIP functionality throughout its infrastructure.

Session Initiation Protocol (SIP) has grown considerably since it first became an IETF standard in 1999. SIP was originally intended purely for video and audio but has now grown to become the control protocol for many interactive services, particularly in the peer-to-peer realm. SIP, and the standards surrounding SIP, provide the mechanisms to look up, negotiate, and manage connections to peers on any network over any other protocol.

The SIP Servlet 1.0 specification allows enterprise applications to use SIP and to support SIP-predominant applications in the Java EE environment.

WebSphere Application Server also provides tooling for the development environment and high performing Edge Components to handle distributed application environments.

In the application server, the Web container and SIP container are converged and are able to share session management, security and other attributes. In this model, an application that includes SIP servlets, HTTP servlets, and portlets can seamlessly interact, regardless of the protocol.

High availability, offered by the Network Deployment (ND) version of the product, of the converged applications is made possible because of the tight integration of HTTP and SIP in the base application server.

In front of a clustered application sits the proxy server, managing the traffic and workload of the SIP and HTTP traffic to the container. This proxy server is a stateless SIP proxy and a HTTP reverse proxy together, which uses the unified clustering framework and high availability (HA) manager services of the ND package to seamlessly monitor the health of the servers. The proxy server also can act as a stand-alone stateless SIP proxy in front of the SIP container in the application server when no HTTP traffic is present.

It's important to note that the SIP function in the proxy server is stateless. The SIP RFC defines two types of proxy servers, one stateful and one stateless. Normally, a SIP proxy is a stateful instance and stateless proxies are specified as such. A stateful proxy participates in the call flows and is implemented using SIP servlets.

The stateless SIP proxy functionality in the proxy server allows the proxy to handle the workload, routing, and session affinity needs of the SIP container with less complexity. Being stateless, the proxy server can be fronted by a simple IP sprayer such as the load balancer component included in the ND package. If a proxy server fails, the affinity is to the container and not to the proxy itself so there is one less potential failure along the message flow.

SIP Infrastructure

The SIP infrastructure is a multi-tiered architecture made up of SIP containers, SIP proxies and an IP sprayer. The SIP container is a general purpose SIP application server. The SIP infrastructure consists of:

- SIP container – Web container extension that implements JSR 116 plus a SIP protocol stack that implements all pertinent RFCs.
- SIP proxy – Stateless edge device that handles I/O concentration, load balancing, and other functions, in a similar manner to the reverse HTTP proxy. This is not the same as the SIP proxy defined by RFC 3261.
- Load balancer – SIP enabled to interoperate with SIP proxies and SIP containers. The extendable SIP proxy handles session affinity and load balancing. The load balancer functions as a highly available IP sprayer to dispatch messages to the proxies.

SIP is a key element for many new applications, especially when converged with HTTP, including:

- Click-To-Call
- Voice over IP
- Third Party Call Control and Call Monitoring
- Presence and Instance Messaging

SIP applications

A *SIP application* is a Java program that uses at least one Session Initiation Protocol (SIP) servlet.

A SIP servlet is a Java-based application component that is managed by a SIP servlet container and that performs SIP signaling. Like other Java-based components, servlets are platform-independent Java classes that are compiled to platform-neutral bytecode that can be loaded dynamically into and run by a Java-enabled SIP application server. Containers, sometimes called servlet engines, are server extensions that handle servlet interactions. SIP servlets interact with clients by exchanging request and response messages through the servlet container.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging. ″Presence″ in this context refers to user status such as ″Active,″ ″Away,″ or ″Do not disturb.″ The standard that defines a programming model for writing SIP-based servlet applications is JSR 116.

SIP container

This product complies with the following SIP standards:

IETF

JCP

For a complete list of the supported Internet Engineering Task Force (IETF) and Java Community Process (JCP) industry standards, see the ″Compliance with industry SIP standards″ topic linked below.

SIP industry standards compliance

The product implementation of Session Initiation Protocol (SIP) complies with industry standards for both a SIP container and SIP applications.

SIP container

This product complies with the following SIP standards:

IETF

JCP

This product also complies with the Internet Engineering Task Force (IETF) and Java Community Process (JCP) industry standards for SIP. The following table contains a list of the IETF and JCP standards.

Table 1. WebSphere Application Server complies with these SIP standards

Standard	Description
RFC 2543	SIP: Session Initiation Protocol
RFC 3261	SIP: Session Initiation Protocol
RFC 3262	Reliability of provisional responses in SIP
RFC 3265	SIP-specific event notification
RFC 3326	The Reason Header field for the SIP
RFC 3515	The SIP Refer method
RFC 3824	Using E.164 numbers with the SIP
RFC 3903	SIP Extension for event state publication
RFC 3263	Locating SIP servers **Note:** SIP does not support use of DNS procedures for a server to send a response to a back-up client if the primary client fails.

SIP applications

This product complies with standards for SIP applications.

Table 2. Compliance with standards for SIP applications

Standard	Description
RFC 2848	The PINT Service Protocol: Extensions to SIP and Session Description Protocol (SDP) for internet protocol (IP) access to telephone call services
RFC 2976	The SIP INFO method
RFC 3050	Common gateway interface for SIP
RFC 3087	Control of service context using SIP request-URI
RFC 3264	An offer and answer model with SDP
RFC 3266	Support for IPv6 in SDP
RFC 3312	Integration of resource management and SIP

Table 2. Compliance with standards for SIP applications (continued)

Standard	Description
RFC 3313	Private SIP extensions for media authorization
RFC 3319	Dynamic Host Configuration Protocol (DHCPv6) options for SIP servers
RFC 3327	SIP Extension Header field for registering non-adjacent contacts
RFC 3372	SIP for telephones (SIP-T): context and architectures
RFC 3398	Integrated Services Digital Network (ISDN) User Part (ISUP) to SIP mapping
RFC 3428	SIP extension for instant messaging
RFC 3455	Private Header (P-Header) extensions to the SIP for the 3rd-Generation Partnership Project (3GPP)
RFC 3578	Mapping of Integrated Services Digital Network (ISDN) User Part (ISUP) overlap signaling to the SIP
RFC 3603	Private SIP proxy-to-proxy extensions for supporting the PacketCable distributed call signaling architecture
RFC 3608	SIP Extension Header field for service route discovery during registration
RFC 3665	SIP basic call flow examples
RFC 3666	SIP Public Switched Telephone Network (PSTN) call flows
RFC 3680	A SIP event package for registrations
RFC 3725	Best current practices for third-party call control (3pcc) in the SIP
RFC 3840	Indicating user agent capabilities in the SIP
RFC 3842	A message summary and message waiting indication event package for the SIP
RFC 3856	A presence event package for the SIP
RFC 3857	A watcher information event template package for the SIP
RFC 3959	The early session disposition type for the SIP
RFC 3960	Early media and ringing tone generation in the SIP
RFC 3976	Interworking SIP and intelligent network (IN) applications
RFC 4032	Update to the SIP preconditions framework
RFC 4092	Usage of the SDP Alternative Network Address Types (ANAT) semantics in the SIP
RFC 4117	Transcoding services invocation in the SIP using third-party call control (3pcc)
RFC 4235	An invite-initiated dialog event package for the SIP
RFC 4240	Basic network media services with SIP
RFC 4353	A framework for conferencing with the SIP
RFC 4354	A SIP event package and data format for various settings in support for the push-to-talk over cellular (PoC) service
RFC 4411	Extending the SIP Reason Header for preemption events
RFC 4457	The SIP P-user-database Private-Header (P-Header)
RFC 4458	SIP URIs for applications such as voicemail and interactive voice response (IVR)
RFC 4483	A mechanism for content indirection in SIP messages
RFC 4497	Interworking between the SIP and QSIG
RFC 4508	Conveying feature tags with the SIP REFER method

Runtime considerations for SIP application developers

You should consider certain product runtime behaviors when you are writing Session Initiation Protocol (SIP) applications.

Container may accept non-SIP URI schemes

The SIP container will not reject a message if it doesn't recognize the scheme in the request URI because the container cannot know which URI schemes are supported by the applications. SIP elements may support a request URI with a scheme other than `sip` or `sips`, for example, the `pres:` scheme has a particular meaning for presence servers, but the container does not recognize it. It is up to the application to determine whether to accept or to reject a specific scheme. SIP elements may translate non-SIP URIs using any mechanism available, resulting in SIP URIs, SIPS URIs, or other schemes, like the `tel` URI scheme of RFC 2806 [9].

Directing requests in a multiple-container environment

In a multiple-container environment (SIP proxy plus SIP containers), when your application sends a request intended initially to be sent externally but later received, it should use the host and ports of the front-most load balancing element (either an IP sprayer for multiple SIP proxies, or the SIP proxy if only one exists). If the application uses the host name of a container instead of the front-most element, the request may be lost in the event of a failure.

For example, an application sends an INVITE request to itself, but the request must pass through an external accounting system through a pushed Route header. The application should set the INVITE request's URI to the host and port of the foremost element to ensure that failover occurs. The request will be routed to the accounting system via the pushed Route, and then sent back to the front load balancing element for processing.

Invoking session listener events

SipSessionListener and SipApplicationSessionListener events are invoked only if an application requests the corresponding session object. You do this by using in your application the method shown in Table 3.

Table 3. Methods that invoke session listener events

Event	Method
SipSessionListener	getSession()
SipApplicationSessionListener	getApplicationSession()

Session activation and passivation

During normal operation, this product never migrates a session from one server to another. Session migration occurs only as a result of a server failure. Therefore the SipSessionActivationListener method's passivation callback is never invoked. However, the activation callback is invoked when a failure forces session failover to a different server.

External resources

If a SIP application performs intensive I/O or accesses an external database, it may be blocked for several milliseconds. If possible, use asynchronous APIs for these resources . Under stress, a blocked SIP application may trigger a Request Timeout or re-transmission.

SIP application attributes

Avoid hanging large objects or BLOBs as SIP Session attributes (via SIPSession.setAttribute API). This may damage the overall performance when combined with high availability (HA). The same recommendation applies for SIPApplicationSession.setAttribute. In most cases, the large object can be replaced by several simple or composed strings.

SIP IBM Rational Application Developer for WebSphere framework

This page provides information about the SIP IBM Rational Application Developer for WebSphere framework.

WebSphere Application Server includes IBM Rational Application Developer for WebSphere to meet all the basic development needs for Java EE applications. Included in IBM Rational Application Developer for WebSphere is support for developing SIP servlet applications. IBM Rational Application Developer for WebSphere provides graphical deployment descriptor editors and basic wizards to get you started writing SIP servlets.

IBM Rational Application Developer for WebSphere also includes many other pieces that integrate well in WebSphere Application Server deployments, such as the Unit Test Environment, which provides the WebSphere Application Server servlet container to run SIP servlets in the development phase of the product, as well as tools for server automation and application packaging.

IBM Rational Application Developer for WebSphere supports:

- SIP servlet development (JSR 116)
- Converged SIP/HTTP applications
- Import/Export SAR packages
- SIP samples (call forward, call block, third party call)

SIP container

A *SIP container* is a Web application server component that invokes the Session Initiation Protocol (SIP) action servlet and that interacts with the action servlet to process SIP requests.

The servlet container provides the network services over which requests and responses are received and sent. It decides which applications to invoke and in what order. The container also contains and manages servlets through their life cycle.

A SIP servlet container manages the network listener points on which it listens for incoming SIP traffic. A listener point is a combination of transport protocol, IP address, and port number. The SIP servlet container supports the transport protocols UDP, TCP, and TLS over TCP.

The SIP servlet container can employ a SIP proxy server to route, load balance, and improve response times between SIP requests and back-end SIP container resources. For more information about the SIP proxy server, see: Session Initiation Protocol proxy server.

SIP converged proxy

SIP in WebSphere offers a converged proxy.

The SIP converged proxy:

- Handles SIP and HTTP
- Fronts clusters of containers, SIP or HTTP
- Provides a highly scalable I/O concentration
- Handles session affinity
- Provides a framework for extending the base functions of proxy using an API consistent with proxy flows (Proxy Filter Layer)
- Provides first pass protocol validation
- Provides a framework for secure proxy functions – SSL termination, Outbound SSL, Client Side Certificates, etc.
- Allows for augmentation by our other products such as WebSphere XD
- Provides DMZ support.

SIP proxy setup considerations

- A single SIP proxy can front multiple SIP clusters.
- An IP sprayer is required for load balancing when deploying multiple SIP proxies into a single cell.
- Each SIP proxy must be configured with a default cluster. This is used to route inbound messages that do not match a cluster routing rule.
- When deploying converged applications, both HTTP and SIP should be enabled on the proxy.
- SIP proxies can be clustered.

SIP port relationships

When multiple servers, either containers or proxies are on the same host, each container or proxy must be configured with its own port.

SIP cluster routing and the default cluster

- A single SIP proxy can front multiple SIP clusters.
- Each SIP proxy must be configured with a default cluster which is used to route all messages that do not have an associated cluster routing rule.
- You can define cluster routing rules at each proxy. These dictate how messages are routed to the various backend clusters being fronted.
- By changing the default cluster, a SIP proxy can reroute messages to a new cluster containing an upgraded version of the deployed applications.

SIP timer summary

Request for Comments (RFC) 3261, “SIP: Session Initiation Protocol,” specifies various timers that SIP uses.

Table 4 summarizes for each SIP timer the default value, the section of RFC 3261 that describes the timer, and the meaning of the timer.

Table 4. Summary of SIP timers

Timer	Default value	Section	Meaning
T1	500 ms	17.1.1.1	Round-trip time (RTT) estimate
T2	4 sec.	17.1.2.2	Maximum retransmission interval for non-INVITE requests and INVITE responses
T4	5 sec.	17.1.2.2	Maximum duration that a message can remain in the network
Timer A	initially T1	17.1.1.2	INVITE request retransmission interval, for UDP only
Timer B	64*T1	17.1.1.2	INVITE transaction timeout timer
Timer C	> 3 min.	16.6 bullet 11	Proxy INVITE transaction timeout
Timer D	> 32 sec. for UDP	17.1.1.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		
Timer E	initially T1	17.1.2.2	Non-INVITE request retransmission interval, UDP only
Timer F	64*T1	17.1.2.2	Non-INVITE transaction timeout timer
Timer G	initially T1	17.2.1	INVITE response retransmission interval
Timer H	64*T1	17.2.1	Wait time for ACK receipt
Timer I	T4 for UDP	17.2.1	Wait time for ACK retransmissions
	0 sec. for TCP and SCTP		

Table 4. Summary of SIP timers (continued)

Timer	Default value	Section	Meaning
Timer J	64*T1 for UDP	17.2.2	Wait time for retransmissions of non-INVITE requests
	0 sec. for TCP and SCTP		
Timer K	T4 for UDP	17.1.2.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		

Developing SIP applications

A SIP application is a set of SIP servlets packaged in a SIP application archive file (SAR).

About this task

A SIP servlet is an application component managed by the SIP container that performs SIP signaling. The programming and deployment models are analogous to Web servlets and therefore will be mapped to the WebSphere administrative model accordingly. It is possible to include Web servlets in a SAR file (along with the required web.xml deployment descriptor) to create what is known as a converged application. See JSR 116 for details on SIP applications, servlets, converged applications, and status codes.

Developing a custom trust association interceptor

When you develop Session Initiation Protocol (SIP) applications, you can create a custom trust association interceptor (TAI).

Before you begin

You may want to familiarize yourself with the general TAI information contained in the Trust Associations documentation. Developing a SIP TAI is similar to developing any other custom interceptors used in trust associations. In fact, a custom TAI for a SIP application is actually an extension of the trust association interceptor model. Refer to the Developing a custom interceptor for trust associations section for more details.

About this task

TAI can be invoked by a SIP servlet request or a SIP servlet response. To implement a custom SIP TAI, you need to write your own Java class.

1. Write a Java class that extends the `com.ibm.wsspi.security.tai.BaseTrustAssociationInterceptor` class and implements the `com.ibm.websphere.security.tai.SIPTrustAssociationInterceptor` interface. Those classes are defined in the *WASProductDir*/plugins/com.ibm.ws.sip.container_1.0.0.jar file, where *WASProductDir* is the fully qualified path name of the directory in which WebSphere Application Server is installed.
2. Declare the following Java methods:

   `public int initialize(Properties properties) throws WebTrustAssociationFailedException;`
   This is invoked before the first message is processed so that the implementation can allocate any resources it needs. For example, it could establish a connection to a database. `WebTrustAssociationFailedException` is defined in the *WASProductDir*/plugins/com.ibm.ws.runtime_1.0.0.jar file. The value of the `properties` argument comes from the **Custom Properties** set in this step.

public void cleanup();

This is invoked when the TAI should free any resources it holds. For example, it could close a connection to a database.

public boolean isTargetProtocolInterceptor(SipServletMessage sipMsg) throws WebTrustAssociationFailedException;

Your custom TAI should use this method to handle the `sipMsg` message. If the method returns `false`, WebSphere ignores your TAI for `sipMsg`.

public TAIResult negotiateValidateandEstablishProtocolTrust (SipServletRequest req, SipServletResponse resp) throws WebTrustAssociationFailedException;

This method returns a TAIResult that indicates the status of the message being processed and a user ID or the unique ID for the user who is trying to authenticate. If authentication succeeds, the TAIResult should contain the status HttpServletResponse.SC_OK and a principal. If authentication fails, the TAIResult should contain a return code of HttpServletResponse.SC_UNAUTHORIZED (401), SC_FORBIDDEN (403), or SC_PROXY_AUTHENTICATION_REQUIRED (407). This only indicates whether or not the container should accept a message for further processing. To challenge an incoming request, the TAI implementation must generate and send its own SipServletResponse containing a challenge. The exception should be thrown for internal TAI errors. Table 5 describes the argument values and resultant actions for the negotiateValidateandEstablishProtocolTrust method.

Table 5. Description of negotiateValidateandEstablishProtocolTrust arguments and actions

Argument or action	For a SIP request	For a SIP response
Value of `req` argument	The incoming request	Null
Value of `resp` argument	Null	The incoming response
Action for valid response credentials	Return TAIResult.status containing SC_OK and a user ID or unique ID	Return TAIResult.status containing SC_OK and a user ID or unique ID
Action for incorrect response credentials	Return the TAIResult with the 4*xx* status	Return the TAIResult with the 4*xx* status

The sequence of events is as follows:

a. The SIP container maps initial requests to applications by using the rules in each applications deployment descriptor; subsequent messages are mapped based on JSR 116 mechanisms.

b. If any of the applications require security, the SIP container invokes any defined TAI implementations for the message.

c. If the message passes security, the container invokes the corresponding applications.

Your TAI implementation can modify a SIP message, but the modified message will not be usable within the request mapping process, because it finishes before the container invokes the TAI.

The com.ibm.wsspi.security.tai.TAIResult class, defined in the *WASProductDir*/plugins/com.ibm.ws.runtime_1.0.0.jar file, has three static methods for creating a TAIResult. The TAIResult `create` methods take an int type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted as follows:

If the value is HttpServletResponse.SC_OK, this response tells WebSphere Application Server that the TAI has completed its negotiation. The response also tells WebSphere Application Server use the information in the TAIResult to create a user identity.

The created TAIResults have the meanings shown in Table 6.

Table 6. Meanings of TAIResults

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status should not be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a Hashtable, the principal is ignored. The contents of the Subject becomes part of the eventual user Subject.

`public String getVersion();`
This method returns the version number of the current TAI implementation.

`public String getType();`
This method's return value is implementation-dependent.

3. Compile the implementation after you have implemented it. For example: `/opt/WebSphere/AppServer/java/bin/javac -classpath /opt/WebSphere/AppServer/plugins/com.ibm.ws.runtime_1.0.0.jar;/opt/WebSphere/AppServer/lib/j2ee.jar;/opt/WebSphere/AppServer/plugins/com.ibm.ws.sip.container_1.0.0.jar myTAIImpl.java`
   a. For each server within a cluster, copy the class file to a location in the WebSphere class path (preferably the *WASProductDir*/plugin/ directory).
   b. Restart all the servers.
4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot-separated and appears in the class path.
5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the `initialize(Properties properties)` method of your implementation when it extends the `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` as described in the previous step.
6. Save and synchronize (if applicable) the configuration.
7. Restart the servers for the custom interceptor to take effect.

Developing SIP applications that support PRACK

A SIP response to an INVITE request can be final or provisional. Final responses are always sent reliably, but provisional responses typically are not. For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional response acknowledgement) method.

Before you begin

For you to be able to develop applications that support PRACK, the following criteria must be met:

- The client that sends the INVITE request must put a 100rel tag in the Supported or the Require header to indicate that the client supports PRACK.
- The SIP servlet must respond by invoking the sendReliably() method instead of the send() method to send the response.

About this task

PRACK is described in the following standards:

- RFC 3262 (“Reliability of Provisional Responses in the Session Initiation Protocol (SIP)”), which extends RFC 3261 (“SIP: Session Initiation Protocol”), adding PRACK and the option tag 100rel.
- Section 6.7.1 (“Reliable Provisional Responses”) of JSR 116 (“SIP Servlet API Version 1.0”).
- For an application acting as a proxy, do this:
  - Make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- For an application acting as a user agent client (UAC), do this:
  - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
  - Within your application’s doProvisionalResponse(...) method, prepare the application to create and send PRACK requests for incoming reliable provisional responses. The application must create the PRACK request on the response’s dialog through a SipSession.createRequest(...) method, and it must set the RAck header according to RFC 3262 Section 7.2 (“RAck”).
  - The application that acts as an UAC will not receive doPrack( ) methods. The UAC sends INVITE and receives Reliable responses. When the UAC receives the Reliable response, it sends PRACK a request to the UAS and receives a 200 OK on the PRACK so it should next implement doResponse( ) in order to receive it.
- For an application acting as a user agent server (UAS), do this:
  - If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an Exception.
  - Make the application declare a SipErrorListener to receive noPrackReceived() events when a reliable provisional response is not acknowledged within 64*T1 seconds, where T1 is a SIP timer. Within the noPrackReceived() event processing, the application should generate and send a 5*xx* error response for the associated INVITE request per JSR 116 Section 6.7.1.
  - Make the application have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first’s acknowledgement results in an Exception.
  - Make sure that the application enforces the RFC 3262 offer/answer semantics surrounding PRACK requests containing session descriptions. Specifically, a servlet must not send a 2*xx* final response if any unacknowledged provisional responses contained a session description.

Setting up SIP application composition

The JSR 116 standard for SIP applications states in section 2.4 that multiple applications may be invoked for the same SIP request. The process of setting up applications to comply with this standard is called application composition.

Before you begin

About this task

Application composition requires that implementations use a cascaded services model. The cascaded services model requires that service applications triggered on the same host are triggered in sequence, as if the triggering occurred on different hosts. Therefore responses flow upstream and hit applications in the reverse order of the corresponding requests.

The JSR 116 standard does not specify how to implement application composition, thus there are many ways to comply with this standard. For WebSphere Application Server, composition of the application depends on the deployed application order, and on the order of mapping rules within the deployment descriptor of each application.

- For an initial incoming request, the SIP container tries each potential rule in order. When the container finds the n^{th} match, the container invokes the corresponding servlet.
- If the servlet must proxy the request, the container scans the rules again to search for additional matches. When the container finds the $(n+1)^{th}$ match, the container invokes the corresponding servlet.

- Any servlet in the same application as the previously invoked servlet is excluded from the matching process. No servlet can be invoked twice for the same SIP request.

You can specify load on start-up priority. The <load-on-startup> in the sip.xml defines the order in which servlets are initialized on startup. If this value is lower than zero, the servlets are initialized when the first request is matched to them according to matching rule and composition order. Zero is a legitimate weight for startup initialization order. If this tag does not exist or if it contains a negative value, the servlet does not initialize at startup.

You should also add <load-on-startup> to the same tag in the web.xml if you are changing it manually. It is the WebContainer that loads servlets (and siplets), and it looks only at the web.xml. When deploying a SAR, only the sip.xml needs to be changed. The web.xml is automatically constructed correctly after deployment.

The load-on-startup tag embedded in the SIP deployment descriptor tag for a servlet dictates the order that the application is loaded on start up of the server. It does not dictate the order that an application gets called when the application is a member of an application composition chain that matches rules to process a new message coming in.

The starting weight for applications and their modules is specified in the deployment.xml file. The order in which modules pickup requests on composition is evaluated by applications weight first and then modules weight. The following steps can be completed in any order to specify applications weight or modules weight from the administrative console.

1. To specify the applications (EARs) weight, expand **Enterprise Applications** → ***applicationName*** → **Startup Behavior** and set the startup order.
2. To specify the modules (WARs) weight, expand **Enterprise Applications** → ***applicationName*** → **Manage Modules** and set the starting weight.
3. Restart the changed applications.

Example

Note:

sip.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sip-app
PUBLIC "-//Java Community Process//DTD SIP Application 1.0//EN"
"http://www.jcp.org/dtd/sip-app_1_0.dtd">
<sip-app>
 <display-name>SIPSampleProxy</display-name>

 <servlet>
  <servlet-name>SIPSampleProxy</servlet-name>
  <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
  <load-on-startup>1</load-on-startup>
 </servlet>

 <servlet-mapping>
  <servlet-name>SIPSampleProxy</servlet-name>
  <pattern>
   <equal>
    <var>request.uri.user</var>
    <value>SIPSampleProxy</value>
   </equal>
  </pattern>
 </servlet-mapping>

 <proxy-config>
  <sequential-search-timeout>1000</sequential-search-timeout>
 </proxy-config>
 <session-config>
  <session-timeout>12</session-timeout>
 </session-config>
</sip-app>
```

web.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN" "http://java.sun.com/dtd/web-app_2_3.dtd">
```

```
<web-app id="WebApp">
 <display-name>SIPSampleProxy</display-name>
 <servlet>
  <servlet-name>SIPSampleProxy</servlet-name>
  <display-name>SIPSampleProxy</display-name>
  <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
 </servlet>
 <servlet-mapping>
  <servlet-name>SIPSampleProxy</servlet-name>
  <url-pattern>/SIPSampleProxy</url-pattern>
 </servlet-mapping>
 <welcome-file-list>
  <welcome-file>index.html</welcome-file>
  <welcome-file>index.htm</welcome-file>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>default.html</welcome-file>
  <welcome-file>default.htm</welcome-file>
  <welcome-file>default.jsp</welcome-file>
 </welcome-file-list>
</web-app>
```

Note:

The following example is for a standalone server.

deployment.xml

```
<?xml version="1.0" encoding="UTF-8" ?>
- <appdeployment:Deployment xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
xmlns:appdeployment="http://www.ibm.com/websphere/appserver/schemas/5.0/appdeployment.xmi"

  <properties xmi:id="Property_1137951186883" name="validateinstall" value="warn" /> </deployedObject>
  <deploymentTargets xmi:type="appdeployment:ServerTarget" xmi:id="ServerTarget_1137951186883"
name="server1" nodeName="OrangeNode10" /> </appdeployment:Deployment>
```

SIP servlets

This topic describes SIP servlets.

The SIP Servlet 1.0 specification (JSR 116) is standardized through Java Specification Request (JSR) 116. The idea behind the specification is to provide a Java application programming interface (API) similar to HTTP servlets, which provides an easy-to-use SIP programming model. Like the popular HTTP servlet programming model, some flexibility is limited to optimize ease-of-use and time-to-value.

However, the SIP Servlet API is different in many ways from HTTP servlets because the protocol is so different. While SIP is a request-response protocol, there is not necessarily only one response to every one request. This complexity and a need for a high performing solution meant that it was easier to make the SIP servlets natively asynchronous. Also, unlike HTTP servlets, the programming model for SIP servlets sought to make client requests easy to create alongside the other logic being written because many applications act as a client or proxy to other servers or proxies.

SipServlet requests

Like HTTP servlets, each SIP servlet extends a base javax.servlet.sip.SipServlet class. All messages come in through the service method, which you can extend. However, because there is not a one-to-one mapping of requests to responses in SIP, the suggested practice is to extend the doRequest or doResponse methods instead. When extending the doRequest or doResponse methods, it is important to call the extended method for the processing to complete.

Each request method, which the specification must support, has a doxxx method just like HTTP. In HTTP, methods such as doGet and doPost exist for GET and POST requests. In SIP, doInvite, doAck, doOptions, doBye, doCancel, doRegister, doSubscribe, doNotify, doMessage, doInfo, and doPrack methods exist for each SIP request method.

Unlike an HTTP servlet, SIP servlets have methods for each of the response types that are supported. So, SIP servlets include the doProvisionalResponse, doSuccessResponse, doRedirectResponse, and doErrorResponse responses. Specifically, the provisional responses (1xx responses) are used to indicate status, the success responses (2xx responses) are used to indicate a successful completion of the transaction, the redirect responses (3xx responses) are used to redirect the client to a moved resource or entity, and the error responses (4xx, 5xx, and 6xx responses) are used to indicate a failure or a specific error condition. These types of response messages are similar to HTTP, but because the SIP Servlet programming model includes a client programming model, it is necessary to have responses handled programmatically as well.

Clarifications of JSR 116

JSR 289 has made some clarifications to JSR 116, as follows:

- JSR 289 Section 4.1.3: Contact Header Field
- JSR 289 Section 5.2: Implicit Transaction State
- JSR 289 Section 5.8: Accessibility of SIP Servlet Messages

SIP SipServletRequest and SipServletResponse classes

The SipServletRequest and SipServletResponse classes are similar to the HttpServletRequest and HttpServletResponse classes.

SipServletRequest and SipServletResponse classes

Each class gives you the capability to access the headers in the SIP message and manipulate them. Because of the asynchronous nature of the requests and responses, this class is also the place to create new responses for the requests. When you extend the doInvite method, only the SipServletRequest class is passed to the method. To send a response to the client, you must call the createResponse method on the Request object to create a response. For example:

```
protected void doInvite(SipServletRequest req) throws
 javax.servlet.ServletException, java.io.IOException {

 //send back a provisional Trying response
 SipServletResponse resp = req.createResponse(100);
resp.send();
```

Because of their asynchronous nature, SIP servlets can seem complicated. However, something as simple as the previous code sample sends a response to a client.

Here is a more complex example of a SIP servlet. With the following method included in a SIP servlet, the servlet blocks all of the calls that do not come from the example.com domain.

```
protected void doInvite(SipServletRequest req) throws
 javax.servlet.ServletException, java.io.IOException {

//check to make sure that the URI is a SIP URI
      if (req.getFrom().getURI().isSipURI()){
                SipURI uri = (SipURI)req.getFrom.getURI();
                if (!uri.getHost().equals("example.com")) {
                   //send forbidden response for calls outside domain
                   req.createResponse(SipServletResponse.SC_FORBIDDEN).send();
                   return;
                }
```

```
            }
            //proxy all other requests on to their original destination
            req.getProxy().proxyTo(req.getRequestURI);
        }
```

SIP SipSession and SipApplicationSession classes

Possibly the most complex portions of the SIP Servlet 1.0 specification are the SipSession and SipApplicationSession classes.

SIP SipSession and SipApplicationSession classes

Both of these classes have some useful purposes and can act as the primary place to store data in applications that are designed for distributed or highly available environments.

The SipSession class is the best representative of a specific point-to-point communication between two entities and is the closest to the HttpSession object. Because historically no proxying or forking existed for the HTTP request in HTTP servlets, the need for something higher than a single point-to-point session did not exist. However, even HTTP users can see the growing need for this type of function since portlets began essentially forking HTTP requests. The SIP users expect the proxying and forking activities that require multiple layers of SIP session management. The SipSession class is the lowest point-to-point layer.

The SipApplicationSession class represents the higher layer of SIP session management. One SipApplicationSession class can own one or more SipSession objects. However, each SipSession class can be related to one SipSession object only. The SipApplicationSession class also supports the attachment of any number of other protocol sessions. Currently, only HTTP sessions are supported by any implementations. The SipApplicationSession class has a getSessions method, which takes the requested protocol type as an argument.

You might find it useful for many applications to combine HTTP and SIP. For example, you might use this approach to tie together HTTP and SIP sessions to monitor a phone call or to start a phone call through a rich HTTP graphical user interface.

Example: SIP servlet simple proxy

This is a servlet example of a simple proxy.

Simple proxy

```
import java.io.IOException;

import javax.servlet.Servlet;
import javax.servlet.ServletException;
import javax.servlet.sip.Proxy;
import javax.servlet.sip.SipFactory;
import javax.servlet.sip.SipServlet;
import javax.servlet.sip.SipServletRequest;
import javax.servlet.sip.SipServletResponse;
import javax.servlet.sip.SipSession;
import javax.servlet.sip.SipURI;
import javax.servlet.sip.URI;

public class SimpleProxy extends SipServlet implements Servlet {

 final static  private String  SHUTDOWN_KEY = new String("shutdown");
 final static  private String  STATE_KEY = new String("state");
 final static  private int   INVITE_RECEIVED = 1;

 /* (non-Java-doc)
  * @see javax.servlet.sip.SipServlet#SipServlet()
  */
 public SimpleProxy() {
```

```
 super();
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doInvite(javax.servlet.sip.SipServletRequest)
 */
protected void doInvite(SipServletRequest request) throws ServletException,
  IOException {

 //log("SimpleProxy: doInvite: TOP");

 try {
  if (request.isInitial() == true)
  {
   // This should cause the sip session to be created. This sample only uses the session on receiving
   // a BYE but the Tivoli performance viewer can be used to track the creation of calls by viewing the
   // active session count.
   Integer state = new Integer(INVITE_RECEIVED);
   SipSession session = request.getSession();
   session.setAttribute(STATE_KEY, state);
            log("SimpleProxy: doInvite: setting attribute");

   Proxy proxy = request.getProxy();

   SipFactory sipFactory = (SipFactory) getServletContext().getAttribute(SIP_FACTORY);
         if (sipFactory == null) {
             throw new ServletException("No SipFactory in context");
         }

         String callingNumber = request.getTo().toString();
         if (callingNumber != null)
         {
             String destStr = format_lookup(callingNumber);
             URI dest = sipFactory.createURI(destStr);

             //log("SimpleProxy: doInvite: Proxying to dest URI = " + dest.toString());

          if (((SipURI)request.getRequestURI()).getTransportParam() != null)
           ((SipURI)dest).setTransportParam(((SipURI)request.getRequestURI()).getTransportParam());

          proxy.setRecordRoute(true);
    proxy.proxyTo(dest);
         }
   else
   {
             //log("SimpleProxy: doInvite: Request is invalid. Did not contain a To: field.");
    SipServletResponse sipresponse = request.createResponse(400);
    sipresponse.send();
   }
  }
  else
  {
         //log("SimpleProxy: doInvite: target refresh, let container handle invite");
   super.doInvite(request);
  }
 }
 catch (Exception e){
  e.printStackTrace();
 }
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doResponse(javax.servlet.sip.SipServletResponse)
 */
protected void doResponse(SipServletResponse response) throws ServletException,
  IOException {
  super.doResponse(response);
```

```
   // Example of using the session object to store session state.
  SipSession session = response.getSession();
  if (session.getAttribute(SHUTDOWN_KEY) != null)
  {
   //log("SimpleProxy: doResponse: invalidating session");
   session.invalidate();
  }
 }

 /* (non-Javadoc)
  * @see javax.servlet.sip.SipServlet#doBye(javax.servlet.sip.SipServletRequest)
  */
 protected void doBye(SipServletRequest request) throws ServletException,
   IOException {

  SipSession session = request.getSession();
  session.setAttribute(SHUTDOWN_KEY, new Boolean(true));

        //log("SimpleProxy: doBye: invalidate session when responses is received.");
  super.doBye(request);
 }

 protected String format_lookup(String toFormat){
  int start_index = toFormat.indexOf('<') + 1;
  int end_index = toFormat.indexOf('>');

  if(start_index == 0){
   //don't worry about it
  }
  if(end_index == -1){
   end_index = toFormat.length();
  }

  return toFormat.substring(start_index, end_index);
 }
}
```

Example: SIP servlet SendOnServlet class

The SendOnServlet class is a simple SIP servlet that would perform the basic function of being called on each INVITE and sending the request on from there.

SendOnServlet class

Function could easily be inserted to log this invite request or reject the INVITE based on some specific criteria.

```
package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class SendOnServlet extends SipServlet {
  public void doInvite(SipServletRequest req)
       throws ServletException, java.io.IOException {
     //send on the request
     req.getProxy().proxyTo(req.getRequestURI);
  }
}
```

The doInvite method could be altered to do something such as reject the invite for some specific criteria simply. In the example doInvite method below, all requests from domains outside of example.com will be rejected with a Forbidden response.

```
   public void doInvite(SipServletRequest req)
throws ServletException, java.io.IOException {
if (req.getFrom().getURI().isSipURI()){
```

```
    SipURI uri = (SipURI)req.getFrom.getURI();
    if (!uri.getHost().equals("example.com")) {
  //send forbidden response for calls outside domain
req.createResponse(SipServletResponse.SC_FORBIDDEN, "Calls outside example.com not accepted").send();
return;
    }
 }
 //proxy all other requests on to their original destination
 req.getProxy().proxyTo(req.getRequestURI());
   }

SendOnServlet deployment descriptor:
<sip-app>
    <display-name>Send-on Servlet</display-name>
    <servlet>
        <servlet-name>SendOnServlet</servlet-name>
        <servlet-class>com.example.SendOnServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>SendOnServlet</servlet-name>
        <pattern>
              <equal>
                <var>request.method</var>
                <value>INVITE</value>
              </equal>
        </pattern>
    </servlet-mapping>
</sip-app>
```

Example: SIP servlet Proxy servlet class

Proxy servlet class

After the initial INVITE, this application will be called on every subsequent SIP message. For each Request and Response, this class will simply print out the action and who it is to or from.

```
package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class ProxyServlet extends SipServlet {
  public void doInvite(SipServletRequest req)
       throws ServletException, java.io.IOException {
     //get the Proxy
     Proxy p=req.getProxy();
     //turn on supervised mode so that all events come through us
     //The default on this is true but it is set to emphasize the function.
     p.setSupervised(true);
     //set record route so we see the ACK, BYE, and OK
     p.setRecordRoute(true);
     //proxy on the request
     p.proxyTo(req.getRequestURI());
  }
public void doRequest(SipServletRequest req)
     throws ServletException, java.io.IOException {
   System.out.println(req.getMethod()+" Request from "+req.getFrom().getDisplayName());
   super.doRequest(req);
}
public void doResponse(SipServletResponse resp)
     throws ServletException, java.io.IOException {
   System.out.println(resp.getReasonPhrase()+" Response from "+resp.getTo().getDisplayName());
   super.doResponse(resp);
}
}
```

```
Proxy deployment descriptor
<sip-app>
    <display-name>ProxyServlet</display-name>
    <servlet>
        <servlet-name>ProxyServlet</servlet-name>
        <servlet-class>com.example.ProxyServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>ProxyServlet</servlet-name>
        <pattern>
              <equal>
                <var>request.method</var>
                <value>INVITE</value>
              </equal>
        </pattern>
    </servlet-mapping>
</sip-app>
```

Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

About this task

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java Platform, Enterprise Edition (Java EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

Before you begin

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

1. Open the administrative console.

   In a browser, go to URL `http://`*`hostname`*`:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.
2. In the left frame click **Applications** → **Install New Application**.
3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type `/ThisApplication`.
4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title “Preparing for the application installation”, but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the web.xml file contents, and try to reload the SAR file.
5. Click **Next**. If you see a screen indicating “Application Security Warnings”, click **Continue**.
6. The **Install New Application** screen should appear with “Step 1: Select application options” highlighted. Select the options you need and click **Next**.
7. “Step 2: Map modules to servers” should appear highlighted now. You can choose the cluster or server where you want to install the application’s modules.
   - If you are installing the application in a stand-alone system, click **Next**.

- If you are installing the application in a clustered system, select **WebSphere:cell=*cellname*,cluster=*cluster_name*** in the **Clusters and Servers** field, select the check box beside the Web module that you want to install, and click **Apply** and **Next**.

8. Now “Step 3: Map virtual hosts for Web modules” should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
   - If you are installing the application in a standalone system, set the value of the drop-down to **default_host**, and click **Next**.
   - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

   Note: You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.
9. You should now see “Step 4: Summary” highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, `Application` *appname*`_sar installed successfully`, where *appname* is the name of the application.
10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.
11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.
12. To confirm that the installation succeeded, in the left frame click **Applications** → **Enterprise Applications**. The newly installed application should appear in the list of installed applications as *appname*_sar.
13. To start the application so that it can service SIP requests, check the box beside *appname*_sar, and click **Start**. You might also want to look at the logs for a successful startup message.

Results

The application can service SIP requests now.

Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the GUI but also from the command line.

- Launch a scripting client. For more information, see AdminApp object for scripted administration.
- List applications.
- Install standalone archive files. For more information about installation, see Installation options for the AdminApp object.
- Edit application configurations.
- Uninstall applications.

Troubleshooting SIP applications

Use this page to troubleshoot SIP applications.

About this task

SIP container troubleshooting basics

- The Average CPU usage of the system should go no higher than 60%-70%.
- The container should use no more than 70% of the allocated VM heap size. Be sure that the system has enough physical memory to accommodate the VM heap size. Call loads and session timeouts will have a big affect on heap usage.

- The maximum garbage collection (GC) time of the VM on which the container is running should not exceed 500 ms and the average should be less than 400 ms. Verbose GC can be used to measure this and the PMI viewer can be used to view GC times, heap usage, active sessions, etc., in graphical form.

Initial troubleshooting checklist:

- Check the listening ports in the configuration.
- Use netstat –an to see listening ports.
- Check to see if virtual hosts are defined
- Check to see if host aliases are defined.
- Is an application installed? Is it started?
- For a proxy configuration: Is a default cluster configured? If proxy and server are on the machine, is there a port conflict?

Results

SIP container symptoms and solutions

If the problem is not resolved, check for specific symptoms.

- **Symptom:** Lots of retransmissions, CPU periodically drops to zero.

  Solution: This is typically a DNS issue caused by Reverse DNS lookups and can be confirmed using a tool like Ethereal. If you do a network capture and send lots of DNS queries that contain an IP address and get back a host name in the response, this could be the problem. Make sure that nscd is running if you are on HP or other platforms that require name service caching. (Windows does not require this.) Another solution is to add host names to the /etc/hosts file.
- **Symptom:** Lots of retransmissions, CPU periodically spikes to 100%.

  Solution: This is typically due to garbage collection and can be verified by turning on verbose GC (accessible on the admin console) and looking at the length of the GC cycles. The solution here is to enable Generational Garbage Collection by setting the JVM optional args to -Xgcpolicy:gencon.
- **Symptom:** Lots of retransmissions, CPU spikes to 100% for long periods of time and Generational Garbage Collection is enabled.

  Solution: This is typically due to SIP session objects either not being invalidated or not timing out over a long period of time. One solution is to set the session timeout value in the sip.xml of the application to a smaller value. The most efficient way to handle this is for the application to call invalidate on the session when the dialog completes (i.e. after receiving a BYE). The following entry in the SystemOut.log file will indicate the session timeout value is for each application installed on the container:

```
SipXMLParser  3 SipXMLParser getAppSessionTTL Setting Expiration time: 7 Minutes, For  App: TCK back-to-back user agent"
```

- **Symptom:** Lots of “480 Service Not Available” messages received from the container when sending new INVITE messages to the SIP container. You will also likely see the following message show up in the SystemOut.log when the server is in this state: ″LoadManager E LoadManager warn.server.oveloaded″.

  Solution: This is typically due to one of the SIP container configurable metrics being exceeded. This includes the ″Maximum Application Sessions″ value and the ″Maximum messages per averaging period″ value. The solution is to adjust these values higher.
- **Symptom:** Lots of resends and calls are not completing accompanied by OutOfMemory exceptions in the SystemErr.log.

  Solution: This usually means that the VM heap size associated with your container is not large enough and should be adjusted upwards. You can adjust this value from the admin console.
- **Symptom:** You receive a “503 Service Unavailable” when sending a SIP request to a SIP proxy.

  Solution: This usually means there is no default cluster (or cluster routing rule that matches the message) set up at the proxy. This can also happen when the SIP proxy is configured well but the backend SIP containers are stopped or have crashed.

- **Symptom:** You receive a “404 Not Found” when sending a SIP request to a SIP proxy.

  Solution: This usually means there is no virtual host set up for the containers that reside in the default cluster. It could also mean that the servers in the proxy’s default cluster do not contain a SIP application or that the message does not match one of the applications installed in the default cluster.
- **Symptom:** An ″out of memory″ type behavior is occurring.

  Solution: This may be due to the maximum heap size being set too low. SIP applications can consume a significant amount of memory because the sessions exist for a long call hold time. The maximum heap size of 512 MB does not provide sufficient memory for the SIP traffic workload. Set the maximum heap size for SIP applications to the minimum recommended value of 768 MB or higher.
- **Symptom:** You receive a “403 Forbidden” when sending a SIP request to a SIP container.

  Solution: This usually means there is no appropriate SIP application found to handle the received SIP request (no match rule that matched the message).

Chapter 4. EJB applications

Task overview: Using enterprise beans in applications

This article provides an overview of the tasks you must perform to use enterprise beans in a Java-based application.

About this task

Use the following steps to develop an Enterprise JavaBeans (EJB) application:

1. **EJB 3.0 beans:** Design a Java Platform, Enterprise Edition (Java EE) application and the enterprise beans that it needs.
2. **EJB 2.x beans:** Design a Java 2 Platform, Enterprise Edition (J2EE) application and the enterprise beans that it needs.
3. Develop any enterprise beans that your application uses.
4. Prepare for assembly. For your EJB 2.x-compliant entity beans, decide on an appropriate access intent policy.
5. Assemble the beans into one or more EJB modules using one of the assembly tools. This process includes setting security. For your EJB 2.x-compliant entity beans, you might also want to designate container-managed persistence (CMP) sequence groups.
6. **EJB 3.0 beans:** Assemble the beans into one or more EJB 3.0 modules using one of the assembly tools.
7. Assemble the modules into a J2EE application using the assembly tool.
8. For a given application server, update the EJB container configuration if needed for the application to be deployed.
9. For a given application server, update the EJB container configuration if needed for the application to be deployed, and determine if you want to batch commands or defer commands for container-managed persistence.
10. Deploy the application in an application server.
11. Test the modules.
    - As needed, debug problems with the container.
    - Debug access problems.
12. Assemble the production application using one of the assembly tools
13. Deploy the application to a production environment.
14. Manage the application:
    a. Manage installed EJB modules. After an application has been installed, you can manage its EJB modules individually through assembly tools.
    b. Manage other aspects of the Java application.
15. Update the module and redeploy it using one of the assembly tools.
16. Tune the performance of the application. See Best practices for developing enterprise beans.

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create Java applications. There are three types of enterprise beans, *entity* beans, *session* beans, and *message-driven* beans.

All beans reside in Enterprise JavaBeans (EJB) containers, which provide an interface between the beans and the application server on which they reside.

EJB 2.1 and earlier versions of the specification define entity beans as a means to store permanent data, so they require connections to a form of persistent storage. This storage might be a database, an existing legacy application, a file, or another type of persistent storage.

The EJB 3.0 specification deprecates EJB 1.1-style entity beans. The Java Persistence API (JPA) specification is intended to replace the deprecated enterprise beans. While the JPA replacement is called an entity class, it should not be confused with entity enterprise beans. A JPA entity is not an enterprise bean and is not required to run in an EJB container.

Session beans typically contain the high-level and mid-level business logic for an application. Each method on a session bean performs a particular high-level operation. For example, submitting an order or transferring money between accounts. Session beans often invoke methods on entity beans in the course of their business logic.

Session beans can be either *stateful* or *stateless*. A stateful bean instance is intended for use by a single client during its lifetime, where the client performs a series of method calls that are related to each other in time for that client. One example is a *shopping cart* where the client adds items to the cart over the course of an online shopping session. In contrast, a stateless bean instance is typically used by many clients during its lifetime, so stateless beans are appropriate for business logic operations that can be completed in the span of a single method invocation. Stateful beans should be used only where absolutely necessary. Using stateless beans improves the ability to debug, maintain, and scale the application.

The EJB 3.0 specification supports stateless and stateful session beans. They follow a simple pattern such as:

- Define the business interface.
- Define the class that implements it.
- Add metadata with annotations or with XML deployment descriptors.

The end result of a simple EJB 3.0 stateful session bean looks like the following:

```
package ejb3demo;

@Stateful
public class Cart3Bean implements ShoppingCart {
    private ArrayList contents = new ArrayList();

public void addToCart (Object o) {
  contents.add(o);
    }

public Collection getContents() {
    return contents;

    }
}
```

EJB components can use annotations such as @EJB and other injectable @Resource references if the module is an EJB 3.0 module.

Web application clients and application clients can use deployment descriptor-defined EJB references. If the reference is for an EJB 3.0 session bean without a home interface, the reference should be defined with a null <home> or <local-home> setting in the deployment descriptor.

Web application clients and application clients can also use @EJB injections for references to EJB session beans within the same enterprise archive (EAR) file, but the binding must either use the AutoLink support within the container or the annotation must use the name of the reference that is defined by the deployment descriptor and bound when the application is installed. For more information about AutoLink, see the topic, ″EJB 3.0 application bindings support.″

Message-driven beans enable asynchronous message servicing.

- The EJB container and a Java Message Service (JMS) provider work together to process messages. When a message arrives from another application component through JMS, the EJB container forwards it through an onMessage method call to a message-driven bean instance, which then processes the message. In other respects, message-driven beans are similar to stateless session beans.
- The EJB container and a Java Connector Architecture (JCA) resource adapter work together to process messages from an enterprise information system (EIS). When a message arrives from an EIS, the resource adapter receives the message and forwards it to a message-driven bean, which then processes the message. The message-driven bean is provided services such as transaction support by the EJB container in the same way that other enterprise beans are provided service.

Beans that require data access use *data sources*, which are administrative resources that define pools of connections to persistent storage mechanisms.

EJB modules

An Enterprise JavaBeans (EJB) module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:

- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

  It is not necessary to use XML deployment descriptors in EJB 3.0 modules, although XML descriptors are supported. Instead of deployment descriptors, you can use annotations to provide component metadata.

You can deploy an EJB module as a stand alone application, or combine it with other EJB modules or with Web modules to create a Java application. An EJB module is installed and run in an enterprise bean container.

If you want to package an EJB 3.0 module with a deployment descriptor, there are several ways to do it. You can package an EJB 3.0 module with an EJB 3.0 style session and/or message-driven beans exclusively; with an EJB 2.1 style session and/or message-driven beans exclusively, or a combination of 2.1 and 3.0 style beans. The XML deployment descriptor must be a Version 3.0 deployment descriptor. It is required that 2.1 entity beans are packaged in modules with 2.1 deployment descriptors.

EJB modules that contain EJB 3.0 beans must be at the EJB 3.0 specification level when running on the product. To set the EJB module to support EJB 3.0 beans, you can set the ejb-jar.xml deployment descriptor level to 3.0, or you can make sure that the module does not contain an ejb-jar.xml deployment descriptor. If the module level is EJB 2.1 or earlier, no EJB 3.0 functions, including annotation scanning or resource injection is performed at runtime.

For more information about packaging and deployment of EJB 3.0 beans, see the topic EJB 3.0 module packaging overview.

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:
- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

WebSphere Application Server provides significant flexibility in the management of database data with entity beans. The Entity EJBs Activate at and Load at configuration settings specify how and when to load and cache data from the corresponding database row data of an enterprise bean. These configuration settings provide the capability to specify enterprise bean caching Options A, B or C, as specified in the EJB 1.1 specifications. You can configure these settings with assembly tools. To read more about how to use the assembly tools see the assembly tool information center.

Between transactions, the state of an entity bean can be cached. The EJB container supports option A, B, and C caching.
- With option A caching, the application server assumes that the entity bean is used within a single container. Clients of that bean must direct their requests to the bean instance within that container. The entity bean has exclusive access to the underlying database, which means that the bean cannot be cloned or participate in workload management if option A caching is used.

  If you intend to use read-only scenarios, the product provides an alternate, higher-performance variation of option A entity beans. This caching option is called *Multithreaded Read-Only*. Similar to standard option A behavior, the EJB container continues to activate the bean just once and leave it active until the EJB container needs space in its active instance cache. However, the EJB container differs from standard option A in the following behaviors:
  - It reloads the state of the bean from persistent storage periodically in response to the user invoking a method on it to pick up any changes that may have been made to the persistent store since the last time the bean was loaded. You can configure this function through a *Reload Interval* setting in the bean's deployment descriptor. For more information, see "Developing read-only entity beans" on page 173.
  - The state of the bean is not written to persistent store by the EJB container at the end of the transaction, nor is the bean's ejbStore() method be invoked.
  - The EJB container permits method invocations from more than one client (thread) on the same bean instance. This differs from the standard EJB component for the internals of a bean. You must keep this aspect in mind when developing your bean, and ensure that any logic in the bean's business methods is overall thread-safe.
- With option B caching, the entity bean remains active in the cache throughout the transaction but is reloaded at the start of each method call.
- With option C caching (the default), the entity bean is always reloaded from the database at the beginning of each transaction. A client can attempt to access the bean and start a new transaction on any container that has been configured to host that bean. This is similar to the session clustering facility described for HTTP sessions in that the entity bean's state is maintained in a shared database that can be accessed from any server when required.

Option A provides maximum enterprise bean performance by caching database data outside of the transaction scope. Generally, Option A is only applicable where the EJB container has exclusive access to the given database. Otherwise, data integrity is compromised. Option B provides more aggressive caching

of Entity EJB object instances, which can result in improved performance over Option C, but also results in greater memory usage. Option C is the most common real-world configuration for Entity EJBs and is the default setting.

The Activate at setting specifies the point at which an enterprise bean is activated and placed in the cache. Removal from the cache and passivation are also governed by this setting. Valid values are Once and Transaction. The Once setting indicates that the bean is activated when it is first accessed in the server process, and passivated (and removed from the cache) at the discretion of the container, for example when the cache becomes full. The Transaction setting indicates that the bean is activated at the start of a transaction and passivated (and removed from the cache) at the end of the transaction. The default value is Transaction.

The Load at setting specifies when the bean loads its state from the database. The value of this property implies whether the container has exclusive or shared access to the database. Valid values are Activation and Transaction. Activation indicates the bean is loaded when it is activated and implies that the container has exclusive access to the database. Transaction indicates that the bean is loaded at the start of a transaction and implies that the container has shared access to the database. The default is Transaction. The settings of the Activate at and Load at properties govern which commit options are used. For Option A (exclusive database access), use Activate at = Once and Load at = Activation. This option reduces database input/output by avoiding calls to the ejbLoad function, but serializes all transactions accessing the bean instance. Option A can increase memory usage by maintaining more objects in the cache, but can provide better response time if bean instances are not generally accessed concurrently by multiple transactions.

Note: When using WebSphere Network Deployment and workload management is enabled, Option A cannot be used.

You must use settings that result in the use of Options B or C. For Option B (shared database access), use Activate at = Once and Load at = Transaction. Option B can increase memory usage by maintaining more objects in the cache. However, because each transaction creates its own copy of an object, there can be multiple copies of an instance in memory at any given time (one per transaction), requiring the database be accessed at each transaction. If an enterprise bean contains a significant number of calls to the ejbActivate function, using Option B can be beneficial because the required object is already in the cache. Otherwise, this option does not provide significant benefit over Option A. For Option C (shared database access), use Activate at = Transaction and Load at = Transaction. Load at = Transaction. This option can reduce memory usage by maintaining fewer objects in the cache. However, there can be multiple copies of an instance in memory at any given time (one per transaction). This option can reduce transaction contention for enterprise bean instances that are accessed concurrently but not updated.

This product supports the cloning of stateful session bean home objects among multiple application servers. However, it does not support the cloning of a specific instance of a stateful session bean. Each instance of a particular stateful session bean can exist in just one application server and can be accessed only by directing requests to that particular application server. State information for a stateful session bean cannot be maintained across multiple members of a server cluster. However, enabling stateful session bean failover and configuring the EJB container to use memory-to-memory replication does enable stateful session bean failover to be replicated to other servers in the cluster so that failover can occur to the backup server if the primary server for a stateful session bean stops for some reason. For more information about stateful session bean failover, see Stateful session bean failover for the EJB container.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans, because message driven beans must exist before messages are posted for them; Startup Beans, which must be processed when the server starts; and EJB types that you specify to initialize when the server starts. .

All other EJB initialization is delayed until the first use of the EJB type. When using local interfaces, the first use is when you perform an InitialContext.lookup method for the type. For remote interfaces, it is when you call the first method on an EJB or its Home.

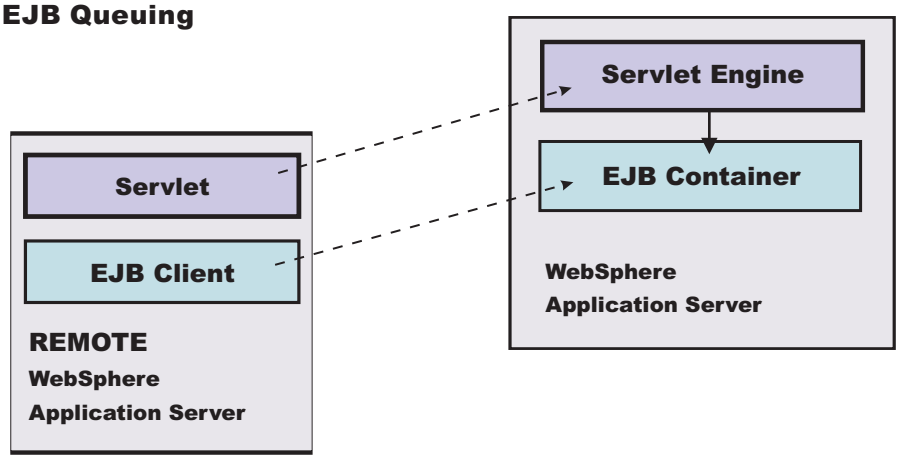
EJB method Invocation Queuing

Method invocations to enterprise beans are only queued for remote clients making the method call. An example of a remote client is an Enterprise JavaBeans (EJB) client running in a separate Java virtual machine (JVM) (another address space) from the enterprise bean. In contrast, no queuing occurs if the EJB client, either a servlet or another enterprise bean, is installed in the same JVM on which the EJB method runs, and on the same thread of execution as the EJB client.

Remote enterprise beans communicate by using the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Method invocations initiated over RMI-IIOP are processed by a server-side object request broker (ORB). The thread pool acts as a queue for incoming requests. However, if a remote method request is issued and there are no more available threads in the thread pool, a new thread is created. After the method request completes the thread is destroyed. Therefore, when the ORB is used to process remote method requests, the EJB container is an open or closed queue, due to the use of unbounded threads.

The following illustration depicts the two queuing options of enterprise beans.

EJB Queuing



Enterprise bean and EJB container troubleshooting tips

If you are having problems starting an Enterprise JavaBeans (EJB) container, or encounter error messages or exceptions that appear to be generated on by an EJB container, follow these steps to resolve the problem:

- Use the administrative console to verify that the application server which hosts the container is running.
- Browse the logs for the application server which hosts the container. Look for the message **server *server_name* open for e-business** in the server log files. If it does not appear, or if you see the message **problems occurred during startup**, browse the server log files for details.

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Application client log error indicates missing JAR file

The following error message appears in the client log file because a Java archive (JAR) file is missing from the classpath on the client machine. The Object Request Broker (ORB) needs this file to unmarshal the nested exception that is part of the EJB exception, returned by the server to the client application. For example, if the EJB returns a DB2® JCC SQL exception nested inside of the EJB exception that it returns to the client, the ORB is not able to unmarshal the nested exception if the db2jcc.jar file that contains the DB2 SQL exception is not in the client classpath.

```
java.rmi.MarshalException: CORBA MARSHAL 0x4942f89a No; nested exception is:
org.omg.CORBA.MARSHAL: Unable to read value
from underlying bridge : Custom marshaling (4) Sender's class does not match
local class  vmcid: 0x4942f000  minor  code: 2202  completed: No*
```

To avoid this error, include the JAR file that contains the class for the nested exception that is returned in the EJB exception.

Enterprise bean cannot be accessed from a servlet, a JSP file, a stand-alone program, or another client

Use these troubleshooting tips for problems related to accessing enterprise beans.

What kind of error are you seeing?

- **javax.naming.NameNotFoundException: Name *name* not found in context ″local″ message** when access is attempted
- **BeanNotReentrantException** is thrown
- **CSITransactionRolledbackException / TransactionRolledbackException** is thrown
- Call fails, Stack trace beginning **EJSContainer E Bean method threw exception [exception_name]** found in JVM log file.
- Call fails, **ObjectNotFoundException or ObjectNotFoundLocalException** when accessing stateful session EJB found in JVM log file.
- Attempt to start container managed persistence (CMP) Enterprise JavaBeans (EJB) module fails with **javax.naming.NameNotFoundException: *dataSourceName***
-
- **Message BBOT0003W is issued**
- Symptom: **CNTR0001W: A Stateful SessionBean could not be passivated**

If the client is remote to the enterprise bean, which means, running in a different application server or as a stand-alone client, browse the logs of the application server hosting the enterprise bean, as well as log files of the client.

ObjectNotFoundException or ObjectNotFoundLocalException when accessing stateful session EJB

A possible cause of this problem is that the stateful session bean timed out and was removed by the container. This event must be addressed in the code, according to the EJB 2.1 and later specification. You can review the EJB 2.1 and 3.0 specifications at `http://java.sun.com/products/ejb/docs.html`.

Stack trace beginning ″EJSContainer E Bean method threw exception [exception_name]″ found in JVM log file

If the exception name indicates an exception thrown by an IBM class that begins with ″com.ibm...″, then search for the exception name within the information center, and in the online help as described below. If ″exception name″ indicates an exception thrown by your application, contact the application developer to determine the cause.

javax.naming.NameNotFoundException: Name name not found in context ″local″

A possible reason for this exception is that the enterprise bean is not local (not running in the same Java virtual machine [JVM] or application server) to the client JSP, servlet, Java application, or other enterprise bean, yet the call is to a ″local″ interface method of the enterprise bean . If access worked in a development environment but not when deployed to WebSphere Application Server, for example, it might be that the enterprise bean and its client were in the same JVM in development, but are in separate processes after deployment.

To resolve this problem, contact the developer of the enterprise bean and determine whether the client call is to a method in the local interface for the enterprise bean. If so, have the client code changed to call a remote interface method, or to promote the local method into the remote interface.

References to enterprise beans with local interfaces are bound in a name space local to the server process with the URL scheme of `local:`.

BeanNotReentrantException is thrown

This problem can occur because client code, typically a servlet or JSP file, is attempting to call the same stateful SessionBean from two different client threads. This situation often results when an application stores the reference to the stateful session bean in a static variable, uses a global (static) JSP variable to refer to the stateful SessionBean reference, or stores the stateful SessionBean reference in the HTTP session object. The application then has the client browser issue a new request to the servlet or JSP file before the previous request has completed.

To resolve this problem, ask the developer of the client code to review the code for these conditions.

CSITransactionRolledbackException / TransactionRolledbackException is thrown

An enterprise bean container creates these high-level exceptions to indicate that an enterprise bean call did not complete. When this exception is thrown, browse the logs to determine the underlying cause.

Some possible causes include:
- The enterprise bean might throw an exception that was not declared as part of its method signature. The container is required to roll back the transaction in this case. Common causes of this situation are where the enterprise bean or code that it calls creates a NullPointerException, ArrayIndexOutOfBoundsException, or other Java runtime exception, or where a BMP bean encounters a JDBC error. The resolution is to investigate the enterprise bean code and resolve the underlying exception, or to add the exception to the problem method signature.
- A transaction might attempt to do additional work after being placed in a `″Marked Rollback″`, `″RollingBack″`, or `″RolledBack″` state. Transactions cannot continue to do work after they are set to one of these states. This situation occurs because the transaction has timed out which, often occurs because of a database deadlock. Work with the application database management tools or administrator to determine whether database transactions called by the enterprise bean are timing out.
- A transaction might fail on commit due to dangling work from local transactions. The local transaction encounters some ″dangling work″ during commit. When a local transactions encounters an ″unresolved action″ the default action is to ″rollback″. You can adjust this action to ″commit″ in an assembly tool. See the assembly tool information center on how to adjust

Attempt to start EJB module fails with ″javax.naming.NameNotFoundException dataSourceName_CMP″exception

This problem can occur because:
- When the DataSource resource was configured, container managed persistence was not selected.

  - To confirm this problem, in the administrative console, browse the properties of the data source given in the NameNotFoundException. On the Configuration panel, look for a check box labeled **Container Managed Persistence**.
  - To correct this problem, select the check box for **Container Managed Persistence**.
- If container managed persistence is selected, it is possible that the CMP DataSource was not bound into the namespace.
  - Look for additional naming warnings or errors in the status bar, and in the hosting application server logs. Check any further naming-exception problems that you find by looking at the topic Application access problems.

Message BBOT0003W is issued

Message BBOT0003W indicates a transaction timeout. The timeout might result in the abnormal termination of the servant where the transaction is running.

- The default timeout value for enterprise bean transactions is 120 seconds. After this time, the transaction times out and the connection closes.
- If the transaction legitimately takes longer than the specified timeout period, on the administrative console:
  1. Go to **Manage Application Servers > server_name**
  2. Select the **Transaction Service properties** page
  3. Increase the **Total transaction lifetime timeout** value
  4. **Save** the configuration

  Note: z/OS will use the value you set for **Total transaction lifetime timeout** as the default transaction timeout setting. If you set a value for this property that is greater than the maximum transaction timeout value, z/OS will use the maximum transaction timeout value as the default.

Symptom:CNTR0001W: A Stateful SessionBean could not be passivated

This error can occur when a Connection object used in the bean is not closed or nulled out.

To confirm this is the problem, look for an exception stack in the logs for the EJB container that hosts the enterprise bean, and looks similar to:

```
StatefulPassi W CNTR0001W:
A Stateful SessionBean could not be passivated: StatefulBeanO
(BeanId(XXX#YYY.jar#ZZZZ),
state = PASSIVATING)
java.io.NotSerializableException: com.ibm.ws.rsadapter.jdbc.WSJdbcConnection
 at java.io.ObjectOutputStream.outputObject((Compiled Code))
 at java.io.ObjectOutputStream.writeObject(ObjectOutputStream.java(Compiled Code))
 at java.io.ObjectOutputStream.outputClassFields((Compiled Code))
 at java.io.ObjectOutputStream.defaultWriteObject((Compiled Code))
 at java.io.ObjectOutputStream.outputObject((Compiled Code))
 at java.io.ObjectOutputStream.writeObject(ObjectOutputStream.java(Compiled Code))
 at com.ibm.ejs.container.passivator.StatefulPassivator.passivate((Compiled Code))

 at com.ibm.ejs.container.StatefulBeanO.passivate((Compiled Code)
 at com.ibm.ejs.container.activator.StatefulASActivationStrategy.atUnitOfWorkEnd
                      ((Compiled Code))
 at com.ibm.ejs.container.activator.Activator.unitOfWorkEnd((Compiled Code))
 at com.ibm.ejs.container.ContainerAS.afterCompletion((Compiled Code)
```

where *XXX,YYY,ZZZ* is the Bean's name.

To correct this problem, the application must close all connections and set the reference to null for all connections. Typically this activity is done in the `ejbPassivate()` method of the bean. Also, note that the bean must have code to reacquire these connections when the bean is reactivated. Otherwise, there are NullPointerExceptions when the application tries to reuse the connections.

Developing enterprise beans

One of two enterprise bean development scenarios is typically used with the product. The first is command-line using Ant, Make, Maven or similar tools. The second is an IDE-based development and build environment. The steps in this article focus on development without an IDE.

Before you begin

Enterprise JavaBeans (EJB) 2.x beans only: Design a J2EE application and the enterprise beans that it needs.

- Before developing entity beans with container-managed persistence (CMP), read the topic Concurrency control.

EJB 3.0 beans only: Design a Java EE application and the enterprise beans that it needs.

- Before developing entity beans with CMP, read the topic, ″Concurrency control.″ Keep in mind that EJB 3.0 modules do not support entity beans. You must continue to place entity beans in your EJB 2.x-level modules.

About this task

The following is more information about the two basic approaches to selecting tools for developing enterprise beans:

- You can use one of the available IDE tools that automatically generate significant parts of the enterprise bean code and contain integrated tools for packaging and testing enterprise beans. The Rational Application Developer product is the recommended IDE. For more information, see the documentation for that product.

  To use the assembly tools with EJB 3.0 modules, you need to add <WAS_HOME>/lib/j2ee.jar to the project's build path to resolve compilation dependencies on the new EJB 3.0 API classes. Code assist works once this is done. If you define a server (see J2EE Perspective), point the server to the product install directory. Before you create the project, the project automatically refers to <WAS_HOME>/lib/j2ee.jar. Be sure to create the server with the setting *Run server with resources on Server*.
- If you have decided to develop enterprise beans without an IDE, you need at least an ASCII text editor. You can also use a Java development tool that does not support enterprise bean development. You can then use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the beans.

  Like the assembly tool, a standard Java EE command-line build environment requires some change to utilize the EJB 3.0 modules. As with previous Java EE application development patterns, you must include the `j2ee.jar` file located in the `<WAS_HOME>/lib/` directory on the compiler classpath. An example of a command-line build environment using Ant is located in the `<WAS_HOME>/samples/src/TechSamp` directory.

The following steps primarily support the second approach, development without an IDE.

1. If necessary, migrate any pre-existing code to the required version of the EJB specification.

   Applications written to the EJB specification versions 1.1, 2.0, and 2.1 can run unchanged in the EJB 3.0 container.
2. Write and compile the components of the enterprise bean.
   - At a minimum, a session bean developed with the EJB 3.0 specification requires a bean class and a business interface.
   - At a minimum, an EJB 1.1 session bean requires a bean class, a home interface, and a remote interface. An EJB 1.1 entity bean requires a bean class, a primary-key class, a home interface, and a remote interface.
   - At a minimum, an EJB 2.x session bean requires a bean class, a home or local home interface, and a remote or local interface. An EJB 2.x entity bean requires a bean class, a primary-key class, a

remote home or local home interface, and a remote or local interface. The types of interfaces go together: If you implement a local interface, you must also define a local home interface.

Note: Optionally, the primary-key class can be *unknown*. See unknown primary-key class for more information.

- A message-driven bean requires only a bean class.

3. For each entity bean, complete work to handle persistence operations.

   For EJB 3.0 modules, consider using the Java Persistence API (JPA) specification to develop plain old Java Object (POJO) persistent entities. Review the topic ″Java Persistence API″ for more information. If you choose to develop entity beans to earlier EJB specifications, follow the steps below:

   - Create a database schema for the entity bean's persistent data.
     – For entity beans with CMP, you must store the bean's persistent data in one of the supported databases. The assembly tool automatically generates SQL code for creating database tables for CMP entity beans. If your CMP beans require complex database mappings, it is recommended that you use Rational Application Developer to generate code for the database tables. For more information on using the assembly tools see the assembly tool information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html
     – For entity beans with bean-managed persistence (BMP), you can create the database and database table by using the database tools or use an existing database and database table.

     For more information on creating databases and database tables, review your database documentation.
   - **(CMP entity beans for EJB 2.x only)**

     Define finder queries with EJB Query Language (EJB QL).

     Define finder queries with EJB Query Language (EJB QL).

     With EJB QL, you define finders in terms of CMP fields and container-managed relationships, as follows:
     – *Public* finders are visible in the bean's home interface. Implemented in the bean class, they return only remote interfaces and collection types.
     – *Private* finders, expressed as SELECT statements, are used only within the bean class. They can return both local and remote interfaces, dependent values, other CMP field types, and collection types.
   - **(CMP entity beans for EJB 1.1 only: an IBM extension)** Create a finder helper interface for each CMP entity bean that contains specialized finder methods (other than the findByPrimaryKey method).

     The following logic is required for each finder method (other than the findByPrimaryKey method) contained in the home interface of an entity bean with CMP:
     – The logic must be defined in a public interface named *Name*`BeanFinderHelper`, where *Name* is the name of the enterprise bean, for example, AccountBeanFinderHelper.
     – The logic must be contained in a String constant named *`findMethodName`*`WhereClause`, where *findMethodName* is the name of the finder method. The String constant can contain zero or more question marks (?) that are replaced from left to right with the value of the finder method's arguments when that method is called.

What to do next

Assemble the beans in one or more EJB modules

Assemble the beans in one or more EJB 3.0 modules.

Enterprise JavaBeans (EJB) 3.0 specification

This topic describes the Enterprise JavaBeans (EJB) 3.0 specification that is the foundation of the development and application programming model for the EJB 3.0 applications. Read this topic for a brief overview of the EJB 3.0 specification.

The EJB 3.0 specification has justifiably been called the most important upgrade to the Java Platform, Enterprise Edition 5 (Java EE 5) programming model. The EJB 3.0 specification represents simplification and streamlining of the business logic and persistence programming models used in Java EE. The ultimate source of information is the specification, which is available on the Sun Microsystems, Inc., Web site at http://java.sun.com.

While the Java Persistence API (JPA) replacement is called an entity class, it should not be confused with entity enterprise beans. A JPA entity is not an enterprise bean and is not required to run in an EJB container.

The EJB 3.0 specification is organized into three areas:

- EJB core contracts and requirements
- EJB 3.0 simplified application programming interface (API)
- JPA

The EJB core contracts and requirements defines the service provider interfaces (SPIs) between the enterprise bean instance and the enterprise bean container. This part of the specification also includes the APIs between the enterprise bean provider and the enterprise bean container, protocols, component and container contracts, system level issues, infrastructure services that are provided by the container to the bean and other information about development packaging and deployment for session, message-driven and entity beans.

The EJB 3.0 simplified API provides information about simplifying EJB APIs and SPIs that exist from previous EJB specification versions.

The JPA document introduces the Plain Old Java Object (POJO)-style persistent entity development guidelines.

Another good source for EJB 3.0 information is Mastering Enterprise JavaBeans 3.0, Fourth Edition. This edition features chapters on session beans and message-driven beans, EJB and Java EE integration and advanced persistence concepts. Also included is coverage of the JPA and POJO using entities with the EJB programming model.

EJB 3.0 considerations

When using Enterprise JavaBeans (EJB) 3.0 modules, keep in mind the following considerations.

Version 7.0 does not support entity beans in EJB 3.0-level modules

IBM® WebSphere® Application Server Version 7.0 does not support the use of bean managed persistence (BMP) and container managed persistence (CMP) entity beans in EJB 3.0-level modules. BMP entity beans are supported in the Feature Pack for EJB 3.0, although CMP beans are not. EJB entity beans may still be used on V7.0, but they must be packaged in an EJB 2.1 or earlier-level module.

Java Platform, Enterprise Edition (Java EE) applications that are packaged with EJB entity beans in EJB 3.0-level modules fail to install on V7.0.

An EJB Java archive (JAR) file is considered to be an EJB 3.0 module when either of the following are true:

- The EJB JAR file contains configuration data in an ejb-jar.xml file with the following EJB 3.0 header specification:

```
<ejb-jar id="ejb-jar_ID" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd">
```

- The EJB JAR file contains beans with EJB 3.0-style source annotations that provide configuration data.

You will need to repackage your EJB 3.0 modules using EJB 2.x and earlier modules. Otherwise, the installation of any applications that contain entity beans will fail.

Annotations

Consider if you will use annotations versus deployment descriptors, or both. See the topic ″EJB 3.0 metadata annotations″ for more information about annotations.

EJB module

WebSphere Application Server Version 7.0 supports EJB module Java archive (JAR) files with an ejb-jar.xml deployment descriptor declared at the 1.1, 2.0, 2.1, or 3.0 level, or with no ejb-jar.xml deployment descriptor present. If no deployment descriptor is present, the EJB module is assumed to be at the 3.0 level or greater.

EJB modules that contain EJB 3.0 beans must be declared to be at the EJB 3.0 level. This can be accomplished either by setting the ejb-jar.xml deployment descriptor level to 3.0, or ensuring that the module does not contain an ejb-jar.xml deployment descriptor. If the module level is 2.1 or earlier, no EJB 3.0-specific functions such as annotation scanning or resource injection will be performed.

Entity beans are not supported in EJB 3.0 level modules. You must place any entity beans in EJB modules at the 2.1 or earlier level.

Java EE application client module

The product provides support for Java EE application client modules. Additionally, it supports injection of EJB references into client components if the injection is defined through the @EJB annotation.

Note: EJB 3.0 does not support the injection of an enterprise bean that creates a new enterprise bean of itself. Do not inject an enterprise bean that creates a new enterprise bean of itself.

Defining an ejb-ref reference to an EJB 3.0 business interface from a Java EE client component descriptor

It is possible to define an ejb-ref from an application-client.xml descriptor that points to an EJB 3.0 business interface. EJB 3.0 business interfaces are accessed directly without the use of a home, yet the ejb-ref element in Java EE requires that a home interface type be specified. Therefore, you must include the <home></home> stanza in the ejb-ref definition, but specify a null value as shown in the example below. For the value of the <remote> stanza, specify the EJB 3.0 business interface class name. Finally, when you set the binding value, either during application install or through tooling, specify the location where the EJB 3.0 business interface was bound.

For example, the ejb-ref in your client component's application-client.xml file will look similar to the following:

```
<ejb-ref id="EJBRef_1">
 <ejb-ref-name>java_comp-env_name_of_ref</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <home></home>
 <remote>com.ejbs.business.interface.class.name</remote>
</ejb-ref>
```

The corresponding section of the ibm-application-client-bnd.xmi file looks similar to the following. A default EJB binding pattern is used here; the default EJB binding conventions are described in the topic, ″EJB 3.0 applications binding support.″

```
<ejbRefBindings xmi:id="EjbRefBinding_1" jndiName=EJB3App/EJB3Mod.jar/MyBean##com.ejbs.business.interface.class.name">
 <bindingEjbRef href="application-client.xml#EjbRef_1"/>
</ejbRefBindings>
```

EJB 3.0 metadata annotations

Annotations enable you to write metadata for Enterprise JavaBeans (EJB) inside your source code. You can use them instead of extensible markup language (XML) deployment descriptor files. Annotations can also be used *with* descriptor files.

If you installed the Feature Pack for EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 7.0, the default is not to scan pre-Java EE 5 modules during the application install or at server startup

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether or not to scan legacy Web modules for additional metadata. A server level switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** → **server name** → **Process definition** → **Java Virtual Machine** → **Custom properties**.

The product also provides default values for most of the EJB annotations it uses. In many cases, omitting an annotation implies that you want to use the default value.

For the most part, annotations are found in the *javax.ejb* and *javax.persistence* packages.

EJB 3.0 interceptors

An interceptor is a method that is automatically called when the business methods of a bean are invoked.

You can define interceptors for session or message-driven beans. Business method interceptors can be defined to apply to all business methods of a bean class or to specific business methods only.

You denote interceptor classes using the Interceptor annotation on the bean class, or in the deployment descriptor using the <interceptor> element. Interceptor methods are marked with the AroundInvoke annotation or with the <around-invoke> element of the deployment descriptor. The interceptor methods always follow the pattern Object <method_name> (InvocationContext c) throws Exception.

Interceptors that apply to all session and message-driven beans in an ejb-jar file, known as default interceptors, are defined in the deployment descriptor using the <interceptor-binding> element. Interceptor methods can also be applied to specific methods rather than default to all methods or to specific beans by using the Interceptors annotation.

You can define any number of interceptors for a bean class. They are invoked in the order that they are specified. Interceptors defined in external classes are processed before interceptors defined within a bean class.

EJB 3.0 interceptors

An interceptor is a method that is automatically called when the business methods of a bean are invoked.

You can define interceptors for session or message-driven beans. Business method interceptors can be defined to apply to all business methods of a bean class or to specific business methods only.

You denote interceptor classes using the Interceptor annotation on the bean class, or in the deployment descriptor using the <interceptor> element. Interceptor methods are marked with the AroundInvoke annotation or with the <around-invoke> element of the deployment descriptor. The interceptor methods always follow the pattern Object <method_name> (InvocationContext c) throws Exception.

Interceptors that apply to all session and message-driven beans in an ejb-jar file, known as default interceptors, are defined in the deployment descriptor using the <interceptor-binding> element. Interceptor methods can also be applied to specific methods rather than default to all methods or to specific beans by using the Interceptors annotation.

You can define any number of interceptors for a bean class. They are invoked in the order that they are specified. Interceptors defined in external classes are processed before interceptors defined within a bean class.

Create stubs command

The createEJBStubs command creates stub classes for remote interfaces of EJB version 3.0 beans packaged in Java archive (JAR) or Enterprise archive (EAR) files. It also provides an option to create a single stub class from an interface class located in a directory or a JAR file. Several command options are provided to package the generated stub classes in different ways. See the Syntax and Examples sections below for more details.

This command is found in the <WAS_HOME>/bin directory as:
- createEJBStubs.bat - Windows platforms
- createEJBStubs.sh - Unix based platforms
- createEjbStubs - iSeries platform

The command searches the input JAR or EAR file, looking for EJB version 3.0 modules that contain beans with remote interfaces. When remote interfaces are found, the corresponding stub classes are generated and packaged according to the command options specified. In the case where the input specified is a single interface class, the tool assumes this class is an EJB version 3.0 remote interface class and generates a remote stub class.

For many client-side scenarios, the WebSphere Application Server Just-In-Time (JIT) deployment feature dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB 3.0 business interfaces. However, there are some scenarios where the JIT deploy environment is not available to dynamically generate these classes. In these scenarios, the createEJBStubs command must be used instead to generate and embed the client-side stub class files in your client application. If your client environment is one of the following, use the createEJBStubs command:
- ″Bare″ Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- A WebSphere Application Server container (web container, EJB container, or application client container) from a version earlier than version 7, or without the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

Syntax

createEJBStubs *input_ class_ name* | *input_JAR_name* | *input_EAR_name* [**-help**] [**-newfile [new_file]**] [**-updatefile [update_file]**] [**-quiet**] [**-verbose**] [**-logfile log_file**] [**-appendlog**] [**-cp class_path**] [**-trace**]

createEJBStubs

This is the command to create EJB stub classes for a single interface class file, a JAR file, or an EAR file. When invoked without any arguments, or only –help, the createEJBStubs command displays a list of options that can be specified, and a list of example invocations with detailed explanations.

input_class_name **or** *input_EAR_name* **or** *input_JAR_name*

The first parameter is a required element for the command. It must contain the source class, JAR, or EAR file to process.

This parameter may be the fully qualified name of a single interface class (e.g. com.ibm.myRemoteInterface). Note that the package name segments are separated by “.” characters, no path name proceeds the class name, and the “.class” extension is not included. For this interface class input, you must use the class path option (e.g. –cp my_path, or –cp my_path/my_interfaces.jar) to specify where the interface class will be found. The generated stub class will be placed in the package-defined directory structure, starting with the current directory where the command is invoked.

This parameter may also be a JAR or EAR file. In this case the path must be specified (e.g. my_path/my_Server_App.ear). The generated stub classes will be placed in the same module or

modules with the beans, or in the same module or modules with the remote interface classes, depending on whether the –updatefile option is specified. See below for more details.

-help Provides the command syntax, including a list of options that can be specified, and example invocations with detailed explanations.

-newfile [new_file]
Requests that a new file is generated containing the original files in the input JAR or EAR plus the stub classes. When this option is not specified, the stubs are written back into the original JAR or EAR file. If this option is specified, but the new_file name is not provided, a new file name is constructed by appending the input JAR or EAR file name with ″_withStubs″. This option is not allowed when the first input parameter is an interface class.

-updatefile [update_file]
Requests that a second file (e.g. in addition to the input file) is updated with stub classes. This option also provides a different packaging behavior. The stub classes are packaged in the same module or modules as the remote interface classes. By contrast, when this option is not specified, the stub classes are packaged in the same module or modules with the bean classes. If this option is specified, but the update_file name is not provided only the original JAR or EAR file is updated with stub classes. This option is not allowed when the first input parameter is an interface class.

-quiet Requests the suppression of messages. The -quiet option cannot be specified with either the –verbose or the –trace options. Error messages are still displayed.

-verbose
Requests that additional informational messages be output. The -verbose option cannot be specified with either the -quiet or the –trace options.

-logfile log_file
Requests that messages be printed to a log file in addition to the console. If this option is specified, the log_file name must also be provided.

-appendlog
Requests that messages be appended to an existing log file. If this option is specified, the -logfile option must also be specified.

-cp class_path
Requests that the classloader includes the specified the class path where additional class or jar files are located, which are necessary for the remote interface classes to be loaded. The class path may include multiple segments where each path is separated from a previous path by the default path separator character of the operating system. Each path can specify either a JAR file, or a directory. If this option is specified, the class_path name must also be provided.

-trace Request that detailed trace output be generated. This is intended to collect information for use by IBM service to resolve problems. The trace output is English-only. This option cannot be specified with either the –quiet or the –verbose options.

Examples

createEJBStubs com.ibm.myRemoteInterface -cp my_path

Generate the stub class for one remote interface class and place it in the package-defined directory structure, starting at the current directory. The my_path directory will be used as the class path. If the remote interface class to process is in a JAR file, the –cp my_path/my_interfaces.jar syntax must be used for the class path specification.

createEJBStubs my_path/my_beans.jar -newfile –quiet

Generate the stub classes for all level 3.0 enterprise beans in the my_beans.jar file that have remote interfaces. Both the generated stub classes and the original JAR file contents are packaged into a new JAR file named “my_beans_withStubs.jar” because the optional new_file name parameter is not specified along with the –newfile option. Output messages are suppressed except for error notifications.

createEJBStubs my_path/my_Server_App.ear -logfile myLog.out

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into the original EAR file because the –newfile option is not specified. The stub classes are packaged into the same module or modules as the bean classes because the –updatefile option is not specified. Messages are written to both the myLog.out log file and the command window.

createEJBStubs my_path/my_Server_App.ear -updatefile my_path/my_Client_interfaces.jar

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into both the original EAR file and the my_Client_interfaces.jar file. The stub classes are packaged into the same module or modules as the remote interface classes because the –updatefile option is specified.

createEJBStubs my_path/my_Server_App.ear –updatefile

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are only placed into the original EAR file because the optional update_file name parameter is not provided with the –updatefile option. The stub classes are packaged into the same module or modules as the remote interface classes because the -updatefile option is specified.

EJB 3.0 application bindings overview

Before an application that is installed on an application server can start, all Enterprise JavaBeans (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. The jndiName values specified for artifacts must be qualified lookup names.

You do not need to manually assign JNDI bindings names for each of the interfaces or EJB homes on your enterprise beans in EJB 3.0 modules. If you do not explicitly assign bindings, the EJB container assigns default bindings.

For the EJB 3.0 level, the product provides two distinct namespaces for EJB interfaces, depending on whether the interface is local or remote. The same provision applies to EJB homes, which can be considered a special type of interface. The two namespaces are as follows:

- JVM-scoped ejblocal: namespace
- Global JNDI namespace

Local EJB interfaces and homes must always be bound into a JVM-scoped ejblocal: namespace; they are accessible only from within the same application server process.

In contrast, remote EJB interfaces and homes must always be bound into the globally-scoped WebSphere JNDI namespace; they can be accessed from anywhere, including other server processes and other remote clients. Local interfaces cannot be bound into the globally-scoped JNDI namespace, nor can remote interfaces be bound into the JVM-scoped ejblocal: namespace.

The ejblocal: and globally-scoped JNDI namespaces are completely separate and distinct. For example, an EJB local interface bound at ″ejblocal:AccountHome″ is a not at all the same as a remote interface bound at ″AccountHome″ in the globally-scoped namespace. This helps maintain the distinction between your local and remote interface references. Having a JVM-scoped local namespace also makes it possible for your applications to directly look up or reference local EJB interfaces from anywhere in the JVM server process, including across Java Platform, Enterprise Edition (Java EE) application boundaries.

Assigning default JNDI bindings for EJB business interfaces in the EJB 3.0 container with the Application, Module, and Component names

The WebSphere Application Server V7 EJB container assigns default JNDI bindings for EJB 3.0 business interfaces based on Application Name, Module Name, and Component Name, so it is important to understand how these names are defined. Each of these names is a character string.

Java EE applications are packaged in a standardized format called an Enterprise Application Archive (EAR) file. The EAR is a packed file format similar to a .zip or .tar file format, and can thus be visualized as a collection of logical directories and files packed together into a single physical file. Within each EAR file are one or more Java EE module files, which can include:

- Java Application Archive (JAR) files for EJB modules, Java EE application client modules and utility class modules
- Web Application Archive (WAR) files for Web modules
- Other technology-specific modules such as Resource Application Archive (RAR) files and other types of modules

Within each module file are typically one or more Java EE components. Examples of Java EE components are enterprise beans, servlets, and application client main classes.

Since Java EE modules are packaged within Java EE application archives, and Java EE components are in turn packaged within Java EE modules, the ″nesting path″ of each component can be used to uniquely identify every component within a Java EE application archive, according to its application name, module name, and component name.

Application name

The name of an application is defined by the following (in order of priority):

- The value of the ″Application Name″ specified to the product administrative console, or the ″appname″ parameter supplied to the wsadmin command-line scripting tool, during installation of the application into the product.
- The value of the <display-name> parameter within the META-INF/application.xml deployment descriptor for the application.
- The EAR file name, excluding its ″.ear″ file suffix. For example, an application EAR file named CustomerServiceApp.ear would have an application name of ″CustomerServiceApp″ in this case.

Module name

The name of a module is defined as the Uniform Resource Identifier (URI) of the module file, relative to the root of the EAR file in which it resides. Stated another way, the module name is the module's file name relative to the root of the EAR file, including any ″sub-directories″ in which the module file is nested.

In the following example, the CustomerServiceApp application contains three modules whose names are AccountProcessing.jar, Utility/FinanceUtils.jar, and AppPresentation.war:

```
CustomerServiceApp.ear:     AccountProcessing.jar        com/                 mycompany/
               AccountProcessingServiceBean.class            AccountProcessingService.class     Utility/        FinanceUtils.jar
          META-INF/              ejb-jar.xml         com/              mycompany/
 InterestCalculatorServiceBean.class               InterestCalculatorService.class     AppPresentation.war        META-INF/
      web.xml
```

EJB component name

The name of an EJB component is defined by the following, in order of priority:

- The value of the ejb-name tag associated with the bean in the ejb-jar.xml deployment descriptor, if present.
- The value of the ″name″ parameter, if present, in the @Stateless or @Stateful annotation associated with the bean.
- The name of the bean implementation class, without any package-level qualifier.

Bindings

Review the following bindings that are supported by EJB 3.0:

- Default bindings for business interfaces and homes
- Default binding pattern
- User-defined bindings for EJB business interfaces and homes
- User-defined bindings for resolving references and injection targets
- Default resolution of EJB references and EJB injections: The AutoLink feature
- Naming considerations in clustered environments
- User-defined EJB extension settings
- Legacy (XMI) bindings
- User-specified XML bindings

Default bindings for EJB business interfaces and homes

In WebSphere Application Server V7, it is not necessary for you to explicitly define JNDI binding names for each of the your interfaces or EJB homes within an EJB 3.0 module. If you do not explicitly assign bindings, the product's EJB container assigns default bindings using the rules outlined here. This is somewhat different from the EJB support in product prior to the support of the EJB 3.0 specification.

The container performs two default bindings for each interface (business, remote home, or local home) on each enterprise bean. These two bindings are referred to here as the interface's ″short″ binding and its ″long″ binding. The short binding uses just the package-qualified Java class name of the interface, while the long binding uses the enterprise bean's component ID as an extra qualifier before the package-qualified interface class name, with a hash or number sign (# symbol) between the component ID and the interface class name. You can think of the difference between the two forms as being analogous to a ″short″ TCP/IP hostname (just the machine name) versus a ″long″ hostname (machine name with domain name prepended to it).

For example, an interface's short and long default bindings might be ″com.mycompany.AccountService″ and ″AccountApp/module1.jar/ServiceBean#com.mycompany.AccountService″, respectively.

By default, the component ID for EJB default bindings is formed using the enterprise bean's Application Name, Module Name, and Component Name that are defined above, but you can assign any string you want instead. By defining your own string as the component ID, you can set up a naming convention where the enterprise bean's long-form bindings share a common user-defined portion, yet also have a system-defined portion based on the name of each interface class. It also allows you to make the default EJB binding names independent of how you have packaged the enterprise beans within the application/module hierarchy. Overriding an enterprise bean's default component ID is described in the ″User-defined bindings for EJB business interfaces and homes″ section of this topic.

As mentioned earlier in the section on the JVM-scoped local namespace and the globally-scoped JNDI namespace, all local interfaces and homes must be bound into the ejblocal: namespace, which is accessible only within the same server process (JVM), while remote interfaces and homes must be bound into the globally-scoped namespace, which is accessible from anywhere in the WebSphere product cell. As you would expect, the EJB container follows these rules for the default bindings.

In addition, the ″long″ default bindings for remote interfaces follow recommended Java EE best practices in that they are grouped under an ejb context name. By default, EJB remote home and business interfaces are bound into the root of the application server naming context. However, the application server root context is used for binding more than just EJB interfaces, so to keep this context from getting too cluttered, it is a good practice to group EJB-related bindings into a common ″EJB″ sub-context rather than placing them directly in the server root context. It is similar to why you would use subdirectories on a disk volume rather than putting all the files in the root directory.

The short default bindings for remote interfaces are not bound in the ejb context. The short default bindings are located in the root of the server root context. Even though it is a best practice to group all of the EJB-related bindings under an ejb context, there are other considerations including the following:

- The short default bindings provide a simple, direct way to access an EJB interface. Placing them directly in the server root context and referring to them by just the interface name or the interface name prepended with ejblocal: was in keeping with that goal of simplicity.
- At the same time, placing the long default bindings in the ejb context, or the ejblocal: context in the case of a local interface, kept those bindings out of the server's root context and reduced the clutter there enough to allow having the short bindings in the root context.
- It provides a degree of cross-compatibility with other Java EE application servers that use similar naming conventions.

To summarize, all local default bindings, both short and long, are placed in the ejblocal: server/JVM-scoped namespace, while remote default bindings are placed in the server's root context of the globally-scoped namespace if they are short, or in the <server_root>/ejb context (just below the server's root context) if they are long. Thus, the only default bindings in the server's globally-scoped root context are the short bindings for remote interfaces, which is the best balance between providing a simple, portable usage model and keeping the server's globally-scoped root context from becoming too cluttered.

Default binding pattern

The patterns for each type of binding are displayed in the table. In these patterns, strings written in *<bracketed italics>* represent a value. For example, *<package.qualified.interface>* might be something like com.mycompany.AccountService and *<component-id>* might be something like AccountApp/module1.jar/ServiceBean.

Description	Binding pattern
Short form local interfaces and homes	ejblocal:*<package.qualified.interface>*
Short form remote interfaces and homes	*<package.qualified.interface>*
Long form local interfaces and homes	ejblocal:*<component-id>*#*<package.qualified.interface>*
Long form remote interfaces and homes	ejb/*<component-id>*#*<package.qualified.interface>*

The *component-id* defaults to *<application-name>/<module-jar-name>* /*<ejb-name>* unless it is overridden in the EJB module binding file using the component-id attribute as described in the next section, ″Conflicts in short default binding names when multiple enterprise beans implement the same interface.″

Conflicts in short default binding names when multiple enterprise beans implement the same interface

When more than one enterprise bean that is running in the application server implements a given interface, the short default binding name becomes ambiguous because the short name might refer to any of the Enterprise JavaBeans that implement this interface. In order to avoid this situation, you must either explicitly define a binding for each Enterprise JavaBeans that implements the given interface as described in the next section, or disable short default bindings for applications containing these Enterprise JavaBeans by defining a WebSphere product ″JVM custom property″,

com.ibm.websphere.ejbcontainer.disableShortDefaultBindings. For more information about defining the JVM custom property, see the topic ″Java Virtual machine custom properties.″

To use this JVM custom property, set the property name to com.ibm.websphere.ejbcontainer.disableShortFormBinding and the property value to either * (asterisk} as a wildcard value to disable short form default bindings for all applications in the server, or to a colon-delimited sequence of the Java EE application names for which you want to disable short default bindings, for example, PayablesApp:InventoryApp:AccountServicesApp.

Effect of explicit assignment on default bindings

If you explicitly assign a binding definition for an interface or home, no short or long default bindings are performed for that interface.

Note: This only applies to the specific interfaces for which you assign an explicit binding. Other instances on that enterprise bean, without explicitly-assigned bindings, are bound by using default binding names.

User-defined bindings for EJB business interfaces and homes

For cases where you want to manually assign binding locations rather than using the product default bindings, you can use the EJB module binding file to assign your own binding locations to specific interfaces and homes. You can also use this file to only override the component ID portion of the default bindings on one or more enterprise beans in the module. Overriding the component ID provides a middle ground between allowing the bindings to completely default, versus completely specifying the binding name for each interface.

To specify user-defined bindings information for EJB 3.0 modules, place a file named, ibm-ejb-jar-bnd.xml, in the EJB JAR module's META-INF directory.

Note: The suffix on this file is XM**L**, not XM**I**, as in prior versions of product.
Also, when defining a binding for a local interface, you must preface the name with the string ″ejblocal:″ so it is bound into the JVM-scoped ejblocal: namespace.

The ibm-ejb-jar-bnd.xml file is used for EJB 3.0 modules that run on the product, whereas the ibm-ejb-jar.bnd.xmi file is used for pre-EJB 3.0 modules and for Web modules. The binding file format in ibm-ejb-jar.bnd.xml is different from the XMI file format for the following reasons:

- Bindings and extensions that are declared in the XMI file format depend on the presence of a corresponding ejb-jar.xml deployment descriptor file that explicitly refers to unique ID numbers that are attached to elements in that file. This system is no longer viable for EJB 3.0 modules, where it is no longer a requirement for the module to contain an ejb-jar.xml deployment descriptor.
- The XMI file format was designed to be machine-edited only by the product development tools and system management functions; it was effectively part of the product's internal implementation and the file's structure was never documented externally. This made it impossible for developers to manually edit binding files, or create them as part of a WebSphere-independent build process, in a supported manner.
- Rather than referring to encoded ID numbers in the ejb-jar.xml deployment descriptor, the XML-based binding file refers to EJB components by its EJB name. Each EJB component in a module is guaranteed to have a unique EJB name, either by default or through explicit assignment by the developer, so this provides an unambiguous way to target bindings and extensions.
- The new binding files are XML-based, and an XML Schema Definition (xsd) file is provided to externally document the structure. These .xsd files can be consumed by many common XML file editors to assist in syntactic verification and code completion functions. As a result, it is now possible for developers to produce and edit the binding and extension files independently of the Application Server infrastructure.

The following table lists the ibm-ejb-jar-bnd.xml elements and attributes that are used to assign bindings to EJB interfaces and homes for EJB 3.0 modules in WebSphere Application Server V7.

Element or attribute	How used	Example	Comments
<session>	Declares a group of binding assignments for a session bean.	`<session name= "AccountServiceBean"/>`	Requires name attribute and at least one of the following: simple-binding-name attribute, local-home-binding-name attribute, remote-home-binding-name attribute, or <interface> element.
name	Attribute that identifies the ejb-name of the enterprise bean that a <session>, <message-driven>, or <entity>, or other element applies to.	`<session name= "AccountServiceBean"/>`	The ejb-name value is the name declared in the <ejb-name> element of an ejb-jar.xml deployment descriptor file, the name parameter of a @Session or @MessageDriven annotation, or defaults to the unqualified class name of the EJB implementation class annotated with the @Session or @MessageDriven annotation (if no <ejb-name> value is declared in the XML deployment descriptor and no name parameter is declared on the annotation).

Element or attribute	How used	Example	Comments

component-id	Attribute that overrides the default component ID value for an enterprise bean. The default long-form bindings for this enterprise bean uses the specified component ID instead of *<app_name>/ <module_jar_name>/ <bean_name>*.	`<session name= "AccountServiceBean" component-id= "Dept549/ AccountProcessor"/>`
		
		The above example results in the bean whose ejb-name is AccountServiceBean, having its long-form default local interfaces bound at
		`ejblocal:Department549 /AccountProcessor# <package.qualified. interface>`
		
		Its long-form default remote interfaces are bound at
		`ejblocal:Department549 /AccountProcessor# <package.qualified. interface>`
			Can be used alone, or in combination with the <interface> element, the local-home-binding-name attribute, or the remote-home-binding-name attribute. Interfaces that are not assigned explicit bindings will have default bindings performed using the user-specified component ID value. Interfaces that are assigned explicit bindings are bound using those values.
			
			Since the simple-binding-name attribute is intended to apply to all defined interfaces on a given enterprise bean (leaving no interfaces defaulted), applying a component-id in combination with simple-binding-name is typically not useful.

Element or attribute	How used	Example	Comments

simple-binding-name	A simple mechanism for assigning interface bindings for Enterprise JavaBeans that:
	• Implement a single EJB 3.0 business interface, or
	• Implement a pre-EJB 3.0 style component interface (local, remote or both types) with a companion EJB home.
	The value of the attribute is used as the binding location of the enterprise bean's business interface, or the binding location of the Enterprise JavaBeans local and/or remote homes. The binding is placed in the ejblocal: namespace if the interface or home is local, and placed in the application server's root context of the globally-scoped JNDI namespace if the interface or home is remote.
		`<session name= "AccountServiceBean" simple-binding-name ="ejb/AccountService"/>`
		This example results in the bean whose ejb-name is AccountServiceBean, having its local business interface or home, if any, bound at
		`ejblocal:ejb/ AccountService`
		in the local JVM-scoped EJB namespace, and its remote business interface or home (if any) bound at
		`ejb/AccountService`
		in the application server's root context of the globally-scoped JNDI namespace. It is important to note here that the exact value of the attribute, including, in this specific example, the ″ejb″ subcontext name is used even if the interface is a local interface bound into the ejblocal: namespace. When user-defined bindings are specified, the exact name specified by the attribute is used.)
			Not to be used in combination with local-home-binding-name or remote-home-binding-name attributes, or the <interface> element. Also, should not be used on beans that implement more than one business interface (use the <interface> element in that case instead).
			If this attribute is used on an enterprise bean that implements more than one business interface, or a combination of business interface and local/remote component interface with home, the resulting bindings are disambiguated by appending a hash or number sign (# symbol) to the attribute value, followed by the package-qualified class name of each interface and/or home on the enterprise bean. This condition can be avoided, however, by using the <interface> element to define a binding for each of the business interfaces instead of using simple-binding-name.
			Important: defining a simple-binding-name on a bean that implements more than one business interface is not the same as overriding the default component ID for a bean using <component-id>. Remote interface default bindings defined with a component-id are still grouped under the ejb context (as all remote interface default bindings are), while remote interface bindings disambiguated by the EJB container in response to erroneous use of simple-binding-name on a bean with multiple interfaces are not grouped under the ejb context.Additionally, the inclusion of the package-qualified class name always occurs for long-form default bindings, whereas with

Element or attribute	How used	Example	Comments
local-home-binding-name	Attribute to specify the binding location of an enterprise bean's local home.	`<session name= "AccountServiceBean" local-home-binding -name="ejblocal: AccountService"/>`	Not to be used in combination with the simple-binding-name attribute. Since local homes must always be bound into the JVM-scoped namespace, the value must begin with the ejblocal: prefix.
remote-home-binding-name	Attribute to specify the binding location of an enterprise bean's remote home.	`<session name= "AccountServiceBean" remote-home-binding-name= "ejb/services/ AccountService"/>`	Not to be used in combination with the simple-binding-name attribute. The value cannot begin with the ejblocal: prefix, since remote homes cannot be bound into the ejblocal: namespace.
<interface>	A sub-element of the <session> element that assigns a binding to a specific EJB business interface. In contrast to the simple-binding-name, local-home-binding-name and remote-home-binding-name attributes, both a binding-name parameter and a class parameter are necessary (in fact, this distinction is why a separate XML element is necessary rather than an attribute). The class parameter specifies the package-qualified name of the business interface class to be bound.	`<interface class= "com.ejbs.Inventory Service" binding-name= "ejb/Inventory"/>` (declared as a sub-element inside a <session> element)	Not to be used in combination with the simple-binding-name attribute. Since local interfaces must always be bound into the JVM-scoped namespace, the binding-name value must begin with the ejblocal: prefix when this element is applied to a local interface.
binding-name	Attribute to specify the binding location of a business interface bound with the <interface> element.	`<interface class= "com.ejbs.Inventory Service" binding-name ="ejb/Inventory"/>` (declared as a sub-element inside a <session> element)	Required in combination with the <interface> element (and used on that element only). Since local interfaces must always be bound into the JVM-scoped namespace, the binding-name value must begin with the ejblocal: prefix when applied to a local interface.

Binding file Example 1

The following is a basic ibm-ejb-jar-bnd.xml file containing only the elements and attributes that assign binding names to EJB interfaces. It overrides the component ID used for default bindings on the enterprise bean that is named ″S01″, and assigns explicit bindings to some of the interfaces on the enterprise beans, ″S02″ and ″S03″, in this module.

```
<?xml version="1.0" encoding="UTF-8"?> <ejb-jar-bnd
  xmlns="http://websphere.ibm.com/xml/ns/javaee"  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee   http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd"
 version "1.0">      <session name="S01" component-id="Department549/AccountProcessors"/>      <session name="S02"
 simple-binding-name="ejb/session/S02"/>      <session name="S03">     <interface class="com.ejbs.BankAccountService"
 binding-name="ejblocal:session/BAS"/>      </session>  </ejb-jar-bnd>
```

The binding file results in the following:

1. The session bean with ejb-name ″S01″ is assigned a user-defined component ID, overriding the default component ID (application name/ejb-jar module name/bean name) for all interfaces on that bean. Local interfaces on this bean are bound at

   `ejblocal:Department549/AccountProcessors#<package.qualified.interface.name>`

   while remote interfaces are bound at

   `ejb/Department549/AccountProcessors#<package.qualified.interface.name>`

   .
2. The session bean with ejb-name ″S02″ is assumed to have a single EJB 3.0 business interface. Alternatively, it could have a pre-EJB 3.0 ″component″ interface with local home, remote home, or both local and remote homes. The business interface, or component interface's home(s) are bound at

   `ejblocal:ejb/session/S02`

   if it is local, or

   `ejb/session/S02`

   if it is remote.

   If bean S02 has more than one business interface, or business interface(s) and home, a simple-binding-name is ambiguous. In that case, the container disambiguates the binding assignments by appending #<*package.qualified.interface.name*> to the simple binding name ejb/session/S02 for each of the bean's interfaces.
3. The EJB 3.0 business interface com.ejbs.BankAccountService on the session bean with ejb-name ″S03″ is bound at ejblocal:session/BAS.

All other business interfaces and homes on this bean, if present, are assigned default bindings. The com.ejbs.BankAccountService interface is assumed to be local since it was designated for the ejblocal: namespace in this example; an error would occur if the interface were not local.

The next section expands on this example, introducing elements for resolving the targets of various kinds of reference and injection entries that are declared either in the XML deployment descriptor or through annotations.

User-defined bindings for resolving references and injection targets

The previous section showed you how to assign user-defined binding names for business interfaces and homes. This section covers how to resolve linkage targets for references, injection directives and message-driven bean destinations.

Element or attribute	How used	Example	Comments
<jca-adapter>	Defines the JCA 1.5 adapter activation spec, and a message-destination JNDI location, for delivery of messages to a message-driven bean.	`<jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/>`	Requires *activation-spec-binding-name* attribute. If the corresponding message-drive bean does not identify its message destination by using the <message-destination-link> element, then the *destination-binding-name* attribute is also required. Can optionally include activation-spec-auth-alias attribute.
<ejb-ref>	Resolves the target of an ejb-ref declaration, which is declared through the @EJB annotation or through the ejb-ref in the ejb-jar.xml deployment descriptor, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target enterprise bean in the JVM-scoped ejblocal:, or globally-scoped JNDI namespace.	`<ejb-ref name="com.ejbs.BankAccountServiceBean/s02Ref" binding-name="ejb/session/S02"/>`	Requires the name and binding-name attributes.
<message-driven>	Declares a group of binding assignments for a message-driven bean.	`<message-driven name="EventRecorderBean"> <jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/> </message-driven>`	Requires name attribute and <jca-adapter> sub-element.

Element or attribute	How used	Example	Comments
<message-destination>	Associates the name of a message destination, which is a logical name defined in a Java EE module deployment descriptor, with a specific global JNDI name, which is an actual name in the JNDI namespace. <message-destination-ref> elements in the Java EE module deployment descriptor, or @Resource injection directives that inject message destinations, can then use the <message-destination-line> element to refer to this message-destination by the destination logical name, rather than requiring individual <message-destination-ref> binding entries in the binding file for each defined message-destination-ref.	`<message-destination name="EventProcessing Destination" binding-name="jms/ ServiceQueue"/>`	Requires name and binding-name attributes.
<message-destination-ref>	Resolves the target of a message-destination-ref declaration that is declared through the @Resource annotation or through the message-destination-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource environment in the global JNDI namespace.	`<message-destination-ref name="com.ejbs. BankAccountServiceBean/ serviceQueue" binding-name= "jms/ServiceQueue"/>`	Requires the name and binding-name attributes.
<resource-ref>	Resolves the target of a resource-ref declaration that is declared through the @Resource annotation or through resource-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource in the global JNDI namespace.	`<resource-ref name= "com.ejbs. BankAccountServiceBean/ dataSource" binding-name= "jdbc/Default"/>`	Requires the name and binding-name attributes. Can include the authentication-alias or custom-login-configuration attributes.

Element or attribute	How used	Example	Comments
<resource-env-ref>	Resolves the target of a resource-env-ref declaration that is declared through the @Resource annotation or through resource-env-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource environment in the global JNDI namespace.	<resource-env-ref name="com.ejbs. BankAccountServiceBean/ dataFactory" binding-name="jdbc/ Default"/>	Requires the name and binding-name attributes.
name	Attribute that identifies the naming location, typically within the component-specific java:comp/env namespace, that defines the ″source″ side of a reference/target linkage, such as in ejb-ref, resource-ref, resource-env-ref, message-destination, or message-destination-ref.	<ejb-ref name= "com.ejbs. BankAccountServiceBean/ goodBye" binding-name= "ejb/session/S02"/>	
binding-name	Attribute that identifies the naming location within the ejblocal: or globally-scoped JNDI namespace that defines the ″target″ side of a reference/target linkage, such as in ejb-ref, resource-ref, resource-env-ref, message-destination, or message-destination-ref.	<ejb-ref name= "com.ejbs. BankAccountServiceBean/ goodBye" binding-name= "ejb/session/S02"/>	
activation-spec-binding-name	Attribute that identifies the JNDI location of the activation specification associated with the JCA 1.5 adapter to be used to deliver messages to a message-driven bean.	<jca-adapter activation-spec-binding-name=″jms/ InternalProviderSpec″ destination-binding-name=″jms/ ServiceQueue″/>	This name must match the name of a JCA 1.5 activation specification that you define to WebSphere Application Server.
activation-spec-auth-alias	Optional attribute that identifies the name of a J2C authentication alias used for authentication of connections to the JCA resource adapter. A J2C authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.	<jca-adapter activation-spec-binding-name=″jms/ InternalProviderSpec″ activation-spec-auth-alias=″jms/Service47Alias″ destination-binding-name=″jms/ ServiceQueue″/>	This name must match the name of a J2C authorization alias that you define to WebSphere Application Server.

Element or attribute	How used	Example	Comments
destination-binding-name	Attribute that identifies the JNDI name that the message-driven bean uses to look up its JMS destination in the JNDI name space.	<jca-adapter activation-spec-binding-name=″jms/InternalProviderSpec″ destination-binding-name=″jms/ServiceQueue″/>	This name must match the name of a JMS queue or topic that you define to WebSphere Application Server.
authentication-alias	Optional sub-element of the <resource-ref> binding element. If the resource reference is for a connection factory, then an optional JAAS login configuration can be specified; in this case a simple authentication alias name.	<resource-ref name="com.ejbs.BankAccountServiceBean/dataSource" binding-name="jdbc/Default"> <authentication-alias name="defaultAuth"/> <resource-ref>	This name must match the name of a JAAS authentication alias that you define to WebSphere Application Server.
custom-login-configuration	Optional sub-element of the <resource-ref> binding element. If the resource reference is for a connection factory, then an optional JAAS login configuration can be specified; in this case a set of properties (name/value pairs).	<resource-ref name="com.ejbs.BankAccountServiceBean/dataSource" binding-name="jdbc/Default"> <custom-login-configuration-name="customLogin"> <property name="loginParm1" value="ABC123"/> <property name="loginParm2" value="DEF456"/> </custom-login-configuration> </resource-ref>	This name must match the name of a JAAS login configuration that you define to WebSphere Application Server.

Binding file Example 2

Shown below is an expansion of the basic ibm-ejb-jar-bnd.xml file introduced in Example 1.

```
<?xml version="1.0" encoding="UTF-8"?> <ejb-jar-bnd
  xmlns="http://websphere.ibm.com/xml/ns/javaee"  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee   http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd"
 version "1.0">    <session name="S01" component-id="Department549/AccountProcessors"/>    <session name="S02"
 simple-binding-name="ejb/session/S02"/>    <session name="S03">   <interface class="com.ejbs.BankAccountService"
 binding-name="ejblocal:session/BAS"/>   <ejb-ref name="com.ejbs.BankAccountServiceBean/goodBye"
 binding-name="ejb/session/S02"/>   <resource-ref name="com.ejbs.BankAccountServiceBean/dataSource"
 binding-name="jdbc/Default"/>  </session>    <message-driven-name="MO1">     <jca-adapter
 activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/>   </message-driven>
  <session name="S04" simple-binding-name="ejb/session/S04">   <resource-ref name="ejbs.S04Bean/dataSource"
 binding-name="jdbc/Default">   <authentication-alias name="defaultlogin"/>   </resource-ref>  </session>   <session
 name="S05">   <interface class="com.ejbs.InventoryService" binding-name="ejb/session/S05Inventory"/>   <resource-ref
 name="ejbs.S05Bean/dataSource" binding-name="jdbc/Default">    <custom-login-configuration name="customLogin">    <property
 name="loginParm1" value="ABC123"/>    <property name="loginParm2" value="DEF456"/>      </custom-login-configuration>
   </resource-ref>  </session> </ejb-jar-bnd>
```

This binding results in the following:

1. The business interface and home bindings for the session beans named S01, S02 and S03 are unchanged from the previous example.
2. The session bean whose ejb-name is ″S03″ now includes two reference target resolution bindings:
   - The ejb-ref binding resolves the EJB reference defined at java:comp/env/com.ejbs.BankAccountServiceBean/goodBye, to the JNDI location ejb/session/S02 within the

application server's root JNDI context. The EJB reference could also have been defined by an @EJB injection in the class com.ejbs.BankAccountServiceBean, into an instance variable named ″goodBye.″

Note: ejb/session/S02 is the JNDI location of session bean ″S02″ also defined in this same binding file, which means that the reference points to the session bean whose name is ″S02.″

- The resource-ref binding resolves the resource reference defined at java:comp/env/com.ejbs.BankAccountServiceBean/dataSource, to the JNDI location jdbc/Default. The resource reference could also have been defined by a @Resource injection in the class com.ejbs.BankAccountServiceBean, into an instance variable named ″dataSource.″

3. Bindings are defined for a message-driven bean whose ejb-name is ″M01″. The MDB receives messages from a JMS destination defined to WebSphere Application Server, whose JNDI name is jms/ServiceQueue, using a JCA 1.5 adapter whose JCA 1.5 activation spec has been defined to WebSphere Application Server with the name jms/InternalProviderSpec.
4. The session bean whose ejb-name is ″S04″ is assumed to have a single business interface, which is bound at ejb/session/S04 if remote, or ejblocal:ejb/session/S04 if local. It has a resource-ref with name, java:comp/env/ejbs/S04Bean/dataSource. This can also be the class, ejbs.S04Bean, with an @Resource injection into a variable named, dataSource. This resource-ref resolved to the JNDI location jdbc/Default. The resource-ref refers to a J2C connection and connects to this resource using a simple authentication alias named ″defaultlogin″ that has been defined to WebSphere Application Server.
5. A business interface binding is defined for the interface whose class name is com.ejbs.InventoryService implemented by the session bean whose ejb-name is ″S05″; the interface is assumed to be remote since it is not prefixed with ″ejblocal:″ and will thus be bound at ejb/session/S05Inventory in the server's root JNDI context in the globally-scoped namespace. Any other business interfaces implemented by this bean is assigned default bindings. The bean has a resource-ref with name java:comp/env/ejbs.S05Bean/dataSource (or a @Resource injection in the class ejbs.S05Bean into a variable named ″dataSource″) that is resolved to the JNDI location jdbc/Default. The resource-ref refers to a J2C connection and will connect to this resource using a custom login configuration that includes two name-value pairs.

Bindings file Example 3

This example demonstrates how to define and resolve EJB reference bindings to perform JNDI lookups across application server instances within the same WebSphere Application Server cell. It uses two EJB beans: a called bean that defines an explicit binding using the simple-binding-name attribute, and a calling bean that performs an @EJB injection and uses the ejb-ref element within its associated binding file to resolve the reference so it points at the called bean, which resides in a different application server process.

ibm-ejb-jar-bnd.xml (called bean)

```
<?xml version="1.0" encoding="UTF-8"?> <ejb-jar-bnd
 xmlns="http://websphere.ibm.com/xml/ns/javaee"    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ej    b-jar-bnd_1_0.xsd"
 version="1.0">        <session name="FacadeBean" simple-binding-name="ejb/session/FacadeBean"/>  </ejb-jar-bnd>
```

This binding file content assumes that the session bean whose ejb-name is ″FacadeBean″ implements a single business interface (and thus the simple-binding-name attribute can be used, as an alternative to the <interface> sub-element). In this case, the FacadeBean implements a single remote business interface, bound at ejb/session/FacadeBean in the server root JNDI context of the application server where the FacadeBean resides.

Code snippet (calling bean)

```
@EJB(name="ejb/FacadeRemoteRef")  FacadeRemote remoteRef;  try {   output =
 remoteRef.orderStatus(input);           } catch (Exception e) {   // Handle exception, etc.  }
```

This code snippet performs an EJB resource injection into the instance variable named ″remoteRef″, which is of type FacadeRemote. The injection overrides the ″name″ parameter, setting the resulting ejb-ref reference name to ejb/FacadeRemoteRef. The code invokes a business method on the injected reference.

ibm-ejb-jar-bnd.xml (calling bean)

```
<?xml version="1.0" encoding="UTF-8"?> <ejb-jar-bnd
 xmlns="http://websphere.ibm.com/xml/ns/javaee"    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd"
 version="1.0">    <session name="CallingBean">     <ejb-ref name="ejb/FacadeRemoteRef"
 binding-name="cell/nodes/S35NLA1/servers/S35serverA1/ejb/session/FacadeBean"/>   </session> </ejb-bnd-jar>
```

Finally, this binding file resolves the EJB reference with an ejb-ref name of ejb/FacadeRemoteRef to point to the globally-scoped JNDI name of cell/nodes/S35NLA1/servers/S35serverA1/ejb/session/FacadeBean. This globally-scoped JNDI name represents an interface bound at ejb/session/FacadeBean under the server root context of the server named ″S35serverA1″ on the node named ″S35NLA1″ within the WebSphere Application Server cell of the calling bean. To point to a location within a different WebSphere Application Server cell, a CORBAName-style name can be used instead of a standard JNDI name.

Instructions on how to modify the ibm-ejb-jar-bnd.xml file can be found in the topic, Ways to update application files.

The relationship between injections and references

There is a one-to-one correspondence between injection directives and reference declarations - every injection implicitly defines a reference of some type, and conversely, every reference can optionally also define an injection. You can think of an injection annotation as being the mechanism to define references through annotations rather than defining them in the XML deployment descriptor.

By default, an injection defines a reference with a name formed from the package-qualified class name of the component performing the injection, a forward slash (/), then the name of the variable or property being injected into. For example, an injection performed in the class com.ejbs.AccountService, into a variable or property named ″depositService″, results in a reference named java:comp/env/com.ejbs.AccountService/depositService. However, specifying the optional ″name″ parameter on the injection directive overrides this default name and causes the reference to be named according to the value of the ″name″ parameter.

Knowing this rule, it is easy to see how a bindings file can be used not only to resolve targets for references declared in an XML deployment descriptor, but also to resolve targets for references implicitly declared by an annotation injection directive. Simply use the value of the ″name″ parameter on the injection annotation, or the default reference name from the class name and variable/property name if no ″name″ parameter is specified, just as if it were the name of the reference declared in an XML deployment descriptor.

Default resolution of EJB references and EJB injections: The AutoLink feature

AutoLink is a value-add feature of WebSphere Application Server that eliminates the need to explicitly resolve EJB reference targets in certain usage scenarios. In WebSphere Application Server V7, AutoLink is implemented within the boundaries of each WebSphere Application Server process. The AutoLink algorithm works as follows.

When the WebSphere EJB container encounters an EJB reference within a given EJB module, it first checks to see if you have explicitly resolved the target of that reference through inclusion of an entry in the module's binding file. If it finds no explicit resolution of the target in the binding file, the container searches within the referring module for an enterprise bean that implements the interface type you have defined within the reference. If it finds **exactly one** enterprise bean within the module that implements the interface, it uses that enterprise bean as the target for the EJB reference. If the container cannot locate an enterprise bean of that type within the module, it expands the search scope to the application that the

module is part of, and search other modules within that application that are assigned to the same application server as the referring module. Again, if the container finds **exactly one** enterprise bean that implements the target interface, within the application's other modules assigned to the same server as the referring module, it uses that enterprise bean as the reference target.

The scope of AutoLink is limited to the application in which the EJB reference appears, and to the application server on which the referring module is assigned. References to enterprise beans in a different application, enterprise beans in a module assigned to a different application server, or to enterprise beans residing in a module that has been assigned to a WebSphere Application Server cluster, must be explicitly resolved using reference target bindings in the EJB module's `ibm-ejb-jar-bnd.xml` file, or the Web module's `ibm-web-bnd.xmi` file.

It is important to note that AutoLink is only supported for EJB references, not other types of references although it is supported from the EJB container, the Web container, and the application client container. Also, because the scope of the AutoLink function is limited to the server that the referring module is assigned to, or in the case of the Java EE client container, to the server that the client container is configured as its JNDI bootstrap server, it is useful mainly in development environments and other single-server usage scenarios. Even with these present limitations, it can be a significant value during the development experience by removing the need to explicitly resolve EJB references.

Naming considerations in clustered and cross-server environments

The global JNDI naming conventions in the previous sections apply in non-clustered environments and when the lookup target is within the same cluster as the source of the lookup. When a lookup is performed from outside a cluster on a binding that is within a given cluster, the lookup string must be qualified to indicate the name of the cluster in which the target resides, according to the following convention:

```
cell/clusters/<cluster-name>/<name-binding-location>
```

For example, given an EJB interface binding location within the application server root context:

```
ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

If the EJB implementing this interface is assigned to an application server that is a member of a cluster named Cluster47, the lookup string external to that cluster is as follows:

```
cell/clusters/Cluster47/ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

When a lookup is performed across application server processes, the lookup string must be qualified to indicate the name of the node and server in which the target resides, according to the following convention:

```
cell/nodes/<node-name>/servers/<server-name>/<name binding location>
```

Again, given an EJB interface binding location within the application server root context:

```
ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

If the enterprise bean that is implementing this interface is assigned to an application server named Server47A1 that is located on a node named S47NLA1, the cross-server lookup string is as follows:

```
cell/nodes/S47NLA1/servers/Server47A1/ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

User-defined EJB extension settings

For cases where you wish to specify values for WebSphere Application Server EJB Extension settings, you can use an *EJB module extension file* to assign these settings to specific EJB types within that module. You specify extension settings information for EJB 3.0 modules by placing one, or both, of two files into the EJB JAR module's META-INF directory, depending on the type of extension being defined. The names of the two files are `ibm-ejb-jar-ext.xml` and `ibm-ejb-jar-ext-pme.xml`.

Note: The suffix on these files are XM**L**, not XM**I** as in prior versions of WebSphere Application Server.

The ibm-ejb-jar-ext.xml and ibm-ejb-jar-ext-pme.xml files are used for **EJB 3.0** modules running in WebSphere Application Server, whereas the ibm-ejb-jar-ext.xmi and ibm-ejb-jar-ext-pme.xmi files are used for **pre-3.0 EJB** modules. WebSphere Application Server Version 7.0 uses a new XML-based extension file format instead of the previous xmi file format for the following reasons:

1. Bindings and extensions declared in the xmi file format depend on the presence of a corresponding ejb-jar.xml deployment descriptor file, explicitly referring to unique ID numbers attached to elements in that file. This system is no longer viable for EJB 3.0 and later modules, where it is no longer a requirement for the module to contain an ejb-jar.xml deployment descriptor.
2. The xmi file format was designed to be machine-edited only by WebSphere development tools and system management functions; it was effectively part of WebSphere's internal implementation and the file's structure was never documented externally. This made it impossible for developers to manually create or edit binding or extension files, or create them as part of a WebSphere-independent build process, in a supported manner.
3. Rather than referring to encoded ID numbers in ejb-jar.xml, the XML-based extension file format refers to EJB components by their EJB name. Each EJB component in a module is guaranteed to have a unique EJB name, either by default or through explicit assignment by the developer, so this provides an unambiguous way to target bindings and extensions.
4. The new binding and extension file formats are XML-based, and XML Schema Definition (xsd) files are provided to externally document their structure. These .xsd files may be consumed by many common XML file editors to assist in syntactic verification and code completion functions. As a result, it is now possible for developers to produce and edit these binding and extension files independently of WebSphere Application Server infrastructure, using a generic XML editor or scripting system of their choice.

Extensions defined in META-INF/ibm-ejb-jar-ext.xml

The following tables list extension elements and attributes that must be placed in the META-INF/ibm-ejb-jar-ext.xml file. The next section lists elements and attributes that appear in a separate file, META-INF/ibm-ejb-jar-ext-pme.xml.

Element or Attribute	How Used	Example	Remarks
<session>	Declares a group of extension settings for a session bean.	`<session name= "AccountServiceBean"/>`	Requires *name* attribute. In order to have any effect, also include at least one extension setting definition sub-element.
<message-driven>	Declares a group of extension settings for a message-driven bean.	`<message-driven name= "EventProcessorBean"/>`	Requires *name* attribute. In order to have any effect, also include at least one extension setting definition sub-element.

Element or Attribute	How Used	Example	Attribute Default	Remarks
<time-out>	Sub-element to the <session> element that optionally declares the number of seconds between method invocations after which a **stateful** session bean will be no longer available.	`<session name= "ShoppingCartBean"> <time-out value= "600"/></session>`	300 (10 minutes)	Requires *value* attribute, a positive integer. **Only applicable to stateful session beans; must not be used on stateless beans.**

Element or Attribute	How Used	Example	Attribute Default	Remarks
<bean-cache>	Sub-element of <session> element used to declare bean activation/passivation settings for stateful session beans.	`<session name= "ShoppingCartBean> <bean-cache activation-policy= "TRANSACTION"/> </session>`		In order to have any effect, should also include the *activation-policy* attribute.

Element or Attribute	How Used	Example	Attribute Default	Remarks
activation-policy	Attribute of <bean-cache> element that declares the conditions under which the bean instance will be activated and passivated. Applicable to stateful session beans. Allowable values and their meanings are: • **TRANSACTION:** Indicates that the bean activates at the start of a transaction and passivates (and is removed from the active EJB instance cache) at the end of the transaction. • **ONCE:** Indicates that the bean activates when it is first accessed in the server process, and passivates (and is removed from the active EJB instance cache) at the discretion of the container, for example, when the cache becomes full. • **ACTIVITY_SESSION:** Indicates that the bean activates and passivates as follows: 1) On an ActivitySession boundary, if an ActivitySession context is present on activation, 2) On a transaction boundary, if a transaction context (but no ActivitySession context) is present on activation, or otherwise, 3) on an invocation boundary.	`<session name= "ShoppingCartBean> <bean-cache activation-policy= "ONCE"/></session>`	ONCE for stateful session beans.	

Element or Attribute	How Used	Example	Attribute Default	Remarks
<global-transaction>	Sub-element to the <session> and <message-driven> elements that can be used to declare the transaction timeout (in seconds) to be used on transactions started by this specific EJB type (overriding the server setting for global transaction timeout) and also may declare whether this EJB type will propagate global transaction context received through web service atomic transactions, across the heterogeneous Web service environment.	`<session name= "AccountServiceBean" <global-transaction transaction-timeout= "180" send-wsat-context="FALSE"/> </session>`	Server transaction timeout setting for transaction-timeout; FALSE for send-wsat-context	Requires at least one of *transaction-timeout* or *send-wsat-context* attributes.

Element or Attribute	How Used	Example	Attribute Default	Remarks
<local-transaction>	Sub-element to the <session> and <message-driven> elements that can be used to declare settings related to local transactions. Allowed attributes are *boundary*, *resolver*, and *unresolved-action*; these attributes configure, for the component, the behavior of the container's local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present. The meaning of each attribute is as follows: **Boundary** This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are: • **BEAN_METHOD:** This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started. • **ACTIVITY_SESSION:** RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started. **Resolver** This setting specifies the component responsible for	`<session name>= "AccountServiceBean"> <local-transaction boundary= "BEAN_METHOD" resolver= "APPLICATION" unresolved-action= "ROLLBACK"/> </session>`	`boundary="BEAN_ METHOD"; resolver= "APPLICATION"; unresolved-action= "ROLLBACK"`	Requires at least one of *boundary*, *resolver*, or *unresolved-action* attributes.

Element or Attribute	How Used	Example	Attribute Default	Remarks

Element or Attribute	How Used	Example	Attribute Default	Remarks
<method>	Sub-element to the <method-session-attribute> and <run-as-mode> elements that is used to specify the method name, method signature, or method types to which a given setting will apply. Allowed attributes are *type*, *name*, and *params*. The meaning of each attribute is as follows: **type** • **UNSPECIFIED:** The setting will apply to all methods matching the *name* and/or *params* attributes, regardless of interface type. • **REMOTE:** The setting will apply to remote business interface and remote component interface methods matching the *name* and/or *params* attributes. • **LOCAL:** The setting will apply to remote business interface and remote component interface methods matching the *name* and/or *params* attributes. • **HOME:** The setting will apply to remote home interface methods matching the name and/or params attributes matching the name and/or *params* attributes. • **LOCAL_HOME:** The setting will apply to local home interface methods matching the *name* and/or params attributes. • **SERVICE_ENDPOINT**: The setting will apply to methods on the	<session /name= "AccountServiceBean"> <method-session-attribute type= "REQUIRES_NEW"> <method type= "LOCAL" name= "debitAccount" params="java.lang. String[], int, com.xyz. CustomerInfo"/> </method-session-attribute;> </session>		

Element or Attribute	How Used	Example	Attribute Default	Remarks
<run-as-mode>	Sub-element to the <session> and <message-driven> elements that can be used to declare the security identity that a given EJB method will have while the method is being executed. The identity can be set to use the identity of the caller (mode = CALLER_IDENTITY), the identity of the EJB server (mode = SERVER_IDENTITY), or the identity of a specific security role (mode = SPECIFIED_IDENTITY).	<session name= "AccountServiceBean"> <start-at-app- startvalue="TRUE"/> </session>		Requires *mode* attribute and <*method*> sub-element. If the mode is SPECIFIED_IDENTITY, the <specified-identity sub-element is also required.
<start-at-app-start>	Sub-element to the <session> and <message-driven> elements that can be used to inform the EJB container that specified EJB type shall be initialized at the time the application is first started, rather than the time the EJB type is first used by the application.	<session name= "AccountServiceBean"> <start-at-app- startvalue= "TRUE"/></sesssion>	FALSE (initialize EJB type when EJB is first used by application) for beans other than message-driven beans. Always TRUE for message-driven beans.	Requires *value* attribute

Element or Attribute	How Used	Example	Attribute Default	Remarks
<resource-ref>	Sub-element to the <session> and <message-driven> elements, that may be used to declare additional settings on a Java EE resource reference, such as isolation level to be used on transactions driven through the connection referred to by the reference. Allowable attributes include *isolation-level*. The meaning of each attribute is as follows: **isolation-level** • **TRANSACTION_REPEATABLE_READ:** This isolation level prohibits dirty reads and nonrepeatable reads, but it allows phantom reads. • **TRANSACTION_READ_COMMITTED:** This isolation level prohibits dirty reads, but allows nonrepeatable reads and phantom reads. • **TRANSACTION_READ_UNCOMMITTED:** This isolation level allows reading uncommitted changes (data changed by a different transaction that is still in progress). It also allows dirty reads, nonrepeatable reads, and phantom reads. • **TRANSACTION_SERIALIZABLE:** This isolation level prohibits the following types of reads: 1) Dirty reads, in which a transaction reads a database row containing uncommitted changes from a second transaction, 2) Nonrepeatable reads, in which one transaction reads a row, a second	`<session name= "AccountServiceBean"> <resource-ref name="jdbc/Default" isolation-level= "TRANSACTION_NONE"> </session>`		Requires *name* attribute. In order to have any effect, must also include the isolation-level attribute.

Extensions defined in META-INF/ibm-ejb-jar-ext-pme.xml

The following tables list extension elements and attributes that must be placed in the META-INF/ibm-ejb-jar-ext-pme.xml file.

Element or Attribute	How Used	Example	Attribute Default	Remarks
<internationalization>	Element that may be used to declare the locale that will be used by the EJB type (caller's locale or server's locale).	<internationalization> <application> <ejb name="S01"/> <ejb name="S02"/> </application> <run-as-caller> <method type="LOCAL" name="getFoo" params="int"> <ejb name="C01"/> </method></run-as- caller><run-as- server><method type="LOCAL" name= "getBar" params= "int"><ejb name= "C02"/></method> </run-as-server> <run-as-specified name="North American English"><locale lang="en" country= "US" variant="foo"/> <locale lang="en" country="CA" variant= "bar" /> <time-zone name="GMT"/> <method type="LOCAL" name= "getFoo" params= "int"> <ejb name= "C03"/> </method></run-as- specified><run-as- specified name= "North American French"> <locale lang="fr" country= "US" variant="foo"/> <locale lang="fr" country="US" variant="bar" /> <time-zone name= "GMT" /> <method type="LOCAL" name= "getBar" params= "int"> <ejb name= "C04"/></method> </run-as-specified> </internationalization>		For information on this extension, see http://publib.boulder .ibm.com/infocenter/a diehelp/index.jsp?top ic=/com.ibm.etools.j2 ee.pme.ui.doc/concept s/cin_containerattrib ute.html . Due to the complexity of this function, you may wish to use tooling designed for WebSphere Application Server such as Rational Application Developer (RAD) to produce the desired extension file stanzas, then modify the XML file as desired.

Element or Attribute	How Used	Example	Attribute Default	Remarks
<activity-sessions>	Element that optionally declares the type of activity session management to be used on a designated session bean (BEAN or CONTAINER) and for container-managed activity sessions, the type of activity session behavior to be provided by the container.	<activity-sessions> <container-activity-session name="Foo" type="NOT_SUPPORTED"> <methodtype="HOME" name="findByPrimaryKey" params="int"><ejb name="C01"/> </method> </container-activity-session> <./activity-sessions>		For information on this extension, see http://publib.boulder.ibm.com/infocenter/adiehelp/index.jsp?topic=/com.ibm.etools.j2ee.pme.ui.doc/tasks/tas_depejb2.html . Due to the complexity of this function, you may wish to use tooling designed for WebSphere Application Server such as Rational Application Developer
<app-profiles>	Element that optionally declares application profile settings for one or more EJBs	<app-profiles> <defined-access-intent-policy name="foo"><collection-scope type="SESSION"/> <optimistic-read/> <read-ahead-hint hint="foo.bar.baz"/> </defined-access-intent-policy><run-as-task name="TestEJB1.ejbs.C01LocalHome.createjava.lang.Integer" type="RUN_AS_SPECIFIED_TASK"><task name="/> <method type="LOCAL" name"getFoo" params="int"><ejb name="C01"/> </method> </run-as-task> <ejb-component-extension ejb="C01"> <task name="SomeTask"/></ejb-component-extension> </app-profiles>		Due to the complexity of this function, you may wish to use tooling designed for WebSphere Application Server such as Rational Application Developer (RAD) to produce the desired extension file stanzas, then modify the XML file as desired.

Legacy (XMI) bindings

Existing modules and applications can continue to use the legacy binding support provided in the product, therefore, the existing tools and wizards can be used to specify binding and extension information for applications and modules. Use of the legacy support is limited to EAR files and modules using J2EE 1.4-style XML deployment descriptors.

EJB modules that use a version 3.0 XML deployment descriptor schema or do not have an XML deployment descriptor file must use either defaulted bindings and AutoLink, or user-specified XML binding files.

It is required that CMP entity beans always be packaged in a module with a 2.1 XML deployment descriptor schema version so that existing tools can be used to provide mappings, bindings, and extension support.

User-specified XML bindings

The default bindings for each interface and AutoLink reference resolution for each reference can be overridden by specifying bindings for the EJB module by creating a META-INF/ibm-ejb-jar-bnd.xml file.

The schema files that describe the format are located in the <WAS_HOME>/properties/schemas directory. This form of bindings specification can only be used for modules containing either no XML deployment descriptor or an EJB 3.0 deployment descriptor.

Note: It is not required to specify all bindings. Any binding name or reference that is not defined uses the default bindings and AutoLink support.

Bindings can be specified for the following:

- Session beans using the <session> element.
- Message Driven beans using the <message-driven> element

The only attributes and sub-elements supported for the <session> element are:

- id attribute
- name attribute
- simple-binding-name attribute
- component-id attribute
- ejb-ref element
- resource-ref element and its attributes
- resource-env-ref element and its attributes
- message-destination-ref element and its attributes

The only attributes and sub elements supported for the <message-driven> element are:

- id attribute
- name attribute
- jca-adapter attribute
- ejb-ref element and its attributes
- resource-ref element and its attributes
- resource-env-ref element and its attributes
- message-destination-ref element and its attributes

EJB 3.0 module packaging overview

This topic describes application packaging when you use Enterprise JavaBeans (EJB) 3.0 beans.

Packaging applications that use EJB 3.0 beans is similar to the assembly requirements for Java 2 Platform, Enterprise Edition (J2EE) 1.4 applications: components are packaged into modules, and modules are packaged into application enterprise archive (EAR) files. The components and modules both have describing metadata provided in an Extensible Markup Language (XML) deployment descriptor. The EJB 3.0 specification supports an additional method to describing metadata and for packaging persistence units.

The EAR file is a package file format similar to a .zip or .tar file format. The EAR file can be visualized as a collection of logical directories and files that are packaged together into a simple file. Each EAR file includes one or more Java Platform, Enterprise Edition (Java EE) module files, which can include the following:

- Java application archive (JAR) files for EJB modules. Java EE application client modules and utility class modules.
- Web application archive (WAR) files for Web modules.
- Other technology-specific modules such as resource application archive (RAR) files and other types of modules.

EJB modules without deployment descriptors

You can package EJB modules without a deployment descriptor if you are using EJB 3.0 beans. To do this, you must create a JAR file with metadata in an annotation which is located in the EJB component. EJB 3.0 beans do not need an entry in the ejb-jar.xml file for metadata that you have defined through annotations.

If you installed the Feature Pack for EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 7.0, the default is not to scan pre-Java EE 5 modules during the application install or at server startup

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether or not to scan legacy Web modules for additional metadata. A server level switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** → **server name** → **Process definition** → **Java Virtual Machine** → **Custom properties**.

EJB modules with deployment descriptors

You can continue to use EJB modules with deployment descriptors. Modules with deployment descriptors can support any EJB specification version level, including EJB 3.0, but generally these descriptors should reflect the implementation requirements of the components in the module.

An EJB module can have an EJB 2.1-, or earlier, style deployment descriptor, or an EJB 3.0-style deployment descriptor.

For EJB 2.1-style deployment descriptors, it is assumed that the deployment descriptor contains the full metadata for the module, and no additional scanning of annotation metadata occurs.

The EJB container annotation scanning is performed on EJB modules that either have no deployment descriptor or have an ejb-jar.xml deployment descriptor at the EJB 3.0 schema level. In other words, the scan finds the annotation and its describing metadata.

Note: You cannot scan for component annotation metadata contained within shared libraries defined using the WebSphere Application Server system management shared library feature.

Persistence units

Persistence units, including the persistence.xml file and the classes associated with it, can be packaged in the module for which they are required. They can also be packaged in the separate utility JAR file that is packaged in the EAR file with its dependent module.

When a separate utility JAR file is packaged, it is necessary for the module that desires it to use the persistence units to declare a dependency on the utility JAR file using the typical MANIFEST. MF Class-Path: declarations. See the example scenario for this packaging method under the section in this topic called ″Session facades used for persistence scenario″

Note: Packaging of persistence units contained within shared libraries defined using the WebSphere Application Server system management shared library feature is not supported at this time.

Application packaging

Modules that utilize the EJB 3.0 specification should be packaged in an EAR file with a J2EE 1.4 deployment descriptor so that legacy application security management can be used.

You can mix EJB 2.x and earlier beans with EJB 3.0 beans in the same application, but you do need to separate EJB 2.x and earlier beans from EJB 3.0 beans so that they are not in the same modules. EJB 3.0 beans are not recognized in modules that contain EJB 2.1-style, or earlier, deployment descriptors.

In the case that the EAR file only contains the JAR and Web archive (WAR) files, and no application.xml file, the product provides a default J2EE 1.4 deployment descriptor that is based on the following defaults that are outlined in the Java EE specification:

- The application name is assumed to be the name of the EAR file, but with the EAR file extension removed.
- Files that are ending in .war are assumed to be Web modules. The context root of the Web module is the name of the file that is relative to the root of the application package, but with the WAR file extension removed.
- Files that are ending in .jar that are not in the /lib directory, and that contain either an ejb-jar.xml file or at least one class that defines a @Stateful or @Stateless annotation, are assumed to be EJB modules.
- Other JAR files that are not in the /lib directory are not assumed to be EJB modules.

If the application archive file contains an application.xml descriptor, processing occurs according to the directives in that descriptor.

AutoLink

AutoLink provides the ability to automatically resolve EJB references to components contained with an EAR file, without having to specify a JNDI binding name. This simplifies application deployment with large numbers of beans and references if they are unique and unambiguous.

Note: AutoLink should not be used for references to components deployed on a cluster.

JPA packaging

It is recommend that persistence units be packaged in separate JAR files to make them more accessible and reusable. These can be tested outside the container, with or without actual database persistence occurring. Persistence units can be included in standalone applications or into EAR files as utility JAR files. Because of the variety of use cases and potential performance issues when scanning large quantities of classes, it is recommended that the persistence unit defines the classes of the persistence units.

Session facades used for persistence scenario

A common pattern is to use session facades for persistence. Using session bean facades to drive JPA is supported. The EntityManager interface is not thread safe, therefore, servlets should never inject @PersistenceContext. Servlets must either use the facade pattern or use an EntityManagerFactory instance to create an EntityManager on each request.

It is recommended that JPA persistence units be defined in a separate JAR file, apart from the session bean facades. Not only is this a best practice that gives greater flexibility in sharing, it also avoids problems mixing JPA and non-JPA annotated classes.

Typically, a JAR file is created to hold the entity classes and the JPA persistence.xml definition and added to the EAR file as a utility JAR file. The EJB 3.0 module adds a dependency on the JAR file by declaring it in the EJB 3.0 module MANIFEST.MF. For example, if an EAR contains a TradeApp.ear, TradeWeb.war, EJB3Trade.jar, and TradeInfo.jar, the EJB3Trade.jar file would have a MANIFEST.MF that looks like the following:

```
Manifest-Version: 1.0
Class-Path: TradeInfo.jar
```

The session facade in the EJB3Trade.jar file refers to JPA entity classes and persistence units in the TradeInfo.jar file. The Web application defined in the TradeWeb.war file can do the same to work with the JPA entity objects as Data Transfer Objects flowing between the Web and EJB container tiers.

Cross-tier and cross version session bean reference scenario

There are several ways to define and use references to EJB 3.0 session beans. For EJB 3.0 session to session, the @EJB injection target can be used. For cross-tier, for example, Web application to EJB 3.0 session, or cross-version, for example, EJB 2.1 session to EJB 3.0 session, an XML deployment descriptor reference can be used to define ejb-refs and ejb-local-refs. There are two variations of these, depending on whether an EJB 3.0 business interface is referred to, or a pre-EJB 3.0 component-style interface that also defines an EJBLocalHome is referred to. Web applications and client applications can also utilize the @EJB annotation if the component being referenced can be resolved using autolink.

For migration scenarios where session beans are being converted from EJB 2.1 beans to EJB 3.0 beans, the pattern is typically to edit the Session bean class, replace the *implements SessionBean* with *implements the business interface*, remove *extends EJBLocalObject* from the local interface and non-business throws clauses, and add the @Stateful @Local @LocalHome(<localhome>.class) or similar annotations. Existing ejb-refs and ejb-local-refs are bound to the new implementation of the session bean.

Note: The default binding name does change.

The previous scenario uses an EJB 2.1-style client pattern with an EJB 3.0-style session bean implementation. For a more current client style, the client-side can be cleaned up to lookup the session bean business interface directly, rather than going through a home interface. In this case, it is not be necessary to define the @LocalHome(<localhome>.class) annotation. You can use a variant definition of ejb-ref and ejb-local-ref to do this. Use a *null* value for the local-home element value and bind the ejb-local-ref to the session bean's ejblocal: binding rather than the home binding. For example:

```
<ejb-local-ref id="EJBLocalRef_1154112538064">
 <description>com.ibm.persistence.ejb3.order.facadecom.ibm.persistence.ejb3.order.facade</description>
 <ejb-ref-name>ejb/OrderEJB</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <local-home></local-home>
 <local>com.ibm.persistence.ejb3.order.facade.OrderProcessor</local>
</ejb-local-ref>
```

The client code also needs to be adjusted to do the appropriate casting for the object being looked up. In this case, the business interface instead of the home interface:

```
try {
 InitialContext ctx = new InitialContext();
 orderProcessor = (OrderProcessor)ctx.lookup("java:comp/env/ejb/OrderEJB");
}
catch(Exception e)  {
 e.printStackTrace(System.out);
 throw new ServletException(e);
}
```

EJB 3.0 deployment overview

Learn about the Enterprise JavaBeans (EJB) 3.0 deployment model, including to *Just-In-Time* (JIT) deployment.

All Java Platform, Enterprise Edition (Java EE) application server products have some form of EJB deployment phase where your application is customized to run in that particular application server implementation. Typically, this is accomplished by an application server-specific deployment tool, which generates code to bridge your EJB interface and implementation code to the application server's EJB container implementation. Some application server products' deploy tools alter the bytecodes of your application classes rather than using code generation, but the end result is similar.

In WebSphere Application Server, the bridging is accomplished by generating code that *wraps* your EJB implementation classes, connecting them to the product EJB container, which in turn allows the EJB container to host your enterprise beans and provide services to them. If one or more of your enterprise beans has defined remote interfaces, additional code is generated to provide the remote function.

Historically, EJB deployment in the WebSphere product has been performed by the *EJBDeploy* tool that is included with product and packaged with WebSphere product-oriented development tools.

The EJBDeploy tool introspects your EJB external interfaces, generates the wrapper code as .java files, then compiles it using the javac compiler to produce .class files, which are then packaged in your EJB module with your application code. The EJBDeploy tool also runs the rmic tool against the remote EJB interfaces in the application, producing additional *stub* and *tie* class files that interact with the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Object Request Broker (ORB), providing remote object support. Typically, you run the EJBDeploy tool either when you install the application on the product or sometime before you install the application from the command-line tool or within a development tool.

Just-In-Time deployment

The EJB 3.0 support in WebSphere Application Server adds a new feature called Just-In-Time Deployment. With Just-In-Time Deployment, the EJB container dynamically generates the wrapper, stub, and tie classes in-memory as needed when the application is running. Additionally, the Web container and application client containers dynamically generate the stub class required for remote EJB invocations. Effectively, this means that you do not need to process EJB 3.0 modules, Web modules that invoke EJB 3.0 beans, or client modules that invoke EJB 3.0 beans, through the EJBDeploy tool prior to running them in WebSphere.

createEJBStubs tool

Even though the Just-In-Time Deployment feature, in many cases, dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB interfaces, there remain some cases where these stub classes are not dynamically generated. For EJB 3.0 clients not running inside a Web container, EJB container, or client container, that is upgraded to EJB 3.0 level, you must generate the stub classes with the createEJBStubs tool, then make the generated stubs available in the client environment's classpath. Typically you would accomplish this by copying the generated stubs to the location where the client's business interface class resides.

To summarize, the createEJBStubs tool must be used to generate client-side stubs for the following environments:

- ″Bare″ Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- WebSphere Application Server container environments prior to Version 7 that do not have the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

For more information about packaging your EJB module, see the topic, ″EJB 3.0 module packaging overview.″

Developing read-only entity beans

In addition to the existing Enterprise JavaBeans (EJB) caching options, you can develop read-only entity beans.

About this task

You are most likely to want to use it under the following conditions:

- Your application uses data that change relatively infrequently. An example might be a retailing application that uses pricing data that only changes once a week or month.
- Your application can tolerate data that may be stale. The degree of “staleness” that the EJB container allows is configurable by the user.
- The bean is coded in a thread-safe manner, so it can safely be invoked by multiple threads at once.

To use this function, you declare the bean type as *read-only* the same way you currently select the bean caching options, through a selection list within an assembly tool.

To complete this task see the topic, ″Defining bean cache settings for a bean″ in the assembly tool documentation at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html.

Example: Using a read-only entity bean

A usage scenario and example for writing an Enterprise JavaBeans (EJB) application that uses a read-only entity bean.

Usage scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

Example

The customer’s entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it’s a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
    (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...     some other processing, etc. in the interim
```

```
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:
- ActivateAt = ONCE
- LoadAt = DAILY
- ReloadInterval = 2200

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had prior to any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred prior to 22:00. Thus, the item price and shipping cost used remain in sync with each other.

Migrating enterprise bean code to the supported specification

Support for the Enterprise JavaBeans (EJB) 3.0 specification is added for this product.

Before you begin

There should not be migration issues associated with using EJB 3.0 beans. Existing applications should continue to run as-is and compile without error.

Note: The EJB 3.0 specification has deprecated the use of EJB 1.1 style entity beans. While using EJB 3.0 modules in the product has not yet been deprecated, you are encouraged to start migrating to Java Persistence API (JPA) or JDBC.

About this task

Follow these steps as appropriate for your application deployment.

1. Modify enterprise bean code for changes in the specification.
   - You need to migrate the Version 1.1 beans to Version 2.x beans and redploy them on the product. .

     Note: The EJB Version 2.0 specification mandates that prior to the EJB container's running a findBy*Method* query, the state of all enterprise beans enlisted in the current transaction be synchronized with the persistent store. This is done so that the query is performed against current data. If Version 1.1 beans are reassembled into an EJB 2.x-compliant module, the EJB container synchronizes the state of Version 1.1 beans, as well as that of Version 2.x beans. As a result, you might notice some change in application behavior even though the application code for the Version 1.1 beans has not been changed.
2. Reassemble and redeploy all modules to incorporate migrated code.

Migrating enterprise bean code from Version 1.1 to Version 2.1

Enterprise JavaBeans (EJB) Version 2.1-compliant beans can be assembled only in an EJB 2.1-compliant module, although an EJB 2.1-compliant module can contain a mixture of Version 1.x and Version 2.1 beans.

About this task

The EJB Version 2.1 specification mandates that prior to the EJB container starting a findBy*Method* query, the state of all enterprise beans that are enlisted in the current transaction be synchronized with the persistent store. (This action is so the query is performed against current data.) If Version 1.1 beans are reassembled into an EJB 2.1-compliant module, the EJB container synchronizes the state of Version 1.1

beans as well as that of Version 2.1 beans. As a result, you might notice some change in application behavior even though the application code for the Version 1.1 beans has not been changed.

The following information generally applies to any enterprise bean that currently complies with Version 1.1 of the EJB specification. For more information about migrating code for beans produced with the Rational Application Developer tool, see the documentation for that product.

1. In beans with container-managed persistence (CMP) version 1.x, replace each CMP field with abstract get and set methods. In doing so, you must make each bean class abstract.
2. In beans with CMP version 1.x, change all occurrences of `this.`*`field`* `=` *`value`* to `set`*`Field`*`(`*`value`*`)`.
3. In each CMP bean, create abstract get and set methods for the primary key.
4. In beans with CMP version 1.x, create an EJB Query Language statement for each finder method.

   Note: EJB Query Language has the following limitations in Application Developer Version 5:
   - EJB Query Language queries involving beans with keys made up of relationships to other beans appear as invalid and cause errors at deployment time.
   - The IBM EJB Query Language support extends the EJB 2.1 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB Query Language queries strictly according to instructions described in Chapter 11 of the EJB 2.1 specification.
5. In finder methods for beans with CMP version 1.x, return java.util.Collection instead of java.util.Enumeration.
6. Update handling of non-application exceptions.
   - To report non-application exceptions, throw javax.ejb.EJBException instead of java.rmi.RemoteException.
   - Modify rollback behavior as needed: In EJB versions 1.1 and 2.1, all non-application exceptions thrown by the bean instance result in the rollback of the transaction in which the instance is running; the instance is discarded. In EJB 1.0, the container does not roll back the transaction or discard the instance if it throws java.rmi.RemoteException.
7. Update rollback behavior as the result of application exceptions.
   - In EJB versions 1.1 and 2.1, an application exception does not cause the EJB container to automatically roll back a transaction.
   - In EJB Version 1.1, the container performs the rollback only if the instance has called setRollbackOnly() on its EJBContext object.
   - In EJB Version 1.0, the container is required to roll back a transaction when an application exception is passed through a transaction boundary started by the container.
8. Update any CMP setting of application-specific default values to be inside ejbCreate (not using global variables, since EJB 1.1 containers set all fields to generic default values before calling ejbCreate, which overwrites any previous application-specific defaults). This approach also works for EJB 1.0 CMPs.

Adjusting exception handling for EJB wrapped applications migrating from version 5 to version 7

Because of a change in the Java APIs for XML based Remote Procedure Call (JAX-RPC) specification, Enterprise JavaBeans (EJB) applications that could be wrapped in WebSphere Application Server Version 5.1 cannot be wrapped in version 6 or 7 unless you modify the code to the exception handling of the base EJB application.

About this task

Essentially, the JAX-RPC version 1.1 specification states:

```
a service specific exception declared in a remote method signature must be a
checked exception. It must extend java.lang.Exception either directly or indirectly
but it must not be a RuntimeException.
```

So it is no longer possible to directly use java.lang.Exception or java.lang.Throwable types. You must modify your applications using service specific exceptions to comply with the specification.

1. Modify your applications that use service specific exceptions. For example, say that your existing EJB uses a service specific exception called UserException. Inside of UserException is a field called *ex* that is type java.lang.Exception. To successfully wrapper your application with Web services in WebSphere Application Server version 7, you must change the UserException class . In this example, you could modify UserException to make the type of *ex* to be *java.lang.String* instead of java.lang.Exception.

```
new UserException class:

package irwwbase;

/**
 * Insert the type's description here.
 * Creation date: (9/25/00 2:25:18 PM)
 * @author: Administrator
 */

public class UserException extends java.lang.Exception {

       private java.lang.String _infostring = null;
       private java.lang.String ex;
/**
 * UserException constructor comment.
 */

public UserException() {
       super();
}
/**
 * UserException constructor comment.
 */
public UserException (String infostring)
{
       _infostring = infostring;
} // ctor
/**
 * Insert the method's description here.
 * Creation date: (11/29/2001 9:25:50 AM)
 * @param msg java.lang.String
 * @param ex java.lang.Exception
 */
public UserException(String msg,String t) {
       super(msg);
       this.setEx(t);

       }
       /**
        * @return
        */
       public java.lang.String get_infostring() {
              return _infostring;
       }

       /**
        * @return
        */
       public java.lang.String getEx() {
              return ex;
       }

       /**
        * @param string
        */
       public void set_infostring(java.lang.String string) {
```

```
            _infostring = string;
        }

        /**
         * @param Exception
         */
        public void setEx(java.lang.String exception) {
            ex = exception;
        }

        public void printStackTrace(java.io.PrintWriter s) {
          System.out.println("the exception is :"+ex);
          }

}
```

2. Modify all of the exception handling in the enterprise beans that use it. You must ensure that your enterprise beans are coded to accept the new exceptions. In this example, the code might look like this:

```
new EJB exception handling:

try {
      if (isDistributed()) itemCMPEntity = itemCMPEntityHome.findByPrimaryKey(ckey);
      else itemCMPEntityLocal = itemCMPEntityLocalHome.findByPrimaryKey(ckey);
  } catch (Exception ex) {
       System.out.println("%%%%% ERROR: getItemInstance - CMPjdbc " + _className);
       ex.printStackTrace();
       throw new UserException("error on itemCMPEntityHome.findByPrimaryKey(ckey)",ex.getMessage());
   }
```

WebSphere extensions to the Enterprise JavaBeans specification

This article outlines extensions to the Enterprise JavaBeans (EJB) specification provided with the product.

Inheritance in enterprise beans

In the Java language, *inheritance* is the creation of a new class from an existing class or a new interface from an existing interface. This product supports two forms of inheritance: standard class inheritance and EJB inheritance.

In standard class inheritance, the home interface, remote interface, or enterprise bean class inherits properties and methods from base classes that are not themselves enterprise bean classes or interfaces.

By contrast in enterprise bean inheritance, an enterprise bean inherits properties, uch as container-managed persistence (CMP) fields and container-managed relationship (CMR) fields, methods, and method-level control descriptor attributes from another enterprise bean.

For more information, see the documentation for the assembly tools at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html.

Optimistic concurrency control for container-managed persistence

This product supports optimistic concurrency control of data access. See “Concurrency control” on page 194 for more information.

Access intents for EJB persistence

This product supports the application of named data-access policies.

Sequence grouping for container-managed persistence

By designating CMP sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your EJB application. Within each group you specify the order in which the beans update your relational database tables. See “Setting the run time for CMP sequence groups” on page 214 for instructions.

Performance enhancements

Through the lifetime-in-cache settings, this product provides a way for you to improve performance for beans that are only occasionally updated. For more information, see the topic, ″Entity bean assembly settings″ located in the assembly tool documentation at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html.

Some enterprise beans created with the assembly tools can utilize *read-ahead* for loading a bean and its related beans in a single database operation. An entire object graph or any part of the graph can be preloaded by configuring a finder method to use read-ahead.

Assembly and deployment extensions

This product supports IBM extensions of assembly and deployment options.

Enterprise bean development best practices

Use the following guidelines when designing and developing enterprise beans.

- Use a stateless session bean to act as the entry point for business logic.
- Entity beans should use container-managed persistence.
- In an Enterprise JavaBeans (EJB) Version 2.x and later version environments, use local interfaces to improve communication between enterprise beans in the same Java virtual machine.

  Local calls avoid the overhead of RMI/IIOP and use pass-by-reference semantics instead of pass-by-value. For each call, the caller and callee beans share the state of arguments. EJB 2.x and later beans can have both a local and remote interface, but more typically, have one or the other.
- For communicating with remote clients, provide remote and remote home interfaces. For communicating with local clients like servlets, entity beans, and message-driven beans, provide local and local home interfaces.

Batched commands for container managed persistence

From JDBC 2.0 on, *PreparedStatement* objects can maintain a list of commands that can be submitted together as a batch. Instead of multiple database round trips, there is only one database round trip for all the batched persistence requests.

You can enable the use of this feature for EJB container managed persistence (CMP). When you do, the run time defers *ejbStore/ejbCreate/ejbRemove* or the equivalent database persistence requests (insert/update/delete) until they are needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. When the persistence operation finally happens, run time accumulates the database requests and uses JDBC *PreparedStatement* batch operation to make a single JDBC call for multiple rows of the same operation.

The product enables you to make the same settings using assembly tools.

Deferred Create for container managed persistence

For CMP during the *ejbCreate*, the container can create the representation of the entity in the database immediately, or defer it to a later time.

You can turn this option on from the EJB CMP side. When you choose this option, the runtime defers *ejbCreate*, or the equivalent database persistence request, until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

The product enables you to make the same settings using assembly tools. Review the assembly tools information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

Partial column updates for container managed persistence

Previously, the WebSphere Application Server implementation of the Container Managed Persistence (CMP) bean method *ejbStore* stored all of the persistent attributes of the CMP bean to the database, even if only a subset of persistent attribute fields were changed. This needless performance degradation is eliminated in this release of the product.

Note: Entity beans are not supported in EJB 3.0 modules.

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean level persistence option, called *PartialOperation*, in the access intent policy configured for the bean. PartialOperation has two possible values:

NONE Partial update is turned off. All of the persistent attributes of the CMP bean are stored to the database. This is the default value.

UPDATE_ONLY
Specifies that updates to the database occur only for the persistent attributes of the CMP bean that are changed.

For information on how to set partial update, see “Setting partial update for container-managed persistent beans” on page 181.

Performance

Performing partial updates increases performance in several ways:

- by reducing query execution time, since only a subset of the columns are in the query. Improvement is higher for tables with many columns and indexes. When the table has many indexes only the indexes affected by the updated columns need to be updated by the backend database.
- by reducing network input and output since there is less data to be transmitted.
- by saving any processing time for non-trivially mapped columns. For example, if a column uses converters, composers, and transformations to partially inject the input record.
- by eliminating unnecessary firing of update triggers. If a CMP bean field is not changed, any trigger depending only on the corresponding column is not fired.

Although partial update improves performancel, it can adversely affect performance as follows:

- If you enable partial update for a bean that your application modifies several different combinations of columns during the same time span, the prepared statement cache maximum for the connection is reached very quickly. As a result, statement handles are evicted from the cache based on least recent usage. This results in statements being prepared repeatedly, decreasing performance for all CMP functions, not just limited to the ejbStore method.
- Partial update query templates cached in the function set increase memory use. The increase is linear relative to the number of fields in the CMP bean for which the partial update access intent option is turned on.
- The PartialOperation persistent option, when used in combination with the Batch Update persistent option, affects the performance of the batch update because each partial query is different. There is an

execution time cost incurred for generating a partial update query string dynamically. Since query fragments are stored for each column, the execution cost to assemble the query fragments is linear, based on the number of CMP bean fields dirtied.
- There are condition checks for each CMP field, for example, to inspect the dirty flags and to execute the preparedStatement setXXX method calls.

Considerations for using partial update

The performance gains you hope to achieve should be weighed against the possible instances where degradation can occur. You can use the following guidelines to help you make the decision.
- Partial update might not benefit an application that only involves a small table with a few columns and simple data types and no update triggers. The cost to assemble the partial query dynamically outweighs the performance gain.
- Partial update is a benefit if there is a complex data type that is not updated often. An example of a complex data type is an employee bean with a “photo” CMP attribute mapped to a BLOB OR VARGRAPHIC, or similar complex backend type, that is typically stored in a different location in the database manager implementation.
- Partial Update might benefit if there are several VARCHAR type columns and only a very few of them are updated.
- It is better not to use the partial operation if the application can randomly be updating different combinations of columns and the number of assignable columns (non-key) is higher than five. This generates different partial queries and fills up the prepared statement cache quickly. But, if the bean does not have too many columns, for example, four or less, and it has complex data types, you might consider turning partial update on, with the option of increasing the statement cache size to ensure an increased number of queries. For information on increasing the statement cache size, refer to Data source settings.
- Partial Update is beneficial when there are update triggers needed on a subset of columns.
- Partial Update is beneficial when the table has many columns and indexes, and only a few indexes are touched by a typical update.

Restrictions

By default, batch update of *update queries* is disabled for all CMP beans for which partial update is enabled. In other words, partial update takes precedence over batch update. Batch update of delete and insert queries is not affected.

Batch update performance is affected when both batch update and partial update persistence options are used on the same bean, because each partial query is different. You can use the JVM property, *-Dcom.ibm.ws.pm.grouppartialupdate=true*, to group the similar partial update queries into a batch update. Grouping partial updates only helps when there are several partial queries with the same shape in a transaction. Otherwise, grouping partial updates has the opposite affect on performance. Because this setting is not on a bean level basis, you should be careful when turning it on. Because this affects all beans that have both partial update and batch update on, you must make sure that batch update of partial queries does increase performance when viewed across all the beans for which both updates are on.

To set the JVM property:

1. Open the server.xml file.
2. Change the value of *-Dcom.ibm.ws.pm.grouppartialupdate=true* to *-Dcom.ibm.ws.pm.grouppartialupdate=false*.

Setting the run time for batched commands with JVM arguments

This article explains how to set the run time for batched commands with JVM arguments.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.

4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.batch=true*.

Setting the run time for deferred create with JVM arguments

For Container Managed Persistence (CMP) to happen during the ejbCreate, the Enterprise JavaBeans (EJB) container can create the representation of the entity in the database immediately, or defer it to a later time.

About this task

When you choose the defer option, the run time defers ejbCreate, or the equivalent database persistence request, until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.deferredcreate=true*.

Setting partial update for container-managed persistent beans

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean-level persistence option, called *PartialOperation*, in the access intent policy configured for the bean.

About this task

See the topic, ″Partial operation for container managed persistence″ in the assembly tool information center to learn how to complete this task with the assembly tool.

You can access the assembly tool information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

Setting persistence manager cache invalidation

To set persistence manager cache invalidation, follow these steps.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. Select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.ejbpersistence.cacheinvalidation=true*.

Setting the system property to enable remote EJB clients to receive nested or root-cause exceptions

You might want to code your application to perform a given action if a certain kind of exception is the root-cause of a failure and is nested within the exception that you receive. The default behavior in the product might mask a nested or root-cause exception in your application.

About this task

The Enterprise JavaBeans (EJB) container creates a TransactionRolledbackException exception for a remote client when it can create a RemoteException exception instead. With the RemoteException exception, the container does not lose the ability to have root-cause information nested inside the exception.

You can set the following Java virtual machine (JVM) system property to **true** through the administrative console for the product: com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback This change enables the remote client to receive nested exceptions when a rollback occurs.

Note: This property is applicable only for scenarios where the transaction in which the bean method is running was started by the container for this specific method invocation. All of the other scenarios must result in a TransactionRollBackException exception according to the EJB specification.

1. Open the administrative console.
2. Select **Servers**.
3. Select **Servers > Application servers > server_name**.
4. Under Server infrastructure, select **Java and Process Management > Process Definition**.
5. Under Additional properties, select **Java virtual machine > Custom properties > New**.
6. In the **Name** entry field, type **com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback**.
7. In the **Value** entry field, type **true**.
8. Select **OK**.

Unknown primary-key class

When writing an entity bean, the minimum requirements usually include a primary-key class. However, in some cases you might choose not to specify the primary-key class for an entity bean with container-managed persistence (CMP).

Perhaps there is no obvious primary key, or you want to allow the deployer to select the primary key fields at deployment time. The primary key type is usually derived from the type used by the database system that stores the entity objects, and you might not know what this key is.

So, the *unknown key type* is actually a type chosen at deployment time, making it changeable each time the bean is deployed. Your client code must deal with this key as type *Object*.

Currently, WebSphere Application Server supports top-down mapping and enables the deployer to choose *String* keys generated at the application server. For an example of how to use this function, see the Samples Gallery.

Configuring a timer service

To configure a timer service, follow these steps.

1. Open the administrative console.
2. Click **Servers** → **Application servers** → **server_name** → **EJB Container settings** → **EJB timer service settings**. The timer service settings panel is displayed.

3. If you want to use the internal, or pre-configured, scheduler instance, click the **Use internal EJB timer service scheduler instance** radio button. If you choose not to change the default settings, this instance is associated with a Apache Derby database. If you choose to customize the pre-configured instance:
   a. To change the data source (you can use any supported database, such as DB2 or Oracle), enter your **Data source JNDI name**.
   b. Enter your chosen **Data source alias**.
   c. Enter your chosen **Table prefix** if you want to have several server processes use the same database, but different tables.
   d. Enter a **Poll interval** value in milliseconds.
   e. If you want more timers to execute concurrently, enter a new value for **Number of timer threads**.

   For more information about the fields, see “EJB timer service settings” on page 185
4. If you want to configure your own scheduler instance instead of using the pre-configured internal one, click the **Use custom scheduler instance** radio button. Some reasons you might want to use your own instance are:
   - to change scheduler service configuration options not available for customization on this panel
   - to keep EJB Timer tasks in the same database tables as your other tasks
   - you are running in a Clustered environment and want to have a single scheduler instance handle all of the EJB Timers for the cluster. This way, an *ejbTimer* Task created on one cluster member can execute on a different cluster member.

   To use your own instance, you must:
   a. Configure a scheduler instance through the Scheduler Service graphical user interface. See “Using schedulers” on page 1659 for information on how to do this.
   b. Select your **Scheduler JNDI name** from the list.
5. Click **Apply**.
6. Click **OK**.

Configuring a timer service for network deployment

Use this task to configure the Enterprise JavaBeans (EJB) timer service to be used across multiple servers.

About this task

This is largely a question of using the same data source. The steps that follow assume that you have already created a database instance (for example, DB2 or Oracle). From there, you must configure the timer service to use that database.

There are two ways to configure the timer service to share the same database across multiple servers. Choose either step 1 or 2.

1. **Configure a scheduler instance for the cluster, then configure the timer service to use that scheduler instance.**
   a. Configure a scheduler instance for the cluster. This creates for you a *custom scheduler instance*. Next you need to configure the timer service to use that custom instance.
   b. Open the administrative console.
   c. Click **Servers** >**Application Servers** > *servername* > **EJB Container Settings** > **EJB timer service settings**. The timer service settings panel appears.
   d. Select the **Use custom scheduler instance** radio button.
   e. Select your **Scheduler JNDI name** from the dropdown list.
   f. Click **Apply**.
   g. Click **OK**.

2. **Configure the timer service default scheduler instance for each server to use the same data source.**
   a. Select the **Use internal EJB timer service scheduler instance** radio button. To customize the pre-configured instance:
   b. To change the data source (you can use any supported database, such as DB2 or Oracle) select your **Data source JNDI name** from the dropdown list. The default database listed cannot be shared, because it is configured to be visible to one server only, and it uses the single server version of Apache Derby, which can only be accessed by one server process at a time.
   c. Enter your chosen **Datasource Alias**.
   d. Enter your chosen **Table Prefix** if you want to have several server processes use the same database, but different tables.
   e. Enter a **Poll Interval** value in milliseconds. For more information about the fields, see "EJB timer service settings" on page 185
   f. Click **Apply**.
   g. Click **OK**.
   h. Change all of your server processes to use the same database you chose from the **Data source JNDI name** dropdown list earlier.

Example: Using the Timer Service

This example shows the implementation of the *ejbTimeout()* method that is called when the scheduled event occurs.

The ejbTimeout method can contain any code that is typically placed in a business method of the bean. Method-level attributes such as *transaction* or *runAs* can be associated with this method by the application assembler. An instance of the Timer object that causes the method to fire is passed in as an argument to ejbTimeout method.

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the EJB container upon Timer expiration.
  public void ejbTimeout(Timer theTimer) {

    // Any code typically placed in an EJB method can be placed here.

     String whyWasICalled = (String) theTimer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

A Timer is created that starts the ejbTimeout method in 30 seconds. A simple string object is passed in at Timer creation to identify the Timer.

```
// Instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

// Save the entity context passed in upon bean creation.
  theEJBContext = theContext;

}

// This business method causes the ejbTimeout method to begin in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {

  TimerService theTimerService = theEJBContext.getTimerService();
```

```
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTimerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

EJB timer service settings

Use this page to configure and manage the Enterprise JavaBeans (EJB) timer service for a specific EJB container.

To view this administrative console page, click**Servers** → **Server types** → **WebSphere application servers** → **server** → **EJB Container Settings** → **EJB timer service settings**.

The two radio buttons that appear on this page offer you choices that are *mutually exclusive*.

Scheduler type:

Use internal EJB timer service scheduler instance:

The product provides an internal scheduler instance for use by the EJB timer service. The internal scheduler instance is pre-configured for basic EJB timer functionality, and provides limited configuration settings for an EJB timer service. Clicking this button specifies that you want to use the internal scheduler instance to manage your tasks. They are persisted to a Cloudscape database associated with the server process. Selecting this choice locks out the *Use Custom Scheduler Instance* option.

This is the default choice.

Use custom scheduler instance:

You can perform a more advanced configuration for the EJB timer service by defining a custom scheduler instance. Scheduler configuration provides more configuration options than the internal EJB timer service pre-configured scheduler instance. You might want to define a custom scheduler instance when running in a clustered environment, allowing all cluster members to run with a single scheduler instance. This enables EJB Timers created on one cluster member to execute on other cluster members. Providing a custom scheduler instance also enables EJB Timers to be maintained in the same database as other scheduled tasks. Selecting this choice locks out the *Use Internal EJB Timer Service Scheduler Instance* option

Data source JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source where persistent EJB Timers are stored for this EJB container. Any data source available in the name space can be used for EJB Timers. Multiple EJB containers can share a single data source while using different tables by specifying a table prefix.

Data type	String
Default	*jdbc/DefaultEJBTimerDataSource*

Data source alias:

Authentication alias to a user name and password used to access the data source.

Data type	String

Table prefix:

A string prepended to the EJB timer service table names (TASK, TREG, LMGR and LMPR). These tables are created during server start if they do not already exist. See help on the Scheduler Service for information about manually creating these tables. Multiple independent EJB timer services can share the same database if each instance specifies a different prefix string.

Data type	String
Default	*EJBTIMER_*

Poll interval:

The interval at which the EJB timer service daemon polls the database. Each poll operation can be expensive. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources. New Timers set to expire sooner than this interval might not execute until the interval ends. If this value is too large, a potentially large number of timer events might be read into memory, because all the timer events occurring in the next poll interval are read in each time.

Data type	Integer
Units	seconds
Default	300
Range	3 -- 1800

Number of timer threads:

The number of threads used to execute concurrent EJB Timer tasks. Setting the number of Timer Threads to zero disables the EJB timer service.

Data type	Integer
Default	1
Range	0 -- 500

Scheduler JNDI name:

This field is only used when the **Use Custom Scheduler Instance** choice is made. It specifies the JNDI name of a custom Scheduler instance to use for managing and persisting EJB Timers. Internal EJB timer service Scheduler Instance configuration information is not applied to the specified Scheduler instance.

Data type	String

Developing enterprise beans for the timer service

About this task

In WebSphere Application Server, the **EJB Timer Service** implements Enterprise JavaBeans (EJB) Timers as a new kind of Scheduler Service task. By default, an internal (or pre-configured) scheduler instance is used to manage those tasks, and they are persisted to a Apache Derby database associated with the server process.

However, you can perform some basic customization to the internal scheduler instance. For information about how to do this customization, see “Configuring a timer service” on page 182.

Creation and cancellation of Timer objects are transactional and persistent. That is, if a Timer object is created within a transaction and that transaction is later rolled back, the Timer object’s creation is rolled back as well. Similar rules apply to the cancellation of a Timer object. Timer objects also survive across application server shutdowns and restarts.

1. Write your enterprise bean to implement the *javax.ejb.TimedObject* interface, including the *ejbTimeout()* method. The bean calls the *EJBContext.getTimerService()* method to get an instance of the **TimerService**object. The bean calls the TimerService method to create a Timer. This Timer is now associated with that bean.
2. After you create it, you can pass the Timer instance to other Java code as a *local* object.

   Note: For WebSphere Application Server Version 6, no assembly tooling supports the Enterprise JavaBeans timedObject. To set the ejbTimeout method transaction attribute you must manually enter the attributes in the deployment descriptor. See “EJB timer service settings” on page 185 for more information.

Clustered environment considerations for timer service

In a single server environment, it is clear which server instance should invoke the *ejbTimeout()* method on a given bean. In a multi-server clustered environment there are two possibilities.

- Separate timer service database per server process or cluster member. This is the default configuration. Only the server instance or cluster member that created the Timer can access the Timer and run the *ejbTimeout()* method. If the server instance is unavailable, the Timer does not run at the specified time, and does not run until the server is restarted. Also, if an enterprise bean calls the *getTimers()* method, only those timers created on the server instance are found. This can cause unexpected behavior if the enterprise bean attempts to cancel all timers associated with it; for example, when the enterprise bean is removed. This configuration is NOT recommended for production level systems.
- Shared or common timer service database for the cluster. Timers can be created and accessed on any server process or cluster member. Timers created in one server process are found by the *getTimers()* method on other server processes in the cluster. When an entity bean is removed, all timers, no matter where created, are cancelled. However, all timers are executed on a single server in the cluster, that is, the *ejbTimeout()* method is run for all timers on a single server. Which server executes the timers varies depending on which server process obtains a lock on the common database tables. If the server executing timers becomes unavailable, then another server or cluster member takes over and begins executing all timers at their scheduled time. This is the recommended configuration for all production level systems.
-

  Note: When using the EJB Timer service in an application using multi-threaded database access, application flow can introduce deadlock problems.
  To avoid this, use the wsPessimisticUpdate access intent. This access intent causes the finder method in your application to run a *select for update* statement instead of a generic select. This in turn prevents the lock escalation deadlock when multiple threads try to escalate their locks to perform an update.

See “Configuring a timer service” on page 182 for information on how to configure the data source (database) to be used for each server process timer service.

Note: Once the data source for the timer service is changed to point to a different database, the server process automatically attempts to create the required tables in that database on the next server start.

If the user Id associated with the start of the server process is not authorized to create database tables in the configured timer service database, then the tables must be created manually. For more information, see Creating scheduler tables using DDL files.

Timer service commands:

Information about Enterprise JavaBeans (EJB) timers is generally specific to the application that creates the timers, and the timers are not visible outside of the creating application. Therefore, management of EJB timers should be performed by the application that contains the enterprise bean and that creates the EJB timer.

However, you can use the following commands during application development. They provide some basic EJB timer management functions. These commands are not available on *client only* installs.

findEJBTimers

This command displays information about existing EJB timers based on specified filter criteria.

The syntax for this command is:

```
findEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
           -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

where :

server the name of the server process where the EJB timers are located

-all find all EJB timers associated with the server process

timer id
EJB Timer ID that uniquely identifies the timer

application name
find all EJB timers associated with the application

module name
find all EJB timers associated with the module

bean name
find all EJB timers associated with the enterprise bean

host name
host name of the server process

portnumber
port of the server process

connector type
type of connection. For example, SOAP, RMI, or NONE.

userid user to use when connecting to the server process

password
password to use when connecting to the server process

quiet disable output

logfile directs output to a file

replacelog
clears the existing log before executing the command

trace enable trace

help provides command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers created in any of the server processes might be found.

For an example of the findEJBTimers command, see “FindEJBTimers command example” on page 190.

cancelEJBTimers

This command cancels and removes from persistent storage EJB timers based on the specified filter criteria.

The syntax for this command is:

```
cancelEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
           -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

where :

server the name of the server process where the EJB timers are located

-all find all EJB timers associated with the server process

timer id
EJB Timer ID that uniquely identifies the timer

application name
find all EJB timers associated with the application

module name
find all EJB timers associated with the module

bean name
find all EJB timers associated with the enterprise bean

host name
host name of the server process

portnumber
port of the server process

connector type
type of connection. For example, SOAP, RMI, or NONE.

userid user to use when connecting to the server process

password
password to use when connecting to the server process

quiet disable output

logfile directs output to a file

replacelog
clears the existing log before executing the command

trace enable trace

help provides command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers created in any of the server processes might be cancelled.

For an example of the cancelEJBTimers command, see “CancelEJBTimers command example.”

FindEJBTimers command example:

The following examples illustrate how to use the command to find Enterprise JavaBeans (EJB) timers and explain the output statement.

To use the findEJBTimers command to find *all* EJB timers on a server called **server1**:

```
findEJBTimers server1 -all
```

To find all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
findEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

When EJB timers matching the filter criteria are found, the output appears similar to this:

```
EJB Timer : 25     Expiration: Mon Feb 09 13:36:47 CST 2004   Repeating
 EJB        : DefaultApplication.ear Increment.jar Increment
 EJB Key: 8
 Info : Increment Counter
EJB Timer : 26     Expiration: Mon Feb 09 13:36:47 CST 2004   Single
 EJB        : DefaultApplication.ear Increment.jar Increment
 EJB Key: 8
 Info : Decrement Counter
2 EJB Timers found
```

In this output:

- The *EJB Timer* is the unique identifier of the timer.
- *Expiration* is the next time the timer is expected to execute.
- *Repeating* or *Single* indicates whether the EJB timer is single action or repeating.
- *EJB Key* is the *toString()* method output of the primary key for the Entity enterprise bean (not present for other EJB types).
- *Info* is the *toString()* method output of the object passed by the application when the EJB timer was created.

Only the first 40 bytes of *toString()* output are displayed for the Primary Key and Timer Info. This information is only useful if the application overrides the *toString()* method for these objects.

Increment in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

CancelEJBTimers command example:

The following examples illustrate how to use the command to cancel Enterprise JavaBeans (EJB) timers.

To use the cancelEJBTimer command to cancel all EJB timers on a server called **server1**:

```
cancelEJBTimers server1 -all
```

To cancel all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
cancelEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

To cancel a specific EJB timer identified through the FindEJBTimers command or from a system log entry indicating a problem or failure:

```
cancelEJBTimers server1 -id 25
```

Increment in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

Web services support in EJB

The product complies with the Java EE and Enterprise JavaBeans (EJB) specifications by enabling you to expose an EJB stateless session bean as a Web service.

The product supports the Java API for XML Web Services (JAX-WS) 2.0 programming model and the EJB 3.0 specification.

EJB 3.0 does not support the @WebService or @WebMethod annotations on EJB 3.0 stateless session beans, which are used to identify the stateless session bean as a JAX-WS implementation, nor does it support injection of Web services references. You can invoke EJB 3.0 beans indirectly by defining a servlet as the JAX-WS implementation and placing code in the servlet which invokes the target EJB 3.0 bean.

You can do this by declaring a link between the desired endpoint name in the Web service deployment descriptor of the EJB module. During deployment and installation of the bean into the Application Server environment, the bean is linked to the specified Web service endpoint.

If you are writing a stateless session bean to implement a preexisting Web Services Description Language (WSDL) interface, you must remember to implement in your bean all of the methods defined on the WSDL interface.

For more information, see “Developing Web services applications with JAX-WS” on page 487.

Defining data sources for entity beans

Before an application that is installed on an application server can start, all enterprise bean (EJB) references and resource references defined in the application must be bound to the actual enterprise beans or resources that are defined in the application server.

Before you begin

Create a data source or JDBC resource and give it a Java Naming and Directory Interface (JNDI) name.

About this task

For more information, see Application bindings.

Before you do this task, it is assumed that the entity beans in your application are container-managed persistence (CMP) enterprise beans.

Note:
The EJB container handles the persistence of the bean attributes in the underlying persistent store. You must specify which data store is used. You do this by binding an EJB module or individual EJB to a data source.

If you bind an EJB *module* to a data source, all beans in that module use the same data source for persistence. If you specify the data source at the bean level, then that data source is used instead.

See the assembly tool information center for the steps on how to complete this task.

Lightweight local operational mode for entity beans

WebSphere Application Server provides a special operational mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

In lightweight local mode, the container streamlines the processing that it performs before and after every method on the local home interface and local business interface of the bean. This streamlining can result in improved performance when entity bean operations are called locally from within an application. Because some processing is skipped when running in lightweight local mode, this mode can be used in certain scenarios only.

Lightweight local mode is patterned somewhat after the Plain Old Java Object (POJO) entity model introduced in the Enterprise JavaBeans (EJB) 3.0 specification. Using lightweight local mode, you can obtain some of the performance advantages of the POJO entity model without having to convert your existing EJB 2.x application code to the new POJO model. You can apply lightweight local mode to both container-managed persistence (CMP) and bean-managed persistence (BMP) entity types that meet the specific criteria.

Note: Entity beans are not supported in EJB 3.0 modules.

When to use the lightweight local mode

Lightweight local mode is designed for entity beans that are created, found, and called using the *Session Facade* pattern. Under this pattern, entity bean local home and local business methods are called from within methods of a stateless session bean or stateful session bean. The session bean methods, which can be called remotely or locally, provide security control and transaction demarcation for the entity beans that are accessed by the session bean.

You can apply lightweight local mode only to an entity bean that meets the following criteria:
- The bean implements an EJB local interface.
- No security authorization is defined on the entity bean local home or local business interface methods.
- No *run-as* security attribute is defined on the local home or local business methods.
- The classes for the calling bean and the called entity bean are loaded by the same Java classloader.
- The entity bean methods do not call the WebSphere Application Server-specific Internationalization Service or Work Area Service.

The first criterion prevents CMP 1.x beans from supporting lightweight local mode, because the 1.x beans cannot have local interfaces.

In addition, lightweight local mode provides its fullest performance benefits only to entity bean methods that do not need to start a global transaction. This condition is true if you ensure that your entity bean also meets the following criteria:
- A global transaction is already in effect when the entity bean home or business method is called. Typically, this transaction is started by the calling session bean.
- The local business interface methods and the local home methods of the entity bean use the following transaction attributes only: REQUIRED, SUPPORTS, or MANDATORY.

If an entity bean method that is running in lightweight local mode must start a global transaction, the bean still functions normally but only a partial performance benefit is realized.

You can mark an entity bean that defines a remote interface or a TimedObject interface, in addition to the local interface, for lightweight local mode. However, the performance benefit is apparent only when the bean is called through its local interface.

Applying lightweight local mode to an entity bean

WebSphere Application Server provides a special operation mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

About this task

You can apply lightweight local mode to specific EntityBean types within your application with the Marker interface technique.

Marker interface technique

About this task

Use the marker interface technique when a group of beans within the application is related through a common inheritance hierarchy, and all the beans in the hierarchy are to be marked. For an application with a large number of beans in a hierarchy, this technique is the most efficient.

To use a marker interface, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.LightweightLocal** interface. The bean implementation class does not need to directly implement the interface; any parent class or interface can also implement it. For details, see the **com.ibm.websphere.ejbcontainer** package in the API section of the information center.

Using access intent policies

You can use access intent policies to help the product runtime environment manage various aspects of Enterprise JavaBeans (EJB) persistence.

About this task

You apply access intent policies to EJB Version 2.0 and 2.1 entity beans, and their methods, by using an assembly tool. A set of default access intent policies comes with the assembly tool. The Rational Application Developer product provides supported assembly tools. You can also create your own custom policies. Entity beans are not supported in EJB 3.0 modules.

1. Apply default access intent to CMP entity beans. For more information, see the online help available with the assembly tools.
2. Apply access intent policies to methods of container managed persistence entity beans.
3. Create a custom access intent policy with an assembly tool.
4. Apply access intent policies to bean managed persistence (BMP) entity bean methods by using the AccessIntent API.
5. Apply multiple access intent policies to methods by using application profiling.

Access intent policies

An access intent policy is a named set of properties or access intents that govern data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. You can set access intents only within EJB Version 2.x-compliant and later modules for entity beans with CMP Version 2.x.

This product supplies a number of access intent policies that specify permutations of read intent and concurrency control; the pessimistic and update policy can be qualified further. The selected policy determines the appropriate isolation level and locking strategy used by the run time environment.

Note: Access intent policies are specifically designed to supplemant the use of isolation level and access intent method-level modifiers found in the extended deployment descriptor for EJB version 1.1 enterprise beans. You cannot specify isolation level and read-only modifiers for EJB version 2.x and later enterprise beans.

Access intent policies configured on an entity basis define the default access intent for that entity. The default access intent controls the entity unless you specify a different access intent policy based on either method-level configuration or application profiling.

Note: Method level access intents were deprecated in Version 6.x.

You can use application profiling or method level access intent policies to control access intent more precisely. Method-level access intent policies are named and defined at the module level. A module can have one or many policies. Policies are assigned, and apply, to individual methods of the declared interfaces of entity beans and their associated home interfaces. A method-based policy is acted upon by the combination of the EJB container and persistence manager when the method causes the entity to load.

For entity beans that are backed by tables with nullable columns, use an optimistic policy with caution. The top down default mapping excludes nullable fields. You can override this when doing a meet-in-the-middle mapping. The fields used in overqualified updates are specified in the ejb-rdb mapping. If nullable columns are selected as overqualified columns, partial update should also be selected.

Note: When using DB2 for z/OS Version 8, nullable OCC columns create no problems. This is true for JDBC and SQLJ deploy options, and partial and full update.

An entity that is configured with a read-only policy that causes a bean to be activated can cause problems if updates are attempted within the same transaction. Those changes are not committed, and the process displays an exception because data integrity might be compromised.

Concurrency control

Concurrency control is the management of contention for data resources. A concurrency control scheme is considered *pessimistic* when it locks a given resource early in the data-access transaction and does not release it until the transaction is closed. A concurrency control scheme is considered *optimistic* when locks are acquired and released over a very short period of time at the end of a transaction.

The objective of optimistic concurrency is to minimize the time that a given resource is unavailable for use by other transactions. This is especially important with long-running transactions, which under a pessimistic scheme would lock up a resource for unacceptably long periods of time.

Under an optimistic scheme, locks are obtained immediately before a read operation and released immediately after. Update locks are obtained immediately before an update operation and held until the end of the transaction.

To enable optimistic concurrency, this product uses an *overqualified update scheme* to test if the underlying data source has been updated by another transaction since the beginning of the current transaction. With this scheme, the columns marked for update and their original values are added explicitly through a WHERE clause in the UPDATE statement so that the statement fails if the underlying column values have been changed. As a result, this scheme can provide column-level concurrency control; pessimistic schemes can control concurrency at the row level only.

Optimistic schemes typically perform this type of test only at the end of a transaction. If the underlying columns have not been updated since the beginning of the transaction, pending updates to container-managed persistence fields are committed and the locks are released. If locks cannot be acquired or if some other transaction has updated the columns since the beginning of the current transaction, the transaction is rolled back: All work performed within the transaction is lost.

Pessimistic and optimistic concurrency schemes require different transaction isolation levels. Enterprise beans that participate in the same transaction and require different concurrency control schemes cannot operate on the same underlying data connection.

Note: Whether to use optimistic concurrency depends on the type of transaction. Transactions with a high penalty for failure might be better managed with a pessimistic scheme. A high-penalty transaction is one for which recovery is risky or resource-intensive. For low-penalty transactions, it is often worth the risk of failure to gain efficiency through the use of an optimistic scheme. In general, optimistic concurrency is more efficient when update collisions are expected to be infrequent; pessimistic concurrency is more efficient when update collisions are expected to occur often.

Read-ahead hints

Read-ahead schemes enable applications to minimize the number of database round trips by retrieving a working set of container-managed persistence (CMP) beans for the transaction within one query. Read-ahead involves activating the requested CMP beans and caching the data for their related beans, which ensures that data is present for the beans that an application most likely needs next. A *read-ahead hint* is a representation of the related beans to read. The hint is associated with the *findByPrimaryKey* method for the requested bean type, which must be an EJB 2.x-compliant CMP entity bean.

A read-ahead hint takes the form of a character string. You do not have to provide the string; the wizard generates it for you based on the container-managed relationships (CMRs) that are defined for the bean. The following example is provided as supplemental information only. Suppose a CMP bean type A has a finder method that returns instances of bean A. A read-ahead hint for this method is specified using the following notation: `RelB.RelC; RelD`

Interpret the preceding notation as follows:
- Bean type A has a CMR with bean types B and D.
- Bean type B has a CMR with bean type C.

For each bean of type A that is retrieved from the database, its directly-related B and D beans and its indirectly-related C beans are also retrieved. The order of the retrieved bean data columns in each row of the result set is the same as the order in the read-ahead hint: an A bean, a B bean (or null), a C bean (or null), a D bean (or null). For hints in which the same relationship is mentioned more than once, for example, `RelB.RelC;RelB.RelE`, the data columns for a bean occur only once in the result set, at the position the bean first occupies in the hint.

The tokens shown in the notation, like *RelB*, must be CMR field names for the relationships, as defined in the deployment descriptor for the bean. In indirect relationships such as `RelB.RelC`, *RelC* is a CMR field name that is defined in the deployment descriptor for bean type B.

A single read-ahead hint cannot refer to the same bean type in more than one relationship. For example, if a Department bean has an *employees* relationship with the Employee bean and also has a *manager* relationship with the Employee bean, the read-ahead hint cannot specify both *employees* and *manager*.

For more information about how to set read-ahead hints, see the documentation for the Rational Application Developer product.

Run-time behaviors of read-ahead hints

When developing your read-ahead hints, consider the following tips and limitations:
- Read-ahead hints on long or complex paths can result in a query that is too complex to be useful. Read-ahead hints on root or leaf inheritance mappings need particular care. Add up the number of tables that potentially comprise a read-ahead preload to gauge the complexity of the join operations that are required. Consider if the resulting statement constitutes a reasonable query on your target database.
- Read-ahead hints do not work in the following cases:

- Preload paths across M:N relationships
- Preload paths across recursive enterprise bean relationships or recursive fk relationships
- When a read-head hint applies to a SELECT FOR UPDATE statement that requires a table join in a database that does not support the combination of those two operations.

  Generally, the persistence manager issues a SELECT FOR UPDATE statement for a bean only if the bean has an access intent that enforces strict locking policies. Strict locking policies require SELECT FOR UPDATE statements for database select queries. If the database table design requires a join operation to fulfill the statement, many databases issue exceptions because these databases do not support table joins with SELECT FOR UPDATE statements. In those cases, WebSphere Application Server does not implement a read-ahead hint. If the database does provide that support, Application Server implements the read-ahead hints that you configure.

  DB2 Universal Database V8.2 supports SELECT FOR UPDATE statements with table joins.

Database deadlocks caused by lock upgrades

To avoid databse deadlocks caused by lock upgrades, you can change the access intent policy for entity beans from the default of wsPessimisticUpdate-WeakestLockAtLoad to wsPessimisticUpdate, or you can use an optimistic locking approach.

When concurrently accessing data, ensure that the application is prepared for database locking that must occur to secure the integrity of the data.

If an entity bean performs a findByPrimaryKey method, which by default obtains a *Read* lock in the database, and the entity bean is updated within the same transaction, a lock upgrade to *Exclusive*.

If this scenario occurs concurrently on multiple threads, a deadlock can happen. This is because multiple read locks can be obtained at the same time but one exclusive lock can only be obtained when the other locks are dropped. Since all transactions are attempting the lock upgrade in this scenario, the one exclusive lock cannot be obtained.

To avoid this problem, you can change the access intent policy for the entity bean from the default of wsPessimisticUpdate-WeakestLockAtLoad method to wsPessimisticUpdate method. This change enables the application to inform the product and the database that the transaction has updated the enterprise bean. The *Update* lock is immediately obtained on the findByPrimaryKey method. This avoids the lock upgrade when the update is performed at a later time.

The preferred technique to define access intent policies is to change the access intent for the entire entity bean. You can change the access intent for the findByPrimaryKey method, but this was deprecated in Version 6. You might want to change the access intent for an individual method if, for example, the entity bean is involved in some transactions that are read only.

An alternative technique is to use an optimistic approach, where the findByPrimaryKey method does not hold a read lock, so there is no lock upgrade. However, this requires that the application is coded for this in order to handle rollbacks. Optimistic locking is intended for applications that do not expect database contention on a regular basis.

To change the access intent policy for an entity bean, you can use the assembly tool to set the bean level, as described in “Applying access intent policies to beans” on page 198.

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

These settings are applicable only for EJB 2.x and EJB 3.0-compliant entity beans that are packaged in EJB 2.x and EJB 3.0-compliant modules. Connection sharing between beans with bean-managed persistence and those with container-managed persistence is possible if they all use the same access intent policy.

Name:

Specifies a name for a mapping between an access intent policy and one or more methods.

Description:

Contains text that describes the mapping.

Methods - name:

Specifies the name of an enterprise bean method, or the asterisk character (*). The asterisk is used to denote all of the methods of an enterprise bean's remote and home interfaces.

Methods - enterprise bean:

Specifies which enterprise bean contains the methods indicated in the Name setting.

Methods - type:

Used to distinguish between a method with the same signature that is defined in both the home and remote interface. Use `Unspecified` if an access intent policy applies to all methods of the bean.

Data type	String
Range	Valid values are `Home`, `Remote`,`Local`, `LocalHome` or `Unspecified`

Methods - parameters:

Contains a list of fully qualified Java type names of the method parameters. This setting is used to identify a single method among multiple methods with an overloaded method name.

Applied access intent:

Specifies how the container must manage data access for persistence. Configurable both as a default access intent for an entity and as part of a method-level access intent policy.

Data type	String
Default	`wsPessimisticUpdate-WeakestLockAtLoad`. With Oracle, this is the same as wsPessimisticUpdate.
Range	Valid settings are `wsPessimisticUpdate`, `wsPessimisticUpdate-NoCollision`, `wsPessimisticUpdate-Exclusive`, `wsPessimisticUpdate-WeakestLockAtLoad`, `wsPessimisticRead`, `wsOptimisticUpdate`, or `wsOptimisticRead`. Only `wsPessimisticRead` and `wsOptimisticRead` are valid when class-level caching is enabled in the EJB container.

This product supports lazy collections. For each segment of a collection, iterating through the collection (*next()*) does not trigger a remote method call to retrieve the next remote reference. Two policies

(wsPessimisticUpdate and wsPessimisticUpdate-Exclusive) are extremely lazy; the collection increment size is set to 1 to avoid overlocking the application. The other policies have a collection increment size of 25.

If an entity is not configured with an access intent policy, the run-time environment typically uses wsPessimisticUpdate-WeakestLockAtLoad by default. If, however, the **Lifetime in cache** property is set on the bean, the default value of **Applied access intent** is wsOptimisticRead; updates are not permitted.

Additional information about valid settings follows:

Profile name	Concurrency control	Access type	Transaction isolation
wsPessimisticRead (Note 1)	pessimistic	read	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate (Note 2)	pessimistic	update	For Oracle, read committed. Otherwise, repeatable read
wsPessimisticUpdate-Exclusive (Note 3)	pessimistic	update	serializable
wsPessimisticUpdate-NoCollision (Note 4)	pessimistic	update	read committed
wsPessimisticUpdate-WeakestLockAtLoad (Note 5)	pessimistic	update	Repeatable read
wsOptimisticRead	optimistic	read	read committed
wsOptimisticUpdate (Note 6)	optimistic	update	read committed

Notes:
1. Read locks are held for the duration of the transaction.
2. The generated SELECT FOR UPDATE query grabs locks at the beginning of the transaction.
3. SELECT FOR UPDATE is generated; locks are held for the duration of the transaction.
4. A plain SELECT query is generated. No locks are held, but updates are permitted. Use cautiously. This intent enables execution without concurrency control.
5. Where supported by the backend, the generated SELECT query does not include FOR UPDATE; locks are escalated by the persistent store at storage time if updates were made. Otherwise, the same as wsPessimisticUpdate.
6. Generated overqualified-update query forces failure if CMP column values have changed since the beginning of the transaction.

   Be sure to review the rules for forming overqualified-update query predicates. Certain column types (for example, BLOB) are ineligible for inclusion in the overqualified-update query predicate and might affect your design.

Applying access intent policies to beans

You can apply an access intent policy to an application's entity beans through the assembly tool.

About this task

Container-managed persistence (CMP) developers can use *access intent* to provide hints on how the application server run time should manage the details of persistence without having to explicitly manage any of the persistence logic from within their application.

Using the access intent service is also an option for programmers who develop bean-managed persistence (BMP) entity beans. Because the only meaningful difference between BMP and CMP components is the mechanism that provides the persistence logic, BMP beans leverage access intent hints in the same manner as the EJB container manages accent intent for CMP beans. This ability becomes especially

important when BMP entities and CMP entities want to share connections. BMP beans configured with the same concurrency as the CMP beans and implemented to the same isolation level mapping as the CMP can share connections.

Developers can apply access intent policies to BMP entity beans as well as to CMP entity beans. It is expected that BMP developers use only those access intent attributes that are important to a particular BMP bean. The access intent service interface is bound into the *java:comp namespace* for each particular BMP bean. The access intent policy retrieved from the access intent service is current from the time that the *ejbLoad* process is called until the time that the *ejbStore* process completes its invocation.

Note: This is the preferred technique to define access intent policies. Method-level access intent is deprecated in Version 6.0.

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. In the **Access Intent for Entities 2.x (Bean Level)** panel, select the name of the bean.
8. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
9. In the **Access intent name** field, select wsPessimisticUpdate from the drop-down list.
10. Optional: Enter a **Description** to help you remember what this policy does.
11. Optional: Change the **Persistence Option** setting
12. Click **Finish**. The access intent policy for the entity bean is shown in the **Access Intent for Entities 2.x (Bean Level)** panel

Configuring read-read consistency checking with an assembly tool

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. For the Access Intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store, and ensures that no one updates it after the checking.

About this task

For the access intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using an assembly tool. To learn how to complete this task see the topic, ″Adding bean-level access intent for entity beans 2.x″ in the assembly tool documentation at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

Example: Read-read consistency checking

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction.

Usage scenario

For the access intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, but it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in ″Ann's″ bank account. In each case, the data store is shared by this Enterprise JavaBeans (EJB) container managed persistence (CMP) application to calculate the interest and other applications, such as EJB bean managed persistence (BMP) , Java Database Connectivity (JDBC), or legacy applications. Also in each case, the EJB account is configured as a *long-lifetime* bean.

NONE

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- Calculate Ann's interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from cache, with a balance of $100.
- PM performs read-read check on Ann's account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann's data in the cache is refreshed.
- Calculate Ann's interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey(″10001″), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.

- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account ″10001″, Ann's data is read from database, with balance of $100.
- Calculate Ann's interest.
- During end of transaction 2, PM performs read-read check on Ann's account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is a WebSphere Application Server runtime service that enables you to precisely manage an application's persistence.

The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Typically, you configure *bean level* access intent for your applications. You can also apply access intent policies to beans within the scope of *application profiles*. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Support for applying access intent policies at the method level is deprecated in WebSphere Application Server Version 6.0. In this practice of configuring access intent, you apply a policy to methods within the scope of an EJB module so that the policy becomes the default access intent for all requests upon those methods.

Access intent design considerations

Note: Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is configured with multiple access intent policies.

Note: Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles.

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the runtime environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad method is driven to open a connection and read data from a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore method. Read-ahead hints are only used during the execution of a finder for a bean. The collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that do not use the policy is not an error. Only certain attributes of any policy are used, even when the policy is appropriately applied to a method. However,

configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Access intent with BMP entity beans

Access intent's declarative functionality provides great power to you as a CMP entity bean developer. You can provide hints on how the product should manage the details of persistence without having to explicitly manage any of the persistence logic in the application. There are situations, however, in which you might need to develop BMP entity beans. Since the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP entity beans should be able to leverage access intent hints just as the product does on behalf of CMP entity beans. BMP entity beans that use the access intent service participate in application profiling; that is, the value of the access intent attributes can differ from request to request, allowing the BMP entity bean to seamlessly modify its persistence strategy.

You can apply access intent policies to BMP entity bean methods as well as CMP entity bean methods. Because access intent hints are not contractual in nature, there is no obligation for a BMP entity bean to exploit them. BMP entity beans are expected to use only those access intent attributes that are important to that particular bean.

The current access intent policy is bound into the java:comp namespace for a particular BMP entity bean. That policy is current only for the duration of the method call during which the access intent policy was retrieved. In a typical scenario, you would cache the access type during invocation of the ejbLoad method so that appropriate actions can be taken during invocation of the ejbStore method.

Access intent best practices

When applying access intent policies to EJB methods, consider the following issues.

- **Start by configuring the default access intent policy for an entity.** After your application is built and started, you can tune certain access paths in your application using application profiling or method-level access intent.
- **Don't mix access types.** Avoid using both pessimistic and optimistic policies in the same transaction. For most databases, pessimistic and optimistic policies use different isolation levels. This can result in multiple database connections, which prevents you from taking advantage of the performance benefits possible through connection sharing.
- **Take care when applying the `wsPessimisticUpdate-NoCollision` policy.** This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction attempts to update persistent store at any time.

For further information on Java Persistence API (JPA) Access intent, see the topic on JPA Access intent.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tool.

About this task

Note: Method-level access intent is deprecated in Version 6.0.

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

a. Select **File > Import > EAR file > Next**

b. Select the EAR file.

c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.

d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.

e. Select **Finish**

5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. Optional: Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. Optional: Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

    Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.
16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.
18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.
20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of bean managed persistence (BMP) entity bean methods.

1. Look up the access intent service from the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntentService aiService = ic.lookup("java:comp/websphere/AppProfile/AccessIntentService");
```

2. From a method of the remote or local component interface of the BMP, get the current AccessIntent object using the javax.ejb.EntityContext. This is passed to the BMP when the container calls the setEntityContext method. Assume the EntityContext was stored in a variable named myEntityCtx. For example:

```
AccessIntent ai = aiService.getAccessIntent (myEntityCtx);
```

3. Use the get() methods of AccessIntent interface to obtain the desired information. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
   && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
     int exclusive = ai.getPessimisticUpdateLockHint();
     // . . .
}
// . . .
```

For a detailed example of the use of the AccessIntent API, see “Example: Using IBM extended APIs to share connections between CMP beans and BMP beans” on page 977.

Results

Note: The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean's method; the reference does not exist during a request on a container managed persistence (CMP) entity bean. Therefore, access intent object references should not be cached beyond, or used outside of, the scope of the execution of any given BMP method.

AccessIntent interface

The AccessIntent interface is available to bean-managed persistence (BMP) entity beans.

A BMP entity bean can get and use an instance of the AccessIntent interface. For more information see “Using the AccessIntent API” on page 203.

AccessIntent interface

```
package com.ibm.websphere.appprofile.accessintent;

/**
* This interface defines the essential access intents
* available at run time.
*/
public interface AccessIntent {

/**
* Returns the concurrency control intent, which indicates
* the application prefers either pessimistic or optimistic
* concurrency control when accessing the current component
* in the context of the current transaction.
*/
public int getConcurrencyControl();
public final int CONCURRENCY_CONTROL_PESSIMISTIC = 1;
public final int CONCURRENCY_CONTROL_OPTIMISTIC = 2;

/**
* Returns access type intent, which indicates the application
* intends either update or read access of the current component
* in the context of the current transaction.
*/
public int getAccessType();
public final int ACCESS_TYPE_UPDATE= 1;
public final int ACCESS_TYPE_READ = 2;

/**
* Returns an integer value that indicates that the run time should
* assume that there will be no collision on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
```

```
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/*
* Returns an integer value that indicates that the run time should
* assume that there will be collisions on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/**
* Returns the collection access intent, which indicates the
* application intends to access the objects returned by the
* currently executing finder in either serial or random fashion.
*/
public int getCollectionAccess();
public final int COLLECTION_ACCESS_RANDOM = 1;
public final int COLLECTION_ACCESS_SERIAL = 2;

/**
* Returns the collection scope, which indicates the maximum
* lifespan of a lazy collection.
*/
public int getCollectionScope();
public final int COLLECTION_SCOPE_TRANSACTION = 1;
public final int COLLECTION_SCOPE_ACTIVITYSESSION = 2;
public final int COLLECTION_SCOPE_TIMEOUT = 3;

/**
* Returns the timeout value in seconds when collectionScope is Timeout.
*/
public int getCollectionTimeout();

/**
* Returns the number of elements the application requests be contained
* in each segment of the element collection returned by the currently
* executing finder.
*/
public int getCollectionIncrement();

/**
* Returns the ReadAheadHint requested by the application for the currently
* executing finder.
*/
public ReadAheadHint getReadAheadHint();

/**
* Returns the number of elements the application requests be contained in
* each segment of a query made on a database.
*/
public int getResourceManagerPreFetchIncrement();

}
```

Access intent exceptions

The exceptions thrown in response to the application of access intent policies are listed.

com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException

If the method that drives the ejbLoad() method is configured to be read-only but updates are then made within the transaction that loaded the bean's state, an exception is thrown during invocation of the ejbStore() method, and the transaction is rolled back. Likewise, the ejbRemove() method cannot succeed in a transaction that is set as read-only. If an update hint is applied to methods of

entity beans with bean-managed persistence, the same behavior and exception results. The forwarded exception object contains the message string `PMGR1103E: update instance level read only bean beanName`

This exception is also thrown if the applied access intent policy cannot be honored because a finder, ejbSelect, or container-managed relationship (CMR) accessor method returns an inherently read-only result. The forwarded exception object contains the message string `PMGR1001: No such DataAccessSpec - methodName`

The most common occurrence of this error is when a custom finder that contains a read-only EJB Query Language (EJB QL) statement is called with an applied access intent of `wsPessimisticUpdate` or `wsPessimisticUpdate-Exclusive`. These policies require the use of a USE AND KEEP UPDATE LOCKS clause on the SQL SELECT statement to be executed, but a read-only query cannot support USE AND KEEP UPDATE LOCKS. Other examples of read-only queries include joins; the use of ORDER BY, GROUP BY, and DISTINCT keywords.

To eliminate the exception, edit the EJB query so that it does not return an inherently read-only result or change the access intent policy being applied.

- If an update access is required, change the applied access intent setting to `wsPessimisticUpdate-WeakestLockAtLoad` or `wsOptimisticUpdate`.
- If update access is not truly required, use `wsPessimisticRead` or `wsOptimisticRead`.
- If connection sharing between entity beans is required, use `wsPessimisticUpdate-WeakestLockAtLoad` or `wsPessimisticRead`.

com.ibm.websphere.ejb.container.CollectionCannotBeFurtherAccessed

If a lazy collection is driven after it is no longer in scope, and beyond what has already been locally buffered, a CollectionCannotBeFurtherAccessed exception is thrown.

com.ibm.ws.exception.RuntimeWarning

If an application is configured incorrectly, a run-time warning exception is thrown as the application starts; startup is ended. You can validate an application's configuration by choosing the verify function. Some examples of misconfiguration include:

- A method configured with two different access intent policies
- A method configured with an undefined access intent policy

Access intent troubleshooting tips

The following frequently asked questions involving access intent are answered.

Oracle database fails when no access policies are applied

No access intent policies have been applied and the application runs with a DB2 database, but it fails with an Oracle database with the following message:

```
com.ibm.ws.ejbpersistence.utilpm.PersistenceManagerException: PMGR1001E: No such DataAccessSpec
:FindAllCustomers. The backend datastore does not support the SQLStatement needed by this
AccessIntent: (pessimistic update-weakestLockAtLoad)(collections: transaction/25) (resource
manager prefetch: 0) (AccessIntentImpl@d23690a).
```

If you have not configured access intent, all of your data is accessed under the default access intent policy (`wsPessimisticUpdate-WeakestLockAtLoad`). On DB2 the weakest lock is share. On Oracle databases, however, the weakest lock is update; this means that the SQL query must contain a FOR UPDATE clause. To avoid this problem, try to apply an access intent policy that supports optimistic concurrency.

Calling a finder method displays an InconsistentAccessIntentException at run time

This can occur when you use method-level access intent policies to apply more control over how a bean instance is loaded. This exception indicates that the entity bean was previously loaded in the same transaction. This could happen if you called a multifinder method that returned the bean instance with

access intent policy X applied; you are now trying to load the second bean again by calling its findByPrimaryKey method with access intent Y applied. Both methods must have the same access intent policy applied.

Likewise, if the entity was loaded once in the transaction using an access intent policy configured on a finder, you might have called a container-managed relationship (CMR) accessor method that returned the entity bean configured to load using that entity's default access intent.

To avoid this problem, ensure that your code does not load the same bean instance twice within the same transaction with different access intent policies applied. Avoid the use of method-level access intent unless absolutely necessary.

An InconsistentAccessIntentException displays in a container-managed relationship with two beans

There are two beans in a container-managed relationship. The findByPrimaryKey method is called on the first bean and then the getBean2 method is called and a CMR accessor method is called, on the returned instance and an InconsistentAccessIntentException displays.

You are probably using read-ahead. When you loaded the first bean, you caused the second bean to be loaded under the access intent policy applied to the finder method for the first bean. However, you have configured your CMR accessor method from the first bean to the second with a different access intent policy. CMR accessor methods are really finder methods in disguise; the run-time environment behaves as if you were trying to change the access intent for an instance you have already read from persistent store.

To avoid this problem, beans configured in a read-ahead hint are all driven to load with the same access intent policy as the bean to which the read-ahead hint is applied.

A bean with a one-to-many relationship to a second bean displays an UpdateCannotProceedWithIntegrityException error when an instance of the second bean is added to the first bean's collection

A bean with a one-to-many relationship to a second bean displays an UpdateCannotProceedWithIntegrityException error when an instance of the second bean is added to the first bean's collection. The first bean has a pessimistic-update intent policy applied.

The second bean probably has a read intent policy applied. When you add the second bean to the first bean's collection, you are not updating the first bean's state, you are implicitly modifying the second bean's state. The second bean contains a foreign key to the first bean, which is modified.

To avoid this problem, ensure that both ends of the relationship have an update intent policy applied if you expect to change the relationship at run time.

Assembling EJB modules

An enterprise bean is a Java component that can be combined with other resources to create Java Platform Enterprise Edition (Java EE) applications. This topic describes assembling Enterprise JavaBeans (EJB) modules based on the EJB specifications.

Before you begin

This topic assumes that you have created and unit tested an enterprise bean file that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB module to contain enterprise beans and related code artifacts. Group Web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a standalone application or combine it with other modules into an enterprise application.

Use an assembly tool to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file).
- Create a new EJB module.
- Copy code artifacts, such as entity beans, from one EJB module into a new EJB module.

For information on assembling EJB modules, refer to the online documentation or the information center for your assembly tool. The Rational Application Developer product provides supported assembly tools.

- "Assembling EJB 2.x modules"
- "Assembling EJB 3.0 modules" on page 209

What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

Assembling EJB 2.x modules

An enterprise bean is a Java component that can be combined with other resources to create Java EE applications. This topic describes assembling Enterprise JavaBeans (EJB) modules based on the EJB 2.x and earlier specifications.

Before you begin

This topic assumes that you have created and unit tested an enterprise bean (EJB file) that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB module to contain enterprise beans and related code artifacts. Group Web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a standalone application or combine it with other modules into an enterprise application.

Use an assembly tool to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file).
- Create a new EJB module.
- Copy code artifacts (such as entity beans) from one EJB module into a new EJB module.

For information on assembling EJB modules, refer to the online documentation or the information center for your assembly tool at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html.

Results

An EJB module is migrated or created, reflecting the Java EE structure that specifies the location of enterprise bean content files, class files, class paths, the deployment descriptor, and supporting metadata. For more information on the location of the content see the assembly tool information center.

What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

Assembling EJB 3.0 modules

An enterprise bean is a managed Java component that can be combined with other resources to create Java Enterprise Edition (Java EE) applications.

Before you begin

This topic assumes that you have created and unit tested an enterprise bean (EJB file) that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB 3.0 module to contain enterprise beans and related code artifacts. Group Web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a standalone application or combine it with other modules into an enterprise application.

To learn about how to assemble an EJB 3.0 module with an assembly tool see the assembly tool information center.

Rational Application Developer can be extended with additional plug-ins to provide development support specifically for Java Persistence API (JPA).

See the Eclipse open source project, Dali, for a plug-in that provides this extension. See the related links in this topic for the Dali JPA tools Web site.

Note: Issues and problems using this plug-in need to resolved through the Eclipse open source community.

What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

Defining container transactions for EJB modules

Container transaction properties specify how an Enterprise JavaBeans (EJB) container is to manage transaction scopes for the enterprise bean's method invocations.

About this task

A transaction attribute is mapped to one or more methods. Some container transaction settings are not available for all enterprise beans. Also, some methods are not available for particular transaction settings and beans. These rules have been implemented in the Add Container Transaction wizard based on the EJB specification.

To complete this task see the topic, Defining container transactions for EJB modules, in the assembly tool information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

References

References are logical names used to locate external resources for enterprise applications. References are defined in the application’s deployment descriptor file. At deployment, the references are bound to the physical location (global JNDI name) of the resource in the target operational environment.

This product supports the following types of references:
- An EJB reference is a logical name used to locate the home interface of an enterprise bean.
- A resource reference is a logical name used to locate a connection factory object.

These objects define connections to external resources such as databases and messaging systems. The container makes references available in a JNDI naming subcontext. By convention, references are organized as follows:
- EJB references are made available in the java:comp/env/ejb subcontext.
- Resource references are made available as follows:
  - JDBC data source references are declared in the java:comp/env/jdbc subcontext.
  - JMS connection factories are declared in the java:comp/env/jms subcontext.

– Mail connection factories are declared in the java:comp/env/mail subcontext.
– URL connection factories are declared in the java:comp/env/url subcontext.

EJB references

Use this page to view and modify the Enterprise JavaBeans (EJB) references to the enterprise beans. References are logical names used to locate external resources for enterprise applications. References are defined in the application's deployment descriptor file. At deployment, the references are bound to the physical location (global Java Naming and Directory Interface (JNDI) name) of the resource in the target operational environment.

If your application defines EJB references, for **Map EJB references to beans**, specify JNDI names for enterprise beans that represent the logical names that are specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking Finish in the Summary panel.

If the EJB reference is from an EJB 3.0, Web 2.4, or Web 2.5 module, the JNDI name is optional. If the **Allow EJB reference targets to resolved automatically** option is enabled, the JNDI name is optional for all modules. The runtime provides a container default or automatically resolves the EJB reference if a binding is not provided.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → **application_name** → **EJB references**.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

Module

Specifies the name of the Enterprise JavaBeans module used by your application.

EJB

Specifies the name of an enterprise bean that is contained by the module.

URI

Specifies location of the module relative to the root of the application EAR file.

Resource Reference

Specifies the name of the EJB reference that is used in the enterprise bean, if applicable, and declared in the deployment descriptor of the application module.

Class

Specifies the name of a Java class associated with this enterprise bean.

Target Resource JNDI Name

Specifies the JNDI name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Data type String

EJB JNDI names for beans

Use this page to view and modify the Java Naming and Directory Interface (JNDI) names of non-message-driven enterprise beans in your application or module.

If your application uses EJB 2.1 and earlier modules, on the Provide JNDI names for beans panel, specify a JNDI name for each enterprise bean in every EJB 2.1 and earlier module. You must specify a JNDI name for every EJB 2.1 and earlier enterprise bean defined in the application. For example, for the EJB module MyBean.jar, specify MyBean.

The JNDI name for an EJB module can be used for both EJB 3.0 modules and pre-EJB 3.0 modules. For a pre-EJB 3.0 module, you need to provide a JNDI name for the bean. For an EJB 3.0 module, you have three options

- Provide no JNDI names at all
- Select the radio button to provide a JNDI name for the bean, or
- Select the radio button to provide local or remote home JNDI names.

If no JNDI name is provided, the runtime provides a default value. If JNDI name for the bean is provided, you cannot provide any JNDI name for business interface in the Provide JNDI names for business interfaces panel.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → **application** → **EJB JNDI names**.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

EJB module

Specifies the name of the Enterprise JavaBeans module used by your application.

EJB

Specifies the name of an enterprise bean that is contained by the module.

URI

The Uniform Resource Identifier (URI) specifies the location of the module archive relative to the root of the application EAR.

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Data type String

Bind EJB business

Use this administrative console panel to specify Java Naming and Directory (JNDI) name bindings for each enterprise bean with a business interface in an EJB module. Each enterprise bean with a business interface in an EJB module must be bound to a JNDI name. For any business interface that does not provide a JNDI name, or if its bean does not provide a JNDI name, a default binding name is provided. If its bean provides a JNDI name, the default JNDI name for the business interface is provided on top of its bean JNDI name by appending the package-qualifed class name of the interface.

If you specify the JNDI name for a bean in the Provide JNDI names for beans panel, do not specify any business interface JNDI name in this panel for the same bean . If you do not specify the JNDI name for a bean in the Provide JNDI names for beans panel, you can optionally specify a business interface JNDI name. If you do not specify a business interface JNDI name, the runtime provides a container default.

To view this panel in the application installation wizard, click **Applications** → **New applications** → **New Enterprise Application** → **application_path** → **Next** → **Detailed - Show all installation options and parameters** → **Next** → **Step: Bind EJB business**.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

EJB module
Specifies the EJB module that contains the enterprise beans that bind to the JNDI name.

EJB
Specifies the enterprise bean that binds to the JNDI name.

URI
The Uniform Resource Identifier (URI) specifies the location of the module archive relative to the root of the application EAR.

Business interface
Specifies the enterprise bean business interface in an EJB module.

JNDI name
Specifies the JNDI name associated with the enterprise bean business interface in an EJB module.

Sequence grouping for container-managed persistence

After assembling an Enterprise JavaBeans (EJB) module that contains container-managed persistence (CMP) beans, you can prevent certain types of database-related exceptions from occurring during application run time. Using *sequence grouping*, you can specify the order in which entity beans update relational database tables.

Note: Entity beans are not supported in EJB 3.0 modules.

Eliminate exceptions resulting from referential integrity (RI) violations

Sequence grouping is particularly useful for preventing violations of database *referential integrity* (RI). A database RI policy prescribes rules for how data is written to and deleted from the database tables to maintain relational consistency. Run-time requirements for managing bean persistence, however, can cause an EJB application to violate RI rules, which can cause database exceptions. These run-time requirements mandate that:

- Entity bean create and remove operations correlate to the database immediately upon method invocation.
- Entity bean changes are cached by the EJB container until either a finder method is called, or the transaction ends.

Consequently, the order in which entity beans update the database is unpredictable. That randomness translates into high risk of the application violating database RI. Although caching the operations for batch processing overrides these run-time requirements, it does not guarantee a bean persistence sequence that follows any given RI policy.

The only way to guarantee a persistence sequence that honors database RI is to designate the sequence, which you do in the EJB deployment descriptor editor of the assembly tool. Through the sequence grouping feature, you assign beans to CMP groups. Within each group you specify the order in which the persistence manager inserts bean data into the database to accomplish updates without violating RI.

See the “Setting the run time for CMP sequence groups” topic for detailed instructions on designating sequence groups. Consult your database administrator about the RI policy with which you need to synchronize.

Minimize exception risk for optimistic concurrency control schemes

Sequence grouping can also reduce the risk of transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. In these concurrency control schemes, database locks are held for minimal amounts of time so that a maximum number of transactions consistently have access to the data. The relatively unrestricted state of the database can lead to transaction rollback exceptions for two common reasons:

- When concurrent transactions attempt to lock the same table row, database deadlock occurs.
- Transactions can occur in an order that violates application logic.

Use the sequence grouping feature to order bean persistence so that these scenarios are less likely to occur.

Setting the run time for CMP sequence groups

By designating container managed persistence (CMP) sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your Enterprise JavaBeans (EJB) application. Within each group you need to specify the order in which the beans update your relational database tables.

Before you begin

When you define a sequence group, you designate it as one of two types:

- RI_INSERT, for setting a bean persistence sequence to prevent database referential integrity (RI) violations
- UPDATE_LOCK, for setting a bean persistence sequence to minimize exceptions resulting from optimistic concurrency control

About this task

Both types of sequence groups must be created after you have assembled the beans into an EJB module, prior to installing your application on the product. If you need to edit sequence groups, you must uninstall the application, make your changes using the following steps as a guide, and then reinstall your application.

Note: If you already selected or plan to use top-down mapping for mapping your enterprise beans to back end data, you do not need to create a sequence group with an RI_INSERT type. The product does not generate an RI policy for the database schema that it creates when you select top-down mapping.

To learn how to complete this task see the assembly tool information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

What to do next

You are now ready to deploy your EJB module or combine it with other modules into a J2EE application.

Deploying EJB modules

When you deploy an Enterprise JavaBeans (EJB) module, you install that module on a server that has been configured to support deployed modules.

Before you begin

Assemble one or more EJB modules, assemble one or more Web modules, and assemble them into a J2EE application.

Assemble one or more EJB 3.0 modules, assemble one or more Web modules, and assemble them into a J2EE application.

For an overview about the changes to the EJB deployment model for EJB 3.0, see the topic ″EJB 3.0 deployment overview.″

1. Prepare the deployment environment.
2. Update the configuration for each EJB module as needed for the deployment environment.
3. Deploy the application.

What to do next

If you specify that the EJBDeploy tool be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input Java archive (JAR) or enterprise archive (EAR) file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module.

EJB 3.0 deployment overview

Learn about the Enterprise JavaBeans (EJB) 3.0 deployment model, including to *Just-In-Time* (JIT) deployment.

All Java Platform, Enterprise Edition (Java EE) application server products have some form of EJB deployment phase where your application is customized to run in that particular application server implementation. Typically, this is accomplished by an application server-specific deployment tool, which generates code to bridge your EJB interface and implementation code to the application server's EJB container implementation. Some application server products' deploy tools alter the bytecodes of your application classes rather than using code generation, but the end result is similar.

In WebSphere Application Server, the bridging is accomplished by generating code that *wraps* your EJB implementation classes, connecting them to the product EJB container, which in turn allows the EJB container to host your enterprise beans and provide services to them. If one or more of your enterprise beans has defined remote interfaces, additional code is generated to provide the remote function.

Historically, EJB deployment in the WebSphere product has been performed by the *EJBDeploy* tool that is included with product and packaged with WebSphere product-oriented development tools.

The EJBDeploy tool introspects your EJB external interfaces, generates the wrapper code as .java files, then compiles it using the javac compiler to produce .class files, which are then packaged in your EJB module with your application code. The EJBDeploy tool also runs the rmic tool against the remote EJB interfaces in the application, producing additional *stub* and *tie* class files that interact with the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Object Request Broker (ORB), providing

remote object support. Typically, you run the EJBDeploy tool either when you install the application on the product or sometime before you install the application from the command-line tool or within a development tool.

Just-In-Time deployment

The EJB 3.0 support in WebSphere Application Server adds a new feature called Just-In-Time Deployment. With Just-In-Time Deployment, the EJB container dynamically generates the wrapper, stub, and tie classes in-memory as needed when the application is running. Additionally, the Web container and application client containers dynamically generate the stub class required for remote EJB invocations. Effectively, this means that you do not need to process EJB 3.0 modules, Web modules that invoke EJB 3.0 beans, or client modules that invoke EJB 3.0 beans, through the EJBDeploy tool prior to running them in WebSphere.

createEJBStubs tool

Even though the Just-In-Time Deployment feature, in many cases, dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB interfaces, there remain some cases where these stub classes are not dynamically generated. For EJB 3.0 clients not running inside a Web container, EJB container, or client container, that is upgraded to EJB 3.0 level, you must generate the stub classes with the createEJBStubs tool, then make the generated stubs available in the client environment's classpath. Typically you would accomplish this by copying the generated stubs to the location where the client's business interface class resides.

To summarize, the createEJBStubs tool must be used to generate client-side stubs for the following environments:

- ″Bare″ Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- WebSphere Application Server container environments prior to Version 7 that do not have the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

For more information about packaging your EJB module, see the topic, ″EJB 3.0 module packaging overview.″

EJBDEPLOY relationships – troubleshooting tips

Use this information to troubleshoot information for EJBDEPLOY problems.

DB2 for z/OS Version 7.x

Problems might exist when EJBDeploy creates a data relationship in DB2 for z/OS Version 7.x. EJBDeploy creates a table with a composite of the two primary keys of the EJBs that are related to each other. If the composite keys are larger than 254 characters, DB2 for z/OS V7.x does not accept this relationship and the following error can occur:

```
DSNT408I SQLCODE = -613, ERROR:  THE PRIMARY KEY OR A UNIQUE CONSTRAINT
IS TOO LONG OR HAS TOO MANY COLUMNS
DSNT418I SQLSTATE   = 54008 SQLSTATE RETURN CODE
```

This problem can be seen when the primary keys that are created for the two related beans have primary keys that are strings. This results in the composite being made up of 2 varchar(250) primary keys for a total of 500, which is greater than 254 maximum in DB2 for z/OS version 7.x.

Things to consider when utilizing top-down mappings to ensure you do not experience this problem:

- Top-down mappings are a guideline and must be reviewed with the DBA.

- Schemas that are created top-down by EJBDeploy are designed only for testing, and as a guideline for the actual schema required. The use of the meet-in-the-middle mapping does not present this problem.
- The composite key constraint problem is not experienced when using DB2 V8, which has 2K maximum key lengths.

EJBDEPLOY_JVM_OPTIONS

Set the `EJBDEPLOY_JVM_OPTIONS` property to override Java virtual machine (JVM) options that are passed to the code that deploys Enterprise JavaBeans (EJBs) (ejbdeploy.sh). Set this property in one of the following locations: *deploymentmanager*/bin/setupCmdLine.sh or *appServerHome*/bin/setupCmdLine.sh

For example, the following command increases the heap size of the JVM for ejbdeploy.sh:

```
export EJBDEPLOY_JVM_OPTIONS="-Xms128m -Xmx512m"
```

The converter that is defined for the primary key is not invoked on its foreign key value

The mapping for primary key fields to database columns may use a converter to transform the key values. If a container-managed persistence (CMP) bean uses a converter to map its primary key, and that bean has a relationship where the bean at the other end holds a foreign key, the mapping for the foreign key will not use the converter.

The following errors might occur, indicating that the converter defined for the primary key is not invoked on its foreign key value. During the run of the ejbDeploy command , you receive the following message:

```
No type mapping defined for Java datatype1 to Database datatype2
```

During run time, the application does not find the CMP bean at the other end of the relationship.

To work around this limitation, define your own foreign key in the database table, and create a mapping that uses the same converter as defined for the primary key on the enterprise beans at the other end of its relationship.

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications** → **Application Types** → **WebSphere enterprise applications** → **application_name** → **Manage Modules** → **module_name**.

Note: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

URI

Specifies location of the module relative to the root of the application EAR file. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate deployment descriptor

Specifies an alternate deployment descriptor for the module as defined in the application deployment descriptor according to the J2EE specification.

Starting weight

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

Data type	Integer
Default	5000
Range	Greater than 0

Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)

The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

About this task

The Java Persistence API (JPA) represents a simplification of the persistence programming model. JPA functions within the Java EE specification for Enterprise Java Beans (EJB) 3.0 requirements, managing persistence and object/relational mapping. The JPA specification defines the object/relational mapping within its own guidelines instead of relying on vendor-specific mapping implementations. These features make applications that use JPA easier to implement and manage.

In a nutshell, JPA combines the best features from previous persistence mechanisms such as Java Database Connectivity (JDBC) APIs, Object Relational Mapping (ORM) frameworks, and Java Data Objects (JDO). Creating entities under JPA is as simple as Plain Old Java Objects (POJOs). JPA supports the features provided by JDBC without requiring the knowledge of the specific programming models defined by the various JDBC implementations. Like object-relational software and object databases, JPA allows the use of advanced object-oriented concepts such as inheritance. JPA avoids vendor lock-in because it does not rely on a strict specification like JDO and EJB 2.x entities.

The JPA implementation does not mandate that you migrate existing applications. Existing EJB 2.x Container Managed Persistence applications continue to execute without changes. JPA may not be ideal for every application, however, for many applications it provides a better alternative to other persistence implementations.

Use the topics listed below for detailed information about aspects of JPA:

What to do next

Product support for JPA

The implementation of Java Persistence API for the application server can be used on all platforms that are supported for the application server, including iSeries® and z/OS. Java Persistence API for the application server functions with all databases supported in WebSphere Application Server. In addition to these, Java Persistence API for WebSphere Application Server can support databases that are supported by the OpenJPA implementation of JPA.

Note: Databases supported by OpenJPA but not supported by the product have not been tested extensively by IBM and might contain unknown compatibility issues. For a list of supported databases, refer to the OpenJPA user guide.

Additional information

For additional information about OpenJPA, see the OpenJPA User Guide. For information about Java Persistence API specifications, see the link listed below. The information resides on both IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information. Often, the information is not specific to this product but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

- For information on the Java Persistence API specification, consult: http://java.sun.com/javaee/technologies/persistence.jsp.

Related tasks

Configuring Persistence Provider support in the application server
Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

Associating persistence units and data sources
Java Persistence API (JPA) applications allow you to specify the underlying data source used by the persistence provider to access the database.

Configuring OpenJPA caching to improve performance
The OpenJPA implementation allows users the option of storing frequently used data in the memory to improve performance. OpenJPA provides concurrent data and concurrent query caches that allow applications to save persistent object data and query results in memory to share among threads and for use in future queries.

Troubleshooting Java Persistence API (JPA) applications

Java Persistence API (JPA) Architecture

Data persistence, the ability to maintain data between application executions, is vital to enterprise applications because the required access to relational databases. Applications that are developed for this environment must manage persistence themselves or make use of third-party solutions to handle database updates and retrievals with persistence. The Java Persistence API (JPA) provides a mechanism for managing persistence and object-relational mapping and functions for the EJB 3.0 specifications.

The JPA specification defines the object-relational mapping internally, rather than relying on vendor-specific mapping implementations. JPA is based on the Java programming model that applies to Java EE environments, but JPA can function within a Java SE environment for testing application functions.

JPA represents a simplification of the persistence programming model. The JPA specification explicitly defines the object-relational mapping, rather than relying on vendor-specific mapping implementations. JPA standardizes the important task of object-relational mapping by using annotations or XML to map objects into one or more tables of a database. To further simplify the persistence programming model:

- The EntityManager API can persist, update, retrieve, or remove objects from a database

- The EntityManager API and object-relational mapping meta-data handle most of the database operations without requiring you to write JDBC or SQL code to maintain persistence
- JPA provides a query language, extending the independent EJB querying language (also known as JPQL), that you can use to retrieve objects without writing SQL queries specific to the database you are working with.

JPA is designed to operate both inside and outside of a Java Enterprise Edition (Java EE) container. When you run JPA inside a container, the applications can use the container to manage the persistence context. If there is no container to manage JPA, the application must handle the persistence context management itself. Applications that are designed for container-managed persistence do not require as much code implementation to handle persistence, but these applications cannot be used outside of a container. Applications that manage their own persistence can function in a container environment or a Java SE environment.

Elements of a JPA Persistence Provider

Java EE containers that support the EJB 3.0 programming model must support a JPA implementation, also called a persistence provider. A JPA persistence provider uses the following elements to allow for easier persistence management in an EJB 3.0 environment:

- **Persistence unit:** consists of the declarative meta-data that describes the relationship of entity class objects to a relational database. The EntityManagerFactory uses this data to create a persistence context that can be accessed through the EntityManager.
- **EntityManagerFactory:** used to create an EntityManager for database interactions. The application server containers typically supply this function, but the EntityManagerFactory is required if you are using JPA application-managed persistence.
- **Persistence context:** defines the set of active instances that the application is manipulating currently. The persistence context can be created manually or through injection.
- **EntityManager:** the resource manager that maintains the active collection of entity objects that are being used by the application. The EntityManager handles the database interaction and meta-data for object-relational mappings. An instance of an EntityManager represents a persistence context. An application in a container can obtain the EntityManager through injection into the application or by looking it up in the Java component name-space. If the application manages its persistence, the EntityManager is obtained from the EntityManagerFactory.

  Note: Injection of the EntityManager is only supported for the following artifacts:
  - EJB 3.0 session beans
  - EJB 3.0 message-driven beans
  - Servlets, Servlet Filters, and Listeners
  - JSP tag handlers which implement interfaces javax.servlet. jsp.tagext.Tag and javax.servlet.jsp.tagext.SimpleTag
  - Java Server Faces (JSF) managed beans
  - the main class of the application client.
- **Entity objects:** a simple Java class that represents a row in a database table in its simplest form. Entities objects can be concrete classes or abstract classes. They maintain states by using properties or fields.

For more information about persistence, see the section on Java Persistence API Architecture and the section on Persistence in the Apache OpenJPA User's Guide. For more information and examples on specific elements of persistence, refer to the sections on the EntityManagerFactory, and the EntityManager in the Apache OpenJPA User's Guide.

JPA for WebSphere Application Server

JPA for WebSphere Application Server is built on the Apache OpenJPA open source project.

Apache OpenJPA and JPA for WebSphere Application Server

Apache OpenJPA is a compliant implementation of the Sun Microsystems JPA specification. Using OpenJPA as a base implementation, WebSphere Application Server employs extensions to provide additional features and utilities for WebSphere Application Server customers. Because JPA for WebSphere Application Server is built from OpenJPA, all OpenJPA functionality, extensions and configurations are unaffected by the WebSphere Application Server extensions. Users running OpenJPA applications do not need to make any changes to use their applications in WebSphere Application Server.

JPA for WebSphere Application Server provides more than compatibility with OpenJPA. JPA for WebSphere Application Server contains a set of tools for application development and deployment. Other features of JPA for WebSphere Application Server include support for XML mapping, JPA Access Intent, enhanced tracing capabilities, command scripts and translated message files. The provider of JPA for WebSphere Application Server is `com.ibm.websphere.persistence.PersistenceProviderImpl`.

The properties for OpenJPA can be defined in one of two ways. You can either specify the property in the `persistence.xml` file or by using a Java virtual machine (JVM) command line argument on either client or server. See the following examples:

- Specify the OpenJPA property in the `persistence.xml` file.

```
<properties>
 <property name="openjpa.jdbc.SchemaFactory" value="native(ForeignKeys=true)" />
</properties>
```

- Specify the OpenJPA property using a JVM command line argument on the client or server.

```
-Dopenjpa.jdbc.SchemaFactory="native(ForeignKeys=true)"
```

For more information on OpenJPA properties, see Chapter 2 on Configuration and the Part 3 Reference sections in the OpenJPA users guide.

The Extension Properties of JPA for WebSphere Application Server may be specified with the openjpa or wsjpa prefix. You can mix the openjpa and wsjpa prefixes as you wish for a common set of properties. Exceptions to the rule are wsjpa specific configuration properties, which should use the wsjpa prefix only. In the event that a JPA for WebSphere Application Server specific property is used with the openjpa prefix, a warning message will be logged indicating that the offending property will be treated as a wsjpa property. The reverse does not hold true for the openjpa prefix. In that case, the offending property will merely be ignored.

Developing and packaging JPA applications for a Java EE environment

Containers in the application server can provide many of the necessary functions for the Java Persistence API (JPA) in a Java Enterprise Edition (Java EE) environment. The application server also provides JPA tools to assist you with developing applications in a Java EE environment.

About this task

JPA applications require different configuration techniques from applications that use container-managed persistence (CMP) or bean-managed persistence (BMP). They do not follow the typical deployment techniques that are associated with applications that implement CMP or BMP. In JPA applications, you must define a persistence unit and configure the appropriate properties to ensure that the applications can run in a Java EE environment.

The container supports all necessary injections to ensure that applications run in the Java EE environment. For example, the container can inject the @PersistenceUnit and @PersistenceContext for your applications.

1. Generate your entities classes. Depending upon your development model, you might use some or all of the JPA tools:
   - **Top-down mapping:** You start from scratch with the entity definitions and the object-relational mappings, and then you derive the database schemas from that data. If you use this approach, you are most likely concerned with creating the architecture of your object model and then writing your entity classes. These entity classes would eventually drive the creation of your database model. If you are using a top-down mapping of the object model to the relational model, develop the entity classes and then use OpenJPA functionality to generate the database tables that are based on the entity classes. The wsmapping tool would help with this approach.
   - **Bottom-up mapping:** You start with your data model, which are the database schemas, and then you work upwards to your entity classes. The wsreversemapping tool would help with this approach.
   - **Meet in the middle mapping:** probably the most common development model. You have a combination of the data model and the object model partially complete. Depending on the goals and requirements, you will need to negotiate the relationships to resolve any differences. Both the wsmapping tool and the wsreversemapping tool would help with this approach.

   The JPA solution for the application server provides several tools that help with developing JPA applications. Combining these tools with IBM Rational Application Developer provides a solid development environment for either Java EE or Java SE applications. Rational Application Developer includes GUI tools to insert annotations, a customized `persistence.xml` file editor, a database explorer, and other features. Another alternative is the Eclipse Dali project. More information on Rational Application Developer or the Eclipse Dali plugin can be found at their respective web sites.
2. Enhance the entity classes using the JPA enhancer tool, wsenhancer, for the application server. An enhancer is a tool that automatically adds code to your persistent classes after you have written them. The enhancer post-processes the bytecode that is generated by the Java compiler and adds the fields and methods that are necessary to implement the persistence features. To use the wsenhancer tool, type the following at a command prompt:

   ```
   ${app_server_root}/bin/wsenhancer.sh [parameters][arguments]
   ```

   Although JPA for the application server and OpenJPA can automatically enhance the entities at run time, you will obtain better performance if you can enhance your entities when you build the application. The application will not attempt to enhance entities that are already enhanced.
3. Optional: If you are not using the development model for bottom-up mapping, generate or update your database tables automatically or by using the wsmapping tool.
   - By default, the object-relational mapping does not occur automatically, but you can configure the application server to provide that mapping with the openjpa.jdbc.SynchronizeMappings property. This property can accelerate development by automatically ensuring that the database tables match the object model. To enable automatic mapping, include the following line in the `persistence.xml` file:

     ```
     <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema(ForeignKeys=true)"/>
     ```

     Note: To enable automatic object-relational mapping at run time, all of your persistent classes must be listed in the Java .class file, mapping file, and Java archive (JAR) file elements in XML format.
   - To manually update or generate your database tables, run the JPA mapping tool for the application server from the command line to create the tables in the database. For example:

     ```
     ${app_server_root}/bin/wsmapping.sh [parameters][arguments]
     ```
4. Optional: If you are using DB2 and want to use static SQL, run the wsdb2gen command. In order to use the wsdb2gen tool, pureQuery runtime must be installed. The wsdb2gen tool creates *persistence_unit_name*.pdqxml file under the same META-INF directory where your `persistence.xml` file is located. If you have multiple persistence units, wsdb2gen command must be run for each persistence unit. To use the wsdb2gen tool, type the following at a command prompt:

   ```
   ${app_server_root}/bin/wsdb2gen.sh [parameters]
   ```
5. Configure these properties.

a. Specify the configuration options for your database. The application server manages access to data sources. You can configure the data sources, connection pooling, and JTA transaction service in the administrative console. If you have a specific data source for your application, configure the data source before you install your JPA application.
   1) Configure your data sources through the administrative console. See the topic on configuring the JDBC provider and data source for more information.
   2) Specify the Java Naming and Directory Interface (JNDI) names for the <jta-data-source> and <non-jta-data-source> elements. If you use the component name space method for data source retrieval, ensure that your application defines these resource references so that you can use these JNDI names to access the data source. This configuration provides more flexibility if you need to alter the configuration for the data source. For more information on using the JNDI interface, refer to the topic on developing applications that use JNDI. For example, the `persistence.xml` file would have a entry like the following:

      ```
      <jta-data-source>java:comp/env/jdbc/FooBarDataSourceJNDI</jta-data-source>
      ```

b. If you are using pureQuery, configure your data source to use pureQuery. Ensure the `pdq.jar` and `pdqmgmt.jar` files are included on the JDBC provider class path. The JPA provider implementation must be the IBM implementation of JPA provider of `com.ibm.websphere.persistence.PersistenceProviderImpl`. The OpenJPA persistence provider does not provide support for pureQuery. For more information, refer to the topic configuring a data source to use pureQuery.

6. Package the application. There are several packaging options for an application that uses JPA in a Java EE environment. Choose the packaging option that best suits the JPA usage and configuration within the modules of your application. These are some of the most common packaging options. For a definitive list of packaging options, see the Java Persistence API specification.

   Note: If you are using pureQuery, add the *persistence_unit_name*`.pdqxml` files created previous or the or *persistence_unit_name*`.pdqxml` files created in the above Step 4 to the JPA application JAR file. The files are located in same META-INF directory where your `persistence.xml` file is located.

   - For a standalone EJB module or a standalone application client module, package the EJB and application client modules in a standard JAR file. Ensure that you package the application with these conditions:
     – The JAR file must contain your EJB class files or the Java class files for the application client.
     – The META-INF directory of the archive must include your `persistence.xml` file.
     – If your application uses mapping files, orm.xml, or a custom mapping file, the JAR file must contain those files as well. If the location of the orm.xml file is not specified in the persistence unit, the default location is the META-INF directory of the JAR file.
   - For a standalone web module, package the application in a standard Web Application archive (WAR). Ensure that you package the application with these conditions:
     – The WAR file must contain your web application class files. The web application class files must be included in the WEB-INF/classes directory or in a JAR file that is located in the WEB-INF/lib directory of the WAR file.
     – Your `persistence.xml` file must be included in the WEB-INF/classes/META-INF directory or in the META-INF directory of a JAR file that is included in your WEB-INF/lib directory of your WAR file.
     – If your application uses mapping files, orm.xml, or a custom mapping file, the WAR file must also contain those files. Mapping files can reside in the WEB-INF/classes directory or in a JAR file that is contained within the WEB-INF/lib directory of the WAR file. Use the <mapping-file> element of the `persistence.xml` file to specify the location of mapping files. For example:

       ```
       <mapping-file>META-INF/JPAorm.xml</mapping-file>
       ```

- For enterprise application that contains one or more modules, package the application in a standard Enterprise Application archive (EAR). An enterprise application can contain one ore more EJB module, web module, or application client module. Ensure that you package the application with these conditions:
  - If multiple modules use the same persistence unit, you can create a persistence archive and package the persistence archive within your EAR file.
  - Include your entity classes, any necessary supporting classes, your `persistence.xml` file, and additional mapping files in the persistence archive file. Follow the packaging rules for EJB and application client modules for the location of your `persistence.xml` file and mapping files.
  - Each module that uses the persistence archive must have a class path entry in its META-INF/MANIFEST.MF file. Here is an example manifest file:

    ```
    Manifest-Version: 1.0
    Class-Path: MyJPAEntities.jar
    ```

  - If your modules use separate persistence units and share entity classes, you can package the entity classes in a persistence archive and specify different `persistence.xml` file and mapping files for each module. If the modules do not share entity classes or a persistence configuration, package each module as a standalone EJB module, a standalone application client module, or a standalone web archive and then package them in the EAR file.

Example

This is a sample `persistence.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" version="1.0"
             xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd">

    <persistence-unit name="TheWildZooPU" transaction-type="JTA">
        <jta-data-source>jdbc/FooBarDataSourceJNDI</jta-data-source>
        <!-- additional Mapping file, in addition to orm.xml>
        <mapping-file>META-INF/JPAorm.xml</mapping-file>

        <class>com.company.bean.jpa.PersistebleObjectImpl</class>
        <class>com.company.bean.jpa.Animal</class>
        <class>com.company.bean.jpa.Dog</class>
        <class>com.company.bean.jpa.Cat</class>

        <exclude-unlisted-classes>true</exclude-unlisted-classes>

        <properties>
           <property name="openjpa.ConnectionFactoryProperties" value="PrettyPrint=true, PrettyPrintLineLength=72"/>
           <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema(ForeignKeys=true)"/>
        </properties>

     </persistence-unit>
</persistence>
```

What to do next

For more information on any of the commands, classes or other OpenJPA information discussed here, refer to the Apache OpenJPA User's Guide.

Related tasks

"Mapping persistent properties to XML columns" on page 242
If your database supports Extensible Markup Language (XML) column types, you can use mapping tools to manage XML objects. The Java Persistence API (JPA) specification does not contain support for mapping XML columns to Java objects. You have the choice of mapping XML columns to a Java string or a Java byte array field. These mapping techniques make using the XML objects as strings or byte arrays difficult. JPA for the application server allows you to simplify the management of XML objects by using a third-party solution for mapping management.

Associating persistence units and data sources
Java Persistence API (JPA) applications allow you to specify the underlying data source used by the persistence provider to access the database.

Configuring a JDBC provider and data source
For access to relational databases, applications use the JDBC drivers and data sources that you configure for the application server.

"Developing applications that use JNDI" on page 1414
References to enterprise bean (EJB) homes and other artifacts such as data sources are bound to the WebSphere Application Server name space. These objects can be obtained through Java Naming and Directory Interface (JNDI). Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the name space.

Task overview: Data Studio pureQuery
Data Studio pureQuery provides Java Persistence API (JPA) users an alternative way to access a DB2 database. PureQuery supports static Structured Query Language (SQL).

Configuring to use pureQuery in a Java EE environment
Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

Configuring pureQuery to use multiple package collections
Set up a pureQuery Java Persistence API (JPA) application to use multiple DB2 package collections.

wsjpaversion command
Use this command line tool to find out information about the installed version of Java Persistence API (JPA) for WebSphere Application Server.

wsappid command

The Java Persistence API (JPA) specification allows an entity's primary key to be made up of more than one column. In this case, the primary key is referred to as a ″composite″ or ″compound″ primary key. You need to provide an ID class, which is specified by the @IdClass annotation, in order to manage a composite primary key. Use the identity tool for JPA to generate an ID class for entities that use composite primary keys.

Syntax

```
Before running the command, you must have a copy of persistence.xml on the classpath,
or specify it as a properties file through the -p [path_to_persistence.xml]
argument. Issue the command from the bin subdirectory of the app_install_root directory.
```

The command syntax is as follows:

```
wsappid.sh [parameters][arguments]
```

Parameters

The wsappid tool accepts the standard set of command-line arguments that are defined by the configuration framework along with the following:

- **-directory/-d** *<output_directory>*: The path to the output directory. If the directory does not match the generated output ID class package, the package structure will be created beneath the directory. If this

parameter is not specified, the wsappid tool will attempt to find the directory of the .java file for the class that is capable of persistence, and the wsappid tool uses the current directory if a .java file is not found.
- **-ignoreErrors/-i** <true/t | false/f>: If this parameter is set to false, an exception is thrown if the tool is run on any class that does not use the application identity or is not the base class in the inheritance hierarchy.
- **-token/-t** *<token>*: The token that is used to separate the values of stringed primary keys in the string form of the object ID. This option can be used only if there are multiple primary key fields. The default is ″**::**″.
- **-name/-n** *<id_class_name>*: The name of the identity class to generate. If this option is specified, the wsappid tool must be run on exactly one class. If the class meta-data already names an ID class for the object, this option will be ignored. If the name is not fully qualified, the package of the persistence class is appended to form the fully qualified name.
- **suffix** *<id_class_suffix>*: A string with which to suffix each persistent class name to form the identity class name. This option is overridden by the **-name/-n** parameter or by any object ID class that is specified in the meta-data.

Each additional argument to the wsappid tool must be one of the following:
- The full name of a persistent class.
- The `.java` name for a persistent class.
- The `.class` file of a persistent class.

Usage

The identity tool used with JPA for application server simplifies the task of creating an identity class for entities that use composite IDs. A composite ID refers to an identity that uses more than one field as its primary key. The entity class must be compiled, and primary keys need to be identified in the entity class. Run the wsappid tool from the command line in the *app_install_root*/bin/ directory. When you run this command, a new class representing the composite ID of the entity is generated. Messages and errors are logged to the console as specified.

Examples

Consider the following entity :

```
@Entity
public class Employee {

@Id
private int division;

@Id private int id;
// . . .
}
```

Before the entity can be used we need an ID class. For this example, assume that the entity is found in the src/main/java directory.

To generate an ID class for the Magazine entity run:

```
wsappid.sh -s Id src/main/java/Employee.java -d src/main/java
```

A new class, EmployeeId.java, will be generated in the src/main/java directory.

Additional information

You can refer to the Application identity tool in persistence classes in the Apache OpenJPA User's Guide.

wsenhancer command

The entity enhancer tool for Java Persistence API (JPA) applications in the application server inserts bytecode into an entity class file that allows the JPA provider to manage the state of an entity.

JPA with the application server requires that all entity classes be enhanced if you want to manage their state. In a container-managed environment, automated enhancement is provided by the containers. In a Java SE environment, though, there are no containers to manage persistence and you might use this command frequently before packaging application files for testing. After you have created the JPA entities, you can run the wsenhancer tool to inject bytecode into the entities before packaging the JAR file into the EAR file for the application.

Syntax

Before running the command, you must have a copy of persistence.xml on the classpath, or specify it as a properties file through the -p [*path_to_persistence.xml*] argument. Issue the command from the bin subdirectory of the *app_install_root* directory.

The command syntax is as follows:

```
wsenhancer.sh [parameters][arguments]
```

Parameters

The enhancer accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-directory/-d** *<output directory>*: specifies the path to the output directory. If the directory does not match the enhanced class's package, the package structure will be created beneath the directory. By default, the enhancer overwrites the original .class file.
- **-enforcePropertyRestrictions/-epr** <true/t | false/f>: specifies whether to generate an exception when it appears that a property access entity is not obeying the restrictions that are placed on property access. The default is set to false.
- **-addDefaultConstructor/-adc** <true/t | false/f>: specifies that all of the persistent classes define a no-argument constructor. This flag informs the enhancer if it should add a protected no-arg constructor to any persistent classes in which the constructor is not already present.
- **-tmpClassLoader/-tcl** <true/t | false/f>: specifies whether the enhancer should load persistent classes with a temporary class loader. This function allows other code to load the enhanced version of the class afterwards within the same Java Virtual Machine (JVM). The default is set to true.

  Note: If you are encountering class loading problems when running the enhancer, you can set this flag to false as a debugging step.
- For class name, specify one of the following:
  - The full name of a class.
  - The `.java` name for a class.
  - The `.class` file of a class.

If you do not supply any arguments to the enhancer, it will run on the classes in your persistent class list.

Usage

In order to use the wsenhancer tool you need entities defined to JPA specifications, and the entities need to be compiled. Run the wsenhancer tool against the entities before packaging them into a JAR file. If the entities are already packaged, you must extract the entity class files, run the enhancer, and recreate the JAR file.

To enhance your entities:

- Verify that your entities are in the class path, if they are not, add them.
- Run the wsenhancer command. It is found in ${app_server_root}/bin directory.

Messages and errors are logged to the console as specified in the log settings. After invoking the wsenhancer command, your files are enhanced.

Examples

To enhance all entities on the classpath:

```
$ cd build
/home/user/myproject/build $ ${app_server_root}/bin/wsenhancer.sh
```

All entities in myproject will be enhanced.

To enhance a specific entity when you have the source files:

```
$ cd build
/home/user/myproject/build $ ${app_server_root}/bin/wsenhancer.sh Magazine.java
```

To enhance a specific entity when you have the compiled class files:

```
$ export CLASSPATH=target/classes
$ ${app_server_root}/bin/wsenhancer.sh /bin/wsenhancer.sh target/classes/jpa/example/MyEntity.class
```

The entity, Magazine.java, located in myproject will be enhanced.

Additional information

For more information about enhancement tools, refer to the section on persistent classes in the Apache OpenJPA reference documentation.

wsmapping command

The wsmapping tool is used to provide top-down mapping of the entity object model to the database relational model. You can use the wsmapping tool to create database tables.

You can use the wsmapping tool to create database tables.

Syntax

Before running the command, you must have a copy of persistence.xml on the classpath, or specify it as a properties file through the -p [*path_to_persistence.xml*] argument. Issue the command from the bin subdirectory of the *app_install_root* directory.

The command syntax is as follows:

```
wsmapping.sh [options][arguments]
```

Parameters

The mapping tool accepts the standard set of command-line arguments defined by the configuration framework with the following options:

- **-schemaAction/-sa** <add | refresh | drop | build | reflect | retain | createDB | import | export | none>: The action to execute against the schema. These options correspond to the actions of the schema tool. **Add** is the default action if none is specified. Actions can be composed in a list separated by commas.

  Note: The wsmapping tool accepts the -action/-a flag to specify the action to take on individual classes. Unless you are running wsmapping on all of your persistent types at once, or dropping a mapping, you need to use the default **add** action or the **build** action. Otherwise, you might inadvertently drop schema components that are used by classes that you are not currently running the tool against.
- **-schemaFile/-sf** <true/t | false/f>: This option can be used to write the planned schema to an XML document rather than modify the database. The XML document can then be modified, manupulated and committed to the database with the schema tool.

- **-sqlFile/-sql** <stdout | output file>: This option can be used to write the planned schema modifications to an SQL script rather than modify the database. Combine this parameter with a **schemaAction** of build to generate a script that recreates the schema for the current mappings, even if the schema already exists.
- **-dropTables/-dt** <true/t | false/f>: When this option is set to true, schema drops tables that appear to be unused during **retain** and **refresh** actions. The default is true.
- **-dropSequences/-dsq** <true/t | false/f>: If this option is set to true, schema drops sequences that are unused during **retain** and **refresh** actions. The default is true.
- **-openjpatables/-ot** <true/t | false/f>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences with names that start with OPENJPA_. Certain OpenJPA components can use these tables and sequences, such as the table schema factory. When using other actions, the openjpaTables parameter controls whether these tables can be dropped or not. The default setting is false.
- **-ignoreErrors/-i** <true/t | false/f>: If set to false, an exception is displayed if the tool encounters any database errors. The default is set to false.
- **-schemas/-s** *<schema list>*: Denotes a list of schema and table names the OpenJPA should access when running the wsschema tool. This is the equivalent to setting the openjpa.jdbc.Schemas property to run once. This parameter corresponds to the **-schemas/-s** parameter in the wsschema tool. This option is ignored if **-readSchema/-rs** is not set to true.
- **-readSchema/-rs** <true/t | false/f>: Set this option to true to read the entire existing schema when the mapping tool runs. Reading the existing schema ensures that OpenJPA does not generate any mappings that use the table, index, primary key or foreign key names that conflict with existing names.

  Note: Depending on the particular JDBC driver, selecting the **-readSchema/-rs** function can slow down the process for large schemas.
- **-primaryKeys/-pk** <true/t | false/f>: This flag determines if the primary keys can be manipulated on existing tables. The default is true.
- **-foreignKeys/fk** <true/t | false/f>: This flag determines if foreign keys can be manipulated on existing tables. The default is true. This means that to add any new foreign key to a class that has already been mapped, you must explicitly set this parameter flag to true.
- **-indexes/-ix** <true/t | false/f>: This flag determines if indexes can be manipulated on existing tables. The default is true. This means that to add any new indexes to a class that has already been mapped, you must explicitly set this parameter flag to true.
- **-sequences/-sq** <true/t | false/f>: This flag determines if sequences can be manipulated. The default is true.
- **-meta/-m** <true/t | false/f>: This flag determines whether or not a mapping applies to metadata rather than, or in addition to, standard mappings.
- The wsmapping tool accepts the **-action/-a** flag to specify the action to take on each class. Multiple actions can be composed in a list, separated by commas. The available actions are:
  - **buildSchema**: This is the default action. The **buildSchema** action makes the database schema match your existing mappings. If the provided mappings conflict with the class definitions, OpenJPA fails with an informative exception.
  - **validate**: Ensure that the mappings for the given classes are valid and that they match the schema of the database. No mappings of tables are changed as a result of this action. An exception is occurs if any mappings are invalid.

Each additional argument to the wsmapping tool must be one of the following:
- The full name of a persistent class.
- The `.java` name for a persistent class.
- The `.class` file of a persistent class.

If you do not supply any arguments to the wsmapping tool, it runs on the classes in the persistent classes list.

Usage

Before running the wsmapping tool, you need to configure the datasource information, including the URL, user, and password. It is required that the wsenhancer tool is run before the wsmapping tool to insert bytecode into the entity classes. Also, the compiled class files for your entities should be on the classpath (assume entity class files can be found in target/classes) , for example:

```
export CLASSPATH=${CLASSPATH}:target/classes

wsmapping.sh ...
```

To create tables, run the wsmapping command from the ${WAS_HOME}/bin directory. When completed, the database tables are created or updated. Messages and errors are logged to the console as specified by log settings.

wsmapping.sh . . . On Windows :

Note: By specifying the buildSchema parameter to the openjpa.jdbc.SynchronizeMappings property, the mapping tool provides the default mapping that matches with the database schema automatically. You are not required to run this mapping tool if the default mapping satisfies the necessary database schema.

Examples

To create the database tables needed for the Magazine.java file:

```
${WAS_HOME}/bin/wsmapping.sh Magazine.java
```

To drop the tables for Magazine.java:

```
C:\> %WAS_HOME%/bin/wsmapping.sh -sa dropDB Magazine.java
```

To validate the mappings for all classes on the classpath:

```
C:\> %WAS_HOME%/bin/wsmapping.sh -a validate
```

Additional information

Consult chapter 7, Mapping in the OpenJPA reference documentation for more information and examples.

wsreversemapping command

The wsreversemapping tool generates persistent class definitions and metadata from a database schema.

Syntax

Before running the command, you must have a copy of persistence.xml on the classpath, or specify it as a properties file through the -p [*path_to_persistence.xml*] argument. Issue the command from the bin subdirectory of the *app_install_root* directory.

The command syntax is as follows:

```
wsreversemapping.sh [parameters][arguments]
```

Parameters

The wsreversemapping tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-schemas/-s** *<schema and table names>*: A list of schema and table names, separated by commas, to run the reversmapping tool on if no XML schema file is supplied. Each element of the list must follow the naming conventions for the openjpa.jdbc.Schemas property. If this parameter flag is omitted, it defaults to the value of the **Schemas** property. If the **Schemas** property is not defined, then all schemas will be reverse mapped.

- **-package/-p** *<package name>*: The package name of the generated classes. If no package name is given, the generated code will not contain package declarations.
- **-directory/-d** *<output directory>*: All generated code and metadata will be written to the directory at this path. If the path does not match the package of a class, the package structure will be created beneath this directory. This parameter defaults to the current directory.
- **-useSchemaName/-sn** <true/t | false/f>: Set this parameter flag to true to include the schema as well as the table name in the name of each generated class. This can be useful when dealing with multiple schemas that have tables with identical names.
- **-useForeignKeyName/-fkn** <true/t | false/f>: Set this parameter flag to true if you want the field names for relations to be based on the database foreign key name. By default, relation field names are derived from the name of the related class.
- **-nullableAsObject/-no** <true/t | false/f>: By default, all non-foreign key columns are mapped to primitives. Set this parameter flag to true to generate primitive wrapper fields instead for columns that allow null values.
- **-blobAsObject/-bo** <true/t | false/f>: By default, all binary columns are mapped to the byte[] fields. Set this parameter flag to true to map them to Object fields instead.

  Note: When mapped this way, the column is presumed to contain a serialized Java object.
- **-primaryKeyOnJoin/pkj** <true/t | false/f>: The standard reverse mapping tool behavior is to map all tables with primary keys to persistent classes. If your schema has primary keys on many join tables as well, set this flag to true to avoid creating classes for those tables.
- **-inverseRelations/-ir** <true/t | false/f>: Set this parameter flag to false to prevent the creation of inverse one-to-many/one-to-one relations for every many-to-one/one-to-one relation detected.
- **-useDatastoreIdentity/-ds** <true/t | false/f>: Set to true to use datastore identity for tables that have single numeric primary key columns. The tool typically uses application identity for all generated classes.
- **-useBuiltinIdentityClass/-bic** <true/t | false/f>: Set this parameter flag to false to prevent the reversemapping tool from using built-in application identity classes when possible. This will force the tool to create custom application identity classes even when there is only one primary key column.
- **-innerIdentityClasses/-inn** <true/t | false/f>: Set this parameter flag to true to have any generated application identity classed be created as static inner classes within the persistent classes. The default setting is false.
- **-identityClassSuffix/-is** *<suffix>*: Suffix to append to the class names to form application identity class names, or for inner identity classes, the inner class name. The default suffix is `Id`.
- **-typeMap/-typ** <type mapping>: A string that specifies the default Java classes to generate for each SQL type that is seen in the schema. The format is SQLTYPE1=JavaClass1, SQLTYPE2=JavaClass2. The SQL type name first looks for a customization that is based on SQLTYPE(SIZE,PRECISION), then SQLTYPE(SIZE), and then SQLTYPE. If a column with type CHAR is found, it will first look for the CHAR(50,0) type name specification, then it will look for the CHAR(50), and finally it will look for the CHAR. For example, to generate a char array for every char column whose size is exactly 50 characters, and to generate a short for every type name of INTEGER, you might specify: CHAR(50)=char[],INTEGER=short.

  Note: Various databases report different type names differently, one database type may not work for another database. Enable TRACE level logging on the MetaData channel to track which type names JPA for WebSphere Application Server is examining.
- **-customizerClass/-cc** *<class name>*: The full class name of an org.apache.openjpa.jdbc.meta.ReverseCustomizer customization plugin. If you do not specify a reverse customizer of your own, the system defaults to a PropertiesReverseCustomizer. This customizer allows you to specify simple customization options in the properties file given with the -customizerProperties flag.
  - **-customizerProperties/-cp***<properties file or resource>*: The path or resource name of a properties file to pass to the reverse customizer on initialization.
  - **-customizer/-c** *<property name> <property value>*: The given property name will be matched with the corresponding Java bean property in the specified reverse customizer, and set to the given value.

Usage

The wsreversemapping tool is used to perform reverse (bottom-up) mappings of database tables to entity source files. This is useful if developers want to generate Java files from a database for use in other JPA applications. To run this tool:

- You need to have database tables and your database connection configured.
- Run the wsreversemapping tool from the command line in the $ {WAS_HOME}/bin directory.
- The tool will generate .java files for every class along with a XML descriptor file orm.xml

The generated Java files from the wsreversemapping tool might require some editing before they can be used in an application. Also, generated files will not contain annotations. Annotations can be added manually if desired. Messages and errors are logged to the console as specified by the configuration.

Examples

Generate entities based on the information saved in the schema.xml file. Schema.xml was created by running the schema tool. The Java files are created in the **src** directory and use the package com.xyz:

```
${WAS_HOME}/bin/wsreversemapping.sh -pkg com.xyz -d ./src schema.xml
```

Generate entities based on information in a DB2 database. Entities are created in the **src** directory, and use the package com.reversemapped:

```
C:\> %WAS_HOME%/bin/wsreversemapping.bat -sa dropDB Magazine.javapkg com.reversemapped -d src
-connectionDriverName=com.ibm.db2.jcc.DB2Driver -connectionURL=jdbc:db2:localhost:50000/TEST
-connectionUser=db2User -connectionPassword=db2Password
```

Additional information

For more information, consult the mapping section in the Apache OpenJPA User's Guide.

wsschema command

The schema tool can be used to view the database schema in XML form or match an XML schema to an existing database.

Developers may find that they need the wsschema tool for its powerful functions. The wsschema tool can reflect on the current database schema, optionally translating it into an XML representation for further manipulation. Also, the schema tool can take an XML schema definition, calculate the differences between the XML and the existing database schema, and apply the necessary changes to make the databases correspond to the XML schema. The XML format used by the schema tool is abstract from the differences in SQL dialects used by different vendors. The tool also automatically adapts its SQL to meet foreign dependencies, thus the schema tool is useful as a general way to manipulate the schemas.

Syntax

The command syntax is as follows:

```
wsschema.sh [parameters][arguments]
```

Issue the command from the bin subdirectory of the *app_install_root* directory.

Parameters

The wsschema tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-ignoreErrors/-i** <true/t | false/f>: If set to false, an exception will be thrown if the tool encounters any database errors. The default is set to false.
- **-file/-f** *<stdout | output file>*: Use this option to write a SQL script for the planned schema modifications, rather than committing them to the database. When this is used in conjunction with the export or reflect

actions, the named file will be used to write the exported schema XML. If the file names a resource in the CLASSPATH, data will be written to that resource. Use stdout to write to standard output. The default setting is stdout.

- **-openjpatables/-ot** <true/t | false/f>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences whose names start with OPENJPA_. Certain OpenJPA components may use such tables and sequences, such as the table schema factory. When using other actions, openjpaTables controls whether these tables can be dropped or not. The default setting is false.
- **-dropTables/-dt** <true/t | false/f>: When this option is set to true, schema drops tables that appear to be unused during retain and refresh actions. The default is true.
- **-dropSequences/-dsq** <true/t | false/f>: If this option is set to true, schema drops sequences that appear to be unused during retain and refresh actions. The default is true.
- **-sequences/-sq** <true/t | false/f>: This flag determines if sequences may be manipulated. The default is true.
- **-indexes/-ix** <true/t | false/f>: This flag determines if indexes may be manipulated on existing tables. The default is true.
- **-primaryKeys/-pk** <true/t | false/f>: This flag determines if primary keys may be manipulated on existing tables. The default is true.
- **-foreignKeys/fk** <true/t | false/f>: This flag determines if foreign keys may be manipulated on existing tables. The default is true.
- **-record/-r** <true/t | false/f>: This flag permits or prevents writing schema changes made by the schema tool to the current schema factory. Select true to permit writing schema changes or false to prevent writing schema changes. The default is set to true.
- **-schemas/-s** <*schema list*>: Denotes a list of schema and table names the OpenJPA should access when running the schema tool. This is the equivalent to setting the openjpa.jdbc.Schemas property to run once.

Note: The schema tool accepts the **-action/-a** flag. Multiple actions may be composed in a list, separated by commas. The available actions are:

- **add**: This is the default action if no other actions are specified. It updated the schema with the given XML documents by adding tables, columns, indexes, or other components. This action never drops any schema components.
- **retain**: This action keeps all schema components in the given XML definition but drops the rest from the database. This action never adds any schema components.
- **drop**: Drops all schema components in the schema XML. This action will drop tables only if they would have 0 columns after dropping all columns listed in the XML.
- **refresh**: This action is the equivalent of the **retain** and the **add** functions.
- **build**: Generates SQL to build a schema matching the one in the supplied XML file. Unlike the**add** action, this option does not take into account the fact that part of the schema defined in the XML file may already exist in the database. This action is typically used in conjunction with the **-file/-f** parameter flag to write a SQL script. This script may be used later to recreate the schema in the XML.
- **reflect**: Generates a XML representation of the current database schema.
- **createDB**: This action generates SQL to recreate the current database. This action is typically used in conjunction with the **-file/-f** parameter flag to write a SQL script that can be used to recreate the current schema on a new database.
- **dropDB**: Generates SQL to drop the current database. Like the **createDB** action this may be used with the **-file/-f** parameter flag to script a database drop rather than manually perform it.
- **import**: Imports the given XML schema definition into the current schema factory.

  Note: This action will do nothing if the schema factory does not store a record of the schema.
- **export**: Exports the current schema factory's stored schema definition to a XML file.

  Note: This may produce an empty file if the schema factory does not store a record of the schema.
- **deleteTableContents**: This action executes SQL to delete all rows from all tables that OpenJPA finds.

Usage

The wsschema tool is used to obtain a XML file that describes the schema of your database. To generate a XML schema file:

- You need to have database tables and your database connection configured.
- Run the wsschema tool from the command line in the $ {WAS_HOME}/bin directory.
- The tool will generate a XML file that describes the database schema.

Messages and errors are logged to the console as specified by the configuration.

Examples

Add the necessary schema components to the database to match the given XML document without dropping any data:

```
$ wsschema.sh targetSchema.xml
```

Repeat the same action as the previous example, this time not changing the database but instead writing any planned changes to a SQL script:

```
 wsschema.sh -f script.sql targetSchema.xml
```

Write an SQL script that will recreate the current database:

```
$ wsschema.sh -a createDB -f script.sql
```

Refresh the schema and delete all the contents of all the tables that OpenJPA knows about:

```
$ wsschema.bat -a refresh,deleteTableContents
```

Drop the current database:

```
$ wsschema.sh -a dropDB
```

Write a XML representation of the current schema to the file *schema.xml*:

```
$ wsschema.sh -a reflect -f schema.xml
```

Additional information

For more information, refer to chapter 4 JDBC, in the OpenJPA reference documentation.

wsdb2gen command

The command allows users to utilize the pureQuery feature in Java Persistence API (JPA) applications.

Syntax

The command syntax is as follows:

```
wsdb2gen.sh [parameters]
```

Before running the command, your `persistence.xml` file must be in the META-INF directory and the META-INF directory must be in the class path.

Parameters

- **-help** : This parameter displays the help information.
- **-pu** : The name of the persistence unit defined in `persistence.xml` file.
- **-collection** : The collection-id which is assigned to package names. The default is `NULLID`.
- **-url** : The url of the target database. This is used to validate the generated SQL. A url must be specified either in the `persistence.xml` file or as a command option. If both are specified, the url specified in the command option will be used.
- **-user** : The user id

- **-pw** : The corresponding password to connect to target database. If this parameter is not specified, the value found in the `persistence.xml` file will be used.
- **-package** : If this parameter is specified, then the -**package** parameter takes the string value package name and a single DB2 package with the specified name is generated. If the -**package** parameter is not specified, then one package is generated for each entity class. The name consists of seven or fewer letters. For each entity class, the first seven characters of the entity class is used for the package name. If the first seven characters are not unique, then the package name is changed to create a unique name.

Usage

The `persistence.xml` file must be included in the application Java archive (JAR) file and is also used as input in the DB2 bind to create the DB2 package. The wsdb2gen command requires a connection to a database in order to validate generated SQL. The database does not have to be the same as the run time database, but it should be at the same version and release level.

Ensure the following JAR files are on the class path:

- pdq.jar
- pdqmgmt.jar
- db2jcc.jar
- db2jcc_licence_cu.jar.

If the database URL specifies a DB2 for zOS database, then the following JAR file must also be on the class path: db2jcc_licence_cisuz.jar

Examples

```
wsdb2gen.sh  -pu payroll -collection prod1 -url jdbc:db2://myhostname:50000/proddb  -user produser -pw secret
```

ANT Task WsJpaDB2GenTask

The ANT task `WsJpaDB2GenTask` provides an alternative to the wsdb2gen command.

The `WsJpaDB2GenTask` ANT task utility allows users to utilize the pureQuery feature in Java Persistence API (JPA) applications. Instead of executing the wsdb2gen from the command line, you can use the example code in your ANT build XML file to use the `WsJpaDB2GenTask` in your build process.

```
Both the PDQ runtime Java archive (JAR) files, pdq.jar and pdqmgmt.jar, must be specified using the ANT -lib option.
```

Example

The example listed below could be run with the ANT command using the following:

```
<!-- invoke this build using the ANT command
ant jar -noclasspath -lib c:/was7/lib/j2ee.jar
-lib c:/was7/plugins/com.ibm.ws.jpa.jar
-lib c:/sqllib/java/db2jcc.jar
-lib c:/sqllib/java/db2jcc_license_cu.jar
-lib c:/sqllib/java/pdq.jar
-lib c:/sqllib/java/pdqmgmt.jar
-->
```

When calling the ANT command, the JAR files for pureQuery, JPA, and the JDBC driver must be on the library list.

```
<?xml version="1.0"?>

<project name="sample" default="jar">

<taskdef name="enhancer" classname="org.apache.openjpa.ant.PCEnhancerTask" />
```

```
<taskdef name="wsdb2gen" classname="com.ibm.websphere.persistence.pdq.ant.WsJpaDB2GenTask" />

<target name="clean" description="remove intermediate files">
<delete dir="classes"/>
<delete dir="enhanced" />
<delete>
<fileset dir="." includes="META-INF/*.pdqxml" />
<fileset dir="." includes="sample.jar" />
</delete>
</target>

<target name="compile"
description="compile the Java source code to class files">
<mkdir dir="classes"/>
<javac srcdir="." destdir="classes">

<fileset dir="." includes="META-INF/*.xml" />
</jar>
</target>
</project>
```

Developing and packaging JPA applications for a Java SE environment

Prepare and package persistence applications to test outside of the application server container in a Java SE environment.

About this task

JPA applications require different configuration techniques from applications that use container-managed persistence (CMP) or bean-managed persistence (BMP). They do not follow the typical deployment techniques that are associated with applications that implement CMP or BMP. In JPA applications, you must define a persistence unit and configure the appropriate properties in the `persistence.xml` file to ensure that the applications can run in a Java SE environment.

There are some considerations for running JPA applications in a Java SE environment:

- Resource injection is not available. You must configure these services specifically or programmatically.
- The life cycle of the EntityManagerFactory and EntityManager are managed by the application. Applications control the creation, manipulation, and deletion of these constructs programmatically.

For this task, you will need to specify the com.ibm.ws.jpa.thinclient_7.0.0.jar standalone Java archive (JAR) file in your class path. This standalone JAR file is available from the client and server install images. The location of this file on the client install image is ${*app_client_root*}/runtimes/com.ibm.ws.jpa.thinclient_7.0.0.jar.
The location of this file on the server install image is ${*app_server_root*}/runtimes/com.ibm.ws.jpa.thinclient_7.0.0.jar

1. Generate your entities classes. Depending upon your development model, you might use some or all of the JPA tools:
   - **Top-down mapping:** You start from scratch with the entity definitions and the object-relational mappings, and then you derive the database schemas from that data. If you use this approach, you are most likely concerned with creating the architecture of your object model and then writing your entity classes. These entity classes would eventually drive the creation of your database model. If you are using a top-down mapping of the object model to the relational model, develop the entity classes and then use OpenJPA functionality to generate the database tables that are based on the entity classes. The wsmapping tool would help with this approach.
   - **Bottom-up mapping:** You start with your data model, which are the database schemas, and then you work upwards to your entity classes. The wsreversemapping tool would help with this approach.
   - **Meet in the middle mapping:** probably the most common development model. You have a combination of the data model and the object model partially complete. Depending on the goals and requirements, you will need to negotiate the relationships to resolve any differences. Both the wsmapping tool and the wsreversemapping tool would help with this approach.

   The JPA solution for the application server provides several tools that help with developing JPA applications. Combining these tools with IBM Rational Application Developer provides a solid development environment for either Java EE or Java SE applications. Rational Application Developer includes GUI tools to insert annotations, a customized `persistence.xml` file editor, a database explorer, and other features. Another alternative is the Eclipse Dali project. More information on Rational Application Developer or the Eclipse Dali plugin can be found at their respective web sites.
2. Optional: Enhance the entity classes using the JPA enhancer tool, or specify the Java agent to perform dynamic enhancement at run time.
   - Use the wsenhancer tool. The enhancer post-processes the bytecode that is generated by the Java compiler and adds the fields and methods that are necessary to implement the persistence features. For example:

     ```
     ${app_client_root}/bin/wsenhancer.sh [parameters][arguments]
     ```
   - You can specify the Java agent mechanism to perform the dynamic enhancement at run time. For example, type the following at the command prompt:

     ```
     java -javaagent:${app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_7.0.0.jar com.xyz.Main
     ```
3. Optional: If you are not using the development model for bottom-up mapping, generate or update your database tables automatically or by using the wsmapping tool.
   - By default, the object-relational mapping does not occur automatically, but you can configure the application server to provide that mapping with the openjpa.jdbc.SynchronizeMappings property. This property can accelerate development by automatically ensuring that the database tables match the object model. To enable automatic mapping, include the following line in the `persistence.xml` file:

     ```
     <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema(ForeignKeys=true)"/>
     ```

     Note: To enable automatic object-relational mapping at run time, all of your persistent classes must be listed in the Java .class file, mapping file, and Java archive (JAR) file elements in XML format.

- To manually update or generate your database tables, run the JPA mapping tool for the application server from the command line to create the tables in the database. For example:

  ${*app_server_root*}/bin/wsmapping.sh [parameters][arguments]

4. Optional: If you are using DB2 and want to use static SQL, run the wsdb2gen command. In order to use the wsdb2gen tool, pureQuery runtime must be installed. The wsdb2gen tool creates *persistence_unit_name*.pdqxml file under the same META-INF directory where your persistence.xml file is located. If you have multiple persistence units, wsdb2gen command must be run for each persistence unit. To use the wsdb2gen tool, type the following at a command prompt:

   ${*app_server_root*}/bin/wsdb2gen.sh [parameters]

5. Optional: If you are using application-managed identity, generate an application-managed identity class with the wsappid tool. When you use an application-managed identity, one or more of the fields must be an identity field. Use an identity class if your entity has multiple identity fields and at least one of the fields is related to another entity. The application-managed identity tool generates Java code that uses the identity class for any persistent type that implements application-managed identity. For example, type the following at a prompt:

   ${*app_client_root*}/bin/wsappid.sh [parameters][arguments]

6. Configure the properties of the persistence unit in the persistence.xml file that will be used in the JPA application.
   a. Specify your data source. Use the openjpa.Connection property to obtain a connection to the database. When you run a JPA application in a Java SE environment, a JTA data source will be treated as a data source that is not JTA compliant.
   b. Select com.ibm.websphere.persistence.PersistenceProviderImpl as the persistence provider.

      Note: Include the persistence provider in the classpath if you run the JPA application as a standalone application.

   c. Specify your database configuration options. If you are using pureQuery, configure your data source to use pureQuery, ensure the pdq.jar and pdqmgmt.jar files are included on the JDBC provider classpath. For more information, see topic ″Configuring a data source to use pureQuery″. Indicate the database type and method of connection in the persistence.xml file.

      ```
      <property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
      <property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
      ```

   d. Specify the transaction type to RESOURCE_LOCAL. For example, the following entry should be in the persistence.xml file:

      ```
      <persistence-unit name="persistence_unit" transaction-type="RESOURCE_LOCAL">
      ```

   e. Include the location of the object relationship mapping file, orm.xml, and any additional mapping files. For example, the following entry should be in the persistence.xml file:

      ```
      <mapping-file>META-INF/JPAorm.xml</mapping-file>
      ```

   f. Add any vendor specific properties to the persistence unit.
7. Package the application.

   Note: Package the persistence units in separate JAR files to make them more accessible and reusable. If you package the persistence units this way, they can be tested outside the container both with and without the occurrence of database persistence. The persistence units can be included in standalone applications or they can be packaged into EAR files as persistence archive files. If you package the persistence unit into a persistence archive file, all of the application components must be able to access the persistence archive. The application that uses the persistence units must declare a dependency on the persistence archive using the MANIFEST.MF Class-Path: declaration.

   Note: If you are using pureQuery, add the *persistence_unit_name*.pdqxml files created previous or the or *persistence_unit_name*.pdqxml files created in the above Step 4 to the JPA application JAR

file. The files are located in same META-INF directory where your `persistence.xml` file is located.

To package the application:

```
jar -cvf ${jar_Name} ${entity_Path}
```

where ${*jar_Name*} represents the name of the JAR file to create, and ${*entityPath*} represents the root location where the entities reside, which is where you compiled them.

8. When you run your standalone application, specify the com.ibm.ws.jpa.thinclient_7.0.0.jar standalone JAR file in your class path when executing your application. For example, use the following Java call to run the com.xyz.Main standalone application:

```
java -classpath ${app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_7.0.0.jar other_jar_file.jar com.xyz.Main
```

Example

The following is a sample `persistence.xml` file for the Java SE Environment:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" version="1.0"
             xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
                 http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd">

    <persistence-unit name="TheWildZooPU" transaction-type="RESOURCE_LOCAL">

        <!-- additional Mapping file, in addition to orm.xml>
        <mapping-file>META-INF/JPAorm.xml</mapping-file>

        <class>com.company.bean.jpa.PersistebleObjectImpl</class>
        <class>com.company.bean.jpa.Animal</class>
        <class>com.company.bean.jpa.Dog</class>
        <class>com.company.bean.jpa.Cat</class>

        <exclude-unlisted-classes>true</exclude-unlisted-classes>

        <properties>
            <property name="openjpa.ConnectionDriverName"
                      value="org.apache.derby.jdbc.EmbeddedDriver" />
            <property name="openjpa.ConnectionURL"
                      value="jdbc:derby:target/database/jpa-test-database;create=true" />
            <property name="openjpa.Log"
                      value="DefaultLevel=INFO,SQL=TRACE,File=./dist/jpaEnhancerLog.log,Runtime=INFO,Tool=INFO" />
            <property name="openjpa.ConnectionFactoryProperties"
                      value="PrettyPrint=true, PrettyPrintLineLength=72" />
            <property name="openjpa.jdbc.SynchronizeMappings"
                      value="buildSchema(ForeignKeys=true)" />
            <property name="openjpa.ConnectionUserName"
                      value="user" />
            <property name="openjpa.ConnectionPassword"
                      value="password"/>
        </properties>

     </persistence-unit>

</persistence>
```

What to do next

For more information on any of the commands, classes or other OpenJPA information discussed here, refer to the Apache OpenJPA User's Guide.

Related tasks

“Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)” on page 218
The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

Associating persistence units and data sources
Java Persistence API (JPA) applications allow you to specify the underlying data source used by the persistence provider to access the database.

Task overview: Data Studio pureQuery
Data Studio pureQuery provides Java Persistence API (JPA) users an alternative way to access a DB2 database. PureQuery supports static Structured Query Language (SQL).

Configuring to use pureQuery in a Java EE environment
Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2.

Configuring pureQuery to use multiple package collections
Set up a pureQuery Java Persistence API (JPA) application to use multiple DB2 package collections.

Related reference

“wsappid command” on page 225
The Java Persistence API (JPA) specification allows an entity’s primary key to be made up of more than one column. In this case, the primary key is referred to as a ″composite″ or ″compound″ primary key. You need to provide an ID class, which is specified by the @IdClass annotation, in order to manage a composite primary key. Use the identity tool for JPA to generate an ID class for entities that use composite primary keys.

“wsenhancer command” on page 226
The entity enhancer tool for Java Persistence API (JPA) applications in the application server inserts bytecode into an entity class file that allows the JPA provider to manage the state of an entity.

wsjpaversion command
Use this command line tool to find out information about the installed version of Java Persistence API (JPA) for WebSphere Application Server.

“wsmapping command” on page 228
The wsmapping tool is used to provide top-down mapping of the entity object model to the database relational model. You can use the wsmapping tool to create database tables.

“wsreversemapping command” on page 230
The wsreversemapping tool generates persistent class definitions and metadata from a database schema.

“wsschema command” on page 232
The schema tool can be used to view the database schema in XML form or match an XML schema to an existing database.

Enabling SQL statement batching

SQL statement batching can improve the performance of your application server. Java Persistence API (JPA) for WebSphere Application Server uses the Java Database Connectivity (JDBC) addBatch and executeBatch APIs to batch statements.

About this task

By default, statement batching is enabled for DB2 and Oracle databases. To enable SQL statement batching and to set the batch limit for JPA applications, you need to configure the persistence.xml file. The following steps review how to enable and disable statement batching, as well as set the batch limit:

1. Define the UpdateManager property in the persistence.xml file. For example:

```
<property name="openjpa.jdbc.UpdateManager"
value="com.ibm.ws.persistence.jdbc.kernel.OperationOrderUpdateManager(batchLimit=100)"/>
```

Note: The example shows that the SQL statement batch limit is set to 100.

Note: If you are using a DB2 or an Oracle database, by default the SQL statement batching is enabled and set to batchLimit=100. However, if you are using DB2 or Oracle, you are not required to specify this property in the `persistence.xml` file.

2. If you need to disable SQL statement batching, set the batchLimit value to 0 (zero) or remove the property. However, if you are using a DB2 or an Oracle database, you must specify the DBDictionary property, database, and set the defaultBatchLimit to 0 (zero). For example:

```
<property name="openjpa.jdbc.DBDictionary" value="db2(defaultBatchLimit=0)"/>
```

Results

You have now updated the `persistence.xml` file to enable or disable statement batching and set the batch limit.

Database generated version ID

Java Persistence API (JPA) for WebSphere Application Server has extended OpenJPA to work with database generated version IDs. These generated version fields (timestamp or token) can be used to efficiently detect changes to a given row.

Trigger based version ID generation is supported for all databases that WebSphere Application Server supports. Support is based on two Version Strategies in JPA for WebSphere Application Server.

- @VersionStrategy(″com.ibm.websphere.persistence.RowChangeTimestampStrategy″), if the entity version field type is Timestamp, and
- @VersionStrategy(″com.ibm.websphere.persistence.RowChangeVersionStrategy″), if the entity version field type is Long

Database generated version ID example

In this example, the Entity class is defined with the new Version Strategy annotation. The Entity has a surrogate version column.

```
@Entity(name="Item")
@VersionColumn(name="versionField")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable
{
 @Id
 private int id2;

 private String name;

 private double price;

   @OneToOne
   private Owner master;
}
```

The create table statement for this would be:

```
CREATE TABLE ITEM
(ID2  INT  NOT NULL,
 NAME  VARCHAR(50) ,
 PRICE   DOUBLE,
 OWNER_ID INT,
             VERSIONFIELD GENERATED ALWAYS FOR EACH ROW ON
              UPDATE AS ROW CHANGE TIMESTAMP
         PRIMARYKEY(ID2));
```

During any updates to Item (insert or update) the VersionColumn value will be updated in the database. After the update, the value for VersionColumn is retrieved from the database and updated in the in memory object. Thereby the objects in the data cache reflect the correct version value. Here the Entity is using the @VersionColumn which produces a Surrogate Version Id rather than defining an explicit field in the entity .

The Entity could also use @Version annotation to define an explicit version field. The explicit version field could be of type Long or Timestamp corresponding to the @VersionStrategy. During any updates to Item (insert or update) the Version value will be updated in the database. After the update the value for Version would be retrieved from the database and updated in the in memory object. Thereby the objects in the data cache would reflect the right version value.

This is an example where the Entity has a version field defined, and the type Timestamp matches the RowChangeTimestampStrategy in the @VersionStrategy (if the version field type is using type long, then the RowChangeVersionStrategy should be annotated to match) :

```
@Entity(name="Item")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable

{
 @Id
 private int id2;

 private String name;

 private double price;

   @Version
   private Timestamp versionField;

   @OneToOne
   private Owner master;
}
```

For z/OS DB2 V9 and Linux, Unix, and Windows DB2 V9.5, the generated database column must be of type timestamp but we support both the RowChangeTimestampStrategy and the RowChangeVersionStrategy. MS SqlServer only supports a non timestamp generated version ID that goes with the RowChangeVersionStrategy . To use the RowChangeTimestampStrategy, you must use a trigger on a timestamp field in the database. For other databases you can use triggers to simulate database version generation and use either strategy.

Mapping persistent properties to XML columns

If your database supports Extensible Markup Language (XML) column types, you can use mapping tools to manage XML objects. The Java Persistence API (JPA) specification does not contain support for mapping XML columns to Java objects. You have the choice of mapping XML columns to a Java string or a Java byte array field. These mapping techniques make using the XML objects as strings or byte arrays difficult. JPA for the application server allows you to simplify the management of XML objects by using a third-party solution for mapping management.

About this task

DB2, Oracle, and SQLServer databases support XML column types, XPath queries, and indices over these columns.

Persistent properties to XML mapping

An embedded class with XML column support needs to use XML marshalling to write the data to the XML column and unmarshalling to retrieve the data from the XML column. The path expressions and predicates over the embedded class are converted to XML predicates, XPATH expressions, or XQuery expressions and are written to the database.

WebSphere Application Server allows JPA applications to use a third-party tool for XML mapping. This is done through the extension points for custom field mappings. The third-party mapping tool uses the extension points by providing a custom value handler for the persistent fields that are mapped to the XML columns. In OpenJPA, this value handler is named org.apache.openjpa.xmlmapping.XmlValueHandler and this handler requires the @Strategy annotation on the Java field that is mapped to the XML column.

1. Annotate the entity property using the XML value handler strategy. The mapping of persistent properties to XML columns requires the @Strategy and the @Persistent annotation.

   ```
   @Persistent
   @Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
   ```

   The XML value handler for the persistent property is set to org.apache.openjpa.xmlmapping.XmlValueHandler.
2. Change the default for fetch type if it is necessary. For example:

   ```
   @Persistence(fetch=FetchType.LAZY)
   ```

   The fetch type is now LAZY. If a value for the fetch type is not entered, the default is set to EAGER.
3. Annotate your embedded classes with the binding annotations for Java API for XML Binding (JAXB). These bindings can be created from an XML schema by using the Java Architecture for XML Binding Compiler (XJC).
4. Make sure that the class that maps to the root of the XML document is annotated with @XmlRootElement, in addition to the other annotations.
5. Compile your Java sources.
6. Run the enhancer tool on the entities. Refer to the topic on the entity enhancer tool for more information.

Example

For example, shipAddress, a property of Order Entity, is mapped to XML column shipaddr:

```
@Entity
public class Order {
 @Id
 @GeneratedValue(strategy=GenerationType.IDENTITY)
  int oid;
 @Persistent
 @Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
      @Column(name="shipaddr")
      Address shipAddress;
...
```

The OpenJPA mapping tool generates a SHIPADDR column with XML type in the table definition for ORDER table.

“wsenhancer command” on page 226
The entity enhancer tool for Java Persistence API (JPA) applications in the application server inserts bytecode into an entity class file that allows the JPA provider to manage the state of an entity.

JPA Access Intent

Java Persistence API (JPA) Access intent specifies the isolation level and lock level used when reading data from a data source. Access intent controls the JDBC isolation level and whether read, update or exclusive locks are acquired when retrieving data.

About this task

Note: For a JPA persistence provider on the application server, the application can specify isolation and ReadLockMode based on a TaskName. The TaskName provides a better control over applying these characteristics. The application defines a set of entity types and their corresponding access intent for each TaskName defined in a persistence unit.

Note:

- Access intent is available for application in the Java EE server environment
- Access intent is applicable to non-query entity manager interface methods. Query should use query hint interface to set its isolation and read lock values.
- Access intent is only available for DB2 databases.
- Access intent is in effect only when pessimistic lock manager is used. Add the following to the persistence unit’s property list. <property name=″openjpa.LockManager″ value=″pessimistic″/>

The following table compares the Enterprise JavaBeans (EJB) 2.x entity bean access intent with the JPA access intent properties:

Table 7. Access intent Properties and Descriptions

WebSphere EJB 2.x entity bean access intent	JPA access intent	Description
optimistic	isolation: Read Committed	Data is read but no lock is held. Version id is used on update to insure data integrity. Other transactions can read and update data.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic read	isolation: Repeatable Read	Data is read with shared locks. Other transactions attempting to update data are blocked.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic update	isolation: Repeatable Read	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode: WRITE	

Table 7. Access intent Properties and Descriptions (continued)

WebSphere EJB 2.x entity bean access intent	JPA access intent	Description
pessimistic exclusive	isolation: Serializable	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode:WRITE	

A TaskName is set on a transaction context by one of the following:

- TaskName is automatically set via the EJB container when a transaction begins using WebSphere local transaction (EJB unspecifid transaction), JTA global transaction in a Container-Managed Transaction (CMT) or user-initiated global transaction in a Bean-Managed Transaction (BMT)
- TaskName is manually set in an application using the TaskNameAccessor API provided for JPA.

The advantage of using task names is that the access intent can be specified on a request scope rather than specifying it in the `persistence.xml` file, which has an application scope across all entities. Often a query is contained in a method or component which is used in many different transaction contexts. Some of these contexts may require repeatable-read and update lock intent but other contexts do not.

Isolation level and read locks can be specified on:

- An application scope in the `persistence.xml` file. These isolation level and read lock type are properties specified in the persistence.xml file. They apply to all entities define in the persistence unit.
- A transaction scope via task name. Transaction scoped hints will override application scope values.
- Query instance with a query hint. Query hint can be used to override isolation and ReadLockMode for a particular query instance. A query hint will override isolation level and read locks specified at the application or transaction scope.

1. “Setting a TaskName using TaskNameAccessor” This task will show how to use the TaskNameAccessor API to set JPA TaskName at runtime.
2. “Specify TaskName in a JPA persistence unit” on page 247 This task will show how to specify a TaskName in JPA persistence unit

What to do next

For further information on the background and purpose of Access intent, see the topic on Access intent service.

Related concepts

“Access intent service” on page 201
Access intent is a WebSphere Application Server runtime service that enables you to precisely manage an application’s persistence.

Related tasks

“Task overview: Storing and retrieving persistent data with the Java Persistence API (JPA)” on page 218
The Java Persistence API (JPA) for the application server defines the management of persistence and object/relational mapping within Java Enterprise Edition (Java EE) and Java Standard Edition (Java SE) environments.

Setting a TaskName using TaskNameAccessor

Using the TaskNameAccessor API to set Java Persistence API (JPA) TaskName at runtime.

About this task

In the Enterprise JavaBeans (EJB) container, a task name is automatically set by default upon a transaction begins. This action is performed when a component or business method is invoked in a CMT session bean or when an application invoke the `sessionContext.getTransaction().begin()` in a BMT session bean. This TaskName consists of a concatenation of the fully package qualified session bean type, a dot character and the method name. For example: `com.acme.MyCmtSessionBean.methodABC`.

If using JPA in the context of the Web container, an application must use the TaskNameAccessor API to set the TaskName in the current thread of execution.

Note: Once a TaskName is set on a transaction context, application must not set the TaskName again in the same transaction. This will avoid problems with on the JDBC connection for different database access.

This example contains the TaskNameAccessor API definition

```
package com.ibm.websphere.persistence;

public abstract class TaskNameAccessor {

 /**
  * Returns the current task name attached in the current thread context.
  * @return current task name or null if none is found.
  */
 public static String getTaskName ();

 /**
  * Add a user-defined JPA access intent task name to the current thread
  * context.
  *
  * @param taskName
  * @return false if an existing task has already attached in the current
  *         thread or Transaction Synchronization Registry (TSR) is not
  *         available (i.e. in JSE environment).
  */
 public static boolean setTaskName(String taskName);

}
```

This code example shows how to set a TaskName using TaskNameAccessor.

```
package my.company;

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

        ejb1.callee_Method?();
    }

    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }

    @TransactionAttribute(Requires)
    public void callee_Method3() {
```

```
        // In caller's transaction, hence TaskName remains
        //     "my.company.Ejb1.caller_Method1"
    }

    @TransactionAttribute(NotSupported)
    public void callee_LocalTx () {

        // Unspecified transaction, a new local transaction implicitly started.
        // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
    }

}
```

Note: In the above example, an application must be aware of transaction boundary will be subtly changed if Ejb1 uses local interface (@Local). For example, when `caller_Method1()` calls `callee_Method3` or `callee_LocalTx`, this will be treated as a Java method call. No EJB transaction semantics are honored.

What to do next

Once you have completed this step, continue on with "Specify TaskName in a JPA persistence unit."

"Specify TaskName in a JPA persistence unit"
Specifying a TaskName in Java Persistence API (JPA) persistence unit

Specify TaskName in a JPA persistence unit

Specifying a TaskName in Java Persistence API (JPA) persistence unit

About this task

A TaskName is defined in the `persistence.xml` file using the `wsjpa.AccessIntent` property name in a persistence unit. The property value is a list of TaskNames, entity types and access intent definitions. The following example shows the contents of the `wsjpa.AccessIntent` property name in a persistence unit.

```
<property name  = "wsjpa.AccessIntent"
         value = "Tasks=' <taskName> { <entityName> ( <isolationLockValue> ) } ' "/>
                         A            A              A                    | | |
                         |            |              +--------- , --------+ | |
                         |            +----------------- , -----------------+ |
                         +---------------------- , --------------------------+
  Tasks                        ::= <task> [ ',' <task> ]*

  <task>                       ::= <taskName> '{' <entity> [ ',' <entity> ]* '}'

  <entity>                     ::= <entityName> '(' <isolationLockValues> ')'

  <taskName>                   ::= <fully_qualified_identifier>

  <entityName>                 ::= <fully_qualified_identifier>

  <fully_qualified_identifier> ::= <identifier> [ '.' <identifier> ]*

  <identifier>                 ::= <idStartCharacter> [ <idCharacter> ]*

  <idStartCharacter>           ::= Character.isJavaIdentifierStart | '?' | '*'

  <idStartCharacter>           ::= Character.isJavaIdentifierPart  | '?' | '*'
```

```
<isolationLockValues>        ::= <isolationLockValue> [ ',' <isolationLockValue> ]

<isolationLockValue>         ::= <isolation> | <readLock>

<isolation>                  ::= "isolation" '=' <isolationValue>

<readLock>                   ::= "readlock" '=' <readlockValue>

<isolationValue>             ::= "read-uncommitted"|"read-committed"|"repeatable-read"|"serializable"

<readlockValue>              ::= "read" | "write"
```

Before setting the TaskName in a persistence unit, keep the following in mind:

- White spaces are ignored between tokens.
- Only <isolation> and <readLock> contents are not case sensitive.
- <TaskName> is in the form of a fully package qualified method name, such as com.acme.bean.MyBean.increment, or an arbitrary user-defined task name, such as MyProfile.
- <entityName> is in the form of a fully package qualified class name such as com.acme.bean.Entity1.
- The wild card characters '?' or '*' can be used in <TaskName> and <entityName>. ″?″ matches any single character and ″*″ matches zero or more sequence characters.
- Only hintNames isolation and readLock are allowed on a task definition and the order is not significant
- If readLock has the value `write`, then isolation must be `repeatable-read` or `serializable`
- If readLock has the value `read`, it has no effect if the isolation is `read-uncommitted`.

The following code example shows how to specify a TaskName in JPA persistence unit.

```
package my.company;

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

        ejb1.callee_Method?();
    }

    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }

    @TransactionAttribute(Requires)
    public void callee_Method3() {

        // In caller's transaction, hence TaskName remains
        //     "my.company.Ejb1.caller_Method1"
    }

    @TransactionAttribute(NotSupported)
    public void callee_LocalTx () {

        // Unspecified transaction, a new local transaction implicitly started.
        // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
    }

}
```

Since a wild card can be used to specify TaskName and entity type, multiple specification matches may occur at runtime. The order defined in the `wsjpa.AccessIntent` property will be used to search for task names and entity types.

```
<properties>
  <property name="wsjpa.AccessIntent" value="Tasks="
        *.Task1 { *.Employee1 ( isolation=read-uncommitted                ),
                  *.Employee? ( isolation=repeatable-read,  readlock=write ),
                },
        *       { *.Employee3 ( isolation=serializable,     readlock=write ) },
      '" />
</properties>
```

Chapter 5. Client applications

Using application clients

An application client module is a Java Archive (JAR) file that contains a client for accessing a Java application.

About this task

Complete the following steps for developing different types of application clients.

1. Decide on a type of application client. WebSphere Application Server for z/OS does not support a separate client image. Therefore, an application client other than a thin client must run together with the client container that comes with the application server image. See http://www.ibm.com/support/docview.wss?rs=180&uid=swg27006921 for more information about supported platforms.
2. Develop the application client code.
   a. Develop ActiveX application client code.
   b. Develop J2EE application client code.
   c. Develop pluggable application client code.
   d. Develop thin application client code.
3. Assemble the application client using the Application Server Toolkit.
4. Deploy the application client.
   Start the Application Client Resource Configuration Tool.
5. Run the application client.

Example

Application Client for WebSphere Application Server

In a traditional client-server environment, the client requests a service and the server fulfills the request. Multiple clients use a single server. Clients can also access several different servers. This model persists for Java clients except that now these requests use a client runtime environment.

WebSphere Application Server supports the pluggable client.

In this model, the client application requires a servlet to communicate with the enterprise bean, and the servlet must reside on the same machine as the WebSphere Application Server.

The Application Client for WebSphere Application Server Version 7.0 (Application Client) consists of the following client applications:

- Java Platform, Enterprise Edition (Java EE) application client application (Uses services provided by the Java EE Client Container)
- Thin application client application (Does not use services provided by the Java EE Client Container)
- Applet application client application

The Application Client for WebSphere Application Server for z/OS supports the following models:

- Java EE application client application (Uses services provided by the Java EE Client Container)
- Thin application client application (Does not use services provided by the Java EE Client Container)

The Application Client is packaged with the following components:

- Java Runtime Environment (JRE) (or an optional full Software Development Kit) that IBM provides.
- WebSphere Application Server run time for Java EE application client applications or Thin application client applications

- IBM plug-in for Java platforms for Applet client applications (Windows only)

  Note: The Pluggable application client is a kind of Thin application client. However, the Pluggable application client uses a Sun JRE and Software Development Kit instead of the JRE and Software Development Kit that IBM provides. The Sun JRE has to be the same version as the IBM JRE.

The *Applet client* model has a Java applet embedded in a HyperText Markup Language (HTML) document residing on a remote client machine from the WebSphere Application Server. With this type of client, the user accesses an enterprise bean in the WebSphere Application Server through the Java applet in the HTML document.

The *Java EE application client* is a Java application program that accesses enterprise beans, Java DataBase Connectivity (JDBC) APIs, and Java Message Service message queues. The Java EE application client program runs on client machines. This program follows the same Java programming model as other Java programs; however, the Java EE application client depends on the Application Client run time to configure its execution environment, and uses the Java Naming and Directory Interface (JNDI) name space to access resources.

The *Pluggable and Thin application clients* provide a lightweight Java client programming model. These clients are useful in situations where the client application requires a thinner, more lightweight environment than the one offered by the Java EE application client. The difference between the Thin application client and the Pluggable application client is that the Thin application client includes a Java virtual machine (JVM) API, and the Pluggable application client requires the user to provide this code. The Pluggable application client supports the Sun JRE that is directly downloaded from Sun Web site, however, the Sun JRE has to be the same version as the IBM JRE. The Application Client for WebSphere Application Server for Windows installs the ORB.properties file to configure the Sun JRE to use the IBM ORB implementation that is installed as part of the Pluggable Application Client. The Thin application client uses the IBM Developer Kit for the Java platform.

The Java EE application client programming model provides the benefits of the Java EE platform for the Java client application. Use the Java EE application client to develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere Application Server platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the Java EE platform, you can put the client application code from one Java EE platform implementation to another. The client application package can require redeployment using each Java EE platform deployment tool, but the code that comprises the client application remains the same.

The Application Client run time supplies a container that provides access to system services for the client application code. The client application code must contain a main method. The Application Client run time invokes this main method after the environment initializes and runs until the Java virtual machine code terminates.

The Java EE platform supports the Application Client use of *nicknames* or *short names*, defined within the client application deployment descriptor. These deployment descriptors identify enterprise beans or local resources (JDBC, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the client application code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the Application Client can require redeployment.

The Application Client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Application Client run time also provides support for security authentication to enterprise beans and local resources.

The Application Client uses the Java Remote Method Invocation-Internet InterORB Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the Java EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

View the Samples gallery for more information about the Application Client.

Application client functions

This topic provides information about available functions in the different types of clients.

Use the following table to identify the available functions in the different types of clients.

Note: WebSphere Application Server for z/OS supports only two types of application client:

- J2EE client
- Pluggable client

Available functions	ActiveX client	Applet client	J2EE client	Pluggable client	Thin client
Provides all the benefits of a J2EE platform	Yes	No	Yes	No	No
Portable across all J2EE platforms	No	No	Yes	No	No
Provides the necessary run-time support for communication between a client and a server	Yes	Yes	Yes	Yes	Yes
Supports the use of nicknames in the deployment descriptor files. **Note:** Although you can edit deployment descriptor files, do not use the administrative console to modify them.	Yes	No	Yes	No	No
Supports use of the RMI-IIOP protocol	Yes	Yes	Yes	Yes	Yes
Browser-based application	No	Yes	No	No	No
Enables development of client applications that can access enterprise bean references and CORBA object references	Yes	Yes	Yes	Yes	Yes
Enables the initialization of the client application run-time environment	Yes	No	Yes	No	No
Supports security authentication to enterprise beans	Yes	Limited	Yes	Yes	Yes
Supports security authentication to local resources	Yes	No	Yes	No	No
Requires distribution of application to client machines	Yes	No	Yes	Yes	Yes

Enables access to enterprise beans and other Java classes through Visual Basic, VBScript, and Active Server Pages (ASP) code	Yes	No	No	No	No
Provides a lightweight client suitable for download	No	Yes	No	Yes	Yes
Enables access JNDI APIs for enterprise bean resolution	Yes	Yes	Yes	Yes	Yes
Runs on client machines that use the Sun Java Runtime Environment	No	No	No	Yes	No
Supports CORBA services (using CORBA services can render the application client code nonportable)	No	No	Yes	No	No
Supports JMS connections to the default messaging provider	No	No	Yes	No	Yes
Supports JMS connections to the default messaging provider	No	No	Yes	Yes	Yes

ActiveX application clients

WebSphere Application Server provides an ActiveX to EJB bridge that enables ActiveX programs to access enterprise beans through a set of ActiveX automation objects.

The bridge accomplishes this access by loading the Java virtual machine (JVM) into any ActiveX automation container such as Visual Basic, VBScript, and Active Server Pages (ASP).

There are two main environments in which the ActiveX to EJB bridge runs:
- **Client applications**, such as Visual Basic and VBScript, are programs that a user starts from the command line, desktop icon, or Start menu shortcut.
- **Client services**, such as Active Server Pages, are programs started by some automated means like the Services control panel applet.

The ActiveX to EJB bridge uses the Java Native Interface (JNI) architecture to programmatically access the JVM code. Therefore the JVM code exists in the same process space as the ActiveX application (Visual Basic, VBScript, or ASP) and remains attached to the process until that process terminates. To create JVM code, an ActiveX client program calls the XJBInit() method of the XJB.JClassFactory object. For more information about creating JVM code for an ActiveX program, see ActiveX to EJB bridge, initializing JVM code.

After an ActiveX client program has initialized the JVM code, the program calls several methods to create a proxy object for the Java class. When accessing a Java class or object, the real Java object exists in the JVM code; the automation container contains the proxy for that Java object. The ActiveX program can use the proxy object to access the Java class, object fields, and methods. For more information about using Java proxy objects, see ActiveX to EJB bridge, using Java proxy objects. For more information about calling methods and access fields, see ActiveX to EJB bridge, calling Java methods and ActiveX to EJB bridge, accessing Java fields.

The client program performs primitive data type conversion through the COM IDispatch interface (use of the IUnknown interface is not directly supported). Primitive data types are automatically converted between native automation types and Java types. All other types are handled automatically by the proxy objects For more information about data type conversion, see ActiveX to EJB bridge, converting data types.

Any exceptions thrown in Java code are encapsulated and thrown again as a COM error, from which the ActiveX program can determine the actual Java exceptions. For more information about handling exceptions, see ActiveX to EJB bridge, handling errors.

The ActiveX to EJB bridge supports both free-threaded and apartment-threaded access and implements the free threaded marshaler (FTM) to work in a hybrid environment such as Active Server Pages. For more information about the support for threading, see ActiveX to EJB bridge, using threading.

Applet clients

The applet client provides a browser-based Java run time capable of interacting with enterprise beans directly, instead of indirectly through a servlet.

This client is designed to support users who want a browser-based Java client application programming environment that provides a richer and more robust environment than the one offered by the **Applet > Servlet > enterprise bean** model.

The programming model for this client is a hybrid of the Java application thin client and a servlet client. When accessing enterprise beans from this client, the applet can consider the enterprise bean object references as CORBA object references.

No tooling support exists for this client to develop, assemble or deploy the applet. You are responsible for developing the applet, generating the necessary client bindings for the enterprise beans and CORBA objects, and bundling these pieces together to install or download to the client machine. The Java applet client provides the necessary run time to support communication between the client and the server. The applet client run time is provided through the Java applet browser plug-in that you install on the client machine.

Generate client-side bindings using an assembly tool. An applet can utilize these bindings, or you can generate client-side bindings using the **rmic** command. This command is part of the IBM Developer Kit, Java edition that is installed with the WebSphere Application Server.

The applet client uses the RMI-IIOP protocol. Using this protocol enables the applet to access enterprise bean references and CORBA object references, but the applet is restricted in using some supported CORBA services.

If you combine the enterprise bean and CORBA environments in one applet, you must understand the differences between the two programming models, and you must use and manage each model appropriately.

The applet environment restricts access to external resources from the browser run-time environment. You can make some of these resources available to the applet by setting the correct security policy settings in the WebSphere Application Server `client.policy` file. If given the correct set of permissions, the applet client must explicitly create the connection to the resource using the appropriate API. This client does not perform initialization of any service that the client applet can need. For example, the client application is responsible for the initialization of the naming service, either through the CosNaming, or the Java Naming and Directory Interface (JNDI) APIs.

Java EE application clients

The Java Platform, Enterprise Edition (Java EE) application client programming model provides the benefits of the Java EE Platform for WebSphere Application Server Enterprise product.

The Java EE platform offers the ability to seamlessly develop, assemble, deploy and launch a client application. The tooling provided with the WebSphere platform supports the seamless integration of these stages to help the developer create a client application from start to finish.

When you develop a client application using and adhering to the Java EE platform, you can put the client application code from one Java EE platform implementation to another. The client application package can require redeployment using each Java EE platform deployment tool, but the code that comprises the client application does not change.

The Java EE application client run time supplies a container that provides access to system services for the application client code. The Java EE application client code must contain a main method. The Java EE application client run time invokes this main method after the environment initializes and runs until the Java virtual machine application terminates.

Application clients can use *nicknames* or *short names*, defined within the client application deployment descriptor with the Java EE platform. These deployment descriptors identify enterprise beans or local resources (Java Database Connectivity (JDBC) data sources, J2C connection factories, Java Message Service (JMS), JavaMail and URL APIs) for simplified resolution through JNDI use. This simplified resolution to the enterprise bean reference and local resource reference also eliminates changes to the application client code, when the underlying object or resource either changes or moves to a different server. When these changes occur, the application client can require redeployment. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

Note: Connection pool is not supported in application client. The application client calls the database directly, without a datasource. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational® Application Developer (RAD) or assembly tool. The connection is established between application client and the database. Application client does not have connection pool, but JDBC provider configuration is available in the client deployment descriptors.

The Java EE application client also provides initialization of the run-time environment for the client application. The deployment descriptor defines this unique initialization for each client application. The Java EE application client run time also provides support for security authentication to the enterprise beans and local resources.

The Java EE application client uses the Java Remote Method Invocation technology run over Internet Inter-Orb Protocol (RMI-IIOP). Using this protocol enables the client application to access enterprise bean references and to use Common Object Request Broker Architecture (CORBA) services provided by the Java EE platform implementation. Use of the RMI-IIOP protocol and the accessibility of CORBA services assist users in developing a client application that requires access to both enterprise bean references and CORBA object references.

When you combine the Java EE and the CORBA WebSphere Application Server Enterprise environments or programming models in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

Pluggable application clients

The Pluggable application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

Note: The Pluggable application client is available only on the Windows platform.

The Pluggable application client requires that you have previously installed the Sun Java Runtime Environment (JRE) files. In all other aspects, the Pluggable application client, and the Thin application client are similar.

This client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the Java Platform, Enterprise Edition (Java EE) platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client; however, tooling does exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and after bundling these pieces together, installing them on the client machine.

The Pluggable application client provides the necessary run time to support the communication needs between the client and the server.

The Pluggable application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access enterprise bean references and CORBA object references and use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments in one client application, you must understand the differences between the two programming models to use and manage each appropriately.

The Pluggable application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Serviceability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either the Java Naming and Directory Interface (JNDI) API or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space.

When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Pluggable application client offers access to most of the available client services in the Java EE application client. However, you cannot access the services in the Pluggable application client as easily as you can in the Java EE application client. The Java EE client has the advantage of performing a simple JNDI name space lookup to access the desired service or resource. The Pluggable application client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home object requires the following code in a Java EE application client:

```
java.lang.Object ejbHome =
 initialContext.lookup("java:/comp/env/ejb/MyEJBHome");
MyEJBHome =
 (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

However, you need more explicit code in a Pluggable application client for Java:

```
java.lang.Object ejbHome =
 initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome =
 (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, MyEJBHome.class);
```

In this example, the Java EE application client accesses a logical name from the `java:/comp` name space. The Java EE client run time resolves that name to the physical location and returns the reference to the client application. The pluggable client must know the fully qualified physical location of the enterprise bean Home object in the name space. If this location changes, the pluggable client application must also change the value placed on the lookup() statement.

In the Java EE client, the client application is protected from these changes because it uses the logical name. A change can require a redeployment of the EAR file, but the actual client application code remains the same.

The Pluggable application client is a traditional Java application that contains a *main* function. The WebSphere Pluggable application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services. This client can also access CORBA objects and CORBA-based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and the CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the JNDI implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Pluggable application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Pluggable application client run time.

Thin application clients

The Thin application client provides a lightweight, downloadable Java application run time capable of interacting with enterprise beans.

WebSphere Application Server supports the pluggable client.

The Thin application client is designed to support those users who want a lightweight Java client application programming environment, without the overhead of the Java Platform, Enterprise Edition (Java EE) platform on the client machine. The programming model for this client is heavily influenced by the CORBA programming model, but supports access to enterprise beans.

When accessing enterprise beans from this client, the client application can consider the enterprise beans object references as CORBA object references.

Tooling does not exist on the client, it exists on the server. You are responsible for developing the client application, generating the necessary client bindings for the enterprise bean and CORBA objects, and bundling these pieces together to install on the client machine.

The Thin application client provides the necessary runtime to support the communication needs between the client and the server.

The Thin application client uses the RMI-IIOP protocol. Using this protocol enables the client application to access not only enterprise bean references and CORBA object references, but also allows the client application to use any supported CORBA services. Using the RMI-IIOP protocol along with the accessibility of CORBA services can assist a user in developing a client application that needs to access both enterprise bean references and CORBA object references.

When you combine the Java EE and CORBA environments in one client application, you must understand the differences between the two programming models, to use and manage each appropriately.

The Thin application client run time provides the necessary support for the client application for object resolution, security, Reliability Availability and Servicability (RAS), and other services. However, this client does not support a container that provides easy access to these services. For example, no support exists

for using *nicknames* for enterprise beans or local resource resolution. When resolving to an enterprise bean (using either Java Naming and Directory Interface (JNDI) or CosNaming) sources, the client application must know the location of the name server and the fully qualified name used when the reference was bound into the name space. When resolving to a local resource, the client application cannot resolve to the resource through a JNDI lookup. Instead the client application must explicitly create the connection to the resource using the appropriate API (JDBC, Java Message Service (JMS), and so on). This client does not perform initialization of any of the services that the client application might require. For example, the client application is responsible for the initialization of the naming service, either through CosNaming or JNDI APIs.

The Thin application client offers access to most of the available client services in the Java EE application client. However, you cannot access the services in the thin client as easily as you can in the Java EE application client. The Java EE client has the advantage of performing a simple Java Naming and Directory Interface (JNDI) name space lookup to access the desired service or resource. The thin client must code explicitly for each resource in the client application. For example, looking up an enterprise bean Home requires the following code in a Java EE application client:

```
java.lang.Object ejbHome =  initialContext.lookup("java:comp/env/ejb/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

However, you need more explicit code in a Thin application client:

```
java.lang.Object ejbHome =
  initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

In this example, the Java EE application client accesses a logical name from the `java:comp` name space. The Java EE client run time resolves that name to the physical location and returns the reference to the client application. The Thin application client must know the fully qualified physical location of the enterprise bean Home in the name space. If this location changes, the thin client application must also change the value placed on the lookup() statement.

In the Java EE client, the client application is protected from these changes because it uses the logical name. A change might require a redeployment of the EAR file, but the actual client application code remains the same.

The Thin application client is a traditional Java application that contains a *main* function. The WebSphere Thin application client provides run-time support for accessing remote enterprise beans, and provides the implementation for various services. This client can also access CORBA objects and CORBA based services. When using both environments in one client application, you need to understand the differences between the enterprise bean and CORBA programming models to manage both environments.

For instance, the CORBA programming model requires the CORBA CosNaming name service for object resolution in a name space. The enterprise beans programming model requires the JNDI name service. The client application must initialize and properly manage these two naming services.

Another difference applies to the enterprise bean model. Use the Java Naming and Directory Interface (JNDI) implementation in the enterprise bean model to initialize the Object Request Broker (ORB). The client application is unaware that an ORB is present. The CORBA model, however, requires the client application to explicitly initialize the ORB through the `ORB.init()` static method.

The Thin application client provides a batch command that you can use to set the CLASSPATH and JAVA_HOME environment variables to enable the Thin application client run time.

WebSphere Application Server Version 6.1 and the Application client for WebSphere Application Server Version 6.1 also provides specialized types of Thin application client. The Web Services Thin Client is an unmanaged, stand-alone Java client environment that allows you to run JAX-RPC Web services client

applications to invoke Web services that are hosted by the application server. The Administration Thin Client enables client applications to perform administration tasks outside of the application server environment.

Application client troubleshooting tips

This topic provides debugging tips for resolving common Java 2 Platform Enterprise Edition (J2EE) application client problems. To use this troubleshooting guide, review the trace entries for one of the J2EE application client exceptions, and then locate the exception in the guide.

Some of the errors in the guide are samples, and the actual error you receive can be different than what is shown here. You might find it useful to rerun the `launchClient` command specifying the `-CCverbose=true` option. This option provides additional information when the J2EE application client run time is initializing.

Error: java.lang.NoClassDefFoundError

Explanation This exception is thrown when Java code cannot load the specified class.

Possible causes
- Invalid or non-existent class
- Class path problem
- Manifest problem

Recommended response

Check to determine if the specified class exists in a Java Archive (JAR) file within your Enterprise Archive (EAR) file. If it does, make sure the path for the class is correct. For example, if you get the exception:

```
java.lang.NoClassDefFoundError:
WebSphereSamples.HelloEJB.HelloHome
```

verify that the HelloHome class exists in one of the JAR files in your EAR file. If it exists, verify that the path for the class is WebSphereSamples.HelloEJB.

If both the class and path are correct, then it is a class path issue. Most likely, you do not have the failing class JAR file specified in the client JAR file manifest. To verify this situation, perform the following steps:

1. Open your EAR file with an assembly tool, and select the Application Client.
2. Add the names of the other JAR files in the EAR file to the Classpath field.

This exception is generally caused by a missing Enterprise Java Beans (EJB) module name from the Classpath field.

If you have multiple JAR files to enter in the Classpath field, be sure to separate the JAR names with spaces.

If you still have the problem, you have a situation where a class is loaded from the file system instead of the EAR file. This error is difficult to debug because the offending class is not the one specified in the exception. Instead, another class is loaded from the file system before the one specified in the exception. To correct this error, review the class paths specified with the -CCclasspath option and the class paths configured with the Application Client Resource Configuration Tool.

Alternatively, you can use the Client Container Resource Configuration Scripting tool.

Look for classes that also exist in the EAR file. You must resolve the situation where one of the classes is found on the file system instead of in the `.ear` file. Remove entries from the classpaths, or include the `.jar` files and classes in the `.ear` file instead of referencing them from the file system.

If you use the -CCclasspath parameter or resource classpaths in the tool, and you have configured multiple JAR files or classes, verify they are separated with the correct character for your operating system. Unlike the Classpath field, these class path fields use platform-specific separator characters.
Note: The system class path is not used by the Application Client run time if you use the launchClient batch or shell files. In this case, the system class path would not cause this problem. However, if you load the launchClient class directly, you do have to search through the system class path as well.

Error: com.ibm.websphere.naming.CannotInstantiateObjectException: Exception occurred while attempting to get an instance of the object for the specified reference object. [Root exception is javax.naming.NameNotFoundException: xxxxxxxxxx]

Explanation

This exception occurs when you perform a lookup on an object that is not installed on the host server. Your program can look up the name in the local client Java Naming and Directory Interface (JNDI) name space, but received a NameNotFoundException exception because it is not located on the host server. One typical example is looking up an EJB component that is not installed on the host server that you access. This exception might also occur if the JNDI name you configured in your Application Client module does not match the actual JNDI name of the resource on the host server.

Possible causes

- Incorrect host server invoked
- Resource is not defined
- Resource is not installed
- Application server is not started
- Invalid JNDI configuration

Recommended response

If you are accessing the wrong host server, run the `launchClient` command again with the -CCBootstrapHost parameter specifying the correct host server name. If you are accessing the correct host server, use the product `dumpnamespace` command line tool to see a listing of the host server JNDI name space. If you do not see the failing object name, the resource is either not installed on the host server or the appropriate application server is not started. If you determine the resource is already installed and started, your JNDI name in your client application does not match the global JNDI name on the host server. Use the Application Server Toolkit to compare the JNDI bindings value of the failing object name in the client application to the JNDI bindings value of the object in the host server application. The values must match.

Error: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: ″iiop://[invalidhostname]″. Make sure that the host and port information is correct and that the server identified by the provider URL is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. Root exception is org.omg.CORBA.INTERNAL: JORB0050E: In Profile.getIPAddress(), InetAddress.getByName[invalidhostname] threw an UnknownHostException. minor code: 4942F5B6 completed: Maybe

Explanation

This exception occurs when you specify an invalid host server name.

Possible causes

- Incorrect host server invoked
- Invalid host server name

Recommended response

Run the `launchClient` command again and specify the correct name of your host server with the -CCBootstrapHost parameter.

Error: javax.naming.CommunicationException: Could not obtain an initial context due to a communication failure. Since no provider URL was specified, either the bootrap host and port of an existing ORB was used, or a new ORB instance was created and initialized with the default bootstrap host of ″localhost″ and the default bootstrap port of 2809. Make sure the ORB bootstrap host and port resolve to a running name server. Root exception is org.omg.CORBA.COMM_FAILURE: WRITE_ERROR_SEND_1 minor code: 49421050 completed: No

Explanation

This exception occurs when you run the `launchClient` command to a host server that does not have the Application Server started. You also receive this exception when you specify an invalid host server name. This situation might occur if you do not specify a host server name when you run the launchClient tool. The default behavior is for the launchClient tool to run to the local host, because WebSphere Application Server does not know the name of your host server. This default behavior only works when you are running the client on the same machine with WebSphere Application Server is installed.

Possible causes

- Incorrect host server invoked
- Invalid host server name
- Invalid reference to `localhost`
- Application server is not started
- Invalid bootstrap port

Recommended response

If you are not running to the correct host server, run the `launchClient` command again and specify the name of your host server with the `-CCBootstrapHost` parameter. Otherwise, start the Application Server on the host server and run the `launchClient` command again.

Error: javax.naming.NameNotFoundException: Name comp/env/ejb not found in context ″java:″

Explanation

This exception is thrown when the Java code cannot locate the specified name in the local JNDI name space.

Possible causes

- No binding information for the specified name
- Binding information for the specified name is incorrect
- Wrong class loader was used to load one of the program classes
- A resource reference does not include any client configuration information
- A client container on the deployment manager is trying to use enterprise extensions (not supported)

Recommended response

Open the EAR file with the Application Server Toolkit, and check the bindings for the failing name. Ensure this information is correct. If you are using Resource References, open the EAR file with the Application Client Resource Configuration Tool, and verify that the Resource Reference has client configuration information and the name of the Resource Reference exactly matches the JNDI name of the client configuration. If the values are correct, you might have a class loader error. For detailed information about the configuration tool and opening EAR files, read the Starting the Application Client Resource Configuration Tool in the *Developing and deploying applications* PDF book.

Error: java.lang.ClassCastException: Unable to load class: org.omg.stub.WebSphereSamples.HelloEJB._HelloHome_Stub at com.ibm.rmi.javax.rmi.PortableRemoteObject.narrow(portableRemoteObject.java:269)

Explanation

This exception occurs when the application program attempts to narrow to the EJB home class and the class loaders cannot find the EJB client side bindings.

Possible causes

- The files, *_Stub.class and _Tie.class, are not in the EJB `.jar` file
- Class loader could not find the classes

Recommended response

Look at the EJB `.jar` file located in the `.ear` file and verify the class contains the Enterprise Java Beans (EJB) client side bindings. These are class files with file names that end in `_Stub` and `_Tie`. If the binding classes are in the EJB `.jar` file, then you might have a class loader error.

Error: WSCL0210E: The Enterprise archive file [EAR file name] could not be found. com.ibm.websphere.client.applicationclient.ClientContainerException: com.ibm.etools.archive.exception.OpenFailureException

Explanation

This error occurs when the application client run time cannot read the Enterprise Archive (EAR) file.

Possible causes

The most likely cause of this error is that the system cannot find the EAR file in the path specified on the `launchClient` command.

Recommended response

Verify that the path and file name specified on the `launchclient` command are correct.

The launchClient command appears to hang and does not return to the command line when the client application has finished.

Explanation

When running your application client using the `launchClient` command the WebSphere Application Server run time might need to display the security login dialog. To display this dialog, WebSphere Application Server run time creates an Abstract Window Toolkit (AWT) thread. When your application returns from its main method to the application client run time, the application client run time attempts to return to the operating system and end the Java virtual machine (JVM) code. However, since there is an AWT thread, the JVM code will not end until `System.exit` is called.

Possible causes

The JVM code does not end because there is an AWT thread. Java code requires that `System.exit()` be called to end AWT threads.

Recommended response

- Modify your application to call `System.exit(0)` as the last statement.
- Use the `-CCexitVM=true` parameter when you call the `launchClient` command.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- http://www.ibm.com/software/webservers/appserv/zos_os390/support/

clientUpgrade command

Use the **clientUpgrade** command to migrate previous versions of client resources to Version 7 level resources.

Use the **clientUpgrade** command to migrate Version 5.1.x and Version 6.x client resources to Version 7 level resources. In the process of migrating these resources, the client-resources.xmi file located in the client jars is migrated to the latest level. A backup of the client-resources.xmi file is also located in the client jar. If this command is not executed against the client EAR files before they are installed on Version 7, the client EARs do not operate or install correctly.

The command file is located in the *app_server_root*/bin directory.

```
clientUpgrade EAR_file [-clientJar client_jar ][-logFileLocation logFileLocation]
[-traceString trace_spec [-traceFile file_name ]]
```

Parameters

Supported arguments include the following:

EAR_file
Use this parameter to specify the fully qualified path to the EAR file that contains client JAR files to process.

-clientJar
Use this optional parameter to specify a JAR file for processing. If not specified, the program transforms all client JAR files in the EAR file.

-logFileLocation *log_file_location*
Use this optional parameter to specify an alternate location to store the log output.

-traceString *trace_spec* **-traceFile** *file_name*
Use these optional parameters to gather trace information for IBM Service personnel. Specify a trace_spec of `"*=all=enabled"` (with quotation marks) to gather all trace information.

The following example demonstrates correct syntax:

```
clientUpgrade EAR_file -clientJar ejbJarFile
```

Developing application clients

This topic provides the steps for programming application clients to access resource objects defined on the server.

About this task

To use application clients to access a remote object on the server, develop your application clients as described in the following steps:

1. Create an instance of the object that you want to access from the remote server.
2. Specify the user ID and password on the connection method, when you create a connection to the server. Security must be enabled.
3. Assemble the application client `.ear` file using an assembly tool. Assemble the application client `.ear` file on any development machine where the assembly tool is installed.
4. Add the resource to the client deployment descriptor by completing the binding JNDI name for the resource object on the server.
5. Distribute the configured `.ear` file to the client machines.
6. Deploy the application client.
7. Configure the application client resources.

What to do next

After you develop the application client code, run the application client.

Developing ActiveX application client code

This topic provides an outline for developing an ActiveX Windows program, such as Visual Basic, VBScript, and Active Server Pages, to use the WebSphere ActiveX to EJB bridge to access enterprise beans.

Before you begin

Note: This topic assumes that you are familiar with ActiveX programming and developing on the Windows platform.

Consider the information given in ActiveX to EJB bridge as good programming guidelines.

About this task

To use the ActiveX to EJB bridge to access a Java class, develop your ActiveX program to complete the following steps:

1. Create an instance of the XJB.JClassFactory object.
2. Create Java virtual machine (JVM) code within the ActiveX program process, by calling the XJBInit() method of the XJB.JClassFactory object. After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM code is initialized and ready for use.
3. Create a proxy object for the Java class, by using the XJB.JClassFactory FindClass() and NewInstance() methods. The ActiveX program can use the proxy object to access the Java class, object fields, and methods.
4. Call methods on the Java class, using the Java method invocation syntax, and access Java fields as required.
5. Use the helper functions to do the conversion in cases where automatic conversion is not possible. You can convert between the following data types:
   - Java Byte and Visual Basic Byte
   - Visual Basic Currency types and Java 64-bit
6. Implement methods to handle any errors returned from the Java class. In Visual Basic or VBScript, use the **Err.Number** and **Err.Description** fields to determine the actual Java error.

What to do next

After you develop the ActiveX client code, start the ActiveX application.

Starting an ActiveX application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

About this task

To perform the required configuration, complete one or more of the following tasks:

1. Start an ActiveX application and configure service programs.
2. Start an ActiveX application and configuring non-service programs

Starting an ActiveX application and configuring service programs

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, some initial configuration (to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time) is necessary. This configuration sets up the environment within which the ActiveX service program can run.

Before you begin

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java virtual machine (JVM) version available on a machine using ASP.

About this task

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following task.

On Windows 2000 systems, complete the following steps:

1. Open the Control Panel, then double-click the **System** icon.
2. Click the **Advanced** tab on the System Properties window.
3. Click **Environment Variables**.
4. Edit the Path variable in the System Variables window.
5. Add the following information to the beginning of the path that is displayed in the Variable Value field:

   ```
   C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;
   ```

   where `C:\WebSphere\AppClient` is the directory in which you installed the Java client in the WebSphere product.
6. Click **OK** in the Edit System Variable window to apply the changes.
7. Click **OK** in the Environment Variables window.
8. Click **OK** in the System Properties window.
9. Restart Windows 2000.

What to do next

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

Starting an ActiveX application and configuring non-service programs

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

About this task

To perform the required configuration, complete the following steps:

1. Edit the `setupCmdLineXJB.bat` file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java virtual machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
   - Use the `launchClientXJB.bat` file to start the application. For example:

```
launchClientXJB MyApplication.exe parm1 parm2
```

or

```
launchClientXJB MyApplication.vbp
```

- Use the `setupCmdLineXJB.bat` file to create an environment in which to run the application, then start the application from within that environment.

setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise JavaBeans (EJB) bridge to find its `XJB.JAR` file and the Java run-time environment.

Location

The include file is located in the *was_client_home*`\aspIncludes` directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<--  #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called `WSASPIncludes` that points to the *was_client_home*`\aspIncludes` directory.

Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- **setupCmdLineXJB.bat**

  Sets the client environment variables.
- **launchClientXJB.bat**

  Calls the `setupCmdLineXJB.bat` file and launches the application you specify as its arguments; for example:

  ```
  launchClientXJB.bat myapp.exe parm1 parm2
  ```

  or

  ```
  launchClientXJB MyApplication.vbp
  ```
- **Active Server Pages (ASP) include file**

  An include file is provided for ASP users to automatically set the following page-level (local) environment variables:
  - **com_ibm_websphere_javahome**. Path to the Java run-time directory installed with the WebSphere advanced server client.
  - **com_ibm_websphere_washome**. Path to the WebSphere advanced server client directory.
  - **com_ibm_websphere_namingfactory**. Sets the Java java.naming.factory.initial system property.
  - **com_ibm_websphere_computername**. (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.
- **System settings**

  To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

  was_client_home`\java\jre\bin;`*was_client_home*`\java\jre\bin\classic`

  Where *was_client_home* is the name of the directory where you installed the WebSphere Application Server client (for example, `C:\WebSphere\AppClient`).

  Note: This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

JClassProxy and JObjectProxy classes

The majority of tasks for accessing your Java classes and objects are handled with the JClassProxy and JObjectProxy objects. This topic provides reference information about the object classes of the ActiveX to Enterprise Java Beans (EJB) bridge.

JClassFactory is the object used to access the majority of Java Virtual Machine (JVM) features. This object handles JVM initialization, accesses classes and creates class instances (objects). Use the JClassProxy and JObjectProxy objects to access the majority of your Java classes and objects:

- XJBInit(String astrJavaParameterArray())

  Initializes the JVM environment using an array of strings that represent the command line parameters you normally send to the `java.exe` file.

  If you have invalid parameters in the XJBInit() string array, the following error is displayed:

  ```
  Error: 0x6002 "XJBJNI::Init() Failed to create VM" when calling XJBInit()
  ```

  If you have C++ logging enabled, the activity log displays the invalid parameter.
- JClassProxy FindClass(String strClassName)

  Uses the current thread class loader to load the specified fully qualified class name and returns a JClassProxy object representing the Java Class object.
- JObjectProxy NewInstance()

  Creates a Class instance for the specified JClassProxy object using the parameters supplied to call the Class constructor. For more information about using the JMethodArgs method, see ActiveX to EJB bridge, calling Java methods.

```
JObjectProxy NewInstance(JClassFactory obj, Variant vArg1, Variant vArg2, Variant vArg3, ...)
JObjectProxy NewInstance(JClassFactory obj, JMethodArgs args)
```

- JMethodArgs GetArgsContainer()

  Returns a JMethodArgs object (Class instance).

  You can create a JClassProxy object from the JClassFactory.FindClass() method and from any Java method call that normally return a Java Class object. You can use this object as if you had direct access to the Java Class object. All of the class static methods and fields are accessible as are the java.lang.Class methods. In case of a clash between static method names of the reflected user class and those of the java.lang.Class (for example, getName()), the reflected static methods would execute first.

  For example, the following is a static method called getName(). The java.lang.Class object also has a method called getName():

  – In Java:

  ```
  class foo{
   foo(){};
   public static String getName(){return "abcdef";}
   public static String getName2(){return "ghijkl";}
   public String toString2(){return "xyz";}
  }
  ```

  – In Visual Basic:

  ```
  ...
  Dim clsFoo as Object
  set clsFoo = oXJB.FindClass("foo")
  clsFoo.getName()  ' Returns "abcdef" from the static foo class
  clsFoo.getName2() ' Returns "ghijkl" from the static foo class
  clsFoo.toString() ' Returns "class foo" from the java.lang.Class object.
  oFoo = oXJB.NewInstance(clsFoo)
  oFoo.toString() ' Returns some text from the java.lang.Object's
                  ' toString() method which foo inherits from.
  oFoo.toString2() ' Returns "xyz" from the foo class instance
  ```

  You can create a JObjectProxy object from the JClassFactory.NewInstance() method, and can be created from any Java method call that normally returns a Class instance object. You can use this

object as if you had direct access to the Java object and can access all the static methods and fields of the object. All of object instance methods and fields are accessible (including those accessible through inheritance).

The JMethodArgs object is created from the JClassFactory.GetArgsContainer() method. Use this object as a container for method and constructor arguments. You must use this object when overriding the object type when calling a method (for example, when sending a java.lang.String JProxyObject type to a constructor that normally takes a java.lang.Object type).

You can use two groups of methods to add arguments to the collection: Add and Set. You can use Add to add arguments in the order that they are declared. Alternatively, you can use Set to set an argument based on its position in the argument list (where the first argument is in position 1).

For example, if you had a Java Object Foo that took a constructor of Foo (int, String, Object), you could use a JMethodArgs object as shown in the following code extract:

```
...
Dim oArgs as Object
set oArgs = oXJB.GetArgsContainer()

oArgs.AddInt(CLng(12345))
oArgs.AddString("Apples")
oArgs.AddObject("java.lang.Object", oSomeJObjectProxy)

Dim clsFoo as Object
Dim oFoo as Object
set clsFoo = oXJB.FindClass("com.mypackage.foo")
set oFoo = oXJB.NewInstance(clsFoo, oArgs)

' To reuse the oArgs object, just clear it and use the add method
' again, or alternatively, use the Set method to reset the parameters
' Here, we will use Set
oArgs.SetInt(1, CLng(22222))
oArgs.SetString(2, "Bananas")
oArgs.SetObject(3, "java.lang.Object", oSomeOtherJObjectProxy)

Dim oFoo2 as Object
set oFoo2 = oXJB.NewInstance(clsFoo, oArgs)
```

- AddObject (String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the next available position, casting the object to the class name specified in the first parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  AddObject("java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  AddObject("int[]", oMyArrayOfInts)
  ```

- AddByte (Byte byteArg)

  Adds a primitive byte value to the argument container in the next available position.

- AddBoolean (Boolean bArg)

  Adds a primitive boolean value to the argument container in the next available position.

- AddShort (Integer iArg)

  Adds a primitive short value to the argument container in the next available position.

- AddInt (Long lArg)

  Adds a primitive int value to the argument container in the next available position.

- AddLong (Currency cyArg)

  Adds a primitive long value to the argument container in the next available position.

- AddFloat (Single fArg)

  Adds a primitive float value to the argument container in the next available position.

- AddDouble (Double dArg)

  Adds a primitive double value to the argument container in the next available position.

- AddChar (String strArg)

  Adds a primitive char value to the argument container in the next available position.
- AddString (String strArg)

  Adds the argument in string form to the argument container in the next available position.
- SetObject (Integer iArgPosition, String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the specified position casting it to the class name or primitive type name specified in the second parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  SetObject(1, "java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  SetObject(2, "int[]", MyArrayOfInts)
  ```
- SetByte (Integer iArgPosition, Byte byteArg)

  Sets a primitive byte value to the argument container in the position specified.
- SetBoolean (Integer iArgPosition, Boolean bArg)

  Sets a primitive boolean value to the argument container in the position specified.
- SetShort (Integer iArgPosition, Integer iArg)

  Sets a primitive short value to the argument container in the position specified.
- SetInt (Integer iArgPosition, Long lArg)

  Sets a primitive int value to the argument container in the position specified.
- SetLong (Integer iArgPosition, Currency cyArg)

  Sets a primitive long value to the argument container in the position specified.
- SetFloat (Integer iArgPosition, Single fArg)

  Sets a primitive float value to the argument container in the position specified.
- SetDouble (Integer iArgPosition, Double dArg)

  Sets a primitive double value to the argument container in the position specified.
- SetChar (Integer iArgPosition, String strArg)

  Sets a primitive char value to the argument container in the position specified.
- SetString (Integer iArgPosition, String strArg)

  Sets a java.lang.String value to the argument container in the position specified.
- Object Item(Integer iArgPosition)

  Returns the value of an argument at a specific argument position.
- Clear()

  Removes all arguments from the container and resets the next available position to one.
- Long Count()

  Returns the number of arguments in the container.

Java virtual machine initialization tips

Initialize the Java virtual machine (JVM) code with the ActiveX to Enterprise Java Beans (EJB) bridge. For an ActiveX client program (Visual Basic, VBScript, or ASP) to access Java classes or objects, the first step that the program must do is to create Java virtual machine (JVM) code within its process.

To create JVM code, the ActiveX program calls the XJBInit() method of the XJB.JClassFactory object. When an XJB.JClassFactory object is created and the XJBInit() method called, the JVM is initialized and ready to use.

- To enable the XJB.JClassFactory to find the Java run-time description definition language (DLL) when initializing, the Java Runtime Environment (JRE) bin and `bin\classic` directories must exist in the system path environment variable.
- The XJBInit() method accepts only one parameter: an array of strings. Each string in the array represents a command line argument that for a Java program you would normally specify on the

`Java.exe` command line. This string interface is used to set the class path, stack size, heap size and debug settings. You can get a listing of these parameters by typing `java -?` from the command line.
- If you set a parameter incorrectly, you receive a `0x6002 "Failed to initialize VM"` error message.
- Due to the current limitations of Java Native Interface (JNI), you cannot unload or reinitialize the JVM code after it has loaded. Therefore, after the XJBInit() method has been called once, subsequent calls have no effect other than to create a duplicate JClassFactory object for you to access. It is best to store your XJB.JClassFactory object globally and continue to reuse that object.
- The following Visual Basic extract shows an example of initializing JVM code:

```
Dim oXJB as Object
set oXJB = CreateObject("XJB.JClassFactory")
Dim astrJavaInitProps(0) as String
astrJavaInitProps(0) = _
     "-Djava.class.path=.;c:\myjavaclasses;c:\myjars\myjar.jar"
oXJB.XJBInit(astrJavaInitProps)
```

Example: Developing an ActiveX application client to enterprise beans

This reference topic provides an example of using Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge.

To use Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge:
- After an ActiveX client program (Visual Basic, VBScript, or Active Server Pages (ASP)) has initialized the XJB.JClassFactory object and thereby, the Java virtual machine (JVM), the client program can access Java classes and initialize Java objects. To complete this action, the client program uses the XJB.JClassFactory FindClass() and NewInstance() methods.
- In Java programming, two ways exists to access Java classes: direct invocation through the Java compiler and through the Java Reflection interface. Because the ActiveX to Java bridge needs no compilation and is a complete run-time interface to the Java code, the bridge depends on the latter Reflection interface to access its classes, objects, methods and fields. The XJB.JClassFactory FindClass() and NewInstance() methods behave very similarly to the Java Class.forName() and the Method.invoke() and Field.invoke() methods.
- XJB.JClassFactory.FindClass() takes the fully qualified class name as its only parameter and returns a Proxy Object (JClassProxy). You can use the returned Proxy object like a normal Java Class object and call static methods and access static fields. You can also create a Class Instance (or object), as described below. For example, the following Visual Basic code extract returns a Proxy object for the java.lang.Integer Java class:

  ```
  ...
  Dim clsMyString as Object
  Set clsMyString = oXJB.FindClass("java.lang.Integer")
  ```
- After the proxy is created, you can access its static information directly. For example, you can use the following code extract to convert a decimal integer to its hexadecimal representation:

  ```
  ...
  Dim strHexValue as String
  strHexValue = clsMyString.toHexString(CLng(255))
  ```
- The equivalent Java syntax is: `static String toHexString(int i)`. Because ints units in Java programming are really 32-bit (which translates to Long in Visual Basic), the CLng() function converts the value from the default int to a long. Also, even though the toHexString() function returns a java.lang.String, the code extract does not return an Object proxy. Instead, the returned java.lang.String is automatically converted to a native Visual Basic string.

  To create an object from a class, you use the JClassFactory.NewInstance() method. This method creates an Object instance and takes whatever parameters your class constructor needs. Once the object is created, you have access to all of its public instance methods and fields. For example, you can use the following Visual Basic code extract to create an instance of the java.lang.Integer string:

```
...
Dim oMyInteger as Object
set oMyInteger = oXJB.NewInstance(CLng(255))

Dim strMyInteger as String
strMyInteger = oMyInteger.toString
```

Example: Calling Java methods in the ActiveX to enterprise beans

In the ActiveX to Enterprise Java Beans (EJB) bridge, methods are called using the native language method invocation syntax.

The following differences between Java invocation and ActiveX Automation invocation exist:

- Unlike Java methods, ActiveX does not support method (and constructor) polymorphism; that is, you cannot have two methods in the same class with the same name.
- Java methods are case-sensitive, but ActiveX Automation is not case-sensitive.
- To compensate for Java polymorphic behavior, give the exact parameter types to the method call. The parameter types determine the correct method to invoke. For a listing of correct types to use, see ActiveX to EJB bridge, converting data types.
- For example, the following Visual Basic code fails if the CLng() method was not present or the toHexString syntax was incorrectly typed as ToHexString:

  ```
  ...
  Dim strHexValue as String
  strHexValue = clsMyString.toHexString(CLng(255))
  ```
- Sometimes it is difficult to force some development environments to leave the case of your method calls unchanged. For example, in Visual Basic if you want to call a method `close()` (lowercase), the Visual Basic code capitalizes it `"Close()"`. In Visual Basic, the only way to effectively work around this behavior is to use the CallByName() method. For example:

  ```
  o.Close(123)                                'Incorrect...
  CallByName(o, "close", vbMethod, 123)       'Correct...
  ```

  or in VBScript, use the `Eval` function:

  ```
  o.Close(123)                                 'Incorrect...
  Eval("o.Close(123)")                         'Correct...
  ```
- The return value of a function is always converted dynamically to the correct type. However, you must take care to use the set keyword in Visual Basic. If you expect a non-primitive data type to return, you must use set. (If you expect a primitive data type to return, you do not need to use set.) See the following example for more explanation:

  ```
  Set oMyObject = o.getObject
  iMyInt = o.getInt
  ```
- In some cases, you might not know the type of object returning from a method call, because wrapper classes are converted automatically to primitives (for example, java.lang.Integer returns an ActiveX Automation Long). In such cases, you might need to use your language built-in exception handling techniques to try to coerce the returned type (for example, On Error and Err.Number in Visual Basic).
- Methods with character arguments

  Because ActiveX Automation does not natively support character types supported by Java methods, the ActiveX to EJB bridge uses strings (byte or VT_I1 do not work because characters have multiple bytes in Java code). If you try to call a method that takes a char or java.lang.Character type you must use the JMethodArgs argument container to pass character values to methods or constructors. For more information about how this argument container is used, see Methods with "Object" Type as Argument and Abstract Arguments.
- Methods with "Object" Type as Argument and Abstract Arguments

  Because of the polymorphic nature of Java programming, the ActiveX to Java bridge uses direct argument type mapping to find a method. This method works well in most cases, but sometimes methods are declared with a Parent or Abstract class as an argument type (for example, java.lang.Object). You need the ability to send an object of arbitrary type to a method. To acquire this

ability, you must use the XJB.JMethodArgs object to coerce your parameters to match the parameters on your method. You can get a JMethodArgs instance by using the JClassFactory.GetArgsContainer() method.

The JMethodArgs object is a container for method parameters or arguments. This container enables you to add parameters to it one-by-one and then you can send the JMethodArgs object to your method call. The JClassProxy and JObjectProxy objects recognize the JMethodArgs object and attempt to find the correct method and let the Java language coerce your parameters appropriately.

For example, to add an element to a Hashtable object the method syntax is `Object put(Object key, Object value)`. In Visual Basic, the method usage looks like the following example code:

```
Dim oMyHashtable as Object
Set oMyHashtable = _
    oXJB.NewInstance(oXJB.FindClass("java.utility.Hashtable"))

' This line will not work. The ActiveX to EJB bridge cannot find a method
' called "put" that has a short and String as a parameter:
oMyHashtable.put 100, "Dogs"
oMyHashtable.put 200, "Cats"

' You must use a XJB.JMethodArgs object instead:
Dim oMyHashtableArgs as Object
Set oMyHashtableArgs = oXJB.GetArgsContainer
oMyHashtableArgs.AddObject("java.lang.Object", 100)
oMyHashtableArgs.AddObject("java.lang.Object", "Dogs")

oMyHashtable.put oMyHashTableArgs
' Reuse the same JMethodArgs object by clearing it.
oMyHashtableArgs.Clear
oMyHashtableArgs.AddObject("java.lang.Object", 200)
oMyHashtableArgs.AddObject("java.lang.Object", "Cats")

oMyHashtable.put oMyHashTableArgs
```

Java field programming tips

Using the ActiveX to Enterprise JavaBeans (EJB) bridge to access Java fields has the same case sensitivity issue that it has when invoking methods. Field names must use the same case as the Java field syntax.

Visual Basic code has the same problem with unsolicited case changing on fields as it does with methods. (For more information about this problem, see ActiveX to EJB bridge, calling Java methods). You might use the CallByName() function to set a field in the same way that you call a method in some cases. For fields, use `VBLet` for primitive types and `VBSet` for objects. For example:

```
o.MyField = 123                         'Incorrect...
CallByName(o, "MyField", vbLet, 123)    'Correct...
```

or in VBScript:

```
o.MyField = 123                          'Incorrect...
Eval("o.myField = 123")                  'Correct...
```

ActiveX to Java primitive data type conversion values

All primitive Java data types are automatically converted to native ActiveX Automation types. However, not all Automation data types are converted to Java types (for example, VT_DATE). Variant data types are used for data conversion.

Variant data types are a requirement of any Automation interface, and are used automatically by Visual Basic and VBScript. The tables below provide details about how primitive data types are converted between Automation types and Java types.

Table 8. ActiveX to Java primitive data type conversion

Visual Basic Type	Variant Type	Java Type	Notes®
Byte	VT_I1	byte	Byte in Visual Basic is unsigned, but is signed in Java data type.
Boolean	VT_BOOL	boolean	
Integer	VT_I2	short	
Long	VT_I4	int	
Currency	VT_CY	long	
Single	VT_R4	float	
Double	VT_R8	double	
String	VT_BSTR	java.lang.String	
String	VT_BSTR	char	
Date	VT_DATE	n/a	

Example: Using helper methods for data type conversion

Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible:

- Byte helper function

  Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
      GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

  Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, ″HOWTO: Do 64-bit Arithmetic in VBA″, on the Microsoft® Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
```

```
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                          Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
                          Left$(Value, L - 4) & "." & Right$(Value, 4))
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn

' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1

' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value
```

Array tips for ActiveX application clients

Arrays are very similar between Java and Automation containers like Visual Basic and `VBScript`. This topic provides some important points to consider when passing arrays back and forth between these containers.

Here are some important points to consider when passing arrays back and forth between these containers:

- Java arrays cannot mix types. All Java arrays contain a single type, so when passing arrays of variants to a Java array, you must make sure that all of the elements in the variant array are of the same base type. For example, in Visual Basic code:

  ```
  ...
  Dim VariantArray(1) as Variant
  VariantArray(0) = CLng(123)
  VariantArray(1) = CDbl(123.4)
  oMyJavaObject.foo(VariantArray) '     Illegal!

  VariantArray(0) = CLng(123)
  VariantArray(1) = CLng(1234)
  oMyJavaObject.foo(VariantArray) '     This works
  ```

- Arrays of primitive types are converted using the rules defined in primitive data type conversion.
- Arrays of Java objects are handled through arrays of JObjectProxy objects.

- Arrays of JObjectProxy objects must be fully initialized and of the correct associated Java type. When initializing an array in Visual Basic (for example, Dim oJavaObjects(1) as Object), you must set each object to a JObjectProxy object before you send the array to a Java object. The bridge is unable to determine the type of null or empty object values.
- When receiving an array from a Java method, the lower-bound is always zero. Java methods only support zero-based arrays.
- Nested or multidimensional arrays are treated as zero-based multidimensional arrays in Visual Basic and VBScript containers.
- Uninitialized arrays or Array Types are unsupported. When calling a Java method that takes an array of objects as a parameter, you must fully initialize the array of JObjectProxy objects.

Error handling codes for ActiveX application clients

All exceptions thrown in Java code are encapsulated and thrown again as a COM error through the ISupportErrorInfo interface and the EXCEPINFO structure of IDispatch::Invoke(), the Err object in Visual Basic and VBScript. Because there are no error numbers associated with Java exceptions, whenever a Java exception is thrown, the entire stack trace is stored in the error description text and the error number assigned is 0x6003.

In Visual Basic or VBScript, you need to use the **Err.Number** and **Err.Description** fields to determine the actual Java error. Non-Java errors are thrown as you would expect via the IDispatch interface; for example, if a method cannot be found, then error 438 ″Object doesn't support this property or method″ is thrown.

Error number	Description
0x6001	Java Native Interface (JNI) error
0x6002	Initialization error
0x6003	Java exception. Error description is the Java Stack Trace.
0x6FFF	General Internal Failure

Threading tips

The ActiveX to Enterprise JavaBeans (EJB) bridge supports both free-threaded and apartment-threaded access and implements the Free Threaded Marshaler to work in a hybrid environment such as Active Server Pages (ASP). Each thread created in the ActiveX process is mirrored in the Java environment when the thread communicates through the ActiveX to EJB bridge.

Once all references to Java objects (there are no JObjectProxy or JClassProxy objects) are loaded in an ActiveX thread, the ActiveX to EJB bridge detaches the thread from the Java virtual machine (JVM) code. Therefore, you must be careful that any Java code that you access from a multithreaded Windows application is thread safe. Visual Basic code and VBScript applications are both essentially single threaded. Therefore, Visual Basic and VBScript applications do not have threading issues in the Java programs they access. Active Server Pages and multithreaded C and C++ programs can have issues.

Consider the following scenario:
1. A multithreaded Windows Automation Container (our ActiveX Process) starts. It exists on Thread A.
2. The ActiveX Process initializes the ActiveX to EJB bridge, which starts the JVM code. The JVM attaches to the same thread and internally calls it Thread 1.
3. The ActiveX Process starts two threads: B and C.
4. Thread B in the ActiveX Process uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM attaches to thread B and calls it Thread 2.
5. Thread C in the ActiveX Process never talks to the JVM code, so the JVM never needs to attach to it. This is a case where the JVM code does not have a one-to-one relationship between ActiveX threads and Java threads.

6. Thread B later releases all of the JObjectProxy and JClassProxy objects that it used. The Java Thread 2 is detached.
7. Thread B again uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM code attaches again to the thread and calls it Thread 3.

ActiveX process	JVM access by ActiveX process
Thread A - Created in 1	Thread 1 - Attached in 2
Thread B - Created in 4	Thread 2 - Attached in 4, detached in 6 Thread 3 - Attached in 7
Thread C - Created in 4	

Threads and Active Server Pages

Active Server Pages (ASP) in Microsoft Internet Information Server is a multithreaded environment. When you create the XJB.JClassFactory object, you can store it in the Application collection as an Application-global object. All threads within your ASP environment can now access the same ActiveX to EJB bridge object. Active Server Pages by default creates 10 Apartment Threads per ASP process per CPU. This means that when your ActiveX to EJB bridge object is initialized any of the 10 threads can call this object, not just the thread that created it.

If you need to simulate single-apartment behavior, you can create a Single-Apartment Threaded ActiveX dynamic link library (DLL) in Visual Basic code and encapsulate the ActiveX to the EJB bridge object. This encapsulation guarantees that all access to the JVM object is on the same thread. You need to use the <OBJECT> tag to assign the XJB.JClassFactory to an Application object and must be aware of the consequences of introducing single-threaded behavior to a Web application.

The Microsoft KnowlegeBase has several articles about ASP and threads, including:
- Q243543 INFO: Do Not Store STA Objects in Session or Application
- Q243544 INFO: Component Threading Model Summary Under Active Server Pages
- Q243548 INFO: Design Guidelines for VB Components Under ASP

Example: Viewing a System.out message

The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

This example redirects output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, you need to override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs

' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
```

```
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

Example: Enabling logging and tracing for application clients

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

  The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining `XJBInit()` errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

  To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to `XJBInit()`. If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the `XJBInit()` method. Once the `XJBInit()` method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java `java.lang.System.setProperty()` to set these values also has no effect.

  – `-Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled`

    Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.

  – `-Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled`

    Enables or disables event level messages from appearing in the Windows operating system event log.

  – `-Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled`

    Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

  Viewing the Windows application event log with the event viewer:

  To open the event viewer in the Windows operating system:

  1. Click **Start** > **Settings** > **Control Panel**.
  2. Double-click **Administrative Tools**.
  3. Double-click **Event Viewer**.

  All ActiveX to EJB bridge events display the text `WebSphere XJB` in the source column and in the application log. For information about using Event Viewer, click the **Action** menu in Event Viewer, and then click **Help**.

  To open the even viewer in the Windows operating system, click **Start** > **Programs** > **Administrative Tools** > **Event Viewer**. All ActiveX to EJB bridge events have the text `WebSphere XJB` in the source column and display in the application log. For information about using Event Viewer, click the **Help** menu in Event Viewer.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Since the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
"-DtraceFile=C:\MyTrace.txt"
```

ActiveX client programming best practices

The best way to access Java components is to use the Java language. It is recommended that you do as much programming as possible in the Java language and use a small simple interface between your COM Automation container (for example, Visual Basic) and the Java code. This interface avoids any overhead and performance problems that can occur when moving across the interface.

Note: The following topics are covered:

- Visual Basic guidelines
- CScript and Windows Scripting Host
- Active Server Pages guidelines
- J2EE guidelines

Visual Basic guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with Visual Basic:

- Launch the Visual Basic replication through the `launchClientXJB.bat` file. If you want to run your Visual Basic application through the Visual Basic debugger, run the Visual Basic integrated development environment (IDE) within the ActiveX to EJB bridge environment. After you create your Visual Basic project, you can launch it from a command line; for example, `launchClientXJB MyApplication.vbp`. You can also launch the Visual Basic application alone in the ActiveX to EJB environment, by changing the Visual Basic shortcut on the Windows Start menu so that the `launchClientXJB.bat` file precedes the call to the `VB6.EXE` file.
- Exit the Visual Basic IDE before debugging programs.

  Because the Java virtual machine (JVM) code attaches to the running process, you must exit the Visual Basic editor before debugging your program. If you run the process, then exit your program within the Visual Basic IDE, the JVM code continues to run and you reattach the same JVM code when XJBInit() is called by the debugger. This causes problems if you try to update XJBInit() arguments (for example, classpath) because the changes are not be applied until you restart the Visual Basic program.
- Store the XJB.JClassFactory object globally.

  Because you cannot unload or reinitialize the JVM code, cache the resulting XJB.JClassFactory object as a global variable. The overhead of treating this object as a global variable or passing a single reference around is much less than recreating a new XJB.JClassFactory object and calling the XJBInit() argument more than once.

CScript and Windows Scripting Host

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with CScript and Windows Scripting Host (WSH):

- Launch in ActiveX to EJB environment.

  Launch the VBScript files in the ActiveX to EJB bridge environment, to run VBScript files in `.vbs` files. Two common ways exist to launch your script:
  - `launchClientXJB MyScript.vbs`
  - `launchClientXJB cscript MyScript.vbs`

Active Server Pages guidelines

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with Active Server Pages software:

- Use the ActiveX to EJB Helper functions from the Active Server Pages Application.

  Because Active Server Pages (ASP) code typically use VBScript, you can use the included helper functions in any VBScript environment with minor changes. For more information about these helper functions, see Helper functions for data type conversion. To run outside of the ASP environment,

remove or change all references to the Server, Request, Response, Application and Session objects; for example, change `Server.CreateObject` to `CreateObject`.

- Set JRE path globally in system.

  The XJB.JClassFactory object must be able to find the Java run time dynamic link library (DLL) when initializing. In Internet Information Server, you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. You can only have a single JVM version available on a machine using the ASP application. Also, remember that after you change the system PATH variable you must reboot the Internet Information Server machine so that the Internet Information Server can see the change.
- Set the system TEMP environment variable.

  If the system TEMP environment variable is not set, Internet Information Server stores all temporary files in the `WINNT` directory, which is usually not desired.
- Use high isolation or an isolated process.

  When using the ActiveX to Java bridge with Active Server Pages software, creating your Web application in its own process is recommended. You can only load one JVM instruction in a single process and if you want to have more than one application running with different JVM environment options (for example, different classpaths), then you need to have separate processes.
- Use the Application Unload option.

  When debugging your application, use **Unload** when viewing your ASP application properties in the Internet Information Server administration console to unload the process from memory and thereby unload the JVM code.
- Run one process per application.

  Use only one ASP application per J2EE application or JVM environment, in your ASP environment. If you need separate class paths or JVM settings, you need separate ASP applications (virtual directories with high isolation or an isolated process).
- Store the XJB.JClassFactory object in application scope.

  Because of the one-to-one relationship required between a JVM instruction and a process, and because the JVM code can never detach or shut down from a process independently, cache the XJB.JClassFactory object at application scope and call the XJBInit() method only once.

  Because the ActiveX to EJB bridge employs a free-threaded marshaler, take advantage of the multi-threaded nature of Internet Information Server and the ASP environment. If you choose to reinitialize the XJB.JClassFactory object at Page scope (local variables), then the XJBInit() method can only initialize your local XJB.JClassFactory variable. It is more efficient to use the XJBInit() method once.
- Use VBScript conversion functions.

  Because VBScript code only supports variant data types, use the CStr(), CByte(), CBool(), CCur(), CInt(), Clng(), CSng() and CDbl() functions to tell the activeX to EJB bridge which data type you are using; for example `oMyObject.Foo(CDbl(1.234))`.

J2EE guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with the J2EE environment;

- Store client container objects globally.

  Because you can only have one JVM instruction per process, and a single J2EE client container (com.ibm.websphere.client.applicationclient.launchClient) per JVM instruction, initialize your J2EE client container only once and reuse it. For ASP applications, store the J2EE client container in an application level variable and initialize it only once (either on the Application_OnStart() event in the `global.asa` file or by checking to see if it IsEmpty()).

  A side effect to storing the client container object globally is that you cannot change the client container parameters without destroying the object and creating a new one. These parameters include the EAR file, BootstrapHost, class path, and so on. If you run a Visual Basic application and want to change the client container parameters, you must end the application and restart it. If you run an Active Server

Pages application, you must first unload the application from Internet Information Server (see ″Use the Application Unload Button″ under Active Server Pages guidelines). Then load the Active Server Pages application with the different client container parameters. The parameters set the first time the Active Server Pages application loads. Since the client container is stored on the Internet Information Server, all the browser clients share the parameters using the Active Server Pages application. This behavior is normal for Active Server Pages code, but can be confusing when you try to run to different WebSphere Application Servers using the same Active Server Pages application, which is not supported.

- Reuse custom temporary directory for EAR file extraction.

  By default, the client container launches and extracts the application `.ear` file to your `temp` directory and then sets up the thread class loader to use the extracted EAR file directory and the JAR files included in the client JAR manifest. This process is time consuming and because of some limitations with JVM shutdown through Java Native Interface (JNI) and file locking, these files are never cleaned up.

  Specifically, each time the client container launch() method is called, it extracts the EAR file to a random directory name in your temporary directory on your hard drive. The current Java thread class loader is then changed to point to this extracted directory which in turn locks the files within. In a normal J2EE Java client, these files automatically clean up after the application exits. This cleanup occurs when the client container shutdown hook is called (which never happens in the ActiveX to EJB bridge), which leaves the temporary directory there.

  To avoid these problems, you can specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property before calling the client container launch() method. If the directory does not exist or is empty, you extract the EAR file normally. If the EAR file was previously extracted, the directory is reused. This feature is particularly important for server processes (for example, ASP), which can stop and restart, potentially calling the launchClient() method several times.

  If you need to update your EAR file, delete the temporary directory first. The next time you create the client container object, it extracts the new EAR file to the temporary directory. If you do not delete the temporary directory or change the system property value to point to a different temporary directory, the client container reuses the currently extracted EAR file, and does not use your changed EAR file.

  Note: When specifying the com.ibm.websphere.client.applicationclient.archivedir property, ensure that the directory you specify *is unique* for each EAR file you use. For example, do not point `MyEar1.ear` and `MyEar2.ear` files to the same directory.

  If you choose not to use this system property, go regularly to your Windows `temp` directory and delete the WSTMP* subdirectories. Over a relatively short period of time, these subdirectories can waste a significant amount of space on the hard drive.

Developing applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

Before you begin

Applet clients have the following setup requirements:

- These clients are available on the Windows platforms. Check the prerequisites page for information on platform support and product prerequisites.
- The browser installation precedes the client code installation.

About this task

Unlike typical applets that reside on either Web servers or WebSphere Application Servers and can only communicate using the HTTP protocol, applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

1. Install the Application Client for WebSphere Application Server.

2. Select the applet client feature.
3. From the IBM Control Panel for Java, enter the following code:

```
-Xmx512M
-Djava.security.policy=<app_client_root>\properties\client.policy
-Dwas.install.root=<app_client_root>
-Djava.ext.dirs=<app_client_root>\java\jre\lib\ext;
<app_client_root>\lib;
<app_client_root>\plugins;
<app_client_root>\lib\ext;
<app_client_root>\installedConnectors\
-Djava.class.path=<app_client_root>\properties
-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props
```

Note: The previous entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client. If this sample is being run by a user other than the person who installed the client, the user must enter the entries.

- The Java **Run-Time Parameters** field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.
- Access the IBM Control Panel for Java from the **Start** menu. Click **Start** > **Control panel** > select the IBM Control Panel for Java.
- The applet container is the Web browser and the Java plug-in combination. You must first install the Applet client feature from the Application Client for WebSphere Application Server so that the browser recognizes the IBM product Java plug-in.

View the Samples gallery for more information about application clients.

Accessing secure resources using SSL and applet clients

By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use secure sockets layer (SSL) when needed.

About this task

If you decide that the security requirements for the applet differ from other application client types, then create a new version of the `sas.client.props` and `ssl.client.props` files.

1. Make a copy of the following files so that you can use them for an applet:
   - *<app_client_root>*\properties\sas.client.props
   - *<app_client_root>*\properties\ssl.client.props
2. Edit the copies of the `sas.client.props` and `ssl.client.props` files that you made with your changes.
3. Click **Start** > **Control panel** > select the product Java plug-in to open the Java control panel. To use the files you created in step 1, modify the following values:
   - `-Dcom.ibm.CORBA.ConfigURL=file:`*<app_client_root>*`\properties\sas.client.props`
   - `-Dcom.ibm.SSL.ConfigURL=file:`*<app_client_root>*`\properties\ssl.client.props`

   For more information on the `sas.client.props` and `ssl.client.props` files and WebSphere Application Server security, see the Security section of the information center.

Applet client security requirements

When code is loaded, it is assigned permissions based on the security policy in effect. This policy specifies the permissions that are available for code from various locations. You can initialize this policy from an external policy file.

By default, the client uses the *<app_server_root>*`/properties/client.policy` file. You must update this file with the following permission:

SocketPermission grants permission to open a port and make a connection to a host machine, which is your WebSphere Application Server. In the following example, yourserver.yourcompany.com is the complete host name of your WebSphere Application Server:

```
permission java.util.PropertyPermission "*", "read";
permission java.net.SocketPermission "yourserver.yourcompany.com ,"connect";
```

Example: Applet client tag requirements

Standard applets require the HTML <APPLET> tag to identify the applet to the browser. The <APPLET> tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by <OBJECT> and <EMBED> tags.

The following code example illustrates the applet code using the <APPLET> tag.

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the <OBJECT> and <EMBED> tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

Note: The classid and type values changed from WebSphere Application Server version 6.0.2 for version 6.1. Prior to version 6.1, the classid value was clsid:8AE2D840-EC04-11D4-AC77-006094334AA9 and the type value was application/x-websphere-client. In order to successfully invoke the applet client in WebSphere Application Server version 6.1, these values need to be changed to those in the preceding example.

For more information about the applet client tag, see the Sun Microsystems article, http://java.sun.com/j2se/1.5.0/docs/guide/plugin/developer_guide/using_tags.html.

Example: Applet client code requirements

The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called java.naming.applet. This property informs the InitialContext and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet.

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the third line to your code, which identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

Developing Java EE application client code

This topic provides the steps required to develop Java Platform, Enterprise Edition (Java EE) application client code.

About this task

A *Java EE application client* program operates similarly to a standard Java EE program in that it runs its own ASCII Java virtual machine code and is invoked at its main method. This JVM run-time environment is part of the client container, which provides the following services for the application client:

- Security
- Communications protocol support (for RMI/IIOP, HTTP, and so on)
- Naming support

The Java Virtual Machine application client program differs from a standard Java program because it uses the Java Naming and Directory Interface (JNDI) namespace to access resources. In a standard Java program, the resource information is coded in the program.

Storing the resource information separately from the client application program makes the client application program portable and more flexible.

1. Write the client application program. Write the Java EE application client program on any development machine. At this stage, you do not require access to the WebSphere Application Server.

   Rules: If you are writing a client application program that will run on z/OS, the following rules apply:
   - Client programs may start their own transactions but cannot join in or start transactions in the WebSphere Application Server for z/OS run-time.
   - Application client code must contain a main method.
   - All input and output files for the application client must be in ASCII, because the client run-time runs in an ASCII JVM.

   Using the `javax.naming.InitialContext` class, the client application program uses the look-up operation to access the Java Naming and Directory Interface (JNDI) namespace. The `InitialContext` class provides the `lookup` method to locate resources.

   The following example illustrates how a client application program uses the `InitialContext` class:

```
import javax.naming.*

public class myAppClient
{
    public static void main(String argv[])
    {
        InitialContext initCtx = new InitialContext();
        Object homeObject = initCtx.lookup("java:comp/env/ejb/BasicCalculator");
        BasicCalculatorHome bcHome = (BasicCalculatorHome)
        javax.rmi.PortableRemoteObject.narrow(homeObject, BasicCalculatorHome.class);
        BasicCalculatorHome bc = bcHome.create();                              ...
    }
}
```

   In this example, the program looks up an enterprise bean called `BasicCalculator`. The `BasicCalculator` Enterprise JavaBeans (EJB) reference is located in the client JNDI namespace at `java:comp/env/ejb/BasicCalculator` . Since the actual Enterprise Java Bean run on the server, the application client run time returns a reference to the `BasicCalculator` home interface.

   If the client application program lookup was for a resource reference or an environment entry, then the look up function returns an instance of the configured type as defined by the client application

deployment descriptor. For example, if the program lookup was a JDBC data source, the lookup would return an instance of `javax.sql.DataSource`. Although you can edit deployment descriptor files, do not use the administrative console to modify them.

2. Assemble the application client using an assembly tool.

   The JNDI namespace knows what to return on a lookup because of the information assembled by the assembly tool.

   Assemble the Java EE application client on any development machine with the assembly tool installed.

   When you assemble your application client, provide the application client run time with the required information to initialize the execution environment for your client application program. Refer to documentation for the assembly tool for implementation details.

   Remember following when you configure resources used by your client application program:
   - Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look-up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local Java EE resource. The Java EE specification does not specify a particular implementation of a resource. The following table contains supported resource types and identifies the resources to which the WebSphere Application Server provides a client implementation.

Resource Type	Client Configuration Notes	Client implementation provided by WebSphere Application Server
javax.sql.DataSource	Supports specification of any data source implementation class	No
java.net.URL	Supports specification of custom protocol handlers	Provided by Java Runtime Environment files
javax.mail.Session	Supports custom protocol configuration	Yes - POP3, SMTP, IMAP
javax.jms.QueueConnectionFactory, javax.jms.TopicConnectionFactory, javax.jms.Queue, javax.jms.Topic	Supports configuration of WebSphere embedded messaging, IBM MQ Series and other JMS providers	Yes - WebSphere embedded messaging

3. Assemble the Enterprise Archive (EAR) file.

   The application is contained in an enterprise archive or `.ear` file. The `.ear` file is composed of:
   - Enterprise bean, application client, and user-defined modules or `.jar` files
   - Web applications or `.war` files
   - Metadata describing the applications or application `.xml` files

   You must assemble the `.ear` file on the server machine.

4. Distribute the EAR file.

   The client machines configured to run this client must have access to the `.ear` file.

   If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, and then distribute the configured `.ear` file to the other machines.

   If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.

   You can either distribute the `.ear` files to the correct client machines, or make them available on a network drive.

   Distributing the `.ear` files is the responsibility of the system and network administrator.

5. Deploy the application client.
6. Configure the application client resources.

If the client application defines the local resources, run the ACRCT (`clientConfig` command) on the local machine to reconfigure the `.ear` file. Use the ACRCT to change the configuration. For example, the `.ear` file can contain a DB2 resource, configured as `C:\DB2`. If, however, you installed DB2 in the `D:\Program Files\DB2` directory, use the ACRCT to create a local version of the `.ear` file.

7. Deploy the application client.

   If you plan to deploy the client on z/OS, you have two options for running the Application Client Resource Configuration Tool (ACRCT):
   - Run the ACRCT on Windows, or
   - Review "Starting the Application Client Resource Configuration Tool and opening an EAR file" on page 298.

   Both of these options produce equivalent output; only the tool interfaces are different. The ACRCT on Windows presents a graphical user interface, whereas the ACRCT for z/OS uses a scripting interface.
8. Use the WebSphere Administrative console to install the application client on z/OS.

What to do next

After completing these steps, launch the application client.

Java EE application client class loading

When you run your Java Platform, Enterprise Edition (Java EE) application client, a hierarchy of class loaders is created to load classes used by your application.

The following list describes the hierarchy of class loaders:
- The Application Client for WebSphere Application Server (Application Client) run time sets this value to the `WAS_LOGGING` environment variable.
- The *extensions class loader* class loader is a child to the bootstrap class loader. This class loader contains JAR files in the `java/jre/lib/ext` directory or those JAR files defined by the `-Djava.ext.dirs` parameter on the Java command. The Application Client client run time does not set `-Djava.ext.dirs` parameters. So it uses the JAR files in the `java/jre/lib/ext` directory.
- The *system class loader* class loader contains JAR files and classes that are defined by the `-classpath` parameter on the Java command. The Application Client run time sets this parameter to the `WAS_CLASSPATH` environment variable.
- The *WebSphere class loader* class loader loads the Application Client run time and any classes placed in the Application Client user directories. The directories used by this class loader are defined by the `WAS_EXT_DIRS` environment variable. The `WAS_BOOTCLASSPATH`, `WAS_CLASSPATH`, and the `WAS_EXT_DIRS` environment variables are set in the *app_server_root*`/bin/setupCmdLine` script for WebSphere Application Server installations, or in the *app_server_root*`/bin/setupClient` script for client installations.

As the Java EE application client run time initializes, additional class loaders are created as children of the WebSphere class loader. If your client application uses resources such as Java DataBase Connectivity (JDBC) API, Java Message Service (JMS) API, or Uniform Resource Locator (URL), a different class loader is created to load each of those resources. Finally, the Application Client run time sets the WebSphere class loader to load classes within the `.ear` file by processing the client JAR manifest repeatedly. The system class path, defined by the CLASSPATH environment variable is never used and is not part of the hierarchy of class loaders.

To package your client application correctly, you must understand which class loader loads your classes. When the Java code loads a class, the class loader used to load that class is assigned to it. Any classes subsequently loaded by that class will use that class loader or any of its parents, but it will not use children class loaders.

In some cases the Application Client run time can detect when your client application class is loaded by a different class loader from the one created for it by the Application Client run time. When this detection occurs, you see the following message:

WSCL0205W: The incorrect class loader was used to load [0]

This message occurs when your client application class is loaded by one of the parent class loaders in the hierarchy. This situation is typically caused by having the same classes in the .ear file and on the hard drive. If one of the parent class loaders locates a class, that class loader loads it before the Application Client run time class loader. In some cases, your client application still functions correctly. In most cases, however, you receive ″class not found″ exceptions.

Configuring the classpath fields

When packaging your Java EE client application, you must configure various class path fields. Ideally, you should package everything required by your application into your .ear file. This is the easiest way to distribute your Java EE client application to your clients. However, you should not package such resources as JDBC APIs, JMS APIs, or URLs. In the case of these resources, use class path references to access those classes on the hard drive. You might also have other classes installed on your client machines that you do not need to redistribute. In this case, you also want to use classpath references to access the classes on the hard drive, as described below.

Referencing classes within the EAR file

WebSphere product Java EE applications do not use the system class path. Use the MANIFEST Class path entry to refer to other JAR files within the .ear file. Configure these values using an assembly tool. For example, if your client application needs to access the path of the EJB JAR file, add the deployed enterprise bean module name to your application client class path. The format of the Class path field for each of the different modules (Application Client, EJB, Web) is the same:
- The values must refer to .jar and .class files that are contained within the .ear file.
- The values must be relative to the root of the .ear file.
- The values cannot refer to absolute paths in the file systems.
- Multiple values must be separated by spaces, not colons or semicolons.

Note: This is the Java method for allowing applications to function platform independent.
Typically, you add modules (.jar files) to the root of the .ear file. In this case, you only need to specify the name of the module (.jar file) in the Class path field. If you choose to add a module with a path, you need to specify the path relative to the root of the .ear file.

For referencing .class files, you must specify the directory relative to the root of the .ear file. With an assembly tool, you can add individual class files to the .ear file. It is recommended that these additional class files are packaged in a .jar file. Add this .jar file to the module Class path fields. If you add .class files to the root of the .ear file, add **./** to the module Class path fields.

Consider the following example directory structure in which the file myapp.ear contains an application client JAR file named myclient.jar and a mybeans.jar EJB module. Additional classes reside in class1.jar and utility/class2.zip files. A class named xyz.class is not packaged in a JAR file but is in the root of the EAR file. Specify **./ mybeans.jar utility/class2.zip class1.jar** as the value of the Classpath property. The search order is: myapp.ear/myclient.jar myapp.ear/xyz.class myapp.ear/mybeans.jar myapp.ear/utility/class2.zip myapp.ear/class1.jar

Referencing classes that are not in the EAR file

Use the launchClient -CCclasspath parameter. This parameter is specified at run time and takes platform-specific class path values, which means multiple values are separated by semi-colons or colons. The client and the server are similar in this respect.

Resource class paths

When you configure resources used by your client application using the Application Client Resource Configuration Tool (ACRCT), or the z/OS ACRCT scripting tool, you can specify class paths that are required by the resource. For example, if your application is using a JDBC to a DB2 database, add `db2java.zip` to the class path field of the database provider. These class path values are platform-specific and require semi-colons or colons to separate multiple values.

On WebSphere Application Server for i5/OS®, if you use the IBM Developer Kit for Java JDBC provider to access DB2/400, you do not have to add the `db2_classes.jar` file to the class path. However, if you use the IBM Toolbox for Java JDBC provider, specify the location of the `jt400.jar` file.

Using the launchClient API

If you use the `launchClient` command, the WebSphere class loader hierarchy is created for you. However, if you use the `launchClient` API, you must perform this setup yourself. Copy the `launchClient` shell command in defining the Java system properties.

Assembling application clients

Application client projects contain programs that run on networked client systems. An application client project is deployed as a Java archive (JAR) file.

About this task

Assemble a client module to contain application client code. Group enterprise beans, Web components, and resource adapter code in separate modules.

Use an assembly tool to assemble an application client module in any of the following ways:
- Import an existing application client JAR file.
- Create a new application client module.

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules. Ensure that **Java EE** capability is enabled.
3. Migrate application client JAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your application client JAR files to the assembly tool.
4. Create a new application client.
5. Verify the contents of the new application client in either of the following ways:
   - In the Project Explorer view, expand **Application Client Projects** and view the new module.
   - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

What to do next

After you finish assembling all of your application's modules, you are ready to deploy your application.

To deploy your application, refer to "Deploying J2EE application clients on workstation platforms" on page 292.

For more information, see the online help for the assembly tool.

Running the Pluggable application client code

This topic provides steps to install and use the Pluggable application client.

Before you begin

WebSphere Application Server supports the pluggable client.

Note: As you prepare to install the pluggable application client, remember that pluggable clients are only available on Windows systems.

Both J2EE application clients and Thin application clients can access JMS resources provided by the default messaging provider.

1. Install the pluggable application client by selecting option **Pluggable Application Client** from the **Custom client installation** panel.
2. Set the Java application pluggable client environment by using the **setupClient** command, located in:
   app_client_root\AppClient\bin\setupClient.bat
3. Add your specific Java client application JAR files to the CLASSPATH and start your Java client application from this environment, after setting the environment variables.
4. Run a Java command to invoke your client application.

Example

View the Samples Gallery for more information about the Application Client.

Running Thin application client code

You can run Thin application client environments on machines installed with either a client installation or a server installation. The client installation provides a setup command shell which sets up your environment for either a Thin application client or a Java Platform, Enterprise Edition (Java EE) client application. The server installation provides a command shell which sets up your environment for Java EE application clients only.

Before you begin

Both Java EE application clients and Thin application clients can access JMS resources provided by the default messaging provider.

About this task

WebSphere Application Server supports the pluggable client.

Note: Thin application clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Thin application client is not packaged with Apache Derby 10.2 classes. Likewise, the version 6.1 Thin application client is not packaged with Cloudscape® Version 5.1, Cloudscape Version 10.0, or Cloudscape version 10.1 classes. Therefore, to utilize the JDBC provider classes (such as Apache Derby, Oracle, DB2, Informix®, or Sybase) on a thin client, you must:

1. Add the classes to your Thin application client environment.
2. Make the classes visible to the Thin application client. To do this, add the path to the classes in the client classpath within the script that launched the client program.

Otherwise, any attempt to load a database class (such as through the JNDI lookup of a datasource) results in a ClassNotFoundException.

The Java invocation to run a Thin application client varies between a client and a server. If your Thin application client needs to run on both a client installation and a server installation, follow the steps for developing Thin application clients on a server machine.

1. Install the Thin application client by selecting option **Java EE and Thin application client** from the Application Client for WebSphere Application Server installation.
2. Perform one of the following:
   - Develop Thin application client code for a client machine.
   - Develop Thin application client code for a server machine.

Example

View the Samples gallery for more information about the Application Client.

Note: WebSphere Application Server and the Application client for WebSphere Application Server also provides specialized types of Thin application client. The Web Services Thin Client is an unmanaged, stand-alone Java client environment that allows you to run JAX-RPC Web services client applications to invoke Web services that are hosted by the application server. The Administration Thin Client enables client applications to perform administration tasks outside of the application server environment.

Running Thin application client code on a client machine

This topic provides the steps necessary to run Thin application client code on a client machine.

Before you begin

You must install the Thin application client from the Application Client for WebSphere Application Server installation before performing this task. For more information, see Developing Thin application client code.

1. Set up the Thin application client environment. Run the setupClient command.

   app_client_root/AppClient/bin/setupClient.sh

2. Compile your client application. Run the Java compilation command.

```
$JAVA_HOME/bin/javac -classpath "$WAS_CLASSPATH:
<list_of_your_application_jars_and_classes>" -extdirs $WAS_EXT_DIRS
<your_application_class>.java
```

   •

Example

View the Samples gallery for more information about the Application Client.

Running Thin application client code on a server machine

This topic provides the steps necessary to run Thin application client code on a server machine.

Before you begin

You must install WebSphere Application Server before performing this task.

1. Set up the Thin application client environment.

   Use the setupCmdLine shell.

   app_server_root/bin/setupCmdLine.sh

2. Run the Java compilation command to compile your client application.

```
$JAVA_HOME/bin/javac -classpath "$WAS_CLASSPATH:
<list_of_your_application_jars_and_classes>" -extdirs $WAS_EXT_DIRS
<your_application_class>.java
```

3. Run the application client.

   Perform one of the following methods:
   - Run a Java command to call your main class directly.

```
"$JAVA_HOME/bin/java" $WAS_LOGGING
-Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
-Djava.ext.dirs="$JAVA_HOME/jre/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins: $WAS_HOME/lib/WMQ/java/lib"
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dserver.root="$WAS_HOME" $USER_INSTALL_PROP "$CLIENTSAS" "$CLIENTSSL"
-classpath "$WAS_CLASSPATH;<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

For more information on IIOP and `corbaloc` URLs, see Developing applications that use JNDI.

- Enter a command to use the WebSphere Application Server launcher.

```
"$JAVA_HOME/bin/java" $WAS_LOGGING
-Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
 "-Dws.ext.dirs=<list_of_your_application_jars_and_classes>
$WAS_EXT_DIRS;$WAS_USER_DIRS"
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
"-Dserver.root=$WAS_HOME"
"$CLIENTSAS" "$CLIENTSSL" $USER_INSTALL_PROP -classpath "$WAS_CLASSPATH"
com.ibm.ws.bootstrap.WSLauncher
<fully_qualified_class_name_to_run> <your_application_parameters>
```

Example

View the Samples gallery for more information about the Application Client.

Deploying J2EE application clients on workstation platforms

You can deploy the J2EE application clients on workstation platforms using the methods described in this topic.

Before you begin

After developing an application client, deploy this application on client machines. *Deployment* consists of pulling together the various artifacts that the application client requires.

The *Application Client Resource Configuration Tool* (ACRCT) defines resources for the application client. These configurations are stored in the client `.jar` file within the application `.ear` file. The application client run time uses these configurations for resolving and creating an instance of the resources for the application client.

If you plan to deploy the client on z/OS, run the Application Client Resource Configuration Tool (ACRCT) on Windows. You can also run the ACRCT for distributed platforms locally. If you need to install the ACRCT, see Installing Application Client for WebSphere Application Server.

Note: This task only applies to J2EE application clients. Only perform this task if you configured your J2EE application client to use resource references.

About this task

1. Start the ACRCT and open an EAR file.
2. Configure new data source providers.
3. Configure mail providers and sessions.
4. Configure URL providers and sessions.
5. Configure Java messaging resources.
6. Configure new environment entries.

7. (Optional) Remove application client resources.
8. Save the EAR file.

Resource Adapters for the client

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

The resource adapter support for the J2EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running J2EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Configuring resource adapters

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the **Resource Adapters** folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

clientRAR tool

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the clientRAR tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.

<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

Configuring new connection factories for resource adapters

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters.

About this task

Complete this task to configure new connection factories for resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the **Connection Factories** folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Configuring administered objects

This section helps you configure new administered objects.

Before you begin

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

About this task

Complete this task to configure new administered objects for installed resource adapters.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File** > **Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Resource adapter settings

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type String

Description

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type String

Class Path

Any additional class path. The path to the resource adapter directory is automatically added.

Data type String
Default The path to your Resource Adapter directory.

Native Path

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type String

Resource Adapter Name
A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Data type String

Installed Resource Adapter Path
The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type String
Default ${CONNECTOR_INSTALL_ROOT}

Starting the Application Client Resource Configuration Tool and opening an EAR file
You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

Before you begin

Note: This task only applies to J2EE application clients.

About this task

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

1. Open a command prompt and change to the *app_server_root*`\bin` directory.
2. Run the `clientConfig.bat` file.

   Note: When running the `clientConfig.bat` file on the Microsoft® Windows Vista™ operating system, run the script using the administrator account that was created when the Windows Vista operating system was installed.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   a. Click **File** > **Open**.
   b. Select the file and click **Open**.
   •
4. Save your changes to the file and close the tool:
   a. Click **File** > **Save**.
   b. Click **File** > **Exit**.
   •

Data sources for the Application Client
WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a J2EE application client. If your application client accesses a database directly, you must provide the database drivers on the client machine.

You can contact your database vendor to acquire client database driver code and licenses. In addition, data sources configured on the server and looked up on the client do not participate in global transactions. Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on WebSphere Application Server. For a current list of providers that are supported on WebSphere Application Server visit the WebSphere Application Server prerequisite Web site. (See the following link.)

Data source properties for application clients

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name

Specifies the display name of this data source.

Data type String

Description

Specifies a text description of the data source.

Data type String

JNDI Name

The application client run time uses this field to retrieve configuration information.

Database Name

The name of the database to which you want to connect.

User

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password

Confirms the password.

Custom Properties

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data source providers (JDBC providers) for application clients

You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

About this task

Use this task to connect application clients to relational databases.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the **Data Source Providers** folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example: Configuring data source provider and data source settings

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
```

```
value="{xor}NTs9PBk+PCswLSZlMT4yOg==">
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type String

Description:

Specifies a text description for the resource.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type String
Default Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients

About this task

During this task, you create new data sources for your application client.

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its **Data Sources** folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring mail providers and sessions for application clients

You can edit the configurations of mail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

About this task

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of mail sessions and providers for your application clients to use.

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the mail objects in the tree that is displayed for the EAR file. For example, if your file contains mail sessions, expand **Resources** → ***application*.jar** → **Mail Providers** → ***java_mail_provider_instance*** → **Mail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular mail provider.

Results

The mail session instances are located in the **JavaMail Sessions** folder.

Mail provider settings for application clients

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid e-mail address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid e-mail addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or ″domain″) name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring mail provider and mail session settings for application clients

You can configure mail provider and mail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this topic is to help you configure mail provider and mail session settings.

- Required fields:

  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.
- Example:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

Before you begin

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **Mail Providers** > **Mail Provider** > **Mail Sessions**. Complete one of the following actions:
   - Right click the **Mail Sessions** folder and select **New Factory**.
   - Click **Edit** > **New** on the menu bar.
5. Configure the Mail Session properties in the displayed fields.
6. Click **OK**.
7. Click **File** > **Save** on the menu bar to save your changes.

URLs for application clients

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool

A URL provider implements the function for a particular URL protocol, such as HyperText Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Configuring new URL providers for application clients

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

About this task

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called **URL Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit** > **New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save** on the menu bar to save your changes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

About this task

1. Start the ACRCT.
2. Open an EAR file.

3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources** -> ***application*.jar** -> **URL Providers** -> ***url_provider_instance***
   where ***url_provider_instance*** is a particular URL provider.
4. If you expand the tree further, you will also see the **URLs** folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
```

```
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URLs for your client application.

About this task

1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the **URLs** folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File** > **Save** in the menu bar to save your changes.

Asynchronous messaging in WebSphere Application Server using JMS

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and Java Platform, Enterprise Edition (Java EE) applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product Java EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A Java EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish and subscribe messaging. A Java EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the Java EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the Enterprise JavaBeans (EJB) 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS

destinations, optionally within a transaction, then sent to the message-driven bean in a Java EE application, without the application having to explicitly poll JMS destinations.

Java Message Service providers for clients

This topic describes the different ways client applications can use Java Message Service (JMS) providers with WebSphere Application Server.

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

The service integration technologies of IBM WebSphere Application Server can act as a messaging system when you have configured a service integration bus that is accessed through the default messaging provider. This support is installed as part of WebSphere Application Server, administered through the administrative console, and is fully integrated with the WebSphere Application Server runtime.

WebSphere Application Server also includes support for the following JMS providers:

WebSphere MQ
Provided for use with supported versions of WebSphere MQ.

Generic
Provided for use with any 3rd party messaging system which supports ASF.

For backwards compatibility with earlier releases, WebSphere Application Server also includes support for the V5 default messaging provider which enables you to configure resources for use with the WebSphere Application Server version 5 Embedded Messaging system. The V5 default messaging provider can also be used with a service integration bus.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

The service integration bus also provides access to a default messaging provider. This is a J2EE 1.4 compliant JMS messaging provider which is fully integrated with WebSphere Application Server. You can use it in multiple server configurations for messaging interactions with a WebSphere MQ network.

Configuring Java messaging client resources

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

Before you begin

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Note: When completing this task, you can either create a new messaging provider, or you can use an existing one.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File** > **Save**.

Configuring new JMS providers with the Application Client Resource Configuration Tool

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

Before you begin

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of J2EE resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

About this task

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File -> Save** on the menu bar to save your changes.

JMS provider settings for application clients

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String

Description:

A description of the JMS provider, for administrative purposes.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default
ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default
ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus
Range Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type String

Default Provider queue connection factory settings

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type String

Description:

A description of this queue connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, Destination, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example `localhost:7777:BootstrapBasicMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus, Cluster, Server
Range Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Default Provider topic connection factory settings

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Data type String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type	String

Default Provider queue destination settings

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type	String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Queue Name:

The name of the queue.

Data type	String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Default Provider topic destination settings

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type	String

Description:

A description of the entry.

Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type	String

Topic Space:

The name of the topic space. This field is required.

Data type	String
Default	DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Data type	String

Delivery Mode:

The default mode for messages sent to this destination.

Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Data type	Long
Units	Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

Version 5 Default Provider queue connection factory settings for application clients

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A Version 5 Default Provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A Version 5 Default Provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Range Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type Enum
Default QUEUED

Range

QUEUED
The listener port used for full-function JMS compliant, publish or subscribe support.

DIRECT
The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries® queue manager.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A Version 5 Default Provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer

Units Message priority level

Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.

Unlimited
Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer

Units Milliseconds

Range Greater than or equal to 0

- 0 indicates that messages never timeout.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Version 5 Default Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A Version 5 Default Provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.* **Unlimited** Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out. • Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the MQSeries product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see WebSphere MQ *Using Java*, available from the WebSphere MQ library.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a userid and password explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Default Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the MQSeries queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type String
Default Null
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type Integer
Default Null
Range A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type String
Default Null
Range 1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type Enum
Units Not applicable

Default BINDINGS

Range

BINDINGS
JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that should be addressed through the use of EJB roles.

CLIENT
WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

DIRECT
For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol.

QUEUED
QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type
BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

Topic connection factory transport type
DIRECT is the fastest type and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
 -e default -o DynamicSubscriptionEngine -n
 maxClientQueueSize -v 0 -x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Note: The WebSphere MQ 5.3 JMS cannot be used within WAS 6.1 because WAS 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WAS 6.1. If you are using WebSphere MQ 5.3 for z/OS, you might also have to purchase an additional feature pack.

When running on 64-bit z/OS, the Transport type must be set to CLIENT because the 64-bit WebSphere MQ z/OS is not currently available, and BINDINGS mode cannot be used to connect to 31-bit WebSphere MQ z/OS. You might also need to purchase an additional WebSphere MQ feature pack for this support.

Client ID:

The JMS client identifier used for connections to the MQSeries queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These references are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at http://www.ibm.com/software/integration/wmq/library/, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type Enum
Units Not applicable
Default Cleared
Range
Selected
Unwanted messages are left on the queue.
Cleared
Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type String
Range 1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

`ldap://`*`hostname`*`:[`*`port`*`]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section "Distinguished Names" in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider topic connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

MA0C broker: When creating a WebSphere Application Server v6 topic connection factory for the MA0C broker, you should consider the following attribute values:

BrokerControlQueue
: This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

BrokerVersion
: Set this value to BASIC for the MA0C broker.

ClientID
: Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

XA Enabled
Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you will probably want to set this to 'true' most of the time).

BrokerMessage Selection
This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

Direct Broker Authorization Type
This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS provider.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
Units	En_US ASCII characters
Range	1 through 45 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User** property, you must also specify a value for the **Password** property.

The connection factory **User** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

Data type String

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type String
Range A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type Integer
Range A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager for client connection only.

Data type String
Range 1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type Enum
Default BINDINGS
Range
CLIENT
WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
BINDINGS
JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type String

CCSID:

The coded character set identifier to be used with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the Web container.

Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Version:

Specifies whether the message broker is provided by the WebSphere MQ MA0C SupportPac™ or newer versions of WebSphere family message broker products.

Data type	Enum
Default	Advanced
Range	**Advanced** The message broker is provided by newer versions of WebSphere family message broker products (MQ Integrator and MQ Publish and Subscribe). **Basic** The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

Specifies the level of clean up provided by the publish or subscribe cleanup utility.

Data type	Enum
Default	SAFE
Range	**ASPROP** **NONE** **STRONG**

Cleanup interval:

Specifies the interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type	Integer

Units Milliseconds
Default 6000

Message selection:

Specifies where broker message selection is performed.

Data type Enum
Default BROKER
Range

BROKER
Message selection is done at the broker location.

Message CLIENT
Message selection is done at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

Data type Integer
Default 25

Sparse subscriptions:

Enables sparse subscriptions.

Data type Check box
Default Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh publish or subscribe status.

Data type Integer
Default 6000

Subscription store:

Specifies where WebSphere MQ stores data relating to active JMS subscriptions.

Data type Enum
Default MIGRATE
Range

MIGRATE

QUEUE

BROKER

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default NOT USED
Range

NOT USED
This connection factory does not use multicast transport.

ENABLED
This connection factory always uses multicast transport.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport.

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if available.

Direct authentication:

Specifies whether to use direct broker authorization.

Data type Enum
Default NONE
Range

NONE Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificates.

Proxy Host Name:

Specifies the host name of a proxy to be used for communication with WebSphere MQ.

Data type String

Proxy Port:

Specifies the port number of a proxy to be used for communication with WebSphere MQ.

Data type Integer
Default 0

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the section “Working with Certificate Revocation Lists” in the *WebSphere MQ Security book*; for example at: http://publibfp.boulder.ibm.com/epubs/html/csqzas01/csqzas012w.htm#IDX2254.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the section “Distinguished Names” in the WebSphere MQ Security book.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

WebSphere MQ Provider queue destination settings for application clients

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product for JMS resources. For more information about configuring WebSphere MQ product for JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.

Unlimited
Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type String

Units En_US ASCII characters
Range A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifier supported by WebSphere MQ queue manager.

Data type String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

Indicates that if native encoding is not enabled to select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates that if native encoding is not enabled to select the type of floating point encoding.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination use native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range
Cleared
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Target client:

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range
WebSphere MQ
The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target application supports JMS.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ product JMS resources, see the WebSphere MQ *Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic for administrative purposes within IBM WebSphere Application Server.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Specifies whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them in the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Specifies whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them in the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, type the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property or by messages on the queue never expire (have an unlimited expiry timeout).

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The expiry timeout for messages on this queue is defined by the application that put them in the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.

Unlimited
Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSID identifiers that WebSphere MQ supports.

Data type String

Units Integer
Range 1 through 65535

Integer encoding:

Indicates whether integer encoding is normal or reversed when native encoding is not enabled.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Floating point encoding:

Indicates the type of floating point encoding when native encoding is not enabled.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S/390® floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared

Range

Cleared
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.

Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Target Client:

Specifies whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range

WebSphere MQ
The target is a traditional WebSphere MQ application that does not support JMS.

JMS The target is a JMS compliant application.

Multicast:

Specifies whether this connection factory uses multicast transport.

Data type Enum
Default AS_CF

Range

AS_CF This connection factory uses multicast transport.

DISABLED
This connection factory does not use multicast transport.

NOT_RELIABLE
This connection factory always uses multicast transport.

RELIABLE
This connection factory uses multicast transport when the topic destination is not reliable.

ENABLED
This connection factory uses reliable multicast transport.

Generic JMS connection factory settings for application clients

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String
Default Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.

- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Connection Factories** folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.

5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new JMS destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its **Destinations** folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new resource environment providers for application clients

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment provider configurations for your application client.

About this task

To configure a new resource environment provider, perform the following steps:

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment entries for your client application.

About this task

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the **Resource Environment Entries** folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Managing application clients

You can manage Java Platform, Enterprise Edition (Java EE) application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Perform the following tasks after deploying application clients. This task only applies to Java EE application clients.

After deploying application clients on z/OS, you might want to or need to update the resources that you configured for those clients. To do so, you may complete one of the following tasks:

- Run the Application Client Resource Configuration Tool (ACRCT) on Windows, according to the following steps, and then reinstall the application on z/OS; or
- Review “Starting the Application Client Resource Configuration Tool and opening an EAR file” on page 298.

1. Update data source and data source provider configurations.
2. Update URLs and URL provider configurations.
3. Update mail session configurations.
4. Update JMS provider, connection factories, and destination configurations.
5. Update MQ JMS provider, MQ connection factories and MQ destination configurations.
6. Update Resource Environment Entry and Resource Environment Provider configurations.
7. (Optional) Remove application client resources.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool

You can update the configuration of an existing data source or data source provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Data source provider properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients

You can update URLs and URL provider configurations for application clients using the Application Client Resource Configuration Tool (ACRCT).

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File** > **Save** on the menu bar to save your changes.

Updating mail session configurations for application clients

You can update the configuration of an existing JavaMail session using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit** > **Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File** > **Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients

You can update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   - Right-click the provider, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - WebSphere Application Server Queue connection factory properties
   - WebSphere Application Server Topic connection factory properties
   - WebSphere Application Server Queue destination properties
   - WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients

You can update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

About this task

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.

7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients

You can update the configuration of an existing resource environment entry or resource environment provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.
2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example: Configuring Resource Environment settings:

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients:

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Removing application client resources

You can remove Java Platform, Enterprise Edition (Java EE) application client resources using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to Java EE application clients.

To remove resources for application clients running on z/OS, run the Application Client Resource Configuration Tool (ACRCT) on Windows, according to the steps below, and then reinstall the application on z/OS.

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File** > **Save** to save your work before preceding to delete an object.
2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File** > **Save**.

Installing Application Client for WebSphere Application Server

This topic describes how to install the Application Client for WebSphere Application Server using the installation image on the product CD-ROM.

Before you begin

Running client applications that communicate with a WebSphere Application Server requires that elements of the Application Server are installed on the system on which the client applications run. However, if the system does not have the Application Server installed, you can install Application Client, which provides a stand-alone client run-time environment for your client applications. See the Supported Prerequisites page for more information on supported product platforms.

The steps that follow provide enough detail to guide you through preparing for, choosing, and installing the variety of options and features provided. To prepare for installation and to make yourself familiar with installation options, complete the steps in this topic and read the related topics, before you start to use the installation tools. Specifically, read these topics before installing the product:

- Installing WebSphere Application Client from an i5/OS Qshell command line
- Best practices for installing

It is recommended that you have 350 MB of temporary disk space available before beginning the installation.

In Version 7.0, the Application Client for WebSphere Application Server is installable on a machine with a previous version of Application Client. However, you cannot install a Version 7.0 Application Client on top of a previous version of the Application Client.

1. Install Application Client for WebSphere Application Server using the launchpad.

   Note: The free download Application Client installation is not packaged with the launchPad program.

   a. Click **Launch the installation wizard for Application Client for WebSphere Application Server** from the launchpad tool to launch the InstallShield for MultiPlatforms installation wizard. This action launches the installation wizard.

      The Readme documentation to which the launchpad links is the `readme.html` file in the CD root directory. The readme directory off the root of the CD has more detailed Readme files. The Installation Guide is in the `/docs` directory of the CD root directory.

      Note: Readme file names are based on product offerings.

      When you install application clients, the current working directory must be the directory where the installer binary program is located. This placement is important because the resolution of the class files location is done in the current working directory. For example:

      ```
      cd /app_server_root/AppClient

      ./install
      ```

      or

      ```
       cd <CD mount point>/AppClient

           ./install
      ```

      Failing to use the correct working directory can cause ISMP errors that abort the installation.

      The installation wizard does not upgrade or remove previous Application Clients installation automatically.

   b. As indicated in the previous example, you can start the installation wizard from the product CD-ROM, using the command line.

   c. You can also perform a silent installation using the `-options responsefile -silent` parameter, which causes the installation wizard to read your responses from the options response file, instead of from the interactive graphical user interface. Customize the response file before installing silently. After customizing the file, issue the command to silently install. Silent installation is particularly useful if you install the product often.

      The rest of this procedure assumes that you are using the installation wizard. There are corresponding entries in the response file for every prompt that is described as part of the wizard. Review the description of the response file for more information. Comments in the file describe how to customize its options.

2. Click **Next** to continue when the Welcome panel displays.

   a. Click the radio button beside the **I accept the terms in the license agreement** message if you agree to the license agreement, and click **Next** to continue.

3. The installation wizard checks the system for prerequisites. Click **Next** if you see a success message on the wizard panel. If a warning message displays on the panel, click **Cancel** to exit the installation wizard and install the proper prerequisites to the system.

   Note: Application Client may be fully functional even if some prerequisites are not installed on the system, however it is recommended you update your system to the required level.

   Note: When completing a custom installation in GUI mode, you have installable options such as Applet Client Samples and StandAlone Thin Client Resource Adapters. If you select any of the available options and need to go backwards on the install panels (for instance, to reread the

license agreement), the installable options panel disappears when continuing through the installation panels. To access these panels again, you will have to relaunch the installation wizard.

4. Specify a destination directory. Click **Next** to continue.
   a. Ensure that there is adequate space available in the target directory.
   b. Specify a target directory for the Application Client product.
   c. Enter the required target directory to proceed to the next panel. Deleting the default target location and leaving an installation directory field empty prevents you from continuing the installation process.
5. Choose a type of installation, and click **Next**.

   If you use the GUI you can choose a Typical installation type, which installs Java EE and Thin application client, Samples and IBM Developer Kit, Java 2 Technology Edition, or you can choose the custom installation type. For Windows, there are two custom installation types: Custom Java EE/Thin Client and Custom Pluggable Client. For other platforms, there is only one custom installation type.
   - If you select the **ActiveX to EJB Bridge** feature, then the following message displays in a dialog box: Do you want to add Java runtime to the system path and make it the default JRE? If you answer Yes, then the Java run time is added to the beginning of the system path. If you answer No, then the ActiveX to EJB Bridge does not function from the Active Server Pages (ASP), unless you add the Java run time to the path. To add the Java run time later, see the topic ActiveX application clients or reinstall the Application Client.
   - If you select the **Applet client** feature, then the following message might be displayed: An existing JDK or JRE has been detected on your computer. You chose to install the Applet Client, which will overwrite the registry entries for this JDK or JRE. Do you want to continue and install the Applet Client? If you select Yes, the installation overrides the registry on your machine. If you select No, the Applet client feature is not installed, and you are directed to the back feature dialog box.
   - Install the Software Developer Kit feature, if you need to use any of the utilities that it provides, such as the javaccompiler, the jarutility or the jarsigner utility. The Java 2 Development Kit that IBM provides has two components, Java Runtime Environment (JRE) and a complete Software Developer Kit (SDK). The JRE sub feature is selected by default for the Custom Java EE/Thin Client installation type. The SDK component is optional; however, you must install the SDK component to compile the sample.
   - Install the Pluggable Client samples if you want to make use of the Pluggable Client applications.
   - Install the Software Developer Kit feature, if you need to use any of the utilities that it provides, such as the *javaccompiler*, the *jarutility* or the *jarsigner* utility. The Java 2 Development Kit that IBM provides has two components, Java Runtime Environment (JRE) and a complete Software Developer Kit (SDK). The JRE sub feature is selected by default for the Custom Java EE/Thin Client installation type. The SDK component is optional; however, you must install the SDK component to compile the sample.
6. (Pluggable Client installation type only) Click **Next** to accept the detected Sun JRE, or click Browse to select the location of the installed Sun JRE. The Sun Software Development Kit installation location is optional. However, if the installation location is not provided, the installed Samples do not compile.
   - If Sun JRE has not been installed, the installation cannot be continued. Click **Cancel** to exit the installation. Install the Sun JRE, and restart the Pluggable Custom installation. The Sun JRE panel displays with the JRE path detected, and the Pluggable application client installation continues.
7. Enter the host name of the WebSphere Application Server machine. Click **Next** to continue. The default port number is 2809.
8. Review the summary information, and click **Next** to install the product code or you might also click **Back** to change your specifications.
9. Click **Finish** to exit the wizard, after the Application Client installs.
10. Verify the success of the installer program by examining the Completion panel and the *app_server_root*/`logs/install/log.txt` file for installation status. The installer program records the following indicators of success in the logs:

- `INSTCONFSUCCESS` indicates that the installation is successful and that no further log analysis is required.
- `INSTCONFFAILED` indicates an installation failure that you cannot retry or recover from without reinstalling.

The installation wizard records installation events in the installation log files. Examine messages that the installation program displays. If the Application Client for WebSphere Application Server does not install successfully, read the messages to identify why the installation failed. Correct the problems identified and try installing the product again.

Note: If you are logged in as non-root or non-admin user, you may not get a successful installation. When the installer runs, a log file is created in your home directory. If the installation fails, an attempt is made to move the log to the *app_server_root* directory; however, without the necessary permission to move the file to the *app_server_root* directory, the attempt to move fails and the log remains in your home directory. Look for the following log files in the *user_home*`/waslogs` directory:

- `log.txt`
- `trace.txt.gz`
- `trace.xml.gz`

Results

You successfully installed the Application Client for WebSphere Application Server and the features you selected.

What to do next

Use the installation verification utility to verify a successful installation. If the installation is not successful, fix the error as indicated in the installation error message. For example, if you do not have enough disk space, add more space, and reinstall the Application Client.

Best practices for installing Application Client for WebSphere Application Server

This topic provides tips for installing Application Client on multiple platforms.

All platforms

The following tips pertain to installing Application Client on all platforms:

- Reserve at least 4 to 5MB free space in the target platform temporary directory.
- When specifying a different temporary directory while installing Application Client, the following message is displayed if the target platform default temporary directory does not have enough free space to install Application Client:

```
Error writing file =  There may not be enough
temporary disk space.
Try using -is:tempdir to use a temporary
directory on a partition with more disk
space.
```

  Use the `-is:tempdir` installation option to specify a different temporary directory. For example, the following command uses `/swap` as a temporary directory during installation:

```
./install -is:tempdir /swap
```

- After the installation, when changing the installation settings for the WebSphere Application Server host name and the port number, edit the setupClient file.

Change the DEFAULTSERVERNAME and SERVERPORTNUMBER to the new WebSphere Application Server host name and port number, respectively. If the SERVERPORTNUMBER is not set, then the default is 2809. Review the following example:

```
set DEFAULTSERVERNAME=NDServerName
set SERVERPORTNUMBER=9810
```

The setupClient file is located in the bin subdirectory under the Application Client installation destination.

Specific platforms

The following tips pertain to installing Application Client on the designated platforms:

Installing Application Client for WebSphere Application Server silently

This topic provides the steps necessary to use the installation wizard and perform a silent installation.

About this task

Use these steps to perform a silent installation, which uses the installation wizard to install the product. Instead of displaying a user interface, the silent installation provides interaction between you and the wizard by reading all of your responses from a file that you must customize.

1. Verify that the user ID that you are using to run the silent installation has sufficient authority to perform the task.
2. Customize the option response file.
   a. Locate the sample options response file. The file name is setup.response in the operating system platform directory on the product CD-ROM.
   b. Make a copy to preserve the original response file. For example, copy the file as myoptionsfile.
   c. Edit the copy in your flat file editor of choice, on the target operating system. Read the directions within the response file to choose appropriate values.
   d. Make a non-commented option to have a silent install.
   e. Include custom option responses that reflect parameters for your system.
   f. Follow the instructions in the response file to choose appropriate values.
   g. Save the file.
3. Issue a command to use your custom response file: Install.exe -options myoptionsfile -silent for Windows platforms and install -options ./myoptionsfile -silent for Linux® and UNIX® platforms.

   The sample options response file is located in the AppClient directory on the product CD-ROM.
   a. Issue the following command from a command prompt to update your response file: -OPT silentInstallLicenseAcceptance="true' .

      Issuing this command indicates that you accept all IBM license terms associated with this product, which is necessary for installing application clients.
4. Optional: Restart your machine in response to the prompt that appears on Windows platforms when the installation is complete.

Results

You installed application clients silently by using the response file.

What to do next

To verify the silent install, look for the string INSTCONFSUCCESS in the log.txt file for successful installation and INSTCONFFAILED for a failed installation.

When the InstallShield for MultiPlatforms (ISMP) fails and the log.txt file is not created, the error log file might have been created in one of the following directories:

- When a GUI install fails the logs are in var\tmp\niflogs\log.txt.
- When a silent install fails the logs are in <user_home>\waslogs\log.txt.
- When a silent install for Plugins fails the logs are in <user_home>\plglogs\log.txt.
- When a silent install for HTTP Server fails the logs are in <user_home>\ihslogs\log.txt.

Uninstalling Application Client for WebSphere Application Server

This task describes using the uninstall program to uninstall the Application Client for WebSphere Application Server.

Before you begin

Note: If you have a feature pack installed, uninstalling the Application Client for WebSphere Application Server using the Version 6.1.0 uninstaller program causes the feature pack to stop working because the uninstallation removes the server. However, you can uninstall the feature pack after uninstalling the WebSphere Application Server product.

Note: If you are logged in as a root user and attempt to uninstall an instance of Application Client for WebSphere Application Server that a non-root user installed, the Windows registry will also be wiped clean for the application client instance that the root user installed. If you need to uninstall an instance of application client that a non-root user has installed, be sure that you are logged in as the non-root user.

1. Stop any browsers and any Java processes related to Application Client products.
2. Change directories to the `uninstall` directory before issuing the command to uninstall the application client. The command file is located in the `uninstall` directory.
   - *app_server_root*/`uninstall` directory

     For example, to change directories before uninstalling the product from a Linux platform, issue this command if your installation root is `/opt/IBM/WebSphere/AppClient`:

     ```
     cd /opt/IBM/WebSphere/AppClient/uninstall
     ```
3. Issue the command to uninstall the product.

   The command file is named `uninstall`. Issue the **uninstall** command from the *app_server_root*/`uninstall` directory:

   ```
   ./uninstall
   ```

   The Uninstall wizard begins and displays the Welcome panel.
4. Click **Next** to begin uninstalling the product. The Uninstall wizard displays a Confirmation panel that lists the product and features that you are uninstalling.
5. Click **Next** to continue uninstalling the product. The Uninstall wizard deletes existing profiles first.

   After deleting profiles, the Uninstall wizard deletes core product files by component.
6. Click **Finish** to close the wizard after the wizard removes the product.

Results

Application Client for WebSphere Application Server is uninstalled.

What to do next

Verify the uninstall procedure by viewing the *app_server_root*/`logs/uninstall/log.txt` file for errors. Look for the `INSTCONFSUCCESS`, indicating a successful uninstall in the log file:

```
Uninstall, com.ibm.ws.install.ni.ismp.actions.ISMPLogSuccessMessageAction, msg1,
   INSTCONFSUCCESS
```

The uninstallation wizard records uninstallation events in the uninstallation log files. Examine messages that the uninstallation program displays. If the Application Client for WebSphere Application Server does not uninstall successfully, read the messages to identify why the uninstallation failed. Correct the problems identified and try uninstalling the product again.

Note: If you are logged in as non-root or non-admin user, the uninstall may not be successful. When the uninstaller program runs, a log file is created in your home directory. If the uninstaller program fails, an attempt is made to move the log to the *app_server_root* directory; however, without the necessary permission to move the file to the *app_server_root* directory, the attempt to move fails and the log remains in your home directory. Look for the following log files in the *user_home*/waslogs directory:

- log.txt
- trace.txt.gz
- trace.xml.gz

Running application clients

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs stand-alone Java applications (known as Java EE application clients) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

About this task

You are ready to run your application client using this tool after you:
1. Write the application client program.
2. Assemble and install an application module (.ear file) in the application server run time.
3. Deploy the application using the Application Client Resource Configuration Tool (ACRCT) on Windows.

   Alternatively, you can use the ACRCT scripting tool on z/OS.

This task only applies to Java EE application clients. To launch Java EE application clients using the launchClient script, perform the following steps:

1. Enter the following command to launch Java EE application clients:

   app_server_root/bin/launchClient
2. Pass parameters to the launchClient command or to your application client program as well. The launchClient command allows you to do both. The launchClient command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for launchClient usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   launchClient [-profileName pName | -JVMOptions options | -help | -?] <*userapp*> [-CC<name>=<value>] [app args]

   where
   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

     The default is **default_profile**.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

All other parameters intended for the `launchClient` command must begin with the -CC prefix.

Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

The `launchClient` command retrieves parameters from three places:
- The command line
- A properties file
- System properties

The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

3. Specify the server name.

   By default, the **launchClient** command uses the localhost for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

launchClient tool

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

You can use the `launchClient` command from a node within a Network Deployment environment. **However, do not attempt to use the `launchClient` command from the Deployment Manager.**

Note: All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:
- Use a separate installation for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

```
launchClient [-profileName pName | -JVMOptions options | -help | -?] <userapp> [-CC<name>=<value>] [app args]
```

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CC<name>=<value>* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

  The default is **default_profile**.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *<userapp>* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the `-CCBootstrapHost` parameter or the value, `localhost`, if the `-CCBootstrapHost` parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is `8880` for SOAP connections and `2809` for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify `RMI` to use the RMI connection type, or specify `SOAP` to use the SOAP connection type. The default value is `SOAP`.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

-CCadminConnectorPassword
The password for the user name that the `-CCadminConnectorUser` parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the `-CCjar` parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to `null` to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
your_server_of_choice.com

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is `used`.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the `-CCD`. For example: `-CCDcom.ibm.test.property=testvalue`. You can specify multiple `-CCD` parameters. The general format of this parameter is `-CCD<property key>=<property value>`. For example, `-CCDI18NService.enable=true`.

-CCdumpJavaNameSpace
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

-CCexitVM
Use this option to have the WebSphere Application Server call the `System.exit()` method after the client application completes. The default is `false`.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is `false`.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the `-CC` prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: `verbose=true`.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations,

this value overrides the -CCBootstrapHost and -CCBootstrapPort parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the java.naming.provider.url system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is disable.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is *<app_server_root>*/ properties/client.policy.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is false. For more information, read the topic ″Enabling trace.″

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, basic, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

-CCverbose
This option displays additional information messages. The default is false.

If you are using an EJB client application with security enabled, edit the sas.client.props file, which is located in the *profile_root*/properties directory. Within the file, change the com.ibm.CORBA.loginSource value to *none*.

For more information on the sas.client.props utility, see PropFilePasswordEncoder command reference.

RMI connection with security. Used with the EJB and administrative client application.

Using Jacl:

```
wsadmin.sh -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin.sh -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

rmiportnumber for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

Note: On the AIX®, HP-UX, Linux, i5/OS, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is

a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

Note: When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from Web browser on the client machine.

Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power and OS/400® operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 382
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 383
- “ClientLauncher class” on page 387

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server.

Note: When using the Sun JRE with the Application Client runtime, application resources cannot be downloaded using the https protocol. This is a Sun Microsystems limitation. Install the IBM JRE on the client machine and use IBM Java Web Start to run the WebSphere Application Client application. Sun Java Web Start is supported, but with a limitation that only the http protocol can be used to download the application resource, including the application jnlp description file.

About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows. Follow the instructions for “Installing Application Client for WebSphere Application Server” on page 369.
2. Run the utility programs to create the application client container and runtime package.
   a. Use the “buildClientRuntime tool” on page 390 utility to create the package.
   b. Use the “buildClientLibJars tool” on page 383 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/ properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a Java Server Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

Note: When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

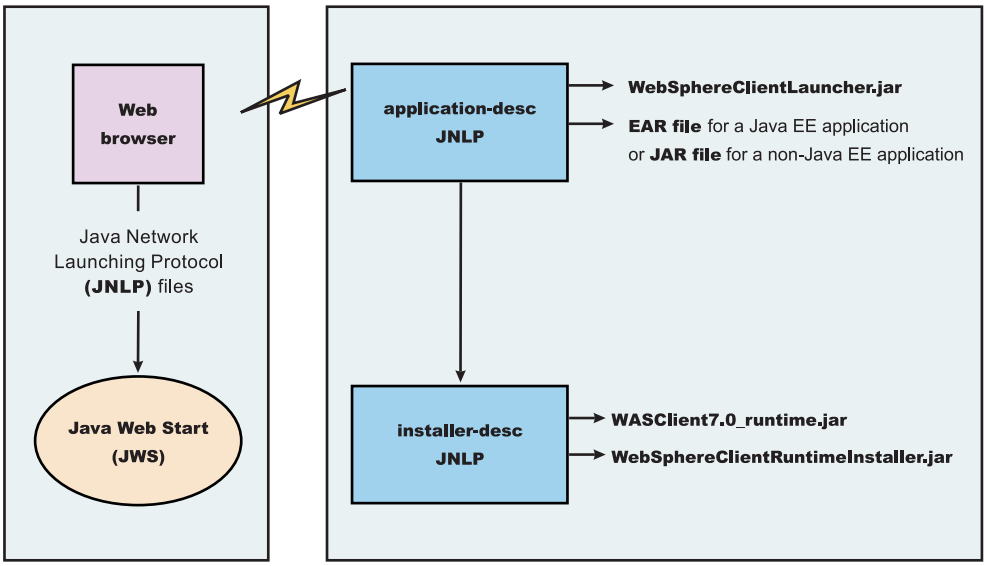
Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a Web browser.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a Web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The Web browser running on a client machine connects to a Web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as Web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a Web browser to connect to the url of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Sun Microsystems Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, version 6, which you can download from the HP Web site

buildClientLibJars tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a Web browser.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

Client application Java Network Launcher Protocol deployment descriptor file

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients run-time dependency that provides the following:

- Java SE Runtime Environment from IBM
- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See “JNLP descriptor file for a Java EE Application client application” on page 385 for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See “JNLP descriptor file for a Thin Application client application” on page 386 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients run-time dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `ssl.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

```
<argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
```

Note: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

```
<argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
<argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
```

JNLP descriptor file for a Java EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
This sample program is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

JNLP descriptor file for a Thin Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

Here is an example of the JNLP descriptor file for a Thin Application client application.

```
This sample program is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a Web browser.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the <*app_client_root*>/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
: If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
: If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Application client launcher for Java Web Start:

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **lauchClient** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main
: If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

com.ibm.websphere.client.launcher.ear
: If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **lauchClient** command line tool supports. However, if only `com.ibm.websphere.client.launcher.main` is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **launchClient** command line tool and the application client launcher for JWS:

-CC argument	launchClient	Application client launcher for JWS
-CCverbose	Yes	Yes
-CCjar	Yes	Yes
-CCclasspath	Yes	N/A
-CCadminConnectorHost	Yes	Yes
-CCadminConnectorPort	Yes	Yes
-CCadminConnectorType	Yes	Yes
-CCadminConnectorUser	Yes	Yes
-CCaltDD	Yes	Yes
-CCBootstrapHost	Yes	Yes
-CCBootstrapPort	Yes	Yes
-CCproviderURL	Yes	Yes
-CCinitonly	Yes	N/A
-CCtrace	Yes	Yes
-CCtracefile	Yes	Yes
-CCsecurityManager	Yes	N/A
-CCsecurityMgrClass	Yes	N/A
-CCsecurityMgrPolicy	Yes	N/A
-CCD	Yes	Yes
-CCexitVM	Yes	Yes
-CCdumpJavaNameSpace	Yes	Yes
-CCsoapConnectorPort	Yes	Yes
-CCtraceMode	Yes	Yes
-CCclassLoaderMode	Yes	Yes

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the 3 macro keys that are currently supported and will be substituted by the launcher:

Table 9.

Macro key	Value
${WAS_ROOT}	Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS.
${JAVA_HOME}	Location of Java home. The return value of System.getProperty("java.home").
${USER_HOME}	Location of user home. The return value of System.getProperty("user.home").

Preparing the application client run time dependency component for Java Web Start

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a Web Archive Resource (WAR) file that can be installed in an Application Server.

Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems, the application client run time dependency component must be built separately for each operating system that client application supports.

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.
2. Change the directory to the installation bin directory.
3. Run the "buildClientRuntime tool" on page 390 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

   For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
   ```
5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start Deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a Web archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start Deployment sample in the application client installation.

Results

Your Web application is ready to serve the application client run time and the JRE environment.

buildClientRuntime tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a Web browser.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a Web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

ClientRuntimeInstaller class:

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/`JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

Using the Java Web Start sample

The EAR file, `WebSphereClientRuntime.ear`, is provided in the JWS directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server product. The name of the new sample is ″Java Web Start Deployment Sample″.

Installing Java Web Start

Learn about the steps that are necessary to install Java Web Start (JWS) on the AIX platform. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from Web browser on the client machine.

Before you begin

Note: This topic applies only to the AIX operating system.

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 389 topic to understand Java Web Start (JWS) technology and components.

Note:

You can use the following resources:

- The IBM implementation of Java Web Start on Java Platform Standard Edition 6 (Java SE 6) that is packaged in the Application Client for WebSphere Application Server

Note: You can use Java Web Start on Java Platform, Standard Edition Developer Kit 6 that IBM provides, packaged in the Application Client for WebSphere Application Server, Version 7.0; Java Web Start on Sun Microsystems Java Standard Edition Software Development Kit 6 or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems Web site for Windows, Linux and Solaris operating systems, or the Java Web Start on HP Software Development Kit (SDK) or RTE for Java 2 version 5.0, which you can download from the HP Web site.

About this task

Use the following steps to install JWS on the AIX platform.

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the client_install_root/java/jre/lib/javaws path.
3. Run the updateSetting.sh script from the path mentioned in the previous step.
4. Change your path to the JWS installed path. For example, enter: `client_install_root/java/jre/javaws`.
5. Run `./javaws` from the path mentioned in the previous step.

Using a static JNLP file with Java Web Start for Application clients

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
              <welcome-file>default.html</welcome-file>
              <welcome-file>default.htm</welcome-file>
              <welcome-file>default.jsp</welcome-file>
       </welcome-file-list>
       <mime-mapping>
       <extension>jnlp</extension>
       <mime-type>application/x-java-jnlp-file</mime-type>
       </mime-mapping>
</web-app>
```

Writing command interfaces

The command package can be used by distributed applications to reduce the number of remote invocations that a client makes. The base interface for all commands is the Command interface.

About this task

Distributed applications are defined by the ability to utilize remote resources as if they were local, but this remote work affects the performance of distributed applications. Distributed applications can improve performance by using remote calls sparingly. For example, if a server does several tasks for a client, the application can run more quickly if the client bundles requests together, reducing the number of individual remote calls. The command package provides a mechanism for collecting sets of requests to be submitted as a unit.

In addition, the command package provides a generic way of making requests. A client instantiates the command, sets its input data, and tells it to run. The command infrastructure determines the target server and passes a copy of the command to it. The server runs the command, sets any output data, and copies it back to the client. The package provides a common way to issue a command, locally or remotely, and independently of the server's implementation. Any server (an enterprise bean, a Java Database

Connectivity (JDBC) server, a servlet, and so on) can be a target of a command if the server supports Java access to its resources and provides a way to copy the command between the client's Java Virtual Machine (JVM) and its own JVM.

The command facility is implemented in the com.ibm.websphere.command Java package. The classes and interfaces in the command package fall into four general categories:

- Interfaces for creating commands
- Classes and interfaces for implementing commands
- Classes and interfaces for determining where the command is run
- Classes defining package-specific exceptions
- Write a command interface. Extend one or more of the three interfaces that are included in the command package. The command interface provides only the client-side interface for generic commands and declares three basic methods:
  - isReadyToCallExecute - This method is called on the client side before the command is passed to the server for execution.
  - execute - This method passes the command to the target and returns any data.
  - reset - This method reverts any output properties to the values they had before the execute method was called so that the object can be reused.
- Implement the command interface. The implementation class for your interface must contain implementations for the isReadyToCallExecute and reset methods. The execute method is implemented for you elsewhere. Most commands do not extend the Command interface directly but use one of the provided extensions: the "TargetableCommand interface" and the "CompensableCommand interface" on page 394.
- Use the command.

TargetableCommand interface

The TargetableCommand interface extends the Command interface and provides for remote execution of commands.

Most commands will be targetable commands. The TargetableCommand interface declares several additional methods:

- setCommandTarget

  This method allows you to specify the target object to a command.
- setCommandTargetName

  This method allows you to specify the target by name to a command
- getCommandTarget

  This method returns the target object of the command.
- getCommandTargetName

  This method returns the name of the target object of the command.
- hasOutputProperties

  This method indicates whether the command has output that must be copied back to the client. (The implementation class also provides a method, setHasOutputProperties, for setting the output of this method. By default, hasOutputProperties returns true.)
- setOutputProperties

  This method saves output values from the command for return to the client.
- performExecute

  This method encapsulates the application-specific work. It is called for you by the execute method declared in the Command interface.

With the exception of the performExecute method, which you must implement, all of these methods are implemented in the TargetableCommandImpl class. This class also implements the execute method declared in the Command interface.

Command interface example application

ModifyCheckingAccountCmd command interface

This example uses an entity bean with container-managed persistence (CMP), called CheckingAccountBean, which enables a client to deposit money, withdraw money, set a balance, get a balance, and retrieve the name on the account. This entity bean also accepts commands from the client. The code examples illustrate the command-related programming. For a servlet-based example, see “Example: Writing a command target (client-side adapter)” on page 409

This command is both targetable and compensable, so the interface extends both TargetableCommand and CompensableCommand interfaces.

```
...
import com.ibm.websphere.exception.*;
import com.ibm.websphere.command.*;
public interface ModifyCheckingAccountCmd
extends TargetableCommand, CompensableCommand {
float getAmount();
float getBalance();
float getOldBalance(); // Used for compensating
float setBalance(float amount);
float setBalance(int amount);
CheckingAccount getCheckingAccount();
void setCheckingAccount(CheckingAccount newCheckingAccount);
TargetPolicy getCmdTargetPolicy();
...
}
```

CompensableCommand interface

The CompensableCommand interface extends the Command interface.

A compensable command is one that has another command (a compensator) associated with it, so that the work of the first can be undone by the compensator. For example, a command that attempts to make an airline reservation followed by a hotel reservation can offer a compensating command that allows the user to cancel the airline reservation if the hotel reservation cannot be made.

The CompensableCommand interface declares one method:

- getCompensatingCommand

  This method returns the command that can be used to undo the effects of the original command.

To create a compensable command, you write an interface that extends the CompensableCommand interface. Such interfaces typically extend the TargetableCommand interface as well. You must implement the getCompensatingCommand method in the implementation class for your interface. You must also implement the compensating command.

Implementing command interfaces

The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

About this task

- To implement an application command interface, write a class that extends the TargetableCommandImpl class and implements your command interface. The structure of the ModifyCheckingAccountCmdImpl class is as follows:

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
...
// Methods
...
}
```

- The class must declare any variables and implement the following methods:
  - Any methods you defined in your command interface.
  - The isReadyToCallExecute and reset methods from the Command interface.
  - The performExecute method from the TargetableCommand interface.
  - The getCompensatingCommand method from the CompensableCommand interface, if your command is compensable. You must also implement the compensating command.

  You can also override the nonfinal implementations provided in the TargetableCommandImpl class. The most likely candidate for reimplementation is the setOutputProperties method, since the default implementation does not save final, transient, or static fields.

Instance and class variables

The ModifyCheckingAccountCmdImpl class declares the variables used by the methods in the class, including the remote interface of the CheckingAccount entity bean, the variables used to capture operations on the checking account (balances and amounts), and a compensating command.

Variables that are used by the ModifyCheckingAccountCmd command

The following code example shows the variables in the ModifyCheckingAccountCmdImpl class:

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
public float balance;
public float amount;
public float oldBalance;
public CheckingAccount checkingAccount;
public ModifyCheckingAccountCompensatorCmd
modifyCheckingAccountCompensatorCmd;
...
}
```

The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

Command-specific methods

The ModifyCheckingAccountCmd interface defines several command-specific methods in addition to extending other interfaces in the command package. These command-specific methods are implemented in the ModifyCheckingAccountCmdImpl class.

Code example: Constructors in the ModifyCheckingAccountCmdImpl class

You must provide a way to instantiate the command. The command package does not specify the mechanism, so you can choose the technique most appropriate for your application. The fastest and most efficient technique is to use constructors. The most flexible technique is to use a factory. Also, since commands are implemented internally as JavaBeans components, you can use the standard Beans.instantiate method. The ModifyCheckingAccountCmd command uses constructors.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
...
// Constructors
// First constructor: relies on the default target policy
public ModifyCheckingAccountCmdImpl(CommandTarget target,
float newAmount)
{
amount = newAmount;
checkingAccount = (CheckingAccount)target;
setCommandTarget(target);
}
// Second constructor: allows you to specify a custom target policy
public ModifyCheckingAccountCmdImpl(CommandTarget target,
float newAmount,
TargetPolicy targetPolicy)
{
setTargetPolicy(targetPolicy);
amount = newAmount;
checkingAccount = (CheckingAccount)target;
setCommandTarget(target);
}
...
}
```

This code example shows the two constructors for the command. The difference between them is that the first uses the default target policy for determining the target of the command and the second allows you to specify a custom policy. For more information on targets and target policies, see “Targets and target policies”.

Both constructors take a CommandTarget object as an argument and cast it to the CheckingAccount type. The CheckingAccount interface extends both the CommandTarget interface and the EJBObject (see Figure 80 on page 160). The resulting checkingAccount object routes the command to the desired server by using the bean’s remote interface. (For more information on CommandTarget objects, see “Writing a command target (server)” on page 159.)

Code example: Command-specific methods in the ModifyCheckingAccountCmdImpl class

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
// Variables
...
// Constructors
...
// Methods in ModifyCheckingAccountCmd interface
public float getAmount() {
return amount;
}
public float getBalance() {
return balance;
}
```

```
public float getOldBalance() {
return oldBalance;
}
public float setBalance(float amount) {
balance = balance + amount;
return balance;
}
public float setBalance(int amount) {
balance += amount ;
return balance;
}
public TargetPolicy getCmdTargetPolicy() {
return getTargetPolicy();
}
public void setCheckingAccount(CheckingAccount newCheckingAccount) {
if (checkingAccount == null) {
checkingAccount = newCheckingAccount;
}
else
System.out.println("Incorrect Checking Account (" +
newCheckingAccount + ") specified");
}
public CheckingAccount getCheckingAccount() {
return checkingAccount;
}
...
}
```

This code example shows the implementation of the following command-specific methods:

- setBalance - sets the balance of the account.
- getAmount - returns the amount of a deposit or withdrawal.
- getOldBalance, getBalance - capture the balance before and after an operation.
- getCmdTargetPolicy - retrieves the current target policy.
- setCheckingAccount, getCheckingAccount - set and retrieve the current checking account.

The ModifyCheckingAccountCmd command operates on a checking account. Because commands are implemented as JavaBeans components, you manage input and output properties of commands using the standard JavaBeans techniques. For example, initialize input properties with set methods (like setCheckingAccount) and retrieve output properties with get methods (like getCheckingAccount). The get methods do not work until after the execute method for the command has been called.

“Implementing command interfaces” on page 394
The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

Example: Implementing methods from the TargetableCommand interface

The TargetableCommand interface declares one method, performExecute, that application programmer must implement.

Methods from the TargetableCommand interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementations for the **ModifyCheckingAccountCmd** command. The implementation of the **performExecute** method is as follows:

- Saves the current balance (so the command can be undone by a compensator command)
- Calculates the new balance
- Sets the current balance to the new balance

- Ensures that the hasOutputProperties method returns true so that the values are returned to the client

In addition, the ModifyCheckingAccountCmdImpl class overrides the default implementation of the setOutputProperties method.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Method from the TargetableCommand interface
public void performExecute() throws Exception {
CheckingAccount checkingAccount = getCheckingAccount();
oldBalance = checkingAccount.getBalance();
balance = oldBalance+amount;
checkingAccount.setBalance(balance);
setHasOutputProperties(true);
}
public void setOutputProperties(TargetableCommand fromCommand) {
try {
if (fromCommand != null) {
ModifyCheckingAccountCmd modifyCheckingAccountCmd =
(ModifyCheckingAccountCmd) fromCommand;
this.oldBalance = modifyCheckingAccountCmd.getOldBalance();
this.balance = modifyCheckingAccountCmd.getBalance();
this.checkingAccount =
modifyCheckingAccountCmd.getCheckingAccount();
this.amount = modifyCheckingAccountCmd.getAmount();
}
}
catch (Exception ex) {
System.out.println("Error in setOutputProperties.");
}
}
...
}
```

"Implementing command interfaces" on page 394
The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

Setting and determining targets

The object that is the target of a TargetableCommand must implement the CommandTarget interface. This object can be an actual server-side object, such as an entity bean, or it can be a client-side adapter for a server.

About this task

The implementor of the CommandTarget interface is responsible for ensuring the proper execution of a command in the desired target server environment. This typically requires the following steps:

1. Copying the command to the target server by using a server-specific protocol.
2. Running the command in the server.
3. Copying the executed command from the target server to the client by using a server-specific protocol.

Example: Implementing methods from the Command interface

The Command interface declares two methods, isReadyToCallExecute and reset, that the application programmer must implement.

Methods from the Command interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementations for the **ModifyCheckingAccountCmd** command. The implementation of the **isReadyToCallExecute** method ensures that the checkingAccount variable is set. The **reset** method sets all of the variables back to starting values.

```
...
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Methods from the Command interface
public boolean isReadyToCallExecute() {
if (checkingAccount != null)
return true;
else
return false;
}
public void reset() {
amount = 0;
balance = 0;
oldBalance = 0;
checkingAccount = null;
targetPolicy = new TargetPolicyDefault();
}
...
}
```

Related tasks

"Implementing command interfaces" on page 394
The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

Example: Implementing methods from the Compensable interface

The CompensableCommand interface declares the **getCompensatingCommand** method that the application programmer must implement.

Method from the CompensableCommand interface in the ModifyCheckingAccountCmdImpl class

The following code example shows the implementation for the **ModifyCheckingAccountCmd** command. The implementation simply returns an instance of the **ModifyCheckingAccountCompensatorCmd** command that is associated with the current command.

```
public class ModifyCheckingAccountCmdImpl extends TargetableCommandImpl
implements ModifyCheckingAccountCmd
{
...
// Method from CompensableCommand interface
public Command getCompensatingCommand() throws CommandException {
modifyCheckingAccountCompensatorCmd =
new ModifyCheckingAccountCompensatorCmd(this);
return (Command)modifyCheckingAccountCompensatorCmd;
}
}
```

Writing the compensating command

An application that uses a compensable command requires two separate commands: the primary command (declared as a CompensableCommand) and the compensating command. In the example application, the primary command is declared in the ModifyCheckingAccountCmd interface and implemented in the ModifyCheckingAccountCmdImpl class. Because this command is also a compensable

command, there is a second command associated with it that is designed to undo its work. When you create a compensable command, you also have to write the compensating command.

Writing a compensating command can require exactly the same steps as writing the original command: writing the interface and providing an implementation class. In some cases, it may be simpler. For example, the command to compensate for the ModifyCheckingAccountCmd does not require any methods beyond those defined for the original command, so it does not need an interface. The compensating command, called ModifyCheckingAccountCompensatorCmd, simply needs to be implemented in a class that extends the TargetableCommandImpl class. This class must:

- Provide a way to instantiate the command; the example uses a constructor.
- Implement the three required methods: isReadyToCallExecute and reset—both from the Command interface and performExecute—from the TargetableCommand interface.

The following code example shows the structure of the implementation class, its variables (references to the original command and to the relevant checking account), and the constructor. The constructor simply instantiates the references to the primary command and account.

```
...
public class ModifyCheckingAccountCompensatorCmd extends TargetableCommandImpl
{
public ModifyCheckingAccountCmdImpl modifyCheckingAccountCmdImpl;
public CheckingAccount checkingAccount;
public ModifyCheckingAccountCompensatorCmd(
ModifyCheckingAccountCmdImpl originalCmd)
{
// Get an instance of the original command
modifyCheckingAccountCmdImpl = originalCmd;
// Get the relevant account
checkingAccount = originalCmd.getCheckingAccount();
}
// Methods from the Command and Targetable Command interfaces
....
}
```

The performExecute method verifies that the actual checking-account balance is consistent with what the original command returns. If so, it replaces the current balance with the previously stored balance by using the ModifyCheckingAccountCmd command. Finally, it saves the most-recent balances in case the compensating command needs to be undone. The reset method has no work to do.

The following code example shows the implementation of the inherited methods. The implementation of the isReadyToCallExecute method ensures that the checkingAccount variable has been instantiated.

```
...
public class ModifyCheckingAccountCompensatorCmd extends TargetableCommandImpl
{
// Variables and constructor
....
// Methods from the Command and TargetableCommand interfaces
public boolean isReadyToCallExecute() {
if (checkingAccount != null)
return true;
else
return false;
}
public void performExecute() throws CommandException
{
try {
ModifyCheckingAccountCmdImpl originalCmd =
modifyCheckingAccountCmdImpl;
// Retrieve the checking account modified by the original command
CheckingAccount checkingAccount = originalCmd.getCheckingAccount();
if (modifyCheckingAccountCmdImpl.balance ==
checkingAccount.getBalance()) {
```

```
// Reset the values on the original command
checkingAccount.setBalance(originalCmd.oldBalance);
float temp = modifyCheckingAccountCmdImpl.balance;
originalCmd.balance = originalCmd.oldBalance;
originalCmd.oldBalance = temp;
}
else {
// Balances are inconsistent, so we cannot compensate
throw new CommandException(
"Object modified since this command ran.");
}
}
catch (Exception e) {
System.out.println(e.getMessage());
}
}
public void reset() {}
}
```

Related tasks

"Implementing command interfaces" on page 394
The command package provides a class, TargetableCommandImpl, that implements all of the methods in the TargetableCommand interface except the performExecute method. It also implements the execute method from the Command interface.

Interfaces for creating commands

The Command interface specifies the most basic aspects of a command. This interface is extended by both the TargetableCommand interface and the CompensableCommand interface, which offer additional features.

To create commands for applications, you must:

- Define an interface that extends one or more of interfaces in the command package.
- Provide an implementation class for your interface.

In practice, most commands implement the TargetableCommand interface, which allows the command to be executed remotely. The following example shows the structure of a command interface for a targetable command:

```
... import com.ibm.websphere.command.*;
public interface MySimpleCommand extends TargetableCommand { // Declare application
methods here }
```

The CompensableCommand interface enables the association of one command with another that can undo the work of the first. Compensable commands also typically implement the TargetableCommand interface. The following example shows the structure of a command interface for a targetable, compensable command:

```
... import com.ibm.websphere.command.*;
public interface MyCommand extends TargetableCommand, CompensableCommand {
// Declare application methods here }
```

Facilities for implementing commands

Commands are implemented by extending the class TargetableCommandImpl, which implements the TargetableCommand interface. The TargetableCommandImpl class is an abstract class that provides some implementations for some of the methods in the TargetableCommand interface (for example, setting return values) and declares additional methods that the application itself must implement (for example, how to execute the command).

You implement your command interface by writing a class that extends the TargetableCommandImpl class and implements your command interface. This class contains the code for the methods in your interface, the methods inherited from extended interfaces (the TargetableCommand and CompensableCommand

interfaces), and the required (abstract) methods in the TargetableCommandImpl class. You can also override the default implementations of other methods provided in the TargetableCommandImpl class. The following example shows the structure of an implementation class for an interface:

```
... import java.lang.reflect.*; import com.ibm.websphere.command.*;
public class MyCommandImpl extends TargetableCommandImpl implements MyCommand
{ // Set instance variables here ... // Implement methods in the MyCommand
interface ... // Implement methods in the CompensableCommand interface ...
// Implement abstract methods in the TargetableCommandImpl class ... }
```

Exceptions in the command package

The command package defines a set of exception classes.

The CommandException class extends the DistributedException class and acts as the base class for the additional command-related exceptions:

- UnauthorizedAccessException
- UnsetInputPropertiesException
- UnavailableCompensableCommandException

Applications can extend the CommandException class to define additional exceptions.

Although the CommandException class extends the DistributedException class, you do not have to import the distributed-exception package, com.ibm.websphere.exception, unless you need to use the features of the DistributedException class in your application.

Targets and target policies

A targetable command extends the TargetableCommand interface, which allows the client to direct a command to a particular server. The TargetableCommand interface (and the TargetableCommandImpl class) provide two ways for a client to specify a target: the setCommandTarget and setCommandTargetName methods.

The setCommandTarget methods allows the client to set the target object directly on the command. The setCommandTargetName method allows the client to refer to the server by name; this approach is useful when the client is not directly aware of server objects. A targetable command also has corresponding getCommandTarget and getCommandTargetName methods.

The command package needs to be able to identify the target of a command. Because there is more than one way to specify the target and because different applications can have different requirements, the command package does not specify a selection algorithm. Instead, it provides a TargetPolicy interface with one method, getCommandTarget, and a default implementation. This enables applications to devise custom algorithms for determining the target of a command when appropriate.

The default target policy

The command package provides a default implementation of the TargetPolicy interface in the TargetPolicyDefault class.

Relevant variables and the methods in the TargetPolicyDefault class

If you use this default implementation, the command determines the target by looking through an ordered sequence of four options:

- The CommandTarget value
- The CommandTargetName value
- A registered mapping of a target for a specific command
- A defined default target

If the command finds no target, it returns null.

The TargetPolicyDefault class provides methods for managing the assignment of commands with targets (registerCommand, unregisterCommand, and listMappings), and a method for setting a default name for the target (setDefaultTargetName). The default target name is com.ibm.websphere.command.LocalTarget, where LocalTarget is a class that runs the command's performExecute method locally.

```
...
public class TargetPolicyDefault implements TargetPolicy, Serializable
{
...
protected String defaultTargetName = "com.ibm.websphere.command.LocalTarget";
public CommandTarget getCommandTarget(TargetableCommand command) {
... }
public Dictionary listMappings() {
... }
public void registerCommand(String commandName, String targetName) {
... }
public void unregisterCommand(String commandName) {
... }
public void seDefaultTargetName(String defaultTargetName) {
... }
}
```

Setting the command target:

The ModifyCheckingAccountImpl class provides two command constructors. One of them takes a command target as an argument and implicitly uses the default target policy to locate the target. The constructor passes a null target, so that the default target policy traverses its choices and eventually finds the default target name, LocalTarget.

Identifying a target with CommandTarget

If you use this default implementation, the command determines the target by looking through an ordered sequence of four options:

- The CommandTarget value
- The CommandTargetName value
- A registered mapping of a target for a specific command
- A defined default target

If the command finds no target, it returns null.

This example uses the same constructor to set the target explicitly. This example differs from the example in "Using a command" on page 408 as follows:

- The command target is set to the checking account rather than null. The default target policy starts to traverse its choices and finds the target in the first place it looks.
- It does not have to call the setCheckingAccount method to indicate the account on which the command should operate; the constructor uses the target variable as both the target and the account.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(checkingAccount, 1000);
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Setting the command target name:

If a client needs to set the target of the command by name, it can use the setCommandTargetName method for the command.

Identifying a target with CommandTargetName

This example compares with the example in “Using a command” on page 408 as follows:

- Both explicitly set the command target in the constructor to null.
- Both use the setCheckingAccount method to indicate the account on which the command should operate.
- This example sets the target name explicitly by using the setCommandTargetName method. When the default target policy traverses its choices, it finds a null for the first choice and a name for the second.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
cmd.setCheckingAccount(checkingAccount);
cmd.setCommandTargetName("com.ibm.sfc.cmd.test.CheckingAccountBean");
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Example: Mapping the command to a target name:

The default target policy also permits commands to be registered with targets. Mapping a command to a target is an administrative task that most appropriately done through a configuration tool.

Mapping a command to a target in an external application

The WebSphere Application Server administrative console does not yet support the configuration of mappings between commands and targets. Applications that require support for the registration of commands with targets must supply the tools to manage the mappings. These tools can be visual interfaces or command-line tools.

The following example shows the registration of a command with a target. The names of the command class and the target are explicit in the code, but in practice, these values would come from fields in a user interface or arguments to a command-line tool. If a program creates a command as shown in the example in “Using a command” on page 408, with a null for the target, when the default target policy traverses its choices, it finds a null for the first and second choices and a mapping for the third.

```
{
...
targetPolicy.registerCommand(
"com.ibm.sfc.cmd.test.ModifyCheckingAccountImpl",
"com.ibm.sfc.cmd.test.CheckingAccountBean");
...
}
```

Example: Customizing target policies

You can define custom target policies by implementing the TargetPolicy interface and providing a getCommandTarget method appropriate for your application. The TargetableCommandImpl class provides setTargetPolicy and getTargetPolicy methods for managing custom target policies.

Custom target policy

So far, the target of all the commands has been a checking-account entity bean. Suppose that someone introduces a session enterprise bean (MySessionBean) that can also act as a command target. The following code example shows a simple custom policy that sets the target of every command to MySessionBean.

```
import java.io.*;
import java.util.*;
import java.beans.*;
import com.ibm.websphere.command.*;
public class CustomTargetPolicy implements TargetPolicy, Serializable {
public CustomTargetPolicy {
super();
}
public CommandTarget getCommandTarget(TargetableCommand command) {
CommandTarget = null;
try {
target = (CommandTarget)Beans.instantiate(null,
"com.ibm.sfc.cmd.test.MySessionBean");
}
catch (Exception e) {
e.printStackTrace();
}
}
}
```

Because commands are implemented as JavaBeans components, using custom target policies requires importing the java.beans package and writing some elementary JavaBeans code. Also, your custom target-policy class must also implement the java.io.Serializable interface.

Example: Using a custom target policy:

The ModifyCheckingAccountImpl class provides two command constructors. One of them implicitly uses the default target policy; the other takes a target policy object as an argument, which enables you to use a custom target policy.

Custom target policy example

The following example uses the second constructor, passing a null target and a custom target policy, so that the custom policy is used to determine the target. After the command is executed, the code uses the reset method to return the target policy to the default.

```
{
...
CheckingAccount checkingAccount
....
try {
CustomTargetPolicy customPolicy = new CustomTargetPolicy();
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000, customPolicy);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
cmd.reset();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
}
```

Writing a command target (server)

A server must implement the CommandTarget interface and its single method, executeCommand, to accept commands.

About this task

The example application implements the CommandTarget interface in an enterprise bean. The target enterprise bean can be a session bean or an entity bean. You can write a target enterprise bean that forwards commands to a specific server, such as another entity bean. In this case, all commands directed at a specific target go through the target enterprise bean. You can also write a target enterprise bean that does the work of the command locally.

Make an enterprise bean the target of a command, as follows:

- Extending the CommandTarget interface when you define the remote interface for the bean, which must also extend the EJBObject interface.
- Implementing the CommandTarget interface when you implement the bean class, which must also implement either the SessionBean or EntityBean interface. The target of the example application is an enterprise bean called CheckingAccountBean. The remote interface for the bean, CheckingAccount, extends the CommandTarget interface in addition to the EJBObject interface. The methods that are declared in the remote interface are independent of those that are used by the command. The executeCommand is declared in neither the home for the bean, nor remote interfaces. The following code example displays the CheckingAccount interface.

```
...
import com.ibm.websphere.command.*;
import javax.ejb.EJBObject;
import java.rmi.RemoteException;
public interface CheckingAccount extends CommandTarget, EJBObject {
float deposit (float amount) throws RemoteException;
float deposit (int amount) throws RemoteException;
String getAccountName() throws RemoteException;
float getBalance() throws RemoteException;
float setBalance(float amount) throws RemoteException;
float withdrawal (float amount) throws RemoteException, Exception;
float withdrawal (int amount) throws RemoteException, Exception;
}
```

  The enterprise bean class, CheckingAccountBean, implements the EntityBean interface as well as the CommandTarget interface. The class contains the business logic for the methods in the remote interface, the necessary life-cycle methods (ejbActivate, ejbStore, and so on), and the executeCommand declared by the CommandTarget interface. The executeCommand method is the only command-specific code in the enterprise bean class. It attempts to run the performExecute method on the command and throws a CommandException if an error occurs. If the performExecute method runs successfully, the executeCommand method uses the hasOutputProperties method to determine if there are output properties that must be returned. If the command has output properties, the method returns the command object to the client. The following code example displays the relevant parts of the CheckingAccountBean class.

```
...
public class CheckingAccountBean implements EntityBean, CommandTarget {
// Bean variables
...
// Business methods from remote interface
...
// Life-cycle methods for CMP entity beans
...
// Method from the CommandTarget interface
public TargetableCommand executeCommand(TargetableCommand command)
throws RemoteException, CommandException
{
try {
command.performExecute();
}
catch (Exception ex) {
if (ex instanceof RemoteException) {
RemoveException remoteException = (RemoteException)ex;
if (remoteException.detail != null) {
```

```
throw new CommandException(remoteException.detail);
}
throw new CommandException(ex);
}
}
if (command.hasOutputProperties()) {
return command;
}
return null;
}
}
```

Example: Compensating command example

To use a compensating command, you must retrieve the compensator that is associated with the primary command and call its execute method.

ModifyCheckingAccountCompensator command

The following code example shows the code used to run the original command and to give the user the option of undoing the work by running the compensating command.

```
{
...
CheckingAccount checkingAccount
....
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
...
System.out.println("Would you like to undo this work? Enter Y or N");
try {
// Retrieve and validate user's response
...
}
...
if (answer.equalsIgnoreCase(Y)) {
Command compensatingCommand = cmd.getCompensatingCommand();
compensatingCommand.execute();
}
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Helper class for running commands

WebSphere Application Server ships a CommandTarget enterprise bean to enable administrators to run a command in a designated server without providing their own implementation of CommandTarget. The EJBCommandTarget class, along with the EJBCommandTarget bean (CommandServerSessionBean), are located in the `EJBCommandTarget.jar` file in the `lib` directory under the WebSphere Application Server installation directory. This is a deployed jar file. You can use this JAR file in a new application or add it into an existing application.

The EJBCommandTarget class serves as a wrapper for a CommandTarget bean. CommandServerSessionBean is the WebSphere Application Server implementation of this CommandTarget bean. A command developer can set this EJBCommandTarget object into the Command. The following is a code example of the EJBCommandTarget bean:

```
EJBCommandTarget target = new EJBCommandTarget();
MyCommand cmd = new MyCommandImpl(Arguments...);
cmd.setCommandTarget(target);
cmd.execute();
```

In the code example, the client creates a MyCommand object. It is then executed in the application server. When the execute method is run, the target (EJBCommandTarget) looks up the CommandServerSessionHome from the InitialContext and executes the executeCommand method on the CommandServerSessionBean. The EJBCommandTarget object ensures that there is only one CommandServerSessionBean per object to avoid extra naming lookup.

An EJBCommandTarget object can be created using four different constructors:

- EJBCommandTarget(⌂MyNamingServerName⌂, ⌂PortNumber⌂, ⌂JNDIName⌂)
- EJBCommandTarget(InitialContext,⌂JNDIName⌂)
- EJBCommandTarget(⌂JNDIName⌂)
- EJBCommandTarget()

The first constructor enables the application to specify the naming server name and the port. The JNDI name of the CommandServerSessionBean can also be specified. The EJBCommandTarget constructs a `iiop://MyNamingServerName:PortNumber` provider URL and looks up the CommandServerSessionBean with the given JNDI name. If null values are passed in for any of the parameters, WebSphere Application Server defaults for server and port and a default JNDI name of CommandServerSession are used.

The second constructor enables the application to specify its own initial context. The EJBCommandTarget object then uses this initial context to look up the CommandServerSession bean with the specified JNDI name.

The third constructor enables the application to set up the naming server (the provider URL) in property files.

The default constructor uses the default values for the provider URL and default JNDI name for the CommandServerSession bean (CommandServerSession).

You do not need to use the EJBCommandTarget class. You can instead create your own custom target policy that uses the EJBCommandTarget bean (CommandServerSessionBean). The EJBCommandTarget object is a convenience class and attempts to address most usage scenarios.

Using a command

To use a command, the client creates an instance of the command and calls the execute method for the command. Depending on the command, calling other methods can be necessary. The specifics will vary with the application.

About this task

In the example application, the server is the CheckingAccountBean, an entity enterprise bean. In order to use this enterprise bean, the client gets a reference to the bean's home interface. The client then uses the reference to the home interface and one of the finder methods for the bean to obtain a reference to the remote interface for the bean. If there is no appropriate bean, the client can create one using a create method on the home interface.

The following code example illustrates the use of the **ModifyCheckingAccountCmd** command. This work takes place after an appropriate CheckingAccount bean has been found or created. The code instantiates a command, setting the input values by using one of the constructors defined for the command. The null argument indicates that the command should look up the server using the default target policy, and 1000

is the amount the command attempts to add to the balance of the checking account. After the command is instantiated, the code calls the setCheckingAccount method to identify the account to be modified. Finally, the execute method on the command is called.

```
{
...
CheckingAccount checkingAccount
...
try {
ModifyCheckingAccountCmd cmd =
new ModifyCheckingAccountCmdImpl(null, 1000);
cmd.setCheckingAccount(checkingAccount);
cmd.execute();
}
catch (Exception e) {
System.out.println(e.getMessage());
}
...
}
```

Example: Writing a command target (client-side adapter)

Commands can be used with any Java application, but the means of sending the command from the client to the server varies. The example in this topic shows how you can send a command to a servlet over the HTTP protocol. The client implements the CommandTarget interface locally.

The structure of a client-side adapter for a target

This example shows the structure of the client-side class; it implements the CommandTarget interface by implementing the executeCommand method.

```
...
import java.io.*;
import java.rmi.*;
import com.ibm.websphere.command.*;
public class ServletCommandTarget implements CommandTarget, Serializable
{
protected String hostName = "localhost";
public static void main(String args[]) throws Exception
{
....
}
public TargetableCommand executeCommand(TargetableCommand command)
throws CommandException
{
....
}
public static final byte[] serialize(Serializable serializable)
throws IOException {
... }
public String getHostName() {
... }
public void setHostName(String hostName) {
... }
private static void showHelp() {
... }
}
```

Instantiating the client-side adapter

The main method in the client-side adapter constructs and intializes the CommandTarget object, as follows:

```
public static void main(String args[]) throws Exception
{
String hostName = InetAddress.getLocalHost().getHostName();
String fileName = "MyServletCommandTarget.ser";
```

```
// Parse the command line
...
// Create and initialize the client-side CommandTarget adapter
ServletCommandTarget servletCommandTarget = new ServletCommandTarget();
servletCommandTarget.setHostName(hostName);
...
// Flush and close output streams
...
}
```

Example: Implementing a client-side adapter:

The CommandTarget interface declares one method, executeCommand, which the client implements. The executeCommand method takes a TargetableCommand object as input; it also returns a TargetableCommand.

A client-side implementation of the executeCommand method

This example shows the implementation of the method used in the client-side adapter. This implementation does the following:

- Serializes the command it receives
- Creates an HTTP connection to the servlet
- Creates input and output streams, to handle the command as it is sent to the server and returned
- Places the command on the output stream
- Sends the command to the server
- Retrieves the returned command from the input stream
- Returns the returned command to the caller of the executeCommand method

```
public TargetableCommand executeCommand(TargetableCommand command)
throws CommandException
{
try {
// Serialize the command
byte[] array = serialize(command);
// Create a connection to the servlet
URL url = new URL
("http://" + hostName +
"/servlet/com.ibm.websphere.command.servlet.CommandServlet");
HttpURLConnection httpURLConnection =
(HttpURLConnection) url.openConnection();
// Set the properties of the connection
...
// Put the serialized command on the output stream
OutputStream outputStream = httpURLConnection.getOutputStream();
outputStream.write(array);
// Create a return stream
InputStream inputStream = httpURLConnection.getInputStream();
// Send the command to the servlet
httpURLConnection.connect();
ObjectInputStream objectInputStream =
new ObjectInputStream(inputStream);
// Retrieve the command returned from the servlet
Object object = objectInputStream.readObject();
if (object instanceof CommandException) {
throw ((CommandException) object);
}
// Pass the returned command back to the calling method
return (TargetableCommand) object;
}
// Handle exceptions
....
}
```

Example: Running the command in the servlet:

The CommandTarget interface declares one method, executeCommand, which the client implements. The executeCommand method takes a TargetableCommand object as input; it also returns a TargetableCommand.

Running the command in the servlet

The servlet that runs the command is shown in the following example. The service method retrieves the command from the input stream and runs the performExecute method on the command. The resulting object, with any output properties that must be returned to the client, is placed on the output stream and sent back to the client.

```
...
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
import com.ibm.websphere.command.*;
public class CommandServlet extends HttpServlet {
...
public void service(HttpServletRequest request,
HttpServletResponse response)
throws ServletException, IOException
{
try {
...
// Create input and output streams
InputStream inputStream = request.getInputStream();
OutputStream outputStream = response.getOutputStream();
// Retrieve the command from the input stream
ObjectInputStream objectInputStream =
new ObjectInputStream(inputStream);
TargetableCommand command = (TargetableCommand)
objectInputStream.readObject();
// Create the command for the return stream
Object returnObject = command;
// Try to run the command's performExecute method
try {
command.performExecute();
}
// Handle exceptions from the performExecute method
...
// Return the command with any output properties
ObjectOutputStream objectOutputStream =
new ObjectOutputStream(outputStream);
objectOutputStream.writeObject(returnObject);
// Flush and close output streams
...
}
catch (Exception ex) {
ex.printStackTrace();
}
}
}
```

The target invokes the performExecute method on the command, but this is not always necessary. In some applications, it can be preferable to implement the work of the command locally. For example, the command can be used only to send input data, so that the target retrieves the data from the command and runs a local database procedure based on the input. You must decide the appropriate way to use commands in your application.

Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the Sun Microsystems JRE that is downloaded from the Sun Microsystems Web site, or the JRE that is downloaded from the HP Web site.

Before you begin

The IBM ORB implementation library is required if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. For example, running the IBM Thin Client for EJB with Sun Microsystems JRE on Windows, Linux, or Solaris, and with the HP JRE on HPUX. The IBM-provided Solaris hybrid and HP hybrid JRE are not considered non-IBM product JRE environments. The IBM Thin Client for EJB can access version 2.x and version 3.0 EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.0 EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient.zos_7.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient.zos_7.0.0.jar` , to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for Version 7.0 WebSphere Application Server where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

The IBM Thin Client for EJB with WebSphere Application Server runs on distributed operating systems with JDK support, including both Version 5 and Version 6. When using the IBM Thin Client for EJB as a standalone Java SE application with a non-IBM product JRE, you must override the default ORB implementation for the JRE through one of following methods:

- Include the com.ibm.ws.orb_7.0.0.jar file in the Java system classpath.
- Override the default ORB implementation in the JRE, using Java Endorsed Standards Override Mechanism.
- Set the java.endorsed.dirs path to a directory that contains the com.ibm.ws.orb_7.0.0.jar file.

When running the IBM Thin Client for EJB as an Eclipse RCP application, it is recommended to use method two, to override the default JRE ORB implementation.

Note: The Pluggable Application Client feature in the application client installer is deprecated. It is replaced by the IBM Thin Client for EJB.

About this task

Run the IBM Thin Client for EJB, by completing the following steps.

1. Invoke the client application. Run the following Java command:

Add the following system properties to the Java command if you want authentication and SSL enabled:

```
export LIBPATH=<app_server_root>/lib:$LIBPATH
<java_install_root>/bin/java
-classpath com.ibm.ws.ejb.thinclient.zos_7.0.0.jar:<list_of_your_application_jars_and_classes>
-Djava.naming.provider.url=iiop://<your_application_server_machine_name>
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
-Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
-Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
<fully_qualified_class_name_to_run>
```

2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

   Recommended SSL configuration settings when running the application with a non-IBM product JRE:

   ```
   com.ibm.ssl.protocol=SSL
   com.ibm.ssl.trustManager=SunX509
   com.ibm.ssl.keyManager=SunX509
   com.ibm.ssl.contextProvider=SunJSSE

   com.ibm.ssl.keyStoreType=JKS
   com.ibm.ssl.keyStoreProvider=SUN
   com.ibm.ssl.keyStore=/home/user1/etc/key.jks

   com.ibm.ssl.trustStoreType=JKS
   com.ibm.ssl.trustStoreProvider=SUN
   com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
   ```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

   You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_7.0.0.jar` file, or add it to the classpath.

What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

Related tasks

Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine

Related reference

ssl.client.props client configuration file

Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Chapter 6. Web services

Task overview: Implementing Web services applications

Use this topic as an introduction to using Web services. WebSphere Application Server supports Web services that are developed and implemented based on a variety of Java programming models. Use Web services when operating across a variety of platforms, including Java Platform, Enterprise Edition (Java EE) and non-Java EE platforms.

Before you begin

Decide if a Web services implementation benefits your business process.

About this task

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Implementing Web services applications is an easy way to integrate application systems together within or outside your business infrastructure that function as stand-alone systems. For example, your customer information database is a stand-alone application, but you want your accounting application to access the customer data. You can create a Web service for the customer database and then enable the accounting application as a Web service client. The accounting application can now access the customer information. By implementing a Web service, these two applications can share information in an efficient way.

Because Web services are easily applied to existing applications and information technology assets, you can develop, deploy and recompose new solutions quickly to address new opportunities. As Web services become more popular, the pool of services grows, promoting development of more robust models of just-in-time application and business integration over the Internet.

You can use Web services applications with the application server by following the steps provided:

1. Plan to use Web services. Review all of the components of Web services to learn how you can make your Web services plan more robust.
2. (Optional) Migrate existing Web services.

   Because Java EE environments emphasize compatibility, most application servers that offer support for the newer JAX-WS and JAXB specifications continue to support the older JAX-RPC specification. A consequence of this is that, existing Web services are likely to remain JAX-RPC based while new ones are developed using JAX-WS and JAXB.

   However, as time passes and applications are revised and rewritten, there might be times when the best strategy is to migrate a JAX-RPC based Web service to one based on JAX-WS and JAXB. This might result from a vendor choosing to provide enhancements to qualities of service that are only available in the new programming models. For example, SOAP 1.2 and SOAP Message Transmission Optimization Mechanism (MTOM) support are only available within the JAX-WS 2.x and JAXB 2.x

programming models and not JAX-RPC. Read about Web services migration best practices to learn more about best practices and examples when migrating JAX-RPC Web services to JAX-WS and JAXB Web services.

Note: Existing JAX-RPC applications wanting to use JAX-WS features must be rewritten using the JAX-WS programming model.

If you have used Web services based on Apache SOAP and now want to develop and implement Web Services for Java EE specification, you need to migrate client applications developed with all versions of 4.0, and versions of 5.0 prior to 5.0.2. See the topic, Migrating Apache SOAP Web services to JAX-RPC Web Services based on Java EE standards.

3. Develop Web services applications. You can develop Web services in one of the following ways:
   a. Develop Web services from existing WSDL files using JAX-WS.

      You can create a JAX-WS Web service by starting with an existing Web Services Description Language (WSDL) file describing the service interface for a JavaBeans or enterprise beans application. Typically, the WSDL file is defined as part of the application modeling process. Using an existing service definition or WSDL file to generate a new application is called a top-down approach to developing Web services.

   b. Develop Web services applications using JAX-WS.

      You can use the Java API for XML-Based Web Services (JAX-WS) programming model to develop Web services. JAX-WS simplifies application development through a standard, annotation-based model to develop Web services applications and clients. A common set of binding rules for XML and Java objects make it easy to incorporate XML data and process functions in Java applications. A further set of enhancements help you optimally send binary attachments, such as images or files, with the Web services requests.

      When developing a JAX-WS Web service starting from existing JavaBeans or stateless session enterprise beans, you can expose the bean as a JAX-WS Web service by using annotations. Adding the @WebService or @WebServiceProvider annotation to the bean defines the bean as a JAX-WS Web service. Enterprise beans that are exposed as JAX-WS Web services must be packaged in EJB 3.0 or higher modules.

      Transforming an existing application into Web services is called a bottoms-up approach to developing Web services. This process is called bottoms-up because you are starting with the implementation rather than starting with an existing service or Web Services Description Language (WSDL) file.

   c. Develop and deploy JAX-WS Web services clients Web services clients that can both access and invoke JAX-WS Web services are developed based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. The application server supports Enterprise JavaBeans™ (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-WS programming model.

   d. Develop Web services applications from existing WSDL files with JAX-RPC.

      You can create a JAX-RPC Web service by starting with an existing WSDL file describing the service interface of an enterprise bean implementation using a top-down approach to developing Web services.

   e. Develop Web services applications with JAX-RPC.

      You can use the Java API for XML-based RPC (JAX-RPC) programming model to develop Web services. When developing a JAX-RPC Web service starting from existing JavaBeans or enterprise beans, you need develop a WSDL file. You can use existing JavaBeans or enterprise beans and then enable the implementation for Web services.

   f. Develop and deploy JAX-RPC Web services clients You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-based remote procedure call (JAX-RPC) specification. The application server supports Enterprise JavaBeans™ (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-RPC programming model.

g. Enable Web services through service integration technologies

   You can use the Web services enablement of the service integration bus (SIBus) to achieve the following goals:

   - Make an internally hosted service that is available at a bus destination available as a Web service.
   - Make an external Web service available internally at a bus destination.
   - Use the Web services gateway to map an existing service, either an internally-hosted service or an external Web service, to a new Web service that is provided by the gateway.

You can develop Web services to take advantage of Web Services Addressing (WS-Addressing), Web Services Resource Framework (WSRF), and Web Services Transaction (WS-Transaction) support.

- Use the WS-Addressing SPI: Performing more advanced Web Service Addressing tasks.

  You can develop Web services to take advantage of Web Services Addressing (WS-Addressing), which aids interoperability between Web services using a standard way to address Web services and providing addressing information in messages.
- Create stateful Web services using the Web Services Resource Framework.

  With the Web Services Resource Framework (WSRF) support in the application server, you can implement a stateful Web service as a WS-Resource, and reference that service it using a WS-Addressing endpoint reference.
- Use WS-Transaction policy to coordinate transactions or business activities for Web services.

  WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the Web services environment. Distributed Web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, Web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs.
- Use WS-Policy to exchange policies in a standard format.

  WS-Policy is an interoperability standard that is used to describe and communicate the policies of a Web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction.

4. Assemble Web services.

   Read about what you need to assemble a Web service and the order in which to assemble the parts, for example an enterprise archive (EAR) file.
5. Deploy Web services.

   Read about the steps necessary to deploy the EAR file that has been configured and enabled for Web services.
6. Administer deployed Web services.

   Once your Web services application is deployed, you can configure security settings, view deployment descriptors and WSDL documents, set the scope of a Web service port, and manage policy sets and service providers. These tasks can be done using the administrative console or with command-line tools.
7. Secure Web services.

   - Manage policy sets using the administrative console.

     Read about creating policy sets that you can use to simplify the security configuration of your Web services applications. Policy sets are only supported by JAX-WS applications.
   - Secure Web services applications using message level security.

Consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies.

8. Publish the WSDL file.

   After installing a Web services application, and optionally modifying the endpoint information, you might need Web Services Description Language (WSDL) files containing the updated endpoint information. Read about the steps necessary to publish the WSDL files so that this information is available.

9. Monitor the performance of Web services applications.

   Read about using the Performance Monitoring Infrastructure (PMI) to measure the time required to process Web services requests.

10. Troubleshoot Web services.

    Read about troubleshooting different processes used to develop, implement and use Web services, including command-line tools, Java compiling errors, client runtime errors and exceptions, serialization and deserialization errors, and authentication challenges and authorization failures with Web services security.

Example

The following example illustrates how a business might use Web services.

The owner of a flower shop wants to start receiving orders from customers through the Web. This owner starts the process by finding wholesale flower suppliers, pricing the product, and completing contracts for future flower orders.

Using Web services, the flower shop owner can find wholesale flower suppliers. One way to find new suppliers is to use a Universal Description, Discovery and Integration (UDDI) registry to search for potential suppliers. When the suppliers are chosen, the registry sends back information on how to contact the flower distributors that meet the criteria of the flower shop owner.

The flower shop owner can request price lists from each of the suppliers by obtaining a WSDL file for each potential supplier. The WSDL can be downloaded from the Web page of the supplier, received through e-mail, or retrieved from the UDDI registry entry of the supplier.

The WSDL describes the procedure call. When using the application server, the procedure call is a JAX-RPC or a JAX-WS procedure call. Either of these procedure call types retrieves the price list. The WSDL file also specifies the Universal Resource Locator (URL), where the request is sent.

The flower shop owner now has to compare the prices received from each supplier, decide which suppliers to do business with, and make arrangements for future orders to fill. The flower shop can now sell merchandise through the Web by using Web services to communicate with suppliers for the best prices and complete the ordering processes. The merchandise price lists need publishing to the Web site and a mechanism is needed for customers to order flowers.

The Web services clients of the flower supplier are deployed on the flower shop server. When a customer makes a transaction to purchase flowers through the Web, the order is sent to the supplier through the procedure call. The supplier responds by sending a confirmation with the order number and shipping date. The suppliers maintain the inventory and the flower shop owner handles billing and customer order management.

Similarly, the flower shop catalog can be composed automatically from the catalogs of each supplier. If the supplier delivers directly to the customer, then the order tracking inquiries can pass directly to the order tracking system of the supplier. The supplier can also use Web services to send invoices for orders by the

flower shop. Processes that previously required forms to fill manually, and fax or mail, can now be done automatically, saving labor costs for both the flower shop and the supplier.

Using Web services is beneficial because a much larger inventory is made available to the flower shop. No merchandise maintenance overhead exists, and the flower shop can offer their customers products that they otherwise might not have. Selling flowers through the Web increases capital for the flower shop without overhead of another store or resources invested into additional products.

For a more detailed scenario, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer, Plants by WebSphere, and how they incorporated the Web services concept.

Refer to the Samples Gallery for additional Samples that demonstrate JAX-WS and JAX-RPC Web services.

Service-oriented architecture

A *service-oriented architecture* (SOA) is a collection of services that communicate with each other, for example, passing data from one service to another or coordinating an activity between one or more services.

Companies want to integrate existing systems to implement Information Technology (IT) support for business processes that cover the entire business value chain. A variety of designs are used, ranging from rigid point-to-point electronic data interchange (EDI) to Web auctions. By using the Internet, companies can make their IT systems available to internal departments or external customers, but the interactions are not flexible and are without standardized architecture.

Because of this increasing demand for technologies that support connecting and sharing resources and data, a need exists for a flexible, standardized architecture. SOA is a flexible architecture that unifies business processes by structuring large applications into building blocks, or small modular functional units or services, for different groups of people to use inside and outside the company. The building blocks can be one of three roles: service provider, service broker, or service requestor. See Web services approach to a service-oriented architecture to learn more about these roles.

Requirements for an SOA

To efficiently use an SOA, follow these requirements:

- **Interoperability between different systems and programming languages**.

  The most important basis for a simple integration between applications on different platforms is to provide a communication protocol. This protocol is available for most systems and programming languages.
- **Clear and unambiguous description language**.

  To use a service offered by a provider, it is not only necessary to be able to access the provider system, but the syntax of the service interface must also be clearly defined in a platform-independent fashion.
- **Retrieval of the service**.

  To support a convenient integration at design time or even system run time, a search mechanism is required to retrieve suitable services. Classify these services as *computer-accessible*, *hierarchical* or *taxonomies* based on what the services in each category do and how they can be invoked.

Web services approach to a service-oriented architecture

You can use Web services in a service-oriented architecture (SOA) environment.

You can use Web services to implement a SOA. A major focus of Web services is to make functional building blocks accessible over standard Internet protocols that are independent from platforms and programming languages. These services can be new applications or just wrapped around existing legacy systems to make them network-enabled. A service can rely on another service to achieve its goals.

Each SOA building block can assume one or more of three roles:

- **Service provider**

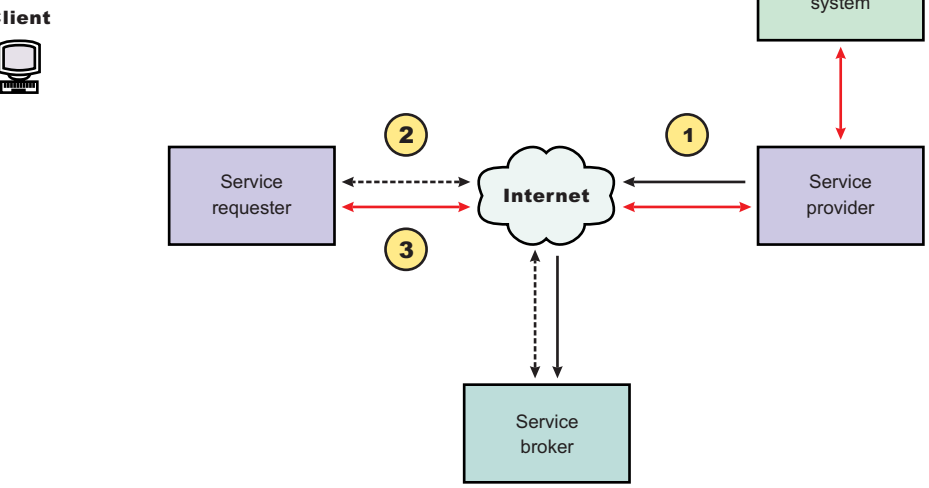
  The service provider creates a Web service and possibly publishes its interface and access information to the service registry. Each provider must decide which services to expose, how to make trade-offs between security and easy availability, how to price the services, or how to exploit free services for other value. The provider also has to decide which category to list the service in for a given broker service and what sort of trading partner agreements are required to use the service.

- **Service broker**

  The service broker, also known as *service registry*, is responsible for making the Web service interface and implementation access information available to any potential service requestor. The implementer of the broker decides the scope of the broker. Public brokers are available through the Internet, while private brokers are only accessible to a limited audience, for example, users of a company intranet. Furthermore, some decisions need to be made about the amount of the offered information. Some brokers specialize in many listings. Others offer high levels of trust in the listed services. Some cover a broad landscape of services and others focus within an industry. Some brokers catalog other brokers. Depending on the business model, brokers can attempt to maximize look-up requests, the number of listings or the accuracy of the listings. The Universal Description, Discovery and Integration (UDDI) specification defines a way to publish and discover information about Web services.

- **Service requester**

  The service requestor or Web service client locates entries in the broker registry using various find operations and then binds to the service provider to invoke one of its Web services.



Characteristics of the SOA

The presented SOA illustrates a loose coupling between the participants, which provides greater flexibility in the following ways:

- A client is coupled to a service. Therefore, the integration of the server takes place outside the scope of the client application programs.
- Old and new functional blocks or applications and systems, are encapsulated into components that work as services.
- Functional components and their interfaces are separate so that new interfaces can be plugged in more easily.
- Within complex applications, the control of business processes can be isolated. A business rule engine can be incorporated to control the workflow of a defined business process. Depending on the state of the workflow, the engine calls the respective services.

- Services can be incorporated dynamically during run time.
- Bindings are specified using configuration files and can be easily adapted to new needs.

Properties of a service-oriented architecture

The service-oriented architecture offers the following properties:

- **Web services are self-contained**

  On the client side, no additional software is required. A programming language with Extensible Markup Language (XML) and HTTP client support is enough to get you started. On the server side, a Web server and a SOAP server are required. It is possible to enable an existing application for Web services without writing a single line of code.
- **Web services are self-describing**

  Neither the client nor the server knows or cares about anything besides the format and content of the request and response messages (loosely coupled application integration). The definition of the message format travels with the message; no external metadata repositories or code generation tool are required.
- **Web services can be published, located, and invoked across the Internet**

  This technology uses established lightweight Internet standards such as HTTP and it leverages the existing infrastructure. Some other standards that are required include, SOAP, Web Services Description Language (WSDL), and UDDI.
- **Web services are language-independent and interoperable**

  The client and server can be implemented in different environments. Existing code does not have to change in order to be Web services-enabled.
- **Web services are inherently open and standard-based**

  XML and HTTP are the major technical foundation for Web services. A large part of the Web service technology has been built using open-source projects.
- **Web services are dynamic**

  Dynamic e-business can become reality using Web services because with UDDI and WSDL you can automate the Web service description and discovery.
- **Web services are composable**

  Simple Web services can be aggregated to more complex ones, either using workflow techniques or by calling lower-layer Web services from a Web service implementation. Web services can be chained together to perform higher-level business functions. This chaining shortens development time and enables best-of-breed implementations.
- **Web services are loosely coupled**

  Traditionally, application design has depended on tight interconnections at both ends. Web services require a simpler level of coordination that supports a more flexible reconfiguration for an integration of the services.
- **Web services provide programmatic access**

  The approach provides no graphical user interface; it operates at the code level. Service consumers need to know the interfaces to Web services, but do not need to know the implementation details of services.
- **Web services provide the ability to wrap existing applications**

  Already existing stand-alone applications can easily integrate into the SOA by implementing a Web service as an interface.

Web services business models supported

This article explains the concept and business models that can be implemented by using Web services in a service-oriented architecture (SOA).

The properties and benefits of using a SOA such as Web services is well suited for binding small modules that perform independent tasks within a highly heterogeneous e-business model. Web services can be easily wrapped around existing applications in your business model and plugged into different business processes.

For connecting to a large monolithic system that does not support the implementation of different flexible business processes, other approaches might be better suited, for example, to satisfy specialized features, such as performance or security.

The following business models are easily implemented by using an architecture including Web services:

- **Business information**

  Sharing of information with consumers or other businesses. Web services can be used to expand the reach through such services as news streams, local weather reports, integrated travel planning, and intelligent agents.
- **Business integration**

  Providing transactional, fee-based services for customers. A global network of suppliers can be easily created. Web services can be implemented in auctions, e-marketplaces, and reservation systems.
- **Business process externalization**

  Web services can be used to model value chains by dynamically integrating processes to a new solution within an organizational unit or even with those of other e-businesses. This modeling can be achieved by dynamically linking internal applications to new partners and suppliers, to offer their services to complement internal services.

To see how these models are implemented using all aspects of Web services, see Web services scenario: Overview which tells the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporates the Web services concept.

Web services

Web services are self-contained, modular applications that you can describe, publish, locate, and invoke over a network.

The application server supports Web services that are developed and implemented based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. The application server supports the Java API for XML Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. The JAX-WS is a strategic programming model that simplifies application development through support of a standard, annotation-based model to develop Web services applications and clients.

A typical Web services scenario is a business application requesting a service from another existing application. The request is processed through a given Web address using SOAP messages over a HTTP, Java Message Service (JMS) transport or invoked directly as Enterprise JavaBeans (EJB). The service receives the request, processes it, and returns a response. Examples of a simple Web service include weather reports or getting stock quotes. The method call is synchronous, that is, the method waits until the result is available. Transaction Web services, supporting quotes, business-to-business (B2B) or business-to-client (B2C) operations include airline reservations and purchase orders.

Web services can include the actual service or the client that accesses the service.

Web services are Web applications that help improve the flexibility of your business processes by integrating with applications that otherwise do not communicate. The inner-library loan program at your local library is a good example of the Web services concept and its evolution. The Web service concept existed even before the term; the concept became widely accepted with the creation of the Internet. Before the Internet was created, you visited your library, searched the collections and checked out your books. If you did not find the book that you wanted, the librarian ran a search for you by computer or phone and

located the book at a nearby library. The librarian ordered the book for you and you picked it up after it was delivered to your local library. By incorporating Web services applications, you can streamline your library visit.

Now, you can search the local library collection and other local libraries at the same time. When other libraries provide your library with a Web service to search their collection (the service might have been provided through Universal Description Discovery and Integration (UDDI), your results yield their resources. You might use another Web service application to check out and send the book to your home. Using Web services applications saves time and provides a convenience for you, as well as freeing the librarian to do other business tasks.

Web services reflect the service-oriented architecture (SOA) approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

The key components of Web services include:

- Web Services Description Language (WSDL)

  WSDL is the XML-based file that describes the Web service. The Web service request uses this file to bind to the service.
- SOAP

  SOAP is the XML-based protocol that the Web service request uses to invoke the service.
- Universal Description, Discovery and Integration Protocol (UDDI)

  UDDI is the registry that hosts the service broker. UDDI is similar to the Yellow Pages in a phone book.

For a more detailed scenario, see Web services scenario: Overview, which tells the story of a fictional online garden supply retailer named Plants by WebSphere, and how this retailer incorporated the Web services concept.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Web Services for Java EE specification

The *Web Services for Java Platform, Enterprise Edition (Java EE)* specification defines the programming model and runtime architecture for implementing Web services based on the Java language. Another name for the Web Services for Java EE specification is the Java Specification Requirements (JSR) 109. The specification includes open standards for developing and implementing Web services.

The Web Services for Java EE specification is based on the Java EE technology and supports the Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) programming model for Web services and clients in a manner that is interoperable and portable across application servers within environments that are scalable and secure. This specification is based on industry standards for Web services, including Web Services Description Language (WSDL) and SOAP, and it describes the development and deployment of Web services.

The application server supports the Web Services for Java EE specification, Version 1.2. This specification supports WSDL Version 1.1, SOAP Version 1.1 and SOAP Version 1.2. Prior to Web Services for Java EE Version 1.2, the JSR 109 specification name was Web Services for Java 2 Platform, Enterprise Edition (J2EE).

You can integrate the Java EE technology with Web services in a variety of ways. You can expose Java EE components as Web services, for example, JavaBeans and enterprise beans. When you expose Java

EE components as Web services, clients that are written in Java code or existing Web service clients that are not written in Java code can access these services. Java EE components can also act as Web service clients.

The Web Services for Java EE specification is the preferred platform for Web-based programming because it provides open standards permitting different types of languages, operating systems and software to communicate seamlessly through the Internet.

For a Java application to act as Web service client, a mapping between the WSDL file and the Java application must exist. For JAX-WS applications, the mapping is defined using annotations. You can optionally use the webservices.xml deployment descriptor to specify the location of the WSDL file and override the value defined in the @WebServices annotation. For JAX-RPC applications, you must define the JAX-RPC mapping file. To learn more about the mapping that is defined between the WSDL file and your Web service application, see the JAX-WS specification or the JAX-RPC specification in the Web services specifications and API documentation depending on the programming model used.

You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request.

This entire process encompassed is based on the Web Services for Java EE specification.

The specification defines the webservices.xml deployment descriptor specifically for Web services. The webservices.xml deployment descriptor file defines the set of Web services that you can deploy in a Web Services for Java EE enabled container.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

For example, if your service implementation class for your JAX-WS Web service includes the @WebService annotation as follows:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

and the webservices.xml specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

then the value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl overrides the annotation value.

See section 5 of the Web Services for Java EE specification for details regarding the correlation between values specified in the Web services deployment descriptor file and the attributes of the @WebService and the @WebServiceProvider annotations.

For JAX-RPC Web services, you must define the deployment characteristics in the webservices.xml deployment descriptor file.

You are responsible for providing various elements to the deployment descriptor, including:

- Port name
- Port service implementation
- Port service endpoint interface
- Port WSDL definition
- Port QName
- MTOM/XOP support for JAX-WS Web services
- Protocol binding for JAX-WS Web services
- JAX-RPC mapping
- Handlers (optional)
- Servlet mapping (optional)

The Enterprise JavaBeans (EJB) 2.1 specification also states that for a Web service developed from a session bean, the EJB deployment descriptor, `ejb-jar.xml`, must contain the service-endpoint element. The service-endpoint value must be the same as that stated in the webservices.xml deployment descriptor.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Artifacts used to develop Web services

With *development artifacts* you can develop an enterprise bean or a JavaBeans module into a Web service. This topic describes artifacts used to develop Web services that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

To create a Web service from an enterprise bean or from a JavaBeans module, the following files are added to the respective Java archive (JAR) file or Web archive (WAR) modules at assembly time:

- **Web Services Description Language (WSDL) Extensible Markup Language (XML) file**

  The WSDL XML file describes the Web service that is implemented.
- **Service Endpoint Interface**

  A Service Endpoint Interface is the Java interface corresponding to the Web service port type implemented. The Service Endpoint Interface is defined by the Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services run time that you are using.
- **webservices.xml**

  The webservices.xml file contains the Java EE deployment descriptor of the Web service specifying how the Web service is implemented. The webservices.xml file is defined in the Web Services for Java EE specification.

  For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

  For JAX-RPC applications, deployment descriptors are required to specify how the Web service is implemented.
- **ibm-webservices-bnd.xmi (JAX-RPC applications only)**

  This file contains WebSphere product-specific deployment information and is defined in ibm-webservices-bnd.xmi assembly properties.
- **Java API for XML-based remote procedure call (JAX-RPC) mapping file**

  The JAX-RPC mapping deployment descriptor specifies how Java elements are mapped to and from WSDL file elements.

The following files are added to an application client, enterprise beans or Web module to permit a Web Services for Java Platform, Enterprise Edition (Java EE) client access to Web services:

- **WSDL file**

The WSDL file is provided by the Web service implementer.

- **Java interfaces for the Web service**

  The Java interfaces are generated from the WSDL file as specified by the JAX-WS or JAX-RPC specification. These bindings are the Service Endpoint Interface based on the WSDL port type, or the service interface, which is based on the WSDL service.
- **ibm-webservicesclient-bnd.xmi (JAX-RPC applications only)**

  This file contains WebSphere product-specific deployment information, such as security information for JAX-RPC applications. For JAX-WS applications, deployment descriptors are not supported and have been replaced by the use of annotations.
- **Other JAX-RPC binding files**

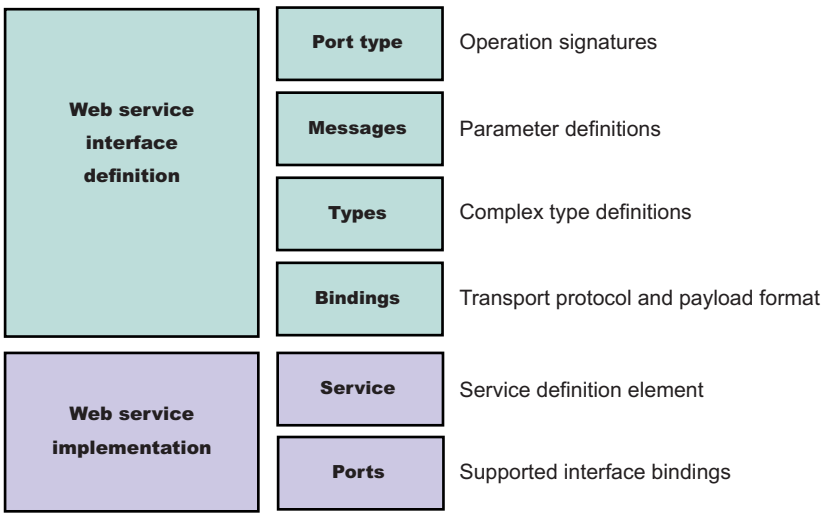
  Additional JAX-RPC binding files that support the client application in mapping SOAP to the Java language are generated from WSDL by the WSDL2Java command tool.

WSDL

Web Services Description Language (WSDL) is an Extensible Markup Language (XML)-based description language. This language was submitted to the World-Wide Web Consortium (W3C) as the industry standard for describing Web services. The power of WSDL is derived from two main architectural principles: the ability to describe a set of business operations and the ability to separate the description into two basic units. These units are a description of the operations and the details of how the operation and the information associated with it are packaged.

A WSDL document defines services as collections of network endpoints, or ports. In WSDL, the abstract definitions of endpoints and messages are separated from their concrete network deployment or data format bindings. This separation supports the reuse of abstract definitions: messages, which are abstract descriptions of exchanged data, and port types, which are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports defines a service. Therefore, a WSDL document is composed of several elements.

The following is the structure of the information in a WSDL file:



A WSDL file contains the following parts:

- **Web service interface definition**

  This part contains the elements and the namespaces.
- **Web service implementation**

  This part contains the definition of the service and ports.

A WSDL file describes a Web service with the following elements:

portType

The description of the operations and associated messages. The portType element defines abstract operations.

```
<portType name="EightBall">
 <operation name="getAnswer">
  <input message="ebs:IngetAnswerRequest"/>
  <output message="ebs:OutgetAnswerResponse"/>
 </operation>
</portType>
```

message

The description of input and output parameters and return values.

```
<message name="IngetAnswerRequest">
 <part name="meth1_inType" type="ebs:questionType"/>
</message>
<message name="OutgetAnswerResponse">
 <part name="meth1_outType" type="ebs:answerType"/>
</message>
```

types

The schema for describing XML types used in the messages.

```
<types>
 <xsd:schema targetNamespace="...">
  <xsd:complexType name="questionType">
   <xsd:element name="question" type="string"/>
  </xsd:complexType>
  <xsd:complexType name="answerType">
  ...
</types>
```

binding

The bindings describe the protocol that is used to access a portType, as well as the data formats for the messages that are defined by a particular portType element.

```
<binding name="EightBallBinding" type="ebs:EightBall">
 <soap:binding style="rpc" transport="schemas.xmlsoap.org/soap/http">
 <operation name="ebs:getAnswer">
 <soap:operation soapAction="urn:EightBall"/>
  <input>
   <soap:body namespace="urn:EightBall" ... />
  ...
```

Service

The services and ports define the location of the Web service.

The service contains the Web service name and a list of ports.

Ports

The ports contain the location of the Web service and the binding used for service access.

```
<service name="EightBall">
 <port binding="ebs:EightBallBinding" name="EightBallPort">
  <soap:address location="localhost:8080/axis/EightBall"/>
 </port>
</service>
```

When creating Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services, you can use a bottom-up development approach when you start from JavaBeans or an enterprise bean, or you can use a top-down development approach when you start with an existing Web Services Description Language (WSDL) file.

When creating JAX-WS Web services for this product, you can start with either a WSDL or an implementation bean class. If you start with an implementation bean class, then use the wsgen command line tool to generate all the Web services server artifacts, including a WSDL if requested. If you start with a WSDL, then use the wsimport command line tool to generate all the Web services artifacts for either the server or client side.

When creating JAX-RPC Web services for this product, you must first have an implementation bean that includes a service endpoint interface. Then, you use the Java2WSDL command-line tool to create a WSDL file that defines the Web services. If you are starting with the WSDL to generate the implementation bean class, run the WSDL2Java command line tool against the WSDL file to create Java APIs and deployment descriptor templates.

Multipart WSDL and WSDL publication

The product supports deployment of Web services using a multipart Web Services Description Language (WSDL) file. In multipart WSDL files, an implementation WSDL file contains the wsdl:service. This implementation WSDL file imports an interface WSDL file, which contains the other WSDL constructs. This supports multiple Web services using the same WSDL interface definition.

The <wsdl:import> element indicates a reference to another WSDL file. If the <wsdl:import> element location attribute does not contain a URL, that is, it contains only a file name, and does not begin with http://, https:// or file://, the imported file must be located in the same directory and must not contain a relative path component. For example, if META-INF/wsdl/A_Impl.wsdl is in your module and contains the <wsdl:import=″A.wsdl″ namespace=″...″/> import statement, the A.wsdl file must also be located in the module META-INF/wsdl directory.

It is recommended that you place all WSDL files in either the META-INF/wsdl directory, if you are using Enterprise JavaBeans (EJB), or the WEB-INF/wsdl directory, if you are using JavaBeans components, even if relative imports are located within the WSDL files. Otherwise, implications exist with the WSDL publication when you use a path like <location=″../interfaces/A_Interface.wsdl″namespace=″...″/>. Using a path like this example fails because the presence of the relative path, regardless of whether the file is located at that path or not. If the location is a Web address, it must be readable at both deployment and server startup.

You can publish the files located in the META-INF/wsdl or the WEB-INF/wsdl directory through either a URL address or file, including WSDL or XML Schema Definition (XSD) files. For example, if the file referenced in the <wsdl-file> element of the webservices.xml deployment descriptor is located in the META-INF/wsdl or the WEB-INF/wsdl directory, it is publishable. If the files imported by the <wsdl-file> are located in the wsdl/ directory or its subdirectory, they are publishable.

If the WSDL file referenced by the <wsdl-file> element is located in a directory other than wsdl, or its subdirectories, the file and its imported files, either WSDL or XSD files, which are in the same directory, are copied to the wsdl directory without modification when the application is installed. These types of files can also be published.

If the <wsdl-file> imports a file located in a different directory (a directory that is not -INF/wsdl or a subdirectory), the file is not copied to the wsdl directory and not available for publishing.

For JAX-WS Web services, you can use an annotation to specify the location of the WSDL. Use the @WebService annotation with the WSDLLocation attribute. The WSDLLocation attribute is optional. If this attribute is not specified, then WSDL is generated and published from the information that is found in the Web service classes. You can optionally specify the location of the WSDL file in the webservices.xml deployment descriptor. However, any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

SOAP

SOAP is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

SOAP 1.1

WebSphere Application Server follows the standards outlined in SOAP 1.1.

SOAP was submitted to the World Wide Web Consortium (W3C) as the basis of the Extensible Markup Language (XML) Protocol Working Group by several companies, including IBM and Lotus®. This protocol consists of three parts:

- An *envelope* that defines a framework for describing message content and processing instructions.
- A set of *encoding rules* for expressing instances of application-defined data types.
- A *convention* for representing remote procedure calls and responses.

SOAP 1.1 is a protocol-independent transport and can be used in combination with a variety of protocols. In Web services that are developed and implemented with WebSphere Application Server, SOAP is used in combination with HTTP, HTTP extension framework, and Java Message Service (JMS). SOAP is also operating-system independent and not tied to any programming language or component technology.

As long as the client can issue XML messages, it does not matter what technology is used to implement the client. Similarly, the service can be implemented in any language, as long as the service can process SOAP messages. Also, both server and client sides can reside on any suitable platform.

SOAP 1.2

The SOAP 1.2 specification is also a W3C recommendation, and WebSphere Application Server follows the standards that are outlined in SOAP 1.2. The SOAP 1.2 specification comes in three parts plus some assertions and a test collection:

- Part 0: Primer
- Part 1: Messaging Framework
- Part 2: Adjuncts
- Specification Assertions and Test Collection

SOAP 1.2 provides a more specific definition of the SOAP processing model, which removes many of the ambiguities that sometimes led to interoperability problems in the absence of the Web Services-Interoperability (WS-I) profiles. SOAP 1.2 should reduce the chances of interoperability issues with SOAP 1.2 implementations between different vendors.

Some of the more significant changes in the SOAP 1.2 specification include:

- The ability to now officially define other transport protocols other than the HTTP protocol as long as vendors conform to the binding framework that is defined in SOAP 1.2. While HTTP is ubiquitous, it is not as reliable of a transport as other things such as TCP/IP, MQ, and so forth.
- The fact that SOAP 1.2 is based on the XML Information Set (XML Infoset). The information set provides a way to describe the XML document using the XSD schema but does not necessarily serialize the document by using XML 1.0 serialization. SOAP 1.1 is based upon XML 1.0 serialization. The information set will make it easier to use other serialization formats such as a binary protocol format. You can use a binary protocol format shrink the message into a much more compact format where some of the verbose tagging information might not be required.

The Java API for XML Web Services (JAX-WS) standard introduces the ability to support both SOAP 1.1 as well as SOAP 1.2.

See “Differences in SOAP versions” on page 440 for additional differences between SOAP 1.1 and SOAP 1.2.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

SOAP with Attachments API for Java interface:

The *SOAP with Attachments API for Java* (SAAJ) interface is used for SOAP messaging that provides a standard way to send XML documents over the Internet from a Java programming model. SAAJ is used to manipulate the SOAP message to the appropriate context as it traverses through the runtime environment.

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

The Java API for XML-Based RPC (JAX-RPC) programming model supports SAAJ 1.2 to manipulate the XML.

The JAX-WS programming model supports SAAJ 1.2 and 1.3. SAAJ 1.3 includes support for SOAP 1.2 messages.

The differences in the SAAJ 1.2 and SAAJ 1.3 specification can be reviewed in the topic ″Differences in SAAJ versions.″

How are messages used in Web services?

Web services use XML technology to exchange messages. These messages conform to XML schema. When developing Web services applications, there are limited XML APIs to work with, for example, Document Object Model (DOM). It is more efficient to manipulate the Java objects and have the serialization and deserialization completed during run time.

Web services uses SOAP messages to represent remote procedure calls between the client and the server. Typically, the SOAP message is deserialized into a series of Java value-type business objects that represent the parameters and return values. In addition, the Java programming model provides APIs that support applications and handlers to manipulate the SOAP message directly. Because there are a limited number of XML schema types that are supported by the programming models, the specification provides the SAAJ data model as an extension to manipulate the message.

To manipulate the XML schema types, you need to map the XML schema types to Java types with a *custom data binder*.

The SAAJ interface

The SAAJ-related classes are located in the javax.xml.soap package. SAAJ builds on the interfaces and abstract classes and many of the classes begin by invoking factory methods to create a factory such as SOAPConnectionFactory and SOAPFactory.

The most commonly used classes are:

- SOAPMessage: Contains the message, both the XML and non-XML parts
- SOAPHeader: Represents the SOAP header XML element
- SOAPBody: Represents the SOAP body XML element
- SOAPElement: Represents the other elements in the SOAP message

Other parts of the SAAJ interface include:

- MessageContext: Contains a SOAP message and related properties
- AttachmentPart: Represents a binary attachment
- SOAPPart: Represents the XML part of the message
- SOAPEnvelope: Represents the SOAP envelope XML element
- SOAPFault: Represents the SOAP fault XML element

The primary interface in the SAAJ model is javax.xml.soap.SOAPElement, also referred to as SOAPElement. Using this model, applications can process an SAAJ model that uses pre-existing DOM code. It is also easier to convert pre-existing DOM objects to SAAJ objects.

Messages created using the SAAJ interface follow SOAP standards. A SOAP message is represented in the SAAJ model as a javax.xml.soap.SOAPMessage object. The XML content of the message is represented by a javax.xml.soap.SOAPPart object. Each SOAP part has a SOAP envelope. This envelope is represented by the SAAJ javax.xml.SOAPEnvelope object. The SOAP specification defines various elements that reside in the SOAP envelope; SAAJ defines objects for the various elements in the SOAP envelope.

The SOAP message can also contain non-XML data that is called attachments. These attachments are represented by SAAJ AttachmentPart objects that are accessible from the SOAPMessage object.

A number of reasons exist as to why handlers and applications use the generic SOAPElement API instead of a tightly bound mapping:

- The Web service might be a conduit to another Web service. In this case, the SOAP message is only forwarded.
- The Web service might manipulate the message using a different data model, for example a Service Data Object (SDO). It is easier to convert the message from a SAAJ DOM to a different data model.
- A handler, for example, a digital signature validation handler, might want to manipulate the message generically.

You might need to go a step further to map your XML schema types, because the SOAPElement interface is not always the best alternative for legacy systems. In this case you might want to use a generic programming model, such as SDO, which is more appropriate for data-centric applications.

The XML schema can be configured to include a custom data binding that pairs the SDO or data object with the Java object. For example, the run time renders an incoming SOAP message into a SOAPElement interface and passes it to the customer data binder for more processing. If the incoming message contains

an SDO, the run time recognizes the data object code, queries its type mapping to locate a custom binder, and builds the SOAPElement interface that represents the SDO code. The SOAPElement is passed to the SDOCustomBinder.

See Custom data binders for more information about the process of developing applications with SOAPElement, SDO and custom binders.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Related concepts

“SOAP” on page 429
SOAP is a specification for the exchange of structured information in a decentralized, distributed environment. As such, it represents the main way of communication between the three key actors in a service oriented architecture (SOA): service provider, service requestor and service broker. The main goal of its design is to be simple and extensible. A SOAP message is used to request a Web service.

“Differences in SOAP versions” on page 440
Both SOAP Version 1.1 and SOAP Version 1.2 are World Wide Web Consortium (W3C) standards. Web services can be deployed that support not only SOAP 1.1 but also support SOAP 1.2. Some changes from SOAP 1.1 that were made to the SOAP 1.2 specification are significant, while other changes are minor.

“Differences in SAAJ versions”
The SOAP with Attachments API for Java (SAAJ) interface Version 1.3 expands the support of SOAP 1.2 messages in a Web services environment. There are several differences between SAAJ 1.2 and SAAJ 1.3 that are presented in this topic.

Web services specifications and APIs

Differences in SAAJ versions:

The SOAP with Attachments API for Java (SAAJ) interface Version 1.3 expands the support of SOAP 1.2 messages in a Web services environment. There are several differences between SAAJ 1.2 and SAAJ 1.3 that are presented in this topic.

In a typical Web services environment, you rely on the underlying code that is based on Java standards to translate a set of Java objects. The SAAJ interface provides APIs to read, write, send and receive SOAP messages, and advocates binary content sent as an attachment to a SOAP message.

SAAJ 1.3 aligns with SOAP 1.1 and SOAP 1.2 messages and is supported by the Java API for XML Web Services (JAX-WS) programming model and the Java API for XML-Based RPC (JAX-RPC) programming model. SAAJ 1.2 works with SOAP 1.1 messages only.

If you migrate your code from SOAP 1.1 to SOAP 1.2, you can continue to use your existing SOAP 1.1 code, if the message is a SOAP 1.2 message. If you upgrade your base code to use SAAJ 1.3, then you can continue to use the existing code that operates on a SOAP 1.1 message. An example of these differences is in SOAP 1.1, where the human readable text of a fault is stored in the faultString element. In SOAP 1.2, the human readable text is stored in the Reason element. Your code might look like the following example:

```
String text = soapFault.getFaultString();
```

The getFaultString () returns the faultString value if the message is based on SOAP 1.1. If you are using SOAP 1.2, the getFaultString () returns the Reason value. In addition, the SAAJ 1.3 interface provides a new method, getReasonText (Locale), that gets a specific Reason value. The getReasonText (Locale) method returns a documented exception if the message is based on SOAP 1.1. The SAAJ 1.3 interface supports existing code to process both SOAP 1.1 and SOAP 1.2 messages.

Other differences between SAAJ 1.2 and SAAJ 1.3 are in the following list:

- SAAJMetaFactory interface

  The SAAJMetaFactory SPI is introduced to support creating SOAP factory classes in a single place.
- SAAJResult class

  The SAAJResult object acts as a holder for the results of a Java API for XML Processing (JAX-P) transformation or a Java Architecture for XML Binding (JAXB) marshalling, in the SAAJ tree. The SAAJResult class is introduced for improved usability when transformation results are expected to be a valid SAAJ tree.
- Overloaded methods that accept a QName instead of a Name

  It is preferred that a QName represents an XML-qualified name. Therefore, overloaded methods are introduced in all of the SAAJ APIs, where a corresponding method accepts a javax.xml.soap.Name name as an argument.
- New methods in AttachmentPart, SOAPBody and SOAPElement interfaces and classes

  Use these new methods to assist you when you are working with the new SOAP features.
- SOAPPart is now a javax.xml.soap.Node method.

  The SOAPPart object is now also considered to be a SOAP node method.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Message Transmission Optimization Mechanism:

SOAP Message Transmission Optimization Mechanism (MTOM) is a standard that is developed by the World Wide Web Consortium (W3C). MTOM describes a mechanism for optimizing the transmission or wire format of a SOAP message by selectively re-encoding portions of the message while still presenting an XML Information Set (Infoset) to the SOAP application.

There are many reasons why you might want to send binary attachments, such as images or files, along with a Web services request. There are ways to accomplish this, such as:

- Encoding with base64 inline in the SOAP payload. However, encoding inline tends to enlarge the size of the SOAP message. Note that base64 encoding might double the size of the binary data.
- Encoding the messages by using SOAP with Attachments (SwA) and to follow the Web Services Interoperability Organization (WS-I) Attachments Profile. WebSphere Application Server currently supports this method.
- Providing optimization of binary message transportation by using XML-binary Optimized Packaging (XOP). Optimization is available only for binary data or content. MTOM uses XOP in the context of SOAP and MIME over HTTP.

XOP defines a serialization mechanism for the XML Infoset with binary content that is not only applicable to SOAP and MIME packaging, but to any XML Infoset and any packaging mechanism. It is an alternate serialization of XML that just happens to look like a MIME multipart/related package, with an XML documents as the root part. That root part is very similar to the XML serialization of the document, except that base64-encoded data is replaced by a reference to one of the MIME parts, which is not base64 encoded. This reference enables you to avoid the bulk and overhead in processing that is associated with encoding. Encoding is the only way a binary data can fit directly into an XML world.

If MTOM mapping generation is disabled, then XOP is disabled. If XOP is disabled, the binary data are not sent by using MIME attachments. Instead, the binary data is base64 encoded as usual.

The MTOM specification is defined in three different parts:

- An abstract feature for optimized transmission or wire format for SOAP messages. This feature is abstract in the sense that the description of the optimization technique as well as the behavior of the SOAP processors at sender, receiver and intermediaries is generic and does not include any references

to technologies such as MIME, HTTP, and so forth. The optimization technique centers around ensuring a SOAP envelope Infoset view for the SOAP processors while encoding selectively certain contents of the SOAP Envelope Infoset that are accessible as canonical lexical representation of the xs:base64Binary data type.

Implementing these abstract features requires concrete specification of two aspects: the optimized wire format and how the optimized wire format flows on a particular transport

- The second part of the MTOM specification addresses the serialization aspect and depends normatively upon MIME Multipart/Related XOP packaging. The serialization aspect is where MTOM relates to XOP.
- As a concrete SOAP HTTP binding level feature, MTOM expands upon the serialization. This part describes how HTTP binding can be used to transport the XOP packages that are holding the SOAP MTOM messages. This part also puts some restrictions on the possible serializations of the SOAP MTOM messages as XOP packages, such as use of XML 1.0 only.

The Java API for XML Web Services (JAX-WS) adds support for sending binary data attachments using MTOM. JAX-WS is the centerpiece of a newly re-architected API stack for Web service that includes JAX-WS 2.0, JAXB 2.0, and SAAJ 1.3. The API stack is sometimes referred to as the integrated stack. JAX-WS is designed to take the place of JAX-RPC in Web services and Web applications.

Attachment approach

Attachment by value or by reference has been the widely accepted technique for handling opaque data in XML-formatted messages.

- **By value** is when the opaque data content is embedded as an element or as an attribute by using either base64 or hexadecimal text encoding approach, which is codified in the XML schema as data types xs:base64Binary and xs:hexBinary, respectively.
- **By reference** is when the opaque data content is referenced externally as element or as attribute by using a URI, which is codified in the XML schema as data type xs:anyURI.

The use of either of these two techniques has its advantages and disadvantages. MTOM is the specification that is focused on resolving these inherent attachments problems.

A different standard is defined by World Wide Web Consortium (W3C) and is called SOAP with Attachments (SwA). SwA was developed as a way to package SOAP messages with attachments. Because some vendors do not support SwA, SwA can be replaced by the more powerful MTOM and XOP mechanisms. SwA and MTOM are conceptually similar, and both encode binary data as a MIME attachment in a MIME document. Using MIME attachments improves the performance of large binary payloads transport.

Additional differences between SwA and MTOM include:

- MTOM uses a standard called XOP, which defines a XOP reference that exists within the SOAP payload. This reference points to the MIME attachment that contains the binary data.
- With MTOM, the XOP reference logically includes the binary data into the XML Information Set (Infoset). With SwA, the href points to data that is not only physically outside the XML document but is not logically included within its Infoset.
- With MTOM, binary attachments can be logically signed as if they were part of the SOAP XML document.
- In additional to IBM, Microsoft .NET supports MTOM, which eliminates some of the interoperability problems found with SwA. Interoperability was treated as the main goal when the co-submitters discussed the suggested modifications.

The MTOM attachment approach takes advantage of the SOAP infrastructure while also gaining transport efficiencies that are provided by SOAP with Attachment (SwA) solution.

SOAP 1.2 and SOAP 1.1

SOAP 1.1 is based on the XML specification. Likely, the SOAP 1.1 implementation will continue to exist for a few years. For those who are still running SOAP 1.1, there is now an interoperable way to use MTOM for attachments support. SAP, Oracle, Microsoft, and IBM have submitted a SOAP 1.1 Binding for MTOM 1.0 specification to W3C, which defines how MTOM can be used with SOAP 1.1 payloads. The specification details the necessary modifications to the SOAP MTOM and XOP specifications that are necessary to successfully use these technologies with SOAP 1.1. See the information at this Web site:http://schemas.xmlsoap.org/soap/mtom/SOAP11MTOM10.pdf

MTOM is a SOAP Version 1.2 feature, which is based on the Infoset. For more information, see “XML information set” on page 438.

Without MTOM, the data is encoded in whatever format is described in the schema (base64 or hex) and then is contained in the XML document. The following example shows a SOAP message with an <xsd:base64Binary> element:

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGODl  ... more base64 encoded data ...  KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

When MTOM is enabled, the binary data that represents the attachment is included as a MIME attachment to the SOAP message. The following example shows an MTOM-enabled SOAP message with attachment data:

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>";
start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
                             href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
         </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
```

```
content-id:
         <1.urn:uuid:0FE43E4D025F0BF3DC115824676468l1@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

XML-binary Optimized Packaging:

XML-binary Optimized Packaging (XOP) specification was standardized by the World Wide Web (W3C) on January 25, 2005. SOAP Message Transmission Optimization Mechanism (MTOM) uses XOP in the context of SOAP and MIME over HTTP.

XML is widely used for data transfer. XML is a popular format for exchanging well-formed documents because it is plain text, human-readable, and structured. For example, SOAP messaging in Web services is based on XML (or is based on XML Infoset with SOAP 1.2). People want to leverage legacy formats like PDF, GIF, JPEG and similar things, while still using an XML model. The desire to integrate XML with pre-existing data formats has been a long-standing and persistent issue for the XML community. Users often want to leverage the structured, extensible markup conventions of XML without abandoning existing data formats that do not readily adhere to XML 1.0 syntax.

As SOAP messaging in Web services becomes more widespread, the next step is how to send non-text based data, such as images and workflow data, along with your message. For example, you might want to send a scanned document in .jpeg format between two applications. The question becomes whether this data can be understood between the various applications.

Much of the value of XML and Web services resides in the ability to use generic XML tools to work with content. Many XML tools and standards for describing and manipulating XML (such as parsers, XPath, XQuery, XSLT, XML encryption and digital signature and XML schema) are not designed to work with non-text data, such as images. These XML tools do not work with non-XML content; these tools require text. The challenge is how non-text data (also called *binary data*) can be embedded or attached with XML. In other words, a way to attach a binary file to a SOAP message is needed.

Encoding is the only way binary data can fit directly into an XML world. Normally, you can embed binary data in an XML document by encoding it as text using Base 64. Base 64 is a serialization that has existed for some time, can be easily implemented out of the box, and has interoperability across platforms. The xsi:base64binary datatype supports this serialization in the XML Schema. Base 64 encodes your binary data into a textual representation that can squeeze into an XML document. Base 64 takes your binary data and translates it into a series of ASCII characters by encoding three octets at a time. Because each octet consists of eight bits, representing them as four printable characters in the ASCII standard, it uses 64 ASCII characters to represent the binary. All platforms can decode and encode using this convention. 6-bit ASCII is widely supported, and no special characters need to be dealt with. However, there is a performance impact for larger messages.

For applications that require speedy operation, Base 64 might not be the solution. If you want to index into such content, query it, transform it, encrypt it, sign it, or describe it, you need to use a different mechanism.

The first attachment specification known as SOAP with Attachments (SwA) was developed. The basic idea of SwA is that the binary message part (the attachment) is thought of as a Multipurpose Internet Mail Extensions (MIME) attachment. MIME is a widely implemented specification for formatting non-ASCII mail message attachments. SwA specifies that the SOAP body can contain a reference to the MIME message part (the attachment) simply by using a URI. The binary part is attached by a reference.

A few disadvantages of SwA include:

- SwA fails in its usability or interoperability. The SOAP infrastructure was created around the SOAP envelope, which didn't work well for attachments. An attachment using SwA means that two data models are used in one message. These two data models do not operate with existing XML technology.

- SwA does not work with the composable character of SOAP. Basically standards, such as WS-Security, were not written to work with attachments. WS-Security needs to work on all the data that needs to be digitally signed or encrypted, and that means all the data in the attachment also. But if it cannot access it, then it will not work and the signature is effectively invalid.

Often, users want to leave their existing non-XML formats as is, to be treated as opaque sequences of octets by XML tools and infrastructure. Such an approach permits widely used formats such as .jpeg and .wav to peacefully coexist with XML. XOP makes it a bit more realistic to use base64-encoded data. At the current time, XOP only permits base64-encoded data to be optimized.

Using XOP means that instances of XML-type base64Binary, if enabled, are transported by using MIME attachments. If XOP is in use, the implementation can automatically encode it. XOP maintains the data model of the XML message because the attachment is treated as base64-encoded data. If an XML stack understands XOP encoding, your application does not need to be changed at all. For example, when it wants to access a .jpeg picture, it can get the character value of the content as a base64-encoded string.

XOP gives people a way to think about MIME messages in a data exchange that they are comfortable with and already use for a lot of other data. The XOP format uses multipart MIME to enable raw binary data to be included into an XML 1.0 document without resorting to base64 encoding.

A companion specification, SOAP Message Transmission Optimization Method (MTOM) then specifies how to bind this format to SOAP. The XOP and MTOM standards should enhance SOAP 1.2 performance. XOP and MTOM together provide the preferred approach for mixing binary data with text-based XML. Coupled together, MTOM and XOP enables us to select what parts of the message need to be sent over the wire as binary while still maintaining the Infoset. These standards enable the attachment of binary data outside of the SOAP envelope as a message part. However, unlike SwA, the binary data is treated very much as it was within the SOAP envelope, meaning one Infoset.

XOP defines a serialization mechanism for XML Infoset with binary content that is not only applicable to SOAP and MIME packaging, but applicable to any XML Infoset and any packaging mechanism. On the other hand, XML is not a good general-purpose packaging mechanism.

An XOP package is created by placing a serialization of the XML Infoset inside of an extensible packaging format (such a MIME). Note that XOP does reuse MIME for the actual packaging on the wire. Then, selected portions of its content that are base64-encoded binary data are extracted and re-encoded, meaning the data is decoded from base64 and placed into the package. The locations of those selected portions are marked in the XML with a special element that links to the packaged data by using URIs.

The SOAP processing engines performs a temporary Base 64 encoding of the binary data just before the message hits the wire. This temporary encoding enables the SOAP processor to work on the Base 64 data; for example, enabling a WS-Signature of the data to be taken and placed into the header. There is no need for expensive decoding at the other end, and the process works in reverse.

Implementations of MTOM and XOP are available in Java (JAX-WS).

This example shows an XML Infoset prior to XOP processing (SOAP):

```
<soap:Envelope
    xmlns:soap='http://www.w3.org/2003/05/soap-envelope'
    xmlns:xmlmime='http://www.w3.org/2004/11/xmlmime'>
  <soap:Body>
    <m:data xmlns:m='http://example.org/stuff'>
      <m:photo
  xmlmime:contentType='image/png'>/aWKKapGGyQ=</m:photo>
      <m:sig
  xmlmime:contentType='application/pkcs7-signature'>Faa7vROi2VQ=</m:sig>
    </m:data>
  </soap:Body>
</soap:Envelope>
```

This example shows an XML Infoset that is serialized as a XOP package (SOAP)

```
MIME-Version: 1.0
Content-Type: Multipart/Related;boundary=MIME_boundary;
    type="application/xop+xml";
    start="<mymessage.xml@example.org>";
    startinfo="application/soap+xml; action=\"ProcessData\""
Content-Description: A SOAP message with my pic and sig in it

--MIME_boundary
Content-Type: application/xop+xml;
    charset=UTF-8;
    type="application/soap+xml; action=\"ProcessData\""
Content-Transfer-Encoding: 8bit
Content-ID: <mymessage.xml@example.org>

<soap:Envelope
    xmlns:soap='http://www.w3.org/2003/05/soap-envelope'
    xmlns:xmlmime='http://www.w3.org/2004/11/xmlmime'>
  <soap:Body>
    <m:data xmlns:m='http://example.org/stuff'>
      <m:photo
  xmlmime:contentType='image/png'><xop:Include
    xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:http://example.org/me.png'/></m:photo>
      <m:sig
  xmlmime:contentType='application/pkcs7-signature'><xop:Include
    xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:http://example.org/my.hsh'/></m:sig>
    </m:data>
  </soap:Body>
</soap:Envelope>

--MIME_boundary
Content-Type: image/png
Content-Transfer-Encoding: binary
Content-ID: <http://example.org/me.png>

// binary octets for png

--MIME_boundary
Content-Type: application/pkcs7-signature
Content-Transfer-Encoding: binary
Content-ID: <http://example.org/my.hsh>

// binary octets for signature

--MIME_boundary--
```

XML information set:

XML Information Set (Infoset) is a World Wide Web Consortium (W3C) specification, dated February 4, 2004. An XML information set is an abstract model of the information that is stored in an XML document. The information set establishes a separation between data and information in a way that suits most common uses of XML. Several of the concrete XML data models are defined by referring to XML information set items and their properties.

Whereas an *XML information set* is an abstract model of the information that is stored in an XML document, an *information item* is an abstract representation of some component of an XML document. SOAP Version 1.2 makes use of this abstraction to define the information in a SOAP message without ever referring to XML Version 1.*x*. The SOAP HTTP binding specifically permits alternative media types that provide for, as a minimum, the transfer of the SOAP XML Infoset.

SOAP Message Transmission Optimization Mechanism (MTOM) describes SOAP 1.2 constructs in terms of information items whereas SOAP 1.1 is defined in terms of XML elements. MTOM enables SOAP bindings to optimize the transmission or wire format (or both) of a SOAP message by selectively encoding portions of the message while still presenting an XML information set to the SOAP application. The SOAP 1.2 attribute is now in the SOAP namespace. The XML information sets require the support of XML namespaces. The core XML recommendation does not require the support of XML namespaces; however namespaces are required to support the XML schema.

The XML information set does not require or favor a specific interface or class of interfaces. The XML information set specification presents the information set as a tree for the sake of clarity and simplicity, but there is no requirement that the XML information set be made available through a tree structure. Other types of interfaces, including but not limited to event-based and query-based interfaces, are also capable of providing information conforming to the information set. As long as the information in the information set is made available to XML applications in one way or another, the requirements of the XML information set are satisfied.

The XML information set provides a set of definitions to be used in other specifications that refer to the information in a well-formed XML document. For any given XML document, there are a number of corresponding information sets.

- A unique minimal information set consisting of the core properties of the core items and nothing else.
- A unique maximal information set consisting of all the core and all the peripheral items with all the peripheral properties, and one for every combination of present and absent peripheral items and properties in between. The in-between information sets must be fully consistent with the maximal information set.

Information set items

The XML information set is a description of the information that is available in a well-formed XML document, and it describes an abstract data model of an XML document in terms of a set of information set items. An information item is an abstract description of some part of an XML document, and each information item has a set of associated named properties. All other information items are accessible from the properties of the document information item, either directly or indirectly through the properties of other information items.

Guidelines for using information set items include:

- There is no requirement for an XML document to be valid in order to have an information set.
- An XML document has an information set if it satisfies the namespace constraints.
- An XML document has an information set if it is well-formed
- Only one document information item is permited in the information set.
- An information set for an XML document consists of two or more information items.
- The information set for any well-formed XML document will contain at least the minimum information items: one document information item and one element information item.
- Each information item has a set of associated properties, some of which are core and some of which are peripheral.

An information set can contain up to eleven different types of information items:

- Document information item
- Element information items
- Attribute information items
- Processing instruction information items
- Unexpanded entity reference information items
- Character information items
- Comment information items
- The Document Type Declaration (DTD) information item

- Unparsed entity information items
- Notation information items
- Namespace information items

Note that the information set of the XML document might not be a complete list of all information items.

Certain kinds of invalidity affect the values assigned to some properties. Entities, notations, elements and attributes can be undeclared. You can have multiple declarations for notations and elements. Multiple declarations are valid for entities and attributes. An ID can be undefined or multiply defined. Such cases are noted where relevant in the information item definitions in the XML Information Set specification.

Syntax

The XML information set uses a square-bracket syntax, meaning the property names are shown in square brackets. For example, the document information item has the following properties:

Table 10.

Property	Description
[children]	An ordered list of child information items, in document order.
[document element]	The element information item corresponding to the document element.
[notations]	An unordered set of notation information items, one for each notation declared in the DTD. If any notation is multiply declared, this property has no value.
[unparsed entities]	An unordered set of unparsed entity information items, one for each unparsed entity declared in the DTD.
[base URI]	The base URI of the document entity.
[character encoding scheme]	The name of the character encoding scheme in which the document entity is expressed.
[standalone]	An indication of the standalone status of the document, either yes or no. This property is derived from the optional standalone document declaration in the XML declaration at the beginning of the document entity, and has no value if there is no standalone document declaration.
[version]	A string representing the XML version of the document. This property is derived from the XML declaration optionally present at the beginning of the document entity, and has no value if there is no XML declaration.
[all declarations processed]	This property is not strictly speaking part of the information set of the document. Rather it is an indication of whether the processor has read the complete DTD. Its value is a boolean. If it is false, then certain properties (indicated in their descriptions below) might be unknown. If it is true, those properties are never unknown.

All information sets are understood to describe the XML document with all entity references already expanded; that is, represented by the information items corresponding to their replacement text. In the case that an entity reference cannot be expanded, because an XML processor has not read its declaration or its value, explicit provision is made for representing such a reference in the information set.

Differences in SOAP versions:

Both SOAP Version 1.1 and SOAP Version 1.2 are World Wide Web Consortium (W3C) standards. Web services can be deployed that support not only SOAP 1.1 but also support SOAP 1.2. Some changes from SOAP 1.1 that were made to the SOAP 1.2 specification are significant, while other changes are minor.

The SOAP 1.2 specification introduces several changes to SOAP 1.1. This information is not intended to be an in-depth description of all the new or changed features for SOAP 1.1 and SOAP 1.2. Instead, this information highlights some of the more important differences between the current versions of SOAP.

The changes to the SOAP 1.2 specification that are significant include the following updates:

- SOAP 1.1 is based on XML 1.0. SOAP 1.2 is based on XML Information Set (XML Infoset).

  The XML information set (infoset) provides a way to describe the XML document with XSD schema. However, the infoset does not necessarily serialize the document with XML 1.0 serialization on which SOAP 1.1 is based.. This new way to describe the XML document helps reveal other serialization formats, such as a binary protocol format. You can use the binary protocol format to compact the message into a compact format, where some of the verbose tagging information might not be required.

  In SOAP 1.2 , you can use the specification of a binding to an underlying protocol to determine which XML serialization is used in the underlying protocol data units. The HTTP binding that is specified in SOAP 1.2 - Part 2 uses XML 1.0 as the serialization of the SOAP message infoset.
- SOAP 1.2 provides the ability to officially define transport protocols, other than using HTTP, as long as the vendor conforms to the binding framework that is defined in SOAP 1.2. While HTTP is ubiquitous, it is not as reliable as other transports including TCP/IP and MQ.
- SOAP 1.2 provides a more specific definition of the SOAP processing model that removes many of the ambiguities that might lead to interoperability errors in the absence of the Web Services-Interoperability (WS-I) profiles. The goal is to significantly reduce the chances of interoperability issues between different vendors that use SOAP 1.2 implementations.
- SOAP with Attachments API for Java (SAAJ) can also stand alone as a simple mechanism to issue SOAP requests. A major change to the SAAJ specification is the ability to represent SOAP 1.1 messages and the additional SOAP 1.2 formatted messages. For example, SAAJ Version 1.3 introduces a new set of constants and methods that are more conducive to SOAP 1.2 (such as getRole(), getRelay()) on SOAP header elements. There are also additional methods on the factories for SAAJ to create appropriate SOAP 1.1 or SOAP 1.2 messages.
- The XML namespaces for the envelope and encoding schemas have changed for SOAP 1.2. These changes distinguish SOAP processors from SOAP 1.1 and SOAP 1.2 messages and supports changes in the SOAP schema, without affecting existing implementations.
- Java Architecture for XML Web Services (JAX-WS) introduces the ability to support both SOAP 1.1 and SOAP 1.2. Because JAX-RPC introduced a requirement to manipulate a SOAP message as it traversed through the run time, there became a need to represent this message in its appropriate SOAP context. In JAX-WS, a number of additional enhancements result from the support for SAAJ 1.3.
- The Web Services Description Language (WSDL) Version 1.1 specification does not discuss SOAP 1.2. SOAP 1.2 is discussed in the draft versions of WSDL 2.0. WSDL Version 1.1 only defines how to render a SOAP 1.1 payload in a WSDL 1.1 document. To resolve how to represent SOAP 1.2-based services, there is another W3C document that defines how to define a SOAP 1.2 payload within a WSDL 1.1 document. Read about WSDL 1.1 binding extensions for SOAP 1.2.
- SOAP 1.1 is a single document. The SOAP 1.2 specification is organized in the following parts:
  - Part 0 is a non-normative introduction to SOAP.
  - Part 1 describes the structure of SOAP messages, the SOAP processing model and a framework for binding SOAP to underlying protocols. Conformant SOAP implementations must implement everything in Part 1.
  - Part 2 describes optional add-ins to the core of SOAP including a data model and encoding, an RPC convention and a binding to HTTP. Conformant SOAP implementations might implement any of the add-ins in Part 2. However, if add-ins are implemented, they must conform to the relevant parts of the specification.

  A fourth document is the Specification Assertions and Test Collection

SOAP 1.2 has a number of changes in syntax and provides additional, clarified semantics from those that are described in SOAP 1.1. The SOAP 1.2 Primer document lists and describes these syntax changes.

JAX-WS

Java API for XML-Based Web Services (JAX-WS) is the next generation Web services programming model complimenting the foundation provided by the Java API for XML-based RPC (JAX-RPC)

programming model. Using JAX-WS, development of Web services and clients is simplified with more platform independence for Java applications by the use of dynamic proxies and Java annotations.

JAX-WS is a programming model that simplifies application development through support of a standard, annotation-based model to develop Web Service applications and clients. The JAX-WS technology strategically aligns itself with the current industry trend towards a more document-centric messaging model and replaces the remote procedure call programming model as defined by JAX-RPC. While the JAX-RPC programming model and applications are still supported by this product, JAX-RPC has limitations and does not support various complex document-centric services. JAX-WS is the strategic programming model for developing Web services and is a required part of the Java Platform, Enterprise Edition 5 (Java EE 5). JAX-WS is also known as JSR 224.

Note: WebSphere Application Server Version 7.0 supports the JAX-WS 2.1 specification. JAX-WS 2.1 extends the functionality of JAX-WS 2.0 to provide support for the WS-Addressing in a standardized API. Using this function, you can create, transmit and use endpoint references to target a Web service endpoint. You can use this API to specify the action uniform resource identifiers (URIs) that are associated with the Web Services Description Language (WSDL) operations of your Web service. JAX-WS 2.1 introduces the concept of *features* as a way to programmatically control specific functions and behaviors. There are three standard features: the AddressingFeature for WS-Addressing, the MTOMFeature when optimizing the transmission of binary attachments, and the RespectBindingFeature for wsdl:binding extensions. JAX-WS 2.1 requires Java Architecture for XML Binding (JAXB) Version 2.1 for data binding.

The implementation of the JAX-WS programming standard provides the following enhancements for developing Web services and clients:

- **Better platform independence for Java applications.**

  Using JAX-WS APIs, development of Web services and clients is simplified with better platform independence for Java applications. JAX-WS takes advantage of the dynamic proxy mechanism to provide a formal delegation model with a pluggable provider. This is an enhancement over JAX-RPC, which relies on the generation of vendor-specific stubs for invocation.

- **Annotations**

  JAX-WS introduces support for annotating Java classes with metadata to indicate that the Java class is a Web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.1 specification. Using annotations within the Java source and within the Java class simplifies development of Web services. Use annotations to define information that is typically specified in deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL files into the source artifacts.

  For example, you can embed a simple @WebService tag in the Java source to expose the bean as a Web service.

  ```
  @WebService

  public class QuoteBean implements StockQuote {

         public float getQuote(String sym) { ... }

  }
  ```

  The @WebService annotation tells the server runtime environment to expose all public methods on that bean as a Web service. Additional levels of granularity can be controlled by adding additional annotations on individual methods or parameters. Using annotations makes it much easier to expose Java artifacts as Web services. In addition, as artifacts are created from using some of the top-down mapping tools starting from a WSDL file, annotations are included within the source and Java classes as a way of capturing the metadata along with the source files.

Using annotations also improves the development of Web services within a team structure because you do not need to define every Web service in a single or common deployment descriptor as required with JAX-RPC Web services. Taking advantage of annotations with JAX-WS Web services enables parallel development of the service and the required metadata.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

For example, if your service implementation class for your JAX-WS Web service includes the following:

– the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

– the webservices.xml file specifies a different file name for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

In this case, the value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl overrides the annotation value.

- **Invoking Web services asynchronously**

  With JAX-WS, Web services are called both synchronously and asynchronously. JAX-WS adds support for both a polling and callback mechanism when calling Web services asynchronously. Using a polling model, a client can issue a request, get a response object back, which is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke Web services.

  For example, a Web service interface might have methods for both synchronous and asynchronous requests. Asynchronous requests are identified in bold in the following example:

```
@WebService
public interface CreditRatingService {
      // sync operation
      Score      getCreditScore(Customer customer);
      // async operation with polling
      Response<Score> getCreditScoreAsync(Customer customer);
      // async operation with callback
      Future<?> getCreditScoreAsync(Customer customer,
         AsyncHandler<Score> handler);
}
```

  The asynchronous invocation that uses the callback mechanism requires an additional input by the client programmer. The callback is an object that contains the application code that is run when an asynchronous response is received. Use the following code example to invoke an asynchronous callback handler:

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerFred,
 new AsyncHandler<Score>() {
    public void handleResponse (
        Response<Score> response)
      {
        Score score = response.get();
```

```
        // do work here...
      }
    }
);
```

Use the following code example to invoke an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerFred);

while (!response.isDone()) {
  // Complete an action while we wait.
}

// No cast needed, because of generics.
Score score = response.get();
```

- **Using resource injection**

  JAX-WS supports resource injection to further simplify development of Web services. JAX-WS uses this key feature of Java EE 5 to shift the burden of creating and initializing common resources in a Java runtime environment from your Web service application to the application container environment, itself. JAX-WS provides support for a subset of annotations that are defined in JSR-250 for resource injection and application life cycle in its runtime environment.

  The application server also supports the usage of the @Resource or @WebServiceRef annotation to declare JAX-WS managed clients and to request injection of JAX-WS services and ports. When either of these annotations are used on a field or method, they result in injection of a JAX-WS service or port instance. The usage of these annotations also results in the type specified by the annotation being bound into the JNDI namespace.

  The @Resource annotation is defined by the JSR-250, Common Annotations specification that is included in Java Platform, Enterprise Edition 5 (Java EE 5). By placing the @Resource annotation on a variable of type javax.xml.ws.WebServiceContext within a service endpoint implementation class, you can request a resource injection and collect the javax.xml.ws.WebServiceContext interface related to that particular endpoint invocation. From the WebServiceContext interface, you can collect the MessageContext for the request associated with the particular method call using the getMessageContext() method.

  The @WebServiceRef annotation is defined by the JAX-WS specification.

  The following example illustrates using the @Resource and @WebServiceRef annotations for resource injection:

```
@WebService
public class MyService {

    @Resource
    private WebServiceContext ctx;

    @Resource
    private SampleService svc;

    @WebServiceRef
    private SamplePort port;

    public String echo (String input) {
        ...
    }

}
```

  Refer to sections 5.2.1 and 5.3 of the JAX-WS specification for more information on resource injection.

- **Data binding with JAXB 2.1**

  JAX-WS leverages the Java Architecture for XML Binding (JAXB) 2.1 API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents. JAXB data binding replaces the data binding described by the JAX-RPC specification.

The JAXB 2.1 specification provides enhancements such as improved compilation support and introduces support for the @XMLSeeAlso annotation. With the improved compilation support, you now have the flexibility to control the whether a new schema file is generated when using the schemagen schema generator and you can configure the xjc schema compiler so that it does not automatically generate new classes for a particular schema. You can use the @XMLSeeAlso annotation to ensure that JAXB is aware of all the classes included in an inheritance hierarchy for a service endpoint interface.**Dynamic and static clients**

The dynamic client API for JAX-WS is called the dispatch client (javax.xml.ws.Dispatch). The dispatch client is an XML messaging oriented client. The data is sent in either PAYLOAD or MESSAGE mode. When using the PAYLOAD mode, the dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS adds the <soap:Envelope> and <soap:Header> elements. When using the MESSAGE mode, the dispatch client is responsible for providing the entire SOAP envelope including the <soap:Envelope>, <soap:Header>, and <soap:Body> elements. JAX-WS does not add anything additional to the message. The dispatch client supports asynchronous invocations using a callback or polling mechanism.

The static client programming model for JAX-WS is the called the proxy client. The proxy client invokes a Web service based on a Service Endpoint interface (SEI), which must be provided.

- **Support for MTOM**

  Using JAX-WS, you can send binary attachments such as images or files along with Web services requests. JAX-WS adds support for optimized transmission of binary data as specified by Message Transmission Optimization Mechanism (MTOM).

- **Multiple data binding technologies**

  JAX-WS exposes the following binding technologies to the end user: XML Source, SOAP Attachments API for Java (SAAJ) 1.3, and Java Architecture for XML Binding (JAXB) 2.1. XML Source enables a user to pass a javax.xml.transform.Source into the runtime environment which represents the data in a Source object to be processed. SAAJ 1.3 now has the ability to pass an entire SOAP document across the interface rather than just the payload itself. This action is done by the client passing the SAAJ SOAPMessage object across the interface. JAX-WS leverages the JAXB 2.1 support as the data binding technology of choice between Java and XML.

- **Support for SOAP 1.2**

  Support for SOAP 1.2 has been added to JAX-WS 2.0. JAX-WS supports both SOAP 1.1 and SOAP 1.2 so that you can send binary attachments such as images or files along with Web services requests. JAX-WS adds support for optimized transmission of binary data as specified by MTOM.

- **Development tools**

  JAX-WS provides the wsgen and wsimport command-line tools for generating portable artifacts for JAX-WS Web services. When creating JAX-WS Web services, you can start with either a WSDL file or an implementation bean class. If you start with an implementation bean class, use the wsgen command-line tool to generate all the Web services server artifacts, including a WSDL file if requested. If you start with a WSDL file, use the wsimport command-line tool to generate all the Web services artifacts for either the server or the client. The wsimport command-line tool processes the WSDL file with schema definitions to generate the portable artifacts, which include the service class, the service endpoint interface class, and the JAXB 2.1 classes for the corresponding XML schema.

- **Support for WS-Addressing (JAX-WS 2.1)**

  JAX-WS 2.1 integrates support for the WS-Addressing standard in to the API. The new API enables you to create, transmit and use endpoint references to target a specific Web service endpoint. You can also explicitly specify the action URIs associated with the Web Services Description Language (WSDL) operations of your Web service.

- **Support for JAX-WS 2.1 features**

  JAX-WS 2.1 introduces the concept of features as a way to programmatically control certain functions or behaviors. There are three standard features: the AddressingFeature , the MTOMFeature, and the RespectBindingFeature. The AddressingFeature is used to enable or disable support for the WS-Addressing Version 1.0 specification. The MTOMFeature is used to enable or disable support for

Message Transmission Optimized Mechanism (MTOM) when sending binary attachments. The RespectBindingFeature is used to enable or disable support for wsdl:binding extensions. The application server supports an additional feature, the SubmissionAddressingFeature, which is used to enable or disable support for WS-Addressing Member Submission specification (prior to the WS-Addressing Version 1.0 level of specification).

JAX-WS client programming model:

The Java API for XML-Based Web Services (JAX-WS) Web service client programming model supports both the Dispatch client API and the Dynamic Proxy client API. The Dispatch client API is a dynamic client programming model, whereas the static client programming model for JAX-WS is the Dynamic Proxy client. The Dispatch and Dynamic Proxy clients enable both synchronous and asynchronous invocation of JAX-WS Web services.

- Dispatch client: Use this client when you want to work at the XML message level or when you want to work without any generated artifacts at the JAX-WS level.
- Dynamic Proxy client: Use this client when you want to invoke a Web service based on a service endpoint interface.

Dispatch client

XML-based Web services use XML messages for communications between Web services and Web services clients. The JAX-WS APIs provide high-level methods to simplify and hide the details of converting between Java method invocations and their associated XML messages. However, in some cases, you might desire to work at the XML message level. Support for invoking services at the XML message level is provided by the Dispatch client API. The Dispatch client API, `javax.xml.ws.Dispatch`, is a dynamic JAX-WS client programming interface. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file. The Dispatch client can send data in either `MESSAGE` or `PAYLOAD` mode. When using the `javax.xml.ws.Service.Mode.MESSAGE` mode, the Dispatch client is responsible for providing the entire SOAP envelope including the `<soap:Envelope>`, `<soap:Header>`, and `<soap:Body>` elements. When using the `javax.xml.ws.Service.Mode.PAYLOAD` mode, the Dispatch client is only responsible for providing the contents of the `<soap:Body>` and JAX-WS includes the payload in a `<soap:Envelope>` element.

The Dispatch client API requires application clients to construct messages or payloads as XML which requires a detailed knowledge of the message or message payload. The Dispatch client supports the following types of objects:

- `javax.xml.transform.Source`: Use `Source` objects to enable clients to use XML APIs directly. You can use `Source` objects with SOAP or HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP or HTTP bindings.
- `javax.xml.soap.SOAPMessage`: Use `SOAPMessage` objects so that clients can work with SOAP messages. You can only use `SOAPMessage` objects with SOAP bindings.
- `javax.activation.DataSource`: Use `DataSource` objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use `DataSource` only with HTTP bindings.

For example, if the input parameter type is `javax.xml.transform.Source`, the call to the Dispatch client API is similar to the following code example:

```
Dispatch<Source> dispatch = ... create a Dispatch<Source>
Source request = ... create a Source object
Source response = dispatch.invoke(request);
```

The Dispatch parameter value determines the return type of the `invoke()` method.

The Dispatch client is invoked in one of three ways:

- Synchronous invocation for requests and responses using the `invoke` method
- Asynchronous invocation for requests and responses using the `invokeAsync` method with a callback or polling object
- One-way invocation using the `invokeOneWay` methods

Refer to Chapter 4, section 3 of the JAX-WS specification for more information on using a Dispatch client.

Dynamic Proxy client

The static client programming model for JAX-WS is the called the Dynamic Proxy client. The Dynamic Proxy client invokes a Web service based on a Service Endpoint Interface (SEI) which must be provided. The Dynamic Proxy client is similar to the stub client in the Java API for XML-based RPC (JAX-RPC) programming model. Although the JAX-WS Dynamic Proxy client and the JAX-RPC stub client are both based on the Service Endpoint Interface (SEI) that is generated from a WSDL file , there is a major difference. The Dynamic Proxy client is dynamically generated at run time using the Java 5 Dynamic Proxy functionality, while the JAX-RPC-based stub client is a non-portable Java file that is generated by tooling. Unlike the JAX-RPC stub clients, the Dynamic Proxy client does not require you to regenerate a stub prior to running the client on an application server for a different vendor because the generated interface does not require the specific vendor information.

The Dynamic Proxy instances extend the `java.lang.reflect.Proxy` class and leverage the Dynamic Proxy function in the base Java SE Runtime Environment (JRE) 6. The client application can then provide an interface that is used to create the proxy instance while the runtime is responsible for dynamically creating a Java object that represents the SEI.

The Dynamic Proxy client is invoked in one of three ways:

- Synchronous invocation for requests and responses using the `invoke` method
- Asynchronous invocation for requests and responses using the `invokeAsync` method with a callback or polling object
- One-way invocation using the `invokeOneWay` methods

Refer to Chapter 4 of the JAX-WS specification for more information on using Dynamic Proxy clients.

Related concepts

"JAX-WS" on page 441
Java API for XML-Based Web Services (JAX-WS) is the next generation Web services programming model complimenting the foundation provided by the Java API for XML-based RPC (JAX-RPC) programming model. Using JAX-WS, development of Web services and clients is simplified with more platform independence for Java applications by the use of dynamic proxies and Java annotations.

Related tasks

"Developing and deploying JAX-WS Web services clients" on page 530
You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-Based Web Services (JAX-WS) programming model.

"Developing a JAX-WS client from a WSDL file" on page 534
Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS Web services clients when starting with a Web Services Description Language (WSDL) file.

"Invoking JAX-WS Web services asynchronously" on page 540
Java API for XML-Based Web Services (JAX-WS) provides support for invoking Web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling Web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

JAX-WS annotations:

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with Web services implementations and to simplify the development of Web services. Annotations describe how a server-side service implementation is accessed as a Web service or how a client-side Java class accesses Web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a Web service and how a client can access the Web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a Web service. Using annotations within the Java source simplifies development and deployment of Web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to Web service invocations.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve backward compatibility with the feature pack in either of two ways:

- You can set the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

  ```
  Manifest-Version: 1.0
  UseWSFEP61ScanPolicy: true
  ```

  When this property is set to `true` in the module's META-INF/MANIFEST.MF file, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.
- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within a module's META-INF/MANIFEST.MF file, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Note: If this JVM property is being used on the z/OS platform, it must be set in both the servant and control regions of the server.

Note: When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated if you wish to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Web Services Metadata Annotations (JSR 181)

Annotation class	Annotation	Properties
`javax.jws.` `WebService`	The **@WebService** annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a Web service interface. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. This annotation is applicable on a client or server SEI or a server endpoint implementation class. • If the annotation references an SEI through the `endpointInterface` attribute, the SEI must also be annotated with the @WebService annotation. • See “Rules for methods on classes annotated with @WebService” on page 467 for additional information.	• Annotation target: Type • Properties: **- name** The name of the `wsdl:portType`. The default value is the unqualified name of the Java class or interface. (String) **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- endpointInterface** Specifies the qualified name of the service endpoint interface that defines the services’ abstract Web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) **- portName** The `wsdl:portName`. The default value is WebService.name +*Port* . (String) **- wsdlLocation** Specifies the Web address of the WSDL document defining the Web service. The Web address is either relative or absolute. (String)

Annotation class	Annotation	Properties
`javax.jws.` `WebMethod`	The **@WebMethod** annotation denotes a method that is a Web service operation. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. **Important:** • The @WebMethod annotation is only supported on classes that are annotated with the @WebService annotation.	• Annotation target: Method • Properties: **- operationName** Specifies the name of the `wsdl:operation` matching this method. The default value is the name of Java method. (String) **- action** Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) **- exclude** Specifies whether to exclude a method from the Web service. The default value is `false`. (Boolean)
`javax.jws.` `Oneway`	The **@Oneway** annotation denotes a method as a Web service one-way operation that only has an input message and no output message. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • There are no properties on the Oneway annotation.

Annotation class	Annotation	Properties
`javax.jws.` `WebParam`	The **@WebParam** annotation customizes the mapping of an individual parameter to a Web service message part and XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Parameter • Properties: **- name** The name of the parameter. If the operation is remote procedure call (RPC) style and the `partName` attribute is not specified, then this is the name of the `wsdl:part` attribute representing the parameter. If the operation is document style or the parameter maps to a header, then `-name` is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is `BARE`, and the mode is `OUT` or `INOUT`. (String) **- partName** Defines the name of `wsdl:part` attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is `BARE`. (String) **- targetNamespace** Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the `targetNamespace` for the Web service. (String) **- mode** The value represents the direction the parameter flows for this method. Valid values are `IN`, `INOUT`, and `OUT`. (String) **- header** Specifies whether the parameter is in a message header rather than a message body. The default value is `false`. (Boolean)

Annotation class	Annotation	Properties
`javax.jws.` `WebResult`	The **@WebResult** annotation customizes the mapping of a return value to a WSDL part or XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- name** Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the `wsdl:part` attribute representing the return value. For document bindings, the `-name` parameter is the local name of the XML element representing the return value. The default value is `return` for RPC and DOCUMENT/WRAPPED bindings. The default value is the method name + `Response` for DOCUMENT/BARE bindings. (String) **- targetNamespace** Specifies the XML namespace for the return value. This parameter is only used if the operation is RPC style or if the operation is DOCUMENT style and the parameter style is BARE. (String) **- header** Specifies whether the result is carried in a header. The default value is `false`. (Boolean) **- partName** Specifies the part name for the result with RPC or DOCUMENT/BARE operations. The default value is `@WebResult.name`. (String)

Annotation class	Annotation	Properties
`javax.jws.HandlerChain`	The **@HandlerChain** annotation associates the Web service with an externally defined handler chain. You can only configure the server side handler by using the @HandlerChain annotation on the Service Endpoint Interface (SEI) or the server endpoint implementation class. Use one of several ways to configure a client side handler. You can configure a client side handler by using the @HandlerChain annotation on the generated service class or SEI. Additionally, you can programmatically register your own implementation of the HandlerResolver interface on the Service, or programmatically set the handler chain on the Binding object.	• Annotation target: Type • Properties: **- file** Specifies the location of the handler chain file. The file location is either an absolute java.net.URL in external form or a relative path from the class file. (String) **- name** Specifies the name of the handler chain in the configuration file. (String)
`javax.jws.SOAPBinding`	The **@SOAPBinding** annotation specifies the mapping of the Web service onto the SOAP message protocol. Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. The method level annotation is limited in what it can specify and is only used if the `style` property is `DOCUMENT`. If the method level annotation is not specified, the **@SOAPBinding** behavior from the type is used.	• Annotation target: Type or Method • Properties: **- style** Defines encoding style for messages sent to and from the Web service. The valid values are `DOCUMENT` and `RPC`. The default value is `DOCUMENT`. (String) **- use** Defines the formatting used for messages sent to and from the Web service. The default value is `LITERAL`. `ENCODED` is not supported. (String) **- parameterStyle** Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are `WRAPPED` or `BARE`. You can only use the `BARE` value with `DOCUMENT` style bindings. The default value is `WRAPPED`. (String)

JAX-WS Annotations (JSR 224)

Annotation class	Annotation	Properties
`javax.xml.ws.Action`	The **@Action** annotation specifies the WS-Addressing action that is associated with a Web service operation. When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- fault** Specifies the array of FaultAction for the wsdl:fault of the operation. (String) **- input** Specifies the action for thewsdl:input of the operation. (String) **- output** Specifies the action for thewsdl:output of the operation. (String)
`javax.xml.ws.BindingType`	The **@BindingType** annotation specifies the binding to use when publishing an endpoint of this type. Apply this annotation to a server endpoint implementation class. **Important:** • You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING` or `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING` as the value for the annotation.	• Annotation target: Type • Properties: **- value** Indicates the binding identifier Web address. Valid values are `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`, `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING`, and `javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING`. The default value is `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.FaultAction`	The **@FaultAction** annotation specifies the WS-Addressing action that is added to a fault response. This annotation must be contained within an @Action annotation. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- value** Specifies the action of the wsdl:fault of the operation. (String) **- output** Specifies the name of the exception class. (String) **- className** Specifies the name of the class representing the request wrapper. (String)
`javax.xml.ws.RequestWrapper`	The **@RequestWrapper** annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` as defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the request wrapper. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.ResponseWrapper`	The **@ResponseWrapper** annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` + *Response*. `operationName` is defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the response wrapper. (String)
`javax.xml.ws.RespectBinding`	The **@RespectBinding** annotation specifies whether the JAX-WS implementation must use the contents of the wsdl:binding for an endpoint. When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to true are supported. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Method • Properties: **- enabled** Specifies whether the wsdl:binding must be used or not. The default value is `true`. (Boolean)
`javax.xml.ws.ServiceMode`	The **@ServiceMode** annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload. **Important:** • The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation.	• Annotation target: Type • Properties: **- value** Indicates whether the provider class accepts the payload of the message, `PAYLOAD` or the entire message `MESSAGE`. The default value is `PAYLOAD`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.soap.Addressing`	The **@Addressing** annotation specifies that this service wants to enable WS-Addressing support. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- enabled** Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean) **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)
`javax.xml.ws.soap.MTOM`	The **@MTOM** annotation specifies whether binary content in the body of a SOAP message is sent using MTOM. Apply this annotation to a service endpoint implementation class.	• Annotation target: Class • Properties: **- enabled** Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is `true`. (Boolean) **- threshold** Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)

Annotation class	Annotation	Properties
`javax.xml.ws.WebFault`	The **@WebFault** annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults. This annotation can only be applied to a fault implementation class on the client or server.	• Annotation target: Type • Properties: **- name** Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) **- targetNamespace** Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) **- faultBean** Specifies the name of the fault bean class. (String)
`javax.xml.ws.WebServiceProvider`	The **@WebServiceProvider** annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. • The @WebServiceProvider annotation is only supported on the service implementation class. Any class with the @WebServiceProvider annotation must implement the javax.xml.ws.Provider interface.	• Annotation target: Type • Properties: **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- portName** The `wsdl:portName`. The default value is the name of the class + *Port*. (String) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.WebServiceRef`	The **@WebServiceRef** annotation defines a reference to a Web service invoked by the client. **Important:** • The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type, Field or Method • Properties: **- name** Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) **- type** Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) **- mappedName** Specified the name to map this resource to. (String) **- value** Indicates the value of the service class and it is a type that extends `javax.xml.ws.Service`. This attribute is required when the type of the reference is a service endpoint interface. (Class) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)
`javax.xml.ws.WebServiceRefs`	The **@WebServiceRefs** annotation associates multiple @WebServiceRef annotations with a specific class. **Important:** • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type • Properties: **- value** Specifies an array for multiple Web service reference declarations. This attribute is required.

JAX-WS Common Annotations (JSR 250)

Annotation class	Annotation	Properties
`javax.annotation.Resource`	The **@Resource** annotation marks a WebServiceContext resource needed by the application. **Important:** Applying this annotation to a WebServiceContext type field on the server endpoint implementation class for a JavaBeans endpoint or a Provider endpoint results in the container injecting an instance of the WebServiceContext into the specified field. When this annotation is used in place of the @WebServiceRef annotation, the rules described for the @WebServiceRef annotation apply.	• Annotation target: Field or Method • Properties: **- type** Indicates the Java type of the resource. You are required to use the default, `java.lang.Object` or `javax.xml.ws.Web ServiceContext` value. If the type is the default, the resource must be injected into a field or a method. In this case, the type of the field or the type of the JavaBeans property defined by the method must be `javax.xml.ws.WebServiceContext`. (Class) If you are using this annotation to inject a Web service, see the description of the @WebServiceRef type attribute.
`javax.annotation.Resources`	The **@Resources** annotation associates multiple @Resource annotations with a specific class and serves as a container for multiple resource declarations.	• Annotation target: Field or Method • Properties: **- value** Specifies an array for multiple @Resource annotations. This attribute is required.
`javax.annotation.PostConstruct`	The **@PostConstruct** annotation marks a method that needs to run after dependency injection is performed on the class. Apply this annotation to a JAX-WS application handler, a server endpoint implementation class.	• Annotation target: Method
`javax.annotation.PreDestroy`	The **@PreDestroy** annotation marks a method that must be run when the instance is in the process of being removed by the container. Apply this annotation to a JAX-WS application handler or a server endpoint implementation class.	• Annotation target: Method

IBM proprietary annotations

Annotation class	Annotation	Properties
`com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing`	The **@SubmissionAddressing** annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification. This annotation is part of the IBM implementation of the JAX-WS 2.1 specification. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)

Rules for methods on classes annotated with @WebService

The following rules apply for methods on classes annotated with the @WebService annotation.

- If the @WebService annotation of an implementation class references an SEI, the implementation class must not have any @WebMethod annotations.
- All public methods for an SEI are considered exposed methods regardless of whether the @WebMethod annotation is specified or not. It is incorrect to have an @WebMethod annotation on an SEI that contains the `exclude` attribute.
- For an implementation class that does not reference an SEI, if the @WebMethod annotation is specified with a value of `exclude=true`, that method is not exposed. If the @WebMethod annotation is not specified, all public methods are exposed including the inherited methods with the exception of methods inherited from java.lang.Object.

JAX-WS application packaging:

You can package a Java Application Programming Interface (API) for XML Web Services (JAX-WS) application as a Web service. A JAX-WS Web service is contained within a Web archive (WAR) file or a WAR module within an enterprise archive (EAR) file.

A JAX-WS enabled WAR file contains:

- A WEB-INF/web.xml file
- Annotated classes that implement the Web services contained in the application module
- [Optional] Web Services Description Language (WSDL) documents that describe the Web services contained in the application module

A WEB-INF/web.xml file is similar to this example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" xmlns="http://java.sun.com/xml/ns/j2ee"
         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
         http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
         version="2.4">
</web-app>
```

The web.xml might contain servlet or servlet-mapping elements. When customizations to the web.xml file are not needed, the WebSphere Application Server runtime defines them dynamically as the module is loaded. For more information on configuring the web.xml file, read about customizing Web URL patterns in the web.xml file for JAX-WS applications.

Annotated classes must contain, at a minimum, a Web service implementation class that includes the `@WebService` annotation. The definition and specification of the Web services-related annotations are provided by the JAX-WS and JSR-181 specifications. The Web service implementation classes can exist within the `WEB-INF/classes` or directory within a Java archive (JAR) file that is contained in the `WEB-INF/lib` directory of the WAR file.

You can optionally include WSDL documents in the JAX-WS application packaging. If the WSDL document for a particular Web service is omitted, then the WebSphere Application Server runtime constructs the WSDL definition dynamically from the annotations contained in the Web service implementation classes. You must include the `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and optionally the `@SOAPBinding` annotations if the WSDL document is omitted.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the

default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

JAXB

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified development of Web services. JAXB leverages the flexibility of platform-neutral XML data in Java applications to bind XML schema to Java applications without requiring extensive knowledge of XML programming.

JAXB is an XML to Java binding technology that supports transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB consists of a runtime application programming interface (API) and accompanying tools that simplify access to XML documents. JAXB also helps to build XML documents that both conform and validate to the XML schema. Java API for XML-Based Web Services (JAX-WS) leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

Note: WebSphere Application Server Version 7.0 supports the JAXB 2.1 specification. JAX-WS 2.1 requires JAXB 2.1 for data binding. JAXB 2.1 provides enhancements such as improved compilation support and support for the @XMLSeeAlso annotation. With JAXB 2.1, you can configure the xjc schema compiler so that it does not automatically generate new classes for a particular schema. Similarly, you can configure the schemagen schema generator to not automatically generate a new schema. This enhancement is useful when you are using a common schema and you do not want a new schema generated. JAXB 2.1 also introduces the @XMLSeeAlso annotation that enables JAXB to bind additional Java classes that it might not otherwise know about when binding a Java class with this annotation. This annotation enables JAXB to know about all classes that are potentially involved in marshalling or unmarshalling as it is not always possible or practical to list all of the subclasses of a given Java class. JAX-WS 2.1 also supports the use of the @XMLSeeAlso annotation on a service endpoint interface (SEI) or on a service implementation bean to ensure all of the classes referenced by the annotation are passed to JAXB for processing.

JAXB provides the xjc schema compiler tool, the schemagen schema generator tool, and a runtime framework. You can use the xjc schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the schemagen schema generator tool to create the XML schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. Data stored in XML documents can be accessed without the need to understand the data structure. You can then use the resulting Java classes to assemble a Web services application.

JAXB annotated classes and artifacts contain all the information needed by the JAXB runtime API to process XML instance documents. The JAXB runtime API supports marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances. Optionally, you can use JAXB to provide XML validation to enforce both incoming and outgoing XML documents to conform to the XML constraints defined within the XML schema.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects for use within JAX-WS applications.

You can also use JAXB independently of JAX-WS when you want to leverage the XML data binding technology to manipulate XML within your Java applications.

The following diagram illustrates the JAXB architecture.

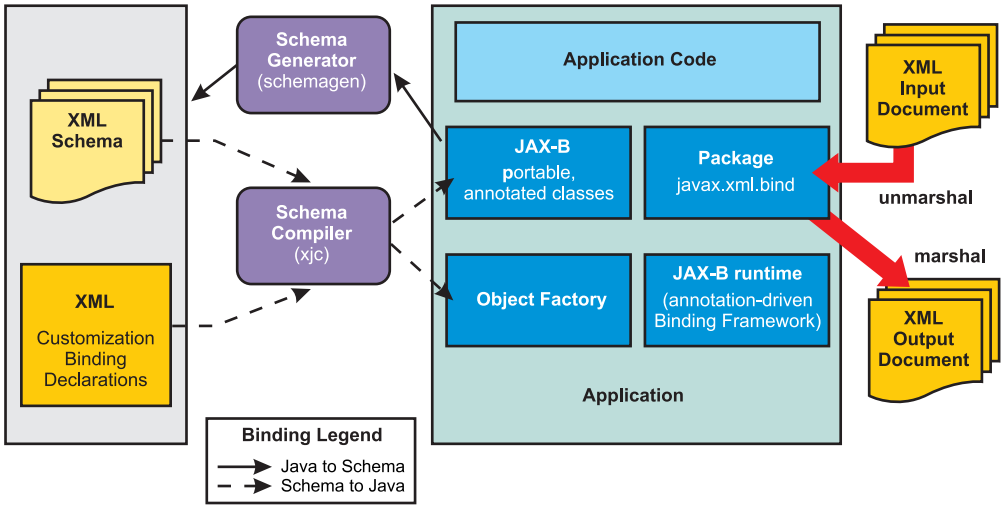

Figure 3. JAXB architecture

JAX-RPC

The *Java API for XML-based RPC (JAX-RPC)* specification enables you to develop SOAP-based interoperable and portable Web services and Web service clients. JAX-RPC 1.1 provides core APIs for developing and deploying Web services on a Java platform and is a part of the Web Services for Java Platform, Enterprise Edition (Java EE) platform. The Java EE platform enables you to develop portable Web services.

WebSphere Application Server implements JAX-RPC 1.1 standards.

The JAX-RPC standard covers the programming model and bindings for using Web Services Description Language (WSDL) for Web services in the Java language. JAX-RPC simplifies development of Web services by shielding you from the underlying complexity of SOAP communication.

On the surface, JAX-RPC looks like another instantiation of remote method invocation (RMI). Essentially, JAX-RPC enables clients to access a Web service as if the Web service was a local object mapped into the client's address space even though the Web service provider is located in another part of the world. The JAX-RPC is done by using the XML-based protocol SOAP, which typically rides on top of HTTP.

JAX-RPC defines the mappings between the WSDL port types and the Java interfaces, as well as between Java language and Extensible Markup Language (XML) schema types.

A JAX-RPC Web service can be created from a JavaBean or a enterprise bean implementation. You can specify the remote procedures by defining remote methods in a Java interface. You only need to code one or more classes that implement the methods. The remaining classes and other artifacts are generated by the Web service vendor's tools. The following is an example of a Web service interface:

```
package com.ibm.mybank.ejb;
import java.rmi.RemoteException;
import com.ibm.mybank.exception.InsufficientFundsException;
/**
 * Remote interface for Enterprise Bean: Transfer
 */
public interface Transfer_SEI extends java.rmi.Remote {
```

```
    public void transferFunds(int fromAcctId, int toAcctId, float amount)
       throws java.rmi.RemoteException;

}
```

The interface definition in JAX-RPC must follow specific rules:

- The interface must extend `java.rmi.Remote` just like RMI.
- Methods must create `java.rmi.RemoteException`.
- Method parameters cannot be remote references.
- Method parameter must be one of the parameters supported by the JAX-RPC specification. The following list are examples of method parameters that are supported. For a complete list of method parameters see the JAX-RPC specification.
  - Primitive types: `boolean`, `byte`, `double`, `float`, `short`, `int` and `long`
  - Object wrappers of primitive types: `java.lang.Boolean`, `java.lang.Byte`, `java.lang.Double`, `java.lang.Float`, `java.lang.Integer`, `java.lang.Long`, `java.lang.Short`
  - `java.lang.String`
  - `java.lang.BigDecimal`
  - `java.lang.BigInteger`
  - `java.lang.Calendar`
  - `java.lang.Date`
- Methods can take value objects which consist of a composite of the types previously listed, in addition to aggregate value objects.

A client creates a stub and invokes methods on it. The stub acts like a proxy for the Web service. From the client code perspective, it seems like a local method invocation. However, each method invocation gets marshaled to the remote server. Marshaling includes encoding the method invocation in XML as prescribed by the SOAP protocol.

The following are key classes and interfaces needed to write Web services and Web service clients:

- **Service interface**: A factory for stubs or dynamic invocation and proxy objects used to invoke methods
- **ServiceFactory class**: A factory for Services.
- **`loadService`**

  The `loadService` method is provided in WebSphere Application Server Version 6.0 to generate the service locator which is required by a JAX-RPC implementation. If you recall, in previous versions there was no specific way to acquire a generated service locator. For managed clients you used a JNDI method to get the service locator and for non-managed clients, you were required to instantiate IBM's specific service locator `ServiceLocator service=new ServiceLocator(...);` which does not offer portability. The `loadService` parameters include:
  - **`wsdlDocumentLocation:`** A URL for the WSDL document location for the service or null.
  - **`serviceName`**: A qualified name for the service
  - **`properties`**: A set of implementation-specific properties to help locate the generated service implementation class.
- **`isUserInRole`**

  The `isUserInRole` method returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical role.
  - **`role`**: The role parameter is a String specifying the name of the role.
- **Service**
- **Call interface**: Used for dynamic invocation
- **Stub interface**: Base interface for stubs

If you are using a stub to access the Web service provider, most of the JAX-RPC API details are hidden from you. The client creates a ServiceFactory (`java.xml.rpc.ServiceFactory`). The client instantiates a Service (`java.xml.rpc.Service`) from the ServiceFactory. The service is a factory object that creates the port. The port is the remote service endpoint interface to the Web service. In the case of DII, the Service object is used to create Call objects, which you can configure to call methods on the Web service's port.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

RMI-IIOP using JAX-RPC:

Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) can be used with JAX-RPC to support non-SOAP bindings.

Java API for XML-based Remote Procedure Call (JAX-RPC) is the Java standard API for invoking Web services through remote procedure calls. A transport is used by a programming language to communicate over the Internet. You can use protocols with the transport such as SOAP and Remote Method Invocation (RMI). You can use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) with JAX-RPC to support non-SOAP bindings.

Using RMI-IIOP with JAX-RPC, enables WebSphere Java clients to invoke enterprise beans using a WSDL file and the JAX-RPC programming model instead of using the standard Web Services for Java Platform, Enterprise Edition (Java EE) programming model. When a enterprise JavaBeans implementation is used to invoke a Web service, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients. To learn more this optimization, read about using enterprise bean bindings to invoke an EJB from a Web services client.

Benefits of using the RMI/IIOP protocol instead of a SOAP- based protocol are:

- XML processing is not required to send and receive messages; Java serialization is used instead.
- The client JAX-RPC call can participate in a user transaction, which is not the case when SOAP is used.

Web Services-Interoperability Basic Profile

The Web Services-Interoperability (WS-I) Basic Profile is a set of non-proprietary Web services specifications that promote interoperability. WebSphere Application Server conforms to the WS-I Basic Profile Version 1.1 and WS-I Basic Security Profile Version 1.0.

The WS-I Basic Profile is governed by a consortium of industry-leading corporations, including IBM, under direction of the WS-I Organization. The profile consists of a set of principles that relate to bringing about open standards for Web services technology. All organizations that are interested in promoting interoperability among Web services are encouraged to become members of the Web Services Interoperability Organization.

Several technology components are used in the composition and implementation of Web services, including messaging, description, discovery, and security. Each of these components are supported by specifications and standards, including SOAP 1.1, Extensible Markup Language (XML) 1.0, HTTP 1.1, Web Services Description Language (WSDL) 1.1, and Universal Description, Discovery and Integration (UDDI). The WS-I Basic Profile specifies how these technology components are used together to achieve interoperability, and mandates specific use of each of the technologies when appropriate. You can read more about the WS-I Basic Profile at the WS-I Organization Web site.

As technology components are updated, these components are also used in the composition and implementation of Web Services. One example is that both SOAP 1.1 and SOAP 1.2 are now supported.

Note: Building on the support for WS-I Basic Profile Version 1.0, WS-I Basic Profile V1.1, Attachment Profile V1.0, and Basic Security Profile (BSP) V1.0, you can implement Web services with WebSphere Application Server Version 7.0 using the following current emerging standard WS-I profiles:

- *WS-I Basic Profile V1.2* builds on WS-I Basic Profile V1.0 and WS-I Basic Profile V1.1 and adds support for WS-Addressing (WS-A) and SOAP Message Transmission Optimization Mechanism (MTOM). The WS-Addressing specification enables the asynchronous message exchange pattern so that you can decouple the service request from the service response. The SOAP header of the sender's request contains the wsa:ReplyTo value that defines the endpoint reference to which the provider's response is sent. Decoupling the request from the response enables long running Web services interactions. Leveraging the asynchronous programming model support in JAX-WS Version 2.1 in combination with WS-Addressing, you can now take advantage of the ability to create Web services invocations where the client can continue to process work without waiting for a response to return. This provides for a more dynamic and efficient model to invoke Web services. Using MTOM, you can send and receive binary data optimally within a SOAP message.
- *WS-I Basic Profile V2.0* builds on top of Basic Profile V1.2 with the addition of support for SOAP 1.2.
- *WS-I Basic Security Profile V1.1* extends the WS-I Basic Security Profile V1.0 standard by profiling the latest WS-Security V1.1 specification.
- *WS-I Reliable Secure Profile 1.0* builds on WS-I Basic Profile V1.2, WS-I Basic Profile V2.0, WS-I Basic Security Profile V1.0, and WS-I Basic Security Profile V1.1 and adds support for WS-Reliable Messaging 1.1, WS-Make Connection 1.0, and WS-Secure Conversation 1.3. WS-Reliable Messaging 1.1 is a session-based protocol that provides message level reliability for Web services interactions. WS-Make Connection 1.0 was developed by the WS-Reliable Messaging workgroup to address scenarios where a Web services endpoint is behind a firewall or the endpoint has no visible endpoint reference. If a Web services endpoint loses connectivity during a reliable session, WS-Make Connection provides an efficient method to re-establish the reliable session. Additionally, WS-Secure Conversation V1.3 is a session-based security protocol that uses an efficient symmetric key based encryption algorithm for message level security. WS-I Reliable Secure Profile V1.0 provides secure reliable session-oriented Web services interactions.

Each of the technology components has requirements that you can read about in more detail at the WS-I Organization Web site. For example, support for Universal Transformation Format (UTF)-16 encoding is required by WS-I Basic Profile. UTF-16 is a kind of Unicode encoding scheme that uses 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet; UTF-16 encoding is typically used for Java and Windows product applications; and UTF-32 is used by various Linux and UNIX systems. Unlike UTF-8, UTF-16 has issues with big-endian and little-endian, and often involves Byte Order Mark (BOM) to indicate the endian. BOM is mandatory for UTF-16 encoding and it can be used in UTF-8.

The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

The following table summarizes some of the properties of each UTF:

Bytes	Encoding form
EF BB BF	UTF-8
FF FE	UTF-16, little-endian
FE FF	UTF-16, big-endian
00 00 FE FF	UTF-32, big-endian
FF FE 00 00	UTF-32, little-endian

BOM is written prior to the XML text, and it indicates to the parser how the XML is encoded. The XML declaration contains the encoding, for example: <?xml version=*xxx* encoding="utf-*xxx*"?>. BOM is used with the encoding to determine how to interpret the XML. Here is an example of a SOAP message and how BOM and UTF encoding are used:

```
POST http://www.whitemesa.net/soap12/add-test-rpc HTTP/1.1
Content-Type: application/soap+xml; charset=utf-16; action=""
SOAPAction:
Host: localhost: 8080
Content-Length: 562

0xFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
 xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString soap:encodingStyle="http://example.org/unknownEncoding"
   xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

In the example code, 0xFF0xFE represents the byte codes, while the *<?xml>* declaration is the textual representation.

Support for styleEncoding is not supported in SOAP 1.2 so here is the same example of the SOAP message but without the encoding information:

```
OxFF0xFE<?xml version="1.0" encoding="utf-16"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2002/12/soap-envelope"
   xmlns:soapenc="http://www.w3.org/2002/12/soap-encoding
 xmlns:tns="http://whitemesa.net/wsdl/soap12-test"
 xmlns:types="http://whitemesa.net/wsdl/soap12-test/encodedTypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soap:Body>
  <q1:echoString xmlns:q1="http://soapinterop.org/">
   <inputString xsi:type="xsd:string">
    Hello SOAP 1.2
   </inputString>
  </q1:echoString>
 </soap:Body>
</soap:Envelope>
```

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

WS-I Attachments Profile

The *Web Services-Interoperability (WS-I) Attachments Profile* is a set of non-proprietary Web services specifications that promote interoperability. This profile compliments the WS-I Basic Profile 1.1 to add support for interoperable SOAP messages with attachments-based Web services.

WebSphere Application Server conforms to the WS-I Attachments Profile 1.0.

Attachments are typically used to send binary data, for example, data that is mapped in Java code to java.awt.Image and javax.activation.DataHandler. The raw data can be sent in the SOAP message, however, this approach is inefficient because an XML parser has to scan the data as it parses the message.

The WS-I Attachments Profile provides a solution to the limitations that are presented by Web Services Description Language (WSDL) 1.1. Because WSDL 1.1 attachments are not part of the XML schema type space, they can be message parts only. As message parts, the attachments cannot be arrays or properties of Java beans. The profile defines the wsi:swaRef XML schema type.Use the wsi:swaRef XML schema type to overcome the limitations of WSDL 1.1 attachments.

The wsi:swaRef type is an extension of the xsd:anyURI type, where its value contains the content-ID of the attachment.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Web services migration scenarios: JAX-RPC to JAX-WS and JAXB

This topic explains scenarios for migrating your Java API for XML-based RPC (JAX-RPC) Web services to Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) Web services.

Changes in the tooling can be largely hidden from the user by a development environment like the assembly tools available with WebSphere Application Server. Also, depending on the data specified in the XML, some methods that were used for the JAX-RPC service can be used with little or no change in a JAX-WS service. There are also conditions that do require changes to be made in the JAX-WS service.

Because Java EE environments emphasize compatibility, most application servers that offer support for the newer JAX-WS and JAXB specifications continue to support the previous JAX-RPC specification. A consequence of this is that existing Web services are likely to remain JAX-RPC based while new Web services are developed using the JAX-WS and JAXB programming models.

However, as time passes and applications are revised and rewritten, there might be times when the best strategy is to migrate a JAX-RPC based Web service to one that is based on the JAX-WS and JAXB programming models. This might result from a vendor choosing to provide enhancements to qualities of service that are only available in the new programming models. For example, SOAP 1.2 and SOAP Message Transmission Optimization Mechanism (MTOM) support are only available within the JAX-WS 2.x and JAXB 2.x programming models and not JAX-RPC.

The following information includes issues that you might have while migrating from JAX-RPC to JAX-WS and JAXB.

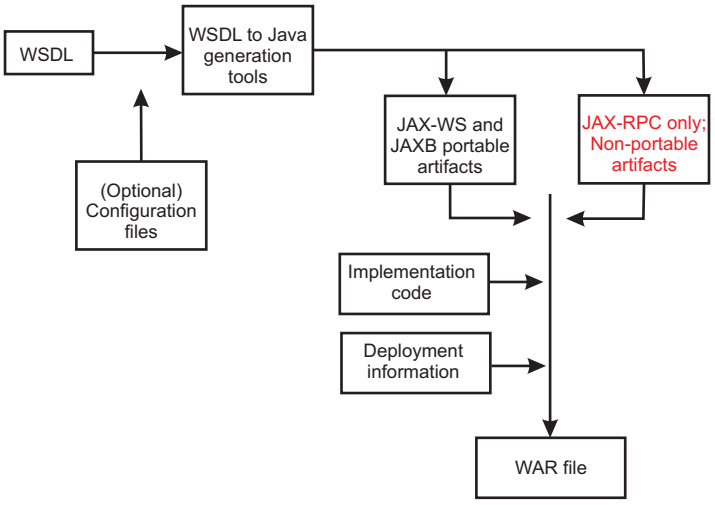
Note: When the terms *migrate*, *migrating*, and *migration* are used in this topic, unless there is some statement to indicate otherwise, the move from a JAX-RPC to a JAX-WS and JAXB environment is being described.

Comparison of JAX-RPC to JAX-WS and JAXB programming models

If you are looking for additional information that describes the changes between the JAX-RPC and JAX-WS and JAXB programming models, IBM developerWorks has published several Web services hints and tips topics.

Development models

The high level combined development models for JAX-RPC and JAX-WS and JAXB are shown the



following image:

At a high level, the models are very similar. The only difference is that the JAX-RPC model produces both portable and non-portable artifacts; the JAX-WS and JAXB model does not produce non-portable artifacts.

The image displays the following components:

- **Web Services Description Language (WSDL) file:** A document conforming to the WSDL recommendation as published by the W3C organization.
- **(Optional) Configuration files**
- **WSDL to Java generation tool:** The specifications describe the mappings required, not the name of the tools. Typically, the tool for JAX-WS and JAXB is wsimport, and for JAX-RPC the tools are wscompile and wsdeploy.
- **Portable artifacts:** These are files generated by the WSDL to Java generation tool that have well-defined mappings in the JAX-RPC or JAX-WS and JAXB, whichever is applicable, specifications. These artifacts can be used without modification between different implementations of JAX-RPC or JAX-WS and JAXB.
- **Non-portable artifacts:** These are files generated by the WSDL to Java generation tool that do not have well-defined mappings in the JAX-RPC or JAX-WS and JAXB, whichever is applicable, specifications. These artifacts generally require modification between different implementations of JAX-RPC or JAX-WS/JAXB.
- **Implementation code:** This is the code that you need to meet particular requirements for implementation.
- **Deployment information:** Additional information that is needed to run the application in a particular environment.
- **Web archive (WAR) file:** In the context of the SampleService image, a WAR file is an archive file that contains all items needed to deploy a Web service into a particular environment. This is sometimes called a *cooked WAR file*.

The Development and runtime environments

A specialized development environment simplifies Web services migration by automating many of the tasks. For development of WebSphere-based applications, including Web services, you can use the assembly tools. You can read more about the use of the assembly tools in the assembly tool information center.

The following sample code in this topic was tested in the following runtime environment:

- IBM WebSphere Application Server V6.1, which includes support for the JAX-RPC specification.
- IBM WebSphere Application Server V6.1 Feature Pack for Web Services, which includes support for the JAX-WS and JAXB specifications.

Examples

The following examples show some of the code changes that you might need to migrate your JAX-RPC Web services to JAX-WS and JAXB Web services. In particular, there is an emphasis on the changes in the implementation code that you must write, from both the client and the server side. If no new function is to be introduced, the changes required to move from JAX-RPC to JAX-WS and JAXB might be few.

Sample Web service

The first example is a sample JAX-RPC-based Web Service that was created from a WSDL file (top-down development); the same WSDL file is used to generate the JAX-WS and JAXB-based service. The WSDL file describes the Web service, SampleService, with these operations described by the following image:

As shown in the image, the five operations offered are:

- xsd:int calcShippingCost(xsd:int, xsd:int)
- xsd:string getAccountNumber(xsd:string)
- xsd:dateTime calculateShippingDate(xsd:dateTime)
- xsd:string ckAvailability(xsd:int) creates invalidDateFault
- Person findSalesRep(xsd:string)

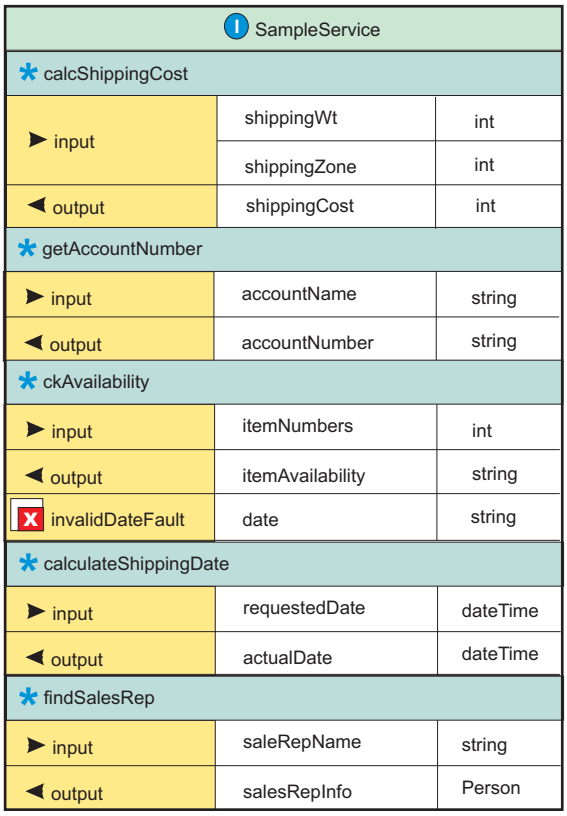
Also assume that Person is defined by the following schema fragment in the WSDL file:

```
<complexType name="Person">
 <sequence>
  <element name="name" type="xsd:string"/>
  <element name="age" type="xsd:int"/>
  <element name="location" type="impl:Address/>
 </sequence>
</complexType>
```

Address is defined by:

```
<complexType name="Address">
 <sequence>
  <element name="street" type="xsd:string"/>
  <element name="city" type="xsd:string"/>
  <element name ="state" type="xsd:string"/>
  <element name="zip" type="xsd:int"/>
 </sequence>
</complexType>
```

The following image also shows that the operation, ckAvailability(xsd:int), which produces an invalidDateFault exception.



Service operations

Review the service code created by the tooling. The following information includes examining what is created for a JAX-RPC runtime and also for a JAX-WS and JAXB runtime.

JAX-RPC

For JAX-RPC, the tooling accepts the WSDL file as input, and, amongst other files, generates the SampleService.java and SampleServiceImpl.java interfaces. The SampleService.java interface defines an interface and the generated code can be review in the following code block. The SampleServiceSoapBindingImpl.java interface provides the skeleton of an implementation, and you typically modify to add your own logic.

JAX-RPC version of SampleService.java:

```
/**
* SampleService.java
*
* This file was auto-generated from WSDL  * by the IBM Web services WSDL2Java emitter.  * cf20633.22 v82906122346
*/
package simple;
public interface SampleService extends java.rmi.Remote {
 public java.lang.Integer calcShippingCost(java.lang.Integer shippingWt,
  java.lang.Integer shippingZone) throws java.rmi.RemoteException;
 public java.lang.String getAccountNumber(java.lang.String accountName)
  throws java.rmi.RemoteException;
 public java.lang.String[] ckAvailability(int[] itemNumbers)
  throws java.rmi.RemoteException, simple.InvalidDateFault;
 public java.util.Calendar calculateShippingDate(
  java.util.Calendar requestedDate)
  throws java.rmi.RemoteException;
 public simple.Person findSalesRep(java.lang.String saleRepName)
  throws java.rmi.RemoteException; }
```

JAX-WS and JAXB

For JAX-WS and JAXB, the tooling accepts the WSDL file as input, and as in the case of JAX-RPC, generates SampleService.java and SampleServiceImpl.java interfaces. As with JAX-RPC, the SampleService.java interface also defines an interface as shown in the following code block. The SampleServiceImpl.java interface provides the skeleton of an implementation, and you typically modify to add your own logic.

Note: The code has been annotated by the tooling.
JAX-WS and JAXB version of the SampleService.java interface:

```
package simple;
 import java.util.List;
 import javax.jws.WebMethod;
 import javax.jws.WebParam;
 import javax.jws.WebResult;
 import javax.jws.WebService;
 import javax.xml.datatype.XMLGregorianCalendar;
 import javax.xml.ws.RequestWrapper;
 import javax.xml.ws.ResponseWrapper;

/**
* This class was generated by the JAX-WS SI.  * JAX-WS RI IBM 2.0_03-06/12/2007 07:44 PM(Raja)-fcs  *
Generated source version: 2.0
*
*/
@WebService(name = "SampleService", targetNamespace = "http://simple") public interface SampleService {

 /**
 *
 * @param shippingWt
 * @param shippingZone
 * @return
 * returns java.lang.Integer
 */
 @WebMethod
 @WebResult(name = "shippingCost", targetNamespace = "")
 @RequestWrapper(localName = "calcShippingCost", targetNamespace = "http://simple",
className = "simple.CalcShippingCost")
 @ResponseWrapper(localName = "calcShippingCostResponse", targetNamespace = "http://simple",
className = "simple.CalcShippingCostResponse")
 public Integer calcShippingCost(
 @WebParam(name = "shippingWt", targetNamespace = "")
 Integer shippingWt,
 @WebParam(name = "shippingZone", targetNamespace = "")
 Integer shippingZone);

 /**
 *
 *
 @param accountName
 * @return
 *     returns java.lang.String
 */
 @WebMethod
 @WebResult(name = "accountNumber", targetNamespace = "")
 @RequestWrapper(localName = "getAccountNumber", targetNamespace = "http://simple",
className = "simple.GetAccountNumber")
 @ResponseWrapper(localName = "getAccountNumberResponse", targetNamespace = "http://simple",
className = "simple.GetAccountNumberResponse")
 public String getAccountNumber(
  @WebParam(name = "accountName", targetNamespace = "")
  String accountName);
 /**
 *
 * @param requestedDate
 * @return
 *     returns javax.xml.datatype.XMLGregorianCalendar
 */
 @WebMethod
 @WebResult(name = "actualDate", targetNamespace = "")
 @RequestWrapper(localName = "calculateShippingDate", targetNamespace = "http://simple",
className = "simple.CalculateShippingDate")
 @ResponseWrapper(localName = "calculateShippingDateResponse", targetNamespace = "http://simple",
className = "simple.CalculateShippingDateResponse")
```

```
 public XMLGregorianCalendar calculateShippingDate(
  @WebParam(name = "requestedDate", targetNamespace = "")
  XMLGregorianCalendar requestedDate);
 /**
 *
 * @param itemNumbers
 * @return
 *     returns java.util.List<java.lang.String>
 * @throws InvalidDateFault_Exception
 */
 @WebMethod
 @WebResult(name = "itemAvailability", targetNamespace = "")
 @RequestWrapper(localName = "ckAvailability", targetNamespace = "http://simple", className = "simple.CkAvailability")
 @ResponseWrapper(localName = "ckAvailabilityResponse", targetNamespace = "http://simple",
className = "simple.CkAvailabilityResponse")
 public List<String> ckAvailability(
  @WebParam(name = "itemNumbers", targetNamespace = "")
  List<Integer> itemNumbers)
  throws InvalidDateFault_Exception
 ;
 /**
 *
 * @param saleRepName
 * @return
 *     returns simple.Person
 */
 @WebMethod
 @WebResult(name = "salesRepInfo", targetNamespace = "")
 @RequestWrapper(localName = "findSalesRep", targetNamespace = "http://simple", className = "simple.FindSalesRep")
 @ResponseWrapper(localName = "findSalesRepResponse", targetNamespace = "http://simple",
className = "simple.FindSalesRepResponse")
 public Person findSalesRep(
 @WebParam(name = "saleRepName", targetNamespace = "")
 String saleRepName);

}
```

Comparing the code examples

At first glance, it might seem that there is little similarity between the interfaces. If you disregard the additional information added by the annotations for JAX-WS and JAXB, the code samples are similar. For example, the calcShippingCost method in the JAX-WS and JAXB version the following lines of code exist:

```
@WebMethod
 @WebResult(name = "shippingCost", targetNamespace = "")
 @RequestWrapper(localName = "calcShippingCost", targetNamespace = "http://simple",
className = "simple.CalcShippingCost")
 @ResponseWrapper(localName = "calcShippingCostResponse", targetNamespace = "http://simple",
className = "simple.CalcShippingCostResponse")
 public Integer calcShippingCost(
  @WebParam(name = "shippingWt", targetNamespace = "")
  Integer shippingWt,
  @WebParam(name = "shippingZone", targetNamespace = "")
  Integer shippingZone);
```

But, if you discard the annotations, the following lines of code are:

```
public Integer calcShippingCost(
        Integer shippingWt,
        Integer shippingZone);
```

These lines are almost identical to what was generated for JAX-RPC. The only difference is that the JAX-RPC code can produce the java.rmi.RemoteException error as follows:

```
public java.lang.Integer calcShippingCost(java.lang.Integer shippingWt,
   java.lang.Integer shippingZone) throws java.rmi.RemoteException;
```

Following this logic, three of the methods have essentially the same signatures:

```
public Integer calcShippingCost(Integer shippingWt, Integer shippingZone)
 public String getAccountNumber(String accountName)
 public Person findSalesRep(String saleRepName)
```

This means that migrating from JAX-RPC to JAX-WS does not directly affect these methods and the original implementation code that is successfully running in the JAX-RPC based environment can probably be used without modification for these methods.

However two of the methods do have different signatures:

For JAX-RPC:

```
public java.util.Calendar calculateShippingDate(
 java.util.Calendar requestedDate)
public java.lang.String[] ckAvailability(int[] itemNumbers)
 throws java.rmi.RemoteException,
 simple.InvalidDateFault
```

JAX-WS and JAXB:

```
public XMLGregorianCalendar calculateShippingDate(
 XMLGregorianCalendar requestedDate)
public List<String> ckAvailability(List<Integer> itemNumbers)
 throws InvalidDateFault_Exception
```

Note:

You might find it easier to compare the skeleton implementation files since the annotations are not present in SampleServiceImpl.java.:

- SampleServiceSoapBindingImpl.java
- SampleServiceImpl.java

The differences in signatures are due to the following reasons:

- Differences mappings from XML names to Java names

  For the calculateShippingDate method, both the input parameter and the return parameter have changed from type java.util.Calendar to type XMLGregorianCalendar. This is because the WSDL specified these parameters to be of type, xsd:dateTime, JAX-RPC maps this data type to java.util.Calendar, while JAX-WS and JAXB maps it to XMLGregorianCalendar.
- Different mappings of arrays from XML to Java

  For the ckAvailability method, the change is due to the data mappings for XML arrays.

  JAX-RPC maps the following WSDL elements:

  ```
  <element maxOccurs="unbounded" name="itemNumbers" type="xsd:int"/>
  <element maxOccurs="unbounded" name="itemAvailability" type="xsd:string"/>
  ```

  The previous elements are mapped to the following Java source:

  ```
  int[] itemNumbers
  java.lang.String[] itemAvailability
  ```

  JAX-WS and JAXB map the following WSDL elements:

  ```
  List<Integer> itemNumbers
  List<String> ckAvailability
  ```
- Different mappings of exceptions

  For the ckAvailability method, the JAX-RPC code generated the following error:

  ```
  simple.InvalidDateFault
  ```

  The JAX-WS code generates the following error:

  ```
  InvalidDateFault_Exception
  ```

  Except for the names, the constructors for these exceptions are different. Therefore, the actual JAX-RPC code that produces the error might be displayed as:

```
throw new InvalidDateFault("this is an InvalidDateFault");
```

For JAX-WS, the code uses a command similar to the following example::

```
throw new InvalidDateFault_Exception( "this is an InvalidDateFault_Exception", new InvalidDateFault());
```

In cases that use exceptions, the code that uses it needs to change.

Migrating the code

Now that the differences between code have been explained, review the original code for the methods that need changing and how to change this code so that it works in a JAX-WS and JAXB environment.

Assume that the original (JAX-RPC) implementation code is similar to following:

```
public java.util.Calendar calculateShippingDate(
     java.util.Calendar requestedDate) throws java.rmi.RemoteException {
// Set the date to the date that was sent to us and add 7 days.
requestedDate.add(java.util.Calendar.DAY_OF_MONTH, 7);

// . . .

return requestedDate;
}
```

You can write the new code to directly use the new types as in the following examples:

```
public XMLGregorianCalendar calculateShippingDate(
XMLGregorianCalendar requestedDate) {
try {
// Create a data type factory.
DatatypeFactory df = DatatypeFactory.newInstance();
// Set the date to the date that was sent to us and add 7 days.
Duration duration = df.newDuration("P7D");
requestedDate.add(duration);

} catch (DatatypeConfigurationException e) {
// TODO Auto-generated catch block
e.printStackTrace();
}

// . . .

return requestedDate;
}
```

Migrating the code for the ckAvailability method

When migrating the code for the ckAvailability method, changes were required because of the way that arrays and exceptions are mapped from XML is different between JAX-RPC and JAX-WS. Assume that the original JAX-RPC Web service code is similar to the following example:

```
public java.lang.String[] ckAvailability(int[] itemNumbers)
{

    String[] myString = new String[itemNumbers.length];
    for (int j = 0; j < myString.length; j++) {

            . . .
             if ( ... )

    throw new simple.InvalidDateFault("InvalidDateFault");

            . . .
            if ( . . .)
               myString[j] = "available:  " + jitemNumbers[j] ;
```

```
            else
               myString[j] = "not available:  " + jitemNumbers[j];

    }
    return myString;
}
```

The previous code accepts an int[] as input and returns a String[]. For the JAX-WS and JAXB version, these are List<Integer> and List<String> elements respectively. Processing for these arrays, and discarding the Exception code, the JAX-RPC code is similar to the following:

```
public java.lang.String[] ckAvailability(int[] itemNumbers)
{

    String[] myString = new String[itemNumbers.length];
    for (int j = 0; j < jitemNumbers.length; j++) {

            . . .
            if ( . . .)
               myString[j] = "available:  " + itemNumbers.get(j);
            else
               myString[j] = "not available:  " + itemNumbers.get(j);
    }
    return myString;
}
```

The following JAX-WS and JAXB equivalent code exists using Lists instead of arrays:

```
List <String> ckAvailability(List <Integer> itemNumbers)
{

    ArrayList<String> retList = new ArrayList<String>();
    for (int count = 0; count < itemNumbers.size(); count++) {

            . . .
            if ( . . .)
               retList.add("available:  " + itemNumbers.get(j));
            else
               retList.add("not available:  " + itemNumbers.get(j));
    }
    return retList;
}
```

The differences in the mappings of exceptions from XML to Java forces the JAX-WS code to use. InvalidDateFault_Exception instead of InvalidDateFault.

This means that you must replace `throw new simple.InvalidDateFault("InvalidDateFault");` with some other code. Therefore, the following line is used for the new code:

```
throw new InvalidDateFault_Exception( "test InvalidDateFault_Exception", new InvalidDateFault());
```

The final JAX-WS and JAXB implementation of the method might be similar to the following code:

```
List <String> ckAvailability(List <Integer> itemNumbers)
{

    ArrayList<String> retList = new ArrayList<String>();
    for (int count = 0; count < itemNumbers.size(); count++) {

if ( . . . ) {
   throw new InvalidDateFault_Exception(
   "test InvalidDateFault_Exception",
   new InvalidDateFault());
}
```

```
. . .
if ( . . .)
   retList.add("available:  " + itemNumbers.get(count));
else
   retList.add("not available:  " + itemNumbers.get(count));
   }
   return retList;
}
```

There are multiple ways that you might choose to migrate the code. With practice and an effective development environment, migrating from JAX-RPC to JAX-WS can be straightforward.

Web services migration best practices

Use these Web services migration best practices when migrating Web services applications.

If you have used the Apache SOAP support to develop Web services client applications in WebSphere Application Server Versions 4, 5, or 5.1, you might need to migrate your applications or the security files for your applications. The following table summarizes the Web services specifications supported by the WebSphere products.

WebSphere Application Server Version	Web services specifications supported
4.0	Apache SOAP 2.2
5.0 and 5.0.1	Apache SOAP 2.3
5.0.2 or later	Java 2 Platform, Enterprise Edition (J2EE), also known as (JSR 109)
6.0.x and 6.1	J2EE (JSR 109)
7.0 or later	Web Services for Java Platform, Enterprise Edition (Java EE) 5 also known as JSR 109

Note: The Apache SOAP 2.2 and Apache SOAP 2.3-based implementations that were available in WebSphere Application Server Version 4.0.*x*, 5.0 and 5.0.1 have been deprecated. It is recommended that applications that are using these SOAP implementations migrate to Web Services for Java EE (JSR 109) support that is provided in current WebSphere Application Server versions.

For more information on migrating your Web services, see Migrating Apache SOAP Web services to Web Services to J2EE standards .

It is recommended that new Web services be developed using the Web services for Java EE specification. For more information, read about implementing Web services applications.

Security cannot be directly migrated from SOAP 2.3 to the Java EE standards. After you have migrated your Web services to the Java EE standards, read about securing Web services for Version 6 applications based on WS-Security.

Follow these best practices for the most optimal migration experience:

The application server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model.

Note: Existing JAX-RPC applications wanting to use JAX-WS features must be rewritten using the JAX-WS programming model.

Redeploy existing JAX-RPC Web services after migrating to a new release of the application server

When migrating to a new release of the application server, it is recommended that you redeploy your Web services applications. You should redeploy your Web services application in the new application server environment because of possible changes to the supported levels of Web services specifications and Web services deployment descriptors in each release. To redeploy your Web service, select **Deploy Web Services** in the Install New Application wizard or use the wsdeploy command. To learn more about this process, see the deploying Web services applications onto application servers documentation.

Migrating a Version 5 Java API for XML-based remote procedure call (JAX-RPC) client that uses SOAP over Java Message Service (JMS) to invoke a Web service

A JAX-RPC client that is run on WebSphere Application Server Version 5, can use SOAP over JMS to invoke a Web service that is run on a Version 5 Application Server.

A user ID and password are not required on the target WebSphere MQ queue. After the application server is migrated to Version 6.*x*, and uses the Version 6.*x* default messaging feature, client requests can fail because basic authentication is enabled. The following error message displays when this migration problem occurs:

```
SibMessage W [:] CWSIT0009W: A client request failed in the application server with
endpoint <endpoint name> in bus <bus_name> with reason: CWSIT0016E: The user
ID null failed authentication in bus <bus_name>.
```

When the application server is migrated to Version 6.*x*, and the default messaging provider (service integration technologies) is used, and administrative and application security is enabled for the server or the cell, the service integration bus queue destination inherits the security characteristics of the server or the cell by default. If the server or the cell has basic authentication enabled, the client request fails.

The following options are available to solve this problem. The solutions are listed by the level of security that they impose:

- Disable administrative and application security on the main security panel within the administrative console. To disable administrative and application security, click **Security > Global security**. Deselect the **Enable administrative security** and **Enable application security** options.
- Modify the settings for the service integration bus that hosts the queue destination so that the bus security is disabled and the bus does not inherit security characteristics from the server or the cell. This option is equivalent to the level of security that you can configure in Version 5.
- Configure the basic authentication on each client that uses the service.

Migrating Apache SOAP Web services

See Migrating Apache SOAP Web services to Web Services for J2EE standards to learn how to migrate Apache SOAP Web services. This topic explains how to migrate Web services that were developed using Apache SOAP to Web services that are developed based on the Web Services for Java 2 Platform, Enterprise Edition (J2EE) specification.

Migrating Web services assembled with early versions of the Application Server Toolkit or Assembly Toolkit

If you are migrating your Web service or Web service components from earlier versions of the Application Server Toolkit or Assembly Toolkit, refer to the following hints and tips to improve your success:

- Secure Web services are not migrated by the J2EE Migration Wizard when Web services are migrated from J2EE 1.3 to J2EE 1.4.
- The migration of secure Web services requires manual steps.

- After the J2EE migration, the secure binding and extension files must be migrated manually to J2EE 1.4 as follows:
  1. Double click on the `webservices.xml` file to open the Web Services editor.
  2. Select the **Binding Configurations** tab to edit the binding file.
  3. Add all the necessary binding configurations under the new sections **Request Consumer Binding Configuration Details** and **Response Generator Binding Configuration Details**.
  4. Select the **Extension** tab to edit the extension file.
  5. Add all the necessary extension configurations under the new sections **Request Consumer Service Configuration Details** and **Response Generator Service Configuration Details**.
  6. Save and exit the editor.

.

WebSphere Application Server roles and goals

A description of several computing roles that members of your organization might perform when working with WebSphere Application Server.

Enterprise architect

The enterprise architect provides overall leadership for all architectural and technological matters with respect to the company's IT environment.

Solution architect

The solution architect designs and coordinates a new solution, application or component with end-to-end responsibility including both hardware and software elements.

The main goal of the solution architect is to design a solution that supports the specification set by the enterprise architect.

System administrator

The system administrator is responsible for managing systems and software, and for installing operating system upgrades and middleware products in many accounts.

The system administrator installs and configures appropriate hardware and software (including middleware) to implement the design provided by the solution architect. Additionally the system administrator monitors and maintains the configured system, modifying and removing previously configured objects as and when required.

Application developer

The application developer creates business applications.

The goal of the application developer is to develop applications that provide the business services described by the solution architect.

Planning to use Web services

You can plan to develop and implement Web services based on a variety of Java programming models.

Before you begin

Read the Web services scenario: Overview to learn about the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporated the Web services concept. You can also review the Samples Gallery for Web services Samples. These Samples demonstrate enterprise beans and JavaBeans components that are available as Web services.

The Samples Gallery includes Samples that demonstrate JAX-WS-based Web services. The JAX-WS Web services Samples demonstrate the simple message exchange patterns using both synchronous and asynchronous invocation of Web services in SOAP 1.1 and SOAP 1.2 environments. The Samples are composed with Web service standards such as WS-Addressing (WS-A) , WS-Reliable Messaging (WS-RM), and WS-Secure Conversation (WS-SC), which you can use to complete a broad range of interoperability tests. The samples demonstrate the use of JavaBeans artifacts and static service endpoints and proxy-based clients. Additionally, a Sample is provided that demonstrates Message Transmission Optimization Mechanism (MTOM).

About this task

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.
You must re-write existing JAX-RPC applications if you want to take advantage of the features of the JAX-WS programming model.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, Web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

1. Identify your goals and design Web services to fit your e-business solution. Consider what you want to accomplish by using Web services. Decide how Web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the Web service.
2. Design your Web services for reliability, availability, manageability and security. For example, you want your Web services to process a transaction in a reasonable time at all hours of the day and provide users with optimal security, such as authentication for buyers. Planning to use Web services to work with WebSphere Application Server helps to meet these requirements.
3. Review the standards used in developing and deploying Web services onto WebSphere Application Server. Development and deployment are based on a variety of Java programming models.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing Web service to implement or you want to develop your own from a JavaBeans implementation or from an Enterprise JavaBeans (EJB) module, you can choose different tasks respective to your resources. You can also use assembly tools to complete development and implementation tasks.
5. Install the application server. For detailed information on installing the application server, read about installing your application serving environment.
6. Review Web services Samples.

Results

You have a design plan for implementing Web services applications into your business architecture.

Developing Web services applications with JAX-WS

You can use the Java API for XML-Based Web Services (JAX-WS) programming model to develop Web services.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

About this task

To develop Web services based on the JAX-WS programming model, you can use a bottom-up development approach starting from existing JavaBeans or enterprise beans or you can use a top-down development approach starting with an existing Web Services Description Language (WSDL) file. This task describes the steps when using the bottom-up development approach.

When developing JAX-WS Web services starting from existing JavaBeans or enterprise beans, you can expose the bean as a JAX-WS Web service by using annotations. Adding the @WebService or @WebServiceProvider annotation to the bean defines the bean as a JAX-WS Web service. JAX-WS Web services can optionally use a service endpoint interface. In addition to annotating the bean and the optional service endpoint interface, you must assemble all the artifacts that the Web service requires, and deploy the resulting application into the application server environment to complete the process of enabling the bean as a Web service. Although the use of a WSDL file is considered a best practice, you are not required to package a WSDL file with your JAX-WS Web services.

Considerations when using JavaBeans

JavaBeans exposed as JAX-WS Web services are supported only over an HTTP transport.

Considerations when using enterprise beans

- The enterprise bean must be a stateless session bean.
- Enterprise beans that are exposed as JAX-WS Web services must be packaged in EJB 3.0 or higher modules.
- JAX-WS applications containing enterprise beans must be deployed with the endptEnabler command.
- JAX-WS Web services using enterprise beans are supported over an HTTP or Java Message Service (JMS) transport.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property,

com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

1. Set up a development environment for Web services. You do not have to set up a development environment if you are using Rational Application Developer.
2. Determine the existing JavaBeans or enterprise beans that you want to expose as a JAX-WS Web service.
3. Develop a JAX-WS service endpoint implementation with annotations.
4. Generate Java artifacts for JAX-WS applications.

   Use JAX-WS tooling to generate the necessary JAX-WS and JAXB artifacts needed for JAX-WS Web services applications when starting from JavaBeans or enterprise beans components.

   If you are developing a service implementation bean that is invoked using the HTTP transport, then the WSDL file generated by the wsgen command-line tool during this step is optional. However, if you are developing a service implementation bean that is invoked using the SOAP over JMS transport, then the WSDL file generated by the wsgen tool during this step is required in subsequent steps, and therefore, not optional.
5. (optional) Enable MTOM for JAX-WS Web services. You can use SOAP Message Transmission Optimization Mechanism (MTOM) to optimize the transmission of binary attachments, such as images or files along with Web services requests.
6. (optional) Develop and configure a webservices.xml deployment descriptor for JAX-WS applications . You can optionally use the webservices.xml deployment descriptor to augment or override application metadata that is specified in annotations within your JAX-WS Web services.
7. Complete the implementation of your Web services application.
   - For JavaBeans applications, complete the JavaBeans implementation.
   - For enterprise beans applications, complete the enterprise beans implementation.
8. (Optional) Customize URL patterns in the web.xml file. When JavaBeans are exposed as JAX-WS endpoints, you can optionally customize the URL patterns within the web.xml deployment descriptor contained in the Web archive (WAR) file.
9. Assemble the artifacts for your Web service.

   Use assembly tools provided with the application server to assemble your Java-based Web services modules.

   If you have assembled an EAR file that contains enterprise beans modules that include Web services, use the endptEnabler command-line tool or an assembly tool before deployment to produce a Web services endpoint WAR file. This tool is also used to specify whether the Web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
10. Deploy the EAR file into the application server. You can now deploy the EAR file that has been configured and enabled for JAX-WS Web services onto the application server.

Results

You have developed a JAX-WS application.

What to do next

After you deploy the EAR file, test the Web service to make sure that the service works with the application server.

Setting up a development environment for Web services

The application server provides command-line tools to develop Web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing Web services.

Before you begin

Before you can set up a Web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a Web services development environment by completing the following actions.

1. Set up the environment.
   Run the **setupCmdLine** script from the */profile_root/<application_server>/bin* directory.
2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:
   ```
   set PATH=%WAS_PATH%;%PATH%
   ```

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement Web services applications. This topic is a good starting point in learning about how to develop and implement a Java EE Web service.

Developing a JAX-WS service endpoint implementation with annotations

Java API for XML-Based Web Services (JAX-WS) supports two different service endpoint implementations types, the standard Web service endpoint interface and a new Provider interface to enable services to work at the XML message level. By using annotations on the service endpoint implementation or client, you can define the service endpoint as a Web service.

Before you begin

Set up a development environment for Web services.

About this task

This task is a required step to develop a JAX-WS Web service.

When developing a JAX-WS Web service starting from existing JavaBeans or enterprise beans, you can expose the bean as a JAX-WS Web service by using annotations. Adding the @WebService or @WebServiceProvider annotation to the bean defines the bean as a JAX-WS Web service.

JAX-WS technology enables the implementation of Web services based on both the standard service endpoint interface and a new Provider interface. JAX-WS service endpoints are similar to the endpoint implementations in the Java API for XML-based RPC (JAX-RPC) specification. Unlike JAX-RPC, the requirement for a service endpoint interface (SEI) is optional for JAX-WS Web services. JAX-WS services that do not have an associated SEI are regarded as having an implicit SEI, whereas services that have an associated SEI are regarded as having an explicit SEI. The service endpoint interfaces required by JAX-WS are also more generic than the service endpoint interfaces required by JAX-RPC. With JAX-WS, the SEI is not required to extend the `java.rmi.Remote` interface as required by the JAX-RPC specification.

The JAX-WS programming model also leverages support for annotating Java classes with metadata to define a service endpoint implementation as a Web service and define how a client can access the Web service. JAX-WS supports annotations based on the Metadata Facility for the Java Programming

Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 (JSR 224) specification, which includes Java Architecture for XML Binding (JAXB) annotations. Using annotations, the service endpoint implementation can independently describe the Web service without requiring a WSDL file. Annotations can provide all of the WSDL information necessary to configure your service endpoint implementation or Web services client. You can specify annotations on the service endpoint interface used by the client and the server, or on the server-side service implementation class.

To develop a JAX-WS Web service, you must annotate your Java class with the `javax.jws.WebService` annotation for JavaBeans or enterprise beans endpoints or the `javax.jws.WebServiceProvider` annotation for a Provider endpoint. These annotations define the Java class as a Web service endpoint. For a JAX-WS service endpoint, the service endpoint interface or service endpoint implementation is a Java interface or class, respectively, that declares the business methods provided by a particular Web service. The only methods on a JAX-WS service endpoint that can be invoked by a Web services client are the business methods that are defined in the explicit or implicit service endpoint interface.

All JAX-WS service endpoints are required to have the @WebService (`javax.jws.WebService`) annotation included on the bean class. If the service implementation bean also uses an SEI, then that endpoint interface must be referenced by the `endpointInterface` attribute on that annotation. If the service implementation bean does not use an SEI, then the service is described by the implicit SEI defined in the bean.

The JAX-WS programming model introduces the new Provider API, `javax.xml.ws.Provider`, as an alternative to service endpoint interfaces. The Provider interface supports a more messaging oriented approach to Web services. With the Provider interface, you can create a Java class that implements a simple interface to produce a generic service implementation class. The Provider interface has one method, the `invoke` method, which uses generics to control both the input and output types when working with various messages or message payloads. All Provider endpoints must be annotated with the @WebServiceProvider (`javax.xml.ws.WebServiceProvider`) annotation. A service implementation cannot specify the @WebService annotation if it implements the `javax.xml.ws.Provider` interface.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

1. Identify your service endpoint requirements for your Web services application.

   First determine if the service implementation is a standard JAX-WS service endpoint or a Provider endpoint. If you choose to use a JAX-WS service endpoint, then determine if you want to use an explicit SEI or if the bean has an implicit SEI.

2. Annotate the service endpoints. A Java class that implements a Web service must specify either the `javax.jws.WebService` or `javax.xml.ws.WebServiceProvider` annotation. Both annotations must not be present on a Java class. The `javax.xml.ws.WebServiceProvider` annotation is only supported on classes that implement the `javax.xml.ws.Provider` interface.
   - If you have an explicit service endpoint interface with the Java class, then use the endpointInterface parameter to specify the service endpoint interface class name in the `javax.jws.WebService` annotation. You can add the @WebMethod annotation to methods of a service endpoint interface to customize the Java-to-WSDL mappings. All public methods are considered exposed methods

regardless of whether the @WebMethod annotation is specified. It is incorrect to have an @WebMethod annotation on an service endpoint interface that contains the `exclude` attribute.

- If you have an implicit service endpoint interface and the @WebMethod annotation is not specified, all public methods are exposed including the inherited methods of parent classes that are also annotated with @WebService annotations. You can use the `exclude` parameter of the @WebMethod annotation to control which methods are exposed.
- If your Web service implementation class implements the Provider interface, use the `javax.xml.ws.WebServiceProvider` annotation on the Provider endpoint.

Results

You have defined the service endpoint implementation that represents the Web services application. See the JAX-WS annotations documentation to learn more about the supported JAX-WS annotations.

Example

Sample JavaBeans service endpoint implementation and interface

The following example illustrates a simple explicit JavaBeans service endpoint implementation and the associated service endpoint interface.

```
/** This is an excerpt from the service implementation file, EchoServicePortTypeImpl.java
package com.ibm.was.wssample.echo;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Marshaller;
import javax.xml.bind.Unmarshaller;
import javax.xml.transform.stream.StreamSource;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType", targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")
public class EchoServicePortTypeImpl implements EchoServicePortType {

                public EchoServicePortTypeImpl() {
                }

                public String invoke(String obj) {
                        String str;
                        ....
                        str = obj;
                        ....

                        return str;

                }

}
/**  This is a sample EchoServicePortType.java service interface */

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.*;

@WebService(name = "EchoServicePortType", targetNamespace = "http://com/ibm/was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")
public interface EchoServicePortType {
```

```
    /** ...the method process ...*/
        @WebMethod
    @WebResult(name = "response", targetNamespace = "http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace = "http://com/ibm/was/wssample/echo/",
className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse", targetNamespace =
"http://com/ibm/was/wssample/echo/", className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace = "http://com/ibm/was/wssample/echo/")
        String arg0);

}
```

Sample Provider endpoint implementation

The following example illustrates a simple Provider service endpoint interface for a Java class.

```
package jaxws.provider.source;

import javax.xml.ws.Provider;
import javax.xml.ws.WebServiceProvider;
import javax.xml.transform.Source;

@WebServiceProvider()
public class SourceProvider implements Provider<Source> {

    public Source invoke(Source data) {
        return data;
    }
}
```

In the Provider implementation example, the `javax.xml.transform.Source` type is specified in the generic `<Source>` method. The generic `<Source>` method specifies that both the input and output types are `Source` objects. An endpoint interface that implements the Provider interface must include a `@WebServiceProvider` annotation.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans.

Generating Java artifacts for JAX-WS applications

Use Java API for XML-Based Web Services (JAX-WS) tools to generate the necessary JAX-WS and Java Architecture for XML Binding (JAXB) Java artifacts that are needed for JAX-WS Web services applications when starting from JavaBeans or enterprise beans components.

Before you begin

To develop a Java API for XML-Based Web Services (JAX-WS) Web service application, you must first develop a service endpoint interface (SEI) implementation that explicitly or implicitly describes the SEI.

About this task

When using a bottom-up approach to develop JAX-WS Web services, use the wsgen command-line tool on the existing service endpoint implementation. The wsgen tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a Web Services Description Language (WSDL) file if the optional *-wsdl* argument is specified.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

You are not required to develop a WSDL file when developing JAX-WS Web services using the bottom-up approach of starting with JavaBeans. The use of annotations provides all of the WSDL information necessary to configure the service endpoint or the client. The application server supports WSDL 1.1 documents that comply with Web Services-Interoperability (WS-I) Basic Profile 1.1 specifications and are either Document/Literal style documents or RPC/Literal style documents. Additionally, WSDL documents with bindings that declare a `USE` attribute of value `LITERAL` are supported while the value, `ENCODED`, is not supported. For WSDL documents that implement a Document/Literal wrapped pattern, a root element is declared in the XML schema and is used as an operation wrapper for a message flow. Separate wrapper element definitions exist for both the request and the response.

To ensure the wsgen command does not miss inherited methods on a service endpoint implementation bean, you must either add the @WebService annotation to the desired superclass or you can override the inherited method in the implementation class with a call to the superclass method. Implementation classes only expose methods from superclasses that are annotated with the @WebService annotation.

Although a WSDL file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. If you are developing an enterprise JavaBeans service implementation bean that is invoked using the SOAP over JMS transport, and you want to publish the WSDL so that the published WSDL file contains the fully resolved JMS endpoint URL, then have wsgen tool generate the WSDL file by specifying the *-wsdl* argument. In this scenario, you must package the WSDL file with your Web service application.

1. Locate your service endpoint implementation class file.
2. Run the wsgen command to generate the portable artifacts. The wsgen tool is located in the *app_server_root*\bin\ directory.

   (Optional) Use the following options with the wsgen command:

   - Use the **-verbose** option to see a list of generated files along with additional informational messages.
   - Use the **-keep** option to keep generated Java files.
   - Use the **-wsdl** option to generate a WSDL file. If you are developing a service implementation bean that will be invoked using the HTTP transport, then the WSDL file generated by the wsgen command-line tool during this step is optional. However, if you are developing a service implementation bean that will be invoked using the SOAP over JMS transport, then the WSDL file generated by the wsgen tool during this step is required in subsequent developing JAX-WS applications steps, so it is not optional.

   Read about wsgen to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS Web service.

Note: The wsgen command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Example

The following example demonstrates how to use the wsgen command to process the service endpoint implementation class to generate JAX-WS artifacts. This example EchoService service implementation class uses an explicit JavaBeans service endpoint.

1. Copy the sample `EchoServicePortTypeImpl` service implementation class file and the associated `EchoServicePortType` service interface class file into a directory. The directory must contain a directory tree structure that corresponds to the `com.ibm.was.wssample.echo` package name for the class file.

```
/* This is a sample EchoServicePortTypeImpl.java file.    */
package com.ibm.was.wssample.echo;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType",
targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")

public class EchoServicePortTypeImpl implements EchoServicePortType {

 public EchoServicePortTypeImpl() {
 }

 public String invoke(String obj) {
  System.out.println(">> JAXB Provider Service:
Request received.\n");
  String str = "Failed";
  if (obj != null) {
   try {
    str = obj;
   } catch (Exception e) {
    e.printStackTrace();
   }
  }
  return str;

 }

}
```

```
/* This is a sample EchoServicePortType.java file.    */
package com.ibm.was.wssample.echo;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;

@WebService(name = "EchoServicePortType", targetNamespace =
"http://com/ibm/was/wssample/echo/",
 wsdlLocation="WEB-INF/wsdl/Echo.wsdl")

public interface EchoServicePortType {

    /**
     *
     * @param arg0
     * @return
```

```
     *     returns java.lang.String
     */
    @WebMethod
    @WebResult(name = "response", targetNamespace =
    "http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace =
    "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse",
     targetNamespace = "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace =
        "http://com/ibm/was/wssample/echo/")
        String arg0);

}
```

2. Run the wsgen command from the *app_server_root*\bin\ directory. The `-cp` option specifies the location of the service implementation class file. The `-s` option specifies the directory for the generated source files. The `-d` option specifies the directory for the generated output files. When using the `-s` or `-d` options, you must first create the directory for the generated output files.

After generating the Java artifacts using the wsgen command, the following files are generated:

```
/generated_source/com/ibm/was/wssample/echo/EchoStringResponse.java
/generated_source/com/ibm/was/wssample/echo/Invoke.java
/generated_artifacts/EchoService.wsdl
/generated_artifacts/EchoService_schema1.xsd
/generated_artifacts/com/ibm/was/wssample/echo/EchoStringResponse.class
/generated_artifacts/com/ibm/was/wssample/echo/Invoke.class
```

The EchoStringResponse.java and Invoke.java files are the generated Java class files. The compiled versions of the generated Java files are EchoStringResponse.class and Invoke.class files. The EchoService.wsdl and EchoService_schema1.xsd files are generated because the -wsdl option was specified.

What to do next

Complete the implementation of your JAX-WS Web service application.

wsgen command for JAX-WS applications

The wsgen command-line tool generates the necessary artifacts required for Java API for XML Web Services (JAX-WS) applications when starting from Java code.

When using a bottoms-up approach to develop JAX-WS Web services and you are starting from a service endpoint implementation, use the wsgen tool to generate the required JAX-WS artifacts.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

The wsgen tool accepts a properly annotated service endpoint implementation using the @WebService annotation as input and generates the following artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a WSDL file if the optional -wsdl argument is specified. The wsgen tool does not automatically generate the WSDL file.

Note: The wsgen command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Syntax

The command line syntax is:

Parameters

The *service_implementation_class* name is the only parameter that is required. The following parameters are optional for the wsgen command:

-classpath <path>
Specifies the location of the service implementation class.

-cp <path>
This is the same as *-classpath <path>*.

-d <directory>
Specifies where to place the generated output files.

-extension
Specifies whether to enable custom extensions for functionality not specified by the JAX-WS specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-keep
Specifies whether to keep the generated source files.

-r <directory>
This parameter is only used in conjunction with the -wsdl parameter. Specifies where to place the generated WSDL file.

-s <directory>
Specifies the directory to place the generated source files.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information will be output and normal command processing will not occur.

-wsdl [:protocol]
By default, the wsgen tool does not generate a WSDL file. This optional parameter causes wsgen to generate a WSDL file and is typically only used to enable a developer to review a WSDL file before the endpoint is deployed. The `protocol` is optional and specifies the protocol used in the `wsdl:binding`. Valid values for `protocol` are `soap 1.1` and `Xsoap 1.2`. The default value is `soap 1.1`. The `Xsoap 1.2` value is not standard and is only used in conjunction with the *-extension* option.

-servicename <name>
This parameter is only used in conjunction with the -wsdl option. Specifies a `wsdl:service` name to be generated in the WSDL file. For example,

```
-servicename "{http://mynamespace/}MyService"
```

-portname
This parameter is only used in conjunction with the -wsdl option. Specifies a `wsdl:port` name to be generated in the WSDL file. For example,

```
-portname "{http://mynamespace/}MyPort"
```

Mapping between Java language, WSDL and XML for JAX-WS applications

Data for Java API for XML Web Services (JAX-WS) applications flows as extensible Markup Language (XML). JAX-WS applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For Web services based on the JAX-WS programming model, mappings between the Java language and XML are specified by the JAX-WS specification and the Java Architecture for XML Binding (JAXB) specification for data bindings. JAX-WS leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

The JAX-WS specification describes the mapping between Web Service Definition Language (WSDL) files and the Java language. The supported mappings include WSDL-to-Java mappings and Java-to-WSDL mappings. WSDL 1.1 is required by the JAX-WS 2.0 specification. You can use annotations to customize the mapping from Java artifacts to their associated WSDL components. Refer to the JAX-WS specification for details describing the WSDL-to-Java mappings and Java-to-WSDL mappings.

Data binding mappings used by the JAX-WS programming model are described by the JAXB specification. Refer to the JAXB specification for details that describe the JAXB mappings for the Java representation of XML content, including the default and custom bindings between XML schema to Java representations.

Enabling MTOM for JAX-WS Web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with Web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web services security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to

send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support. For the server, you can enable MTOM on a JavaBeans endpoint only and not on endpoints that implement the javax.xml.ws.Provider interface.

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your Web services application data that includes a binary attachment.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the **wsimport** command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
   c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on a JavaBeans endpoint.

   To enable MTOM on an endpoint, use the @MTOM (javax.xml.ws.soap.MTOM) annotation on the endpoint. The @MTOM annotation has two parameters, enabled and threshold. The enabled parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The threshold parameter has an integer value, and it specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data.

   Additionally, you can use the @BindingType (javax.xml.ws.BindingType) annotation on a server endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The javax.xml.ws.SOAPBinding class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the @BindingType annotation.. For example:

   ```
   // for SOAP version 1.1
   @BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
   // for SOAP version 1.2
   @BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
   ```

   The presence and value of an @MTOM annotation overrides the value of the @BindingType annotation. For example, if the @BindingType indicates MTOM is enabled, but an @MTOM annotation is present with an enabled value of false, then MTOM is not enabled
3. Enable MTOM on your client using either the `javax.xml.ws.soap.SOAPBinding` or the `javax.xml.ws.soap.MTOMFeature` APIs. Enabling MTOM on the client optimizes the binary messages that are sent to the server.
   a. Enable MTOM on a Dispatch client. The following example uses SOAP version 1.1:

   ```
   - First method:  Using SOAPBinding.setMTOMEnabled()

       SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
       binding.setMTOMEnabled(true);

   - Second method: Using Service.addPort where you specify:

       Service svc = Service.create(serviceName);
       svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);

   - Third method: Using MTOMFeature:

       MTOMFeature mtom = new MTOMFeature();
       Service svc = Service.create(serviceName);
       svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
       Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
   ```

   b. Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
  Service svc = Service.create(serviceName);
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;

  //Enable MTOM using the SOAPBinding
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
  SOAPBinding binding = (SOAPBinding) bp.getBinding();
  binding.setMTOMEnabled(true);

  //Or, enable MTOM with the MTOMFeature
  MTOMFeature mtom = new MTOMFeature();
  MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

Results

You have developed a JAX-WS Web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the Web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
  <types>
    ........
<xs:complexType name="ImageDepot">
       <xs:sequence>
           <xs:element name="imageData"
                       type="xs:base64Binary"
                       xmime:expectedContentTypes="image/jpeg"/>

       </xs:sequence>
    </xs:complexType>
    ........
    </types>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory against the WSDL file to generate a set of JAX-WS portable artifacts.

   Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
        JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
        Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);
```

```
//Enable MTOM.
        SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
        binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
        Service svc = Service.create(serviceName);
        MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
        BindingProvider bp = (BindingProvider) proxy;
        SOAPBinding binding = (SOAPBinding) bp.getBinding();
        binding.setMTOMEnabled(true);
```

   Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the JavaBeans endpoint.

6. Enable MTOM on JavaBeans endpoint.

```
WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")
@BindingType (SOAPBinding.SOAP11HTTP_MTOM_BINDING)
public class MtomSampleService implements MtomSample {
   ....
}
```

   The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM , the same data is encoded in the format that describes the XML schema, either base64 or hex, and included in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment data. The `type` and `content-type` attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
```

```
        </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
        <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The attachment is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGADl  ... more base64 encoded data ...  KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

For additional information, refer to the Samples Gallery which includes a Sample that demonstrates the use of MTOM with JAX-WS Web services.

Developing a webservices.xml deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a Web services application. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) Web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS Web services. For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS Web service requires that you annotate your Java class with the javax.jws.WebService annotation or the javax.jws.WebServiceProvider annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the @WebService and @WebServiceProvider annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the @WebService and @WebServiceProvider annotation attributes. There are also elements in the webservice.xml deployment descriptor that map to other annotations. For example, the deployment descriptor element <protocol-binding> maps to the @BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the Web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Use assembly tools to generate the webservice.xml deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS Web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated webservices.xml deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, META-INF/wsdl/ExampleService.wsdl, overrides the annotation value.

What to do next

Configure the webservice.xml deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

JAX-WS annotations

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with Web services implementations and to simplify the development of Web services. Annotations describe how a server-side service implementation is accessed as a Web service or how a client-side Java class accesses Web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a Web service and how a client can access the Web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a Web service. Using annotations within the Java source simplifies development and deployment of Web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to Web service invocations.

For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file.

You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve backward compatibility with the feature pack in either of two ways:

- You can set the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

  ```
  Manifest-Version: 1.0
  UseWSFEP61ScanPolicy: true
  ```

  When this property is set to `true` in the module's META-INF/MANIFEST.MF file, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.
- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within a module's META-INF/MANIFEST.MF file, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Note: If this JVM property is being used on the z/OS platform, it must be set in both the servant and control regions of the server.

Note: When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated if you wish to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Web Services Metadata Annotations (JSR 181)

Annotation class	Annotation	Properties
`javax.jws.WebService`	The **@WebService** annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a Web service interface. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. This annotation is applicable on a client or server SEI or a server endpoint implementation class. • If the annotation references an SEI through the `endpointInterface` attribute, the SEI must also be annotated with the @WebService annotation. • See “Rules for methods on classes annotated with @WebService” on page 467 for additional information.	• Annotation target: Type • Properties: **- name** The name of the `wsdl:portType`. The default value is the unqualified name of the Java class or interface. (String) **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- endpointInterface** Specifies the qualified name of the service endpoint interface that defines the services’ abstract Web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) **- portName** The `wsdl:portName`. The default value is WebService.name +*Port* . (String) **- wsdlLocation** Specifies the Web address of the WSDL document defining the Web service. The Web address is either relative or absolute. (String)

Annotation class	Annotation	Properties
`javax.jws.` `WebMethod`	The **@WebMethod** annotation denotes a method that is a Web service operation. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. **Important:** • The @WebMethod annotation is only supported on classes that are annotated with the @WebService annotation.	• Annotation target: Method • Properties: **- operationName** Specifies the name of the `wsdl:operation` matching this method. The default value is the name of Java method. (String) **- action** Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) **- exclude** Specifies whether to exclude a method from the Web service. The default value is `false`. (Boolean)
`javax.jws.` `Oneway`	The **@Oneway** annotation denotes a method as a Web service one-way operation that only has an input message and no output message. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • There are no properties on the Oneway annotation.

Annotation class	Annotation	Properties
`javax.jws.` `WebParam`	The **@WebParam** annotation customizes the mapping of an individual parameter to a Web service message part and XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Parameter • Properties: **- name** The name of the parameter. If the operation is remote procedure call (RPC) style and the `partName` attribute is not specified, then this is the name of the `wsdl:part` attribute representing the parameter. If the operation is document style or the parameter maps to a header, then `-name` is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is `BARE`, and the mode is `OUT` or `INOUT`. (String) **- partName** Defines the name of `wsdl:part` attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is `BARE`. (String) **- targetNamespace** Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the `targetNamespace` for the Web service. (String) **- mode** The value represents the direction the parameter flows for this method. Valid values are `IN`, `INOUT`, and `OUT`. (String) **- header** Specifies whether the parameter is in a message header rather than a message body. The default value is `false`. (Boolean)

Annotation class	Annotation	Properties
`javax.jws.` `WebResult`	The **@WebResult** annotation customizes the mapping of a return value to a WSDL part or XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- name** Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the `wsdl:part` attribute representing the return value. For document bindings, the `-name` parameter is the local name of the XML element representing the return value. The default value is `return` for RPC and DOCUMENT/WRAPPED bindings. The default value is the method name + `Response` for DOCUMENT/BARE bindings. (String) **- targetNamespace** Specifies the XML namespace for the return value. This parameter is only used if the operation is RPC style or if the operation is DOCUMENT style and the parameter style is BARE. (String) **- header** Specifies whether the result is carried in a header. The default value is `false`. (Boolean) **- partName** Specifies the part name for the result with RPC or DOCUMENT/BARE operations. The default value is `@WebResult.name`. (String)

Annotation class	Annotation	Properties
`javax.jws.HandlerChain`	The **@HandlerChain** annotation associates the Web service with an externally defined handler chain. You can only configure the server side handler by using the @HandlerChain annotation on the Service Endpoint Interface (SEI) or the server endpoint implementation class. Use one of several ways to configure a client side handler. You can configure a client side handler by using the @HandlerChain annotation on the generated service class or SEI. Additionally, you can programmatically register your own implementation of the HandlerResolver interface on the Service, or programmatically set the handler chain on the Binding object.	• Annotation target: Type • Properties: **- file** Specifies the location of the handler chain file. The file location is either an absolute java.net.URL in external form or a relative path from the class file. (String) **- name** Specifies the name of the handler chain in the configuration file. (String)
`javax.jws.SOAPBinding`	The **@SOAPBinding** annotation specifies the mapping of the Web service onto the SOAP message protocol. Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. The method level annotation is limited in what it can specify and is only used if the `style` property is `DOCUMENT`. If the method level annotation is not specified, the **@SOAPBinding** behavior from the type is used.	• Annotation target: Type or Method • Properties: **- style** Defines encoding style for messages sent to and from the Web service. The valid values are `DOCUMENT` and `RPC`. The default value is `DOCUMENT`. (String) **- use** Defines the formatting used for messages sent to and from the Web service. The default value is `LITERAL`. `ENCODED` is not supported. (String) **- parameterStyle** Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are `WRAPPED` or `BARE`. You can only use the `BARE` value with `DOCUMENT` style bindings. The default value is `WRAPPED`. (String)

JAX-WS Annotations (JSR 224)

Annotation class	Annotation	Properties
`javax.xml.ws.Action`	The **@Action** annotation specifies the WS-Addressing action that is associated with a Web service operation. When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- fault** Specifies the array of FaultAction for the wsdl:fault of the operation. (String) **- input** Specifies the action for thewsdl:input of the operation. (String) **- output** Specifies the action for thewsdl:output of the operation. (String)
`javax.xml.ws.BindingType`	The **@BindingType** annotation specifies the binding to use when publishing an endpoint of this type. Apply this annotation to a server endpoint implementation class. **Important:** • You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING` or `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING` as the value for the annotation.	• Annotation target: Type • Properties: **- value** Indicates the binding identifier Web address. Valid values are `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`, `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING`, and `javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING`. The default value is `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.FaultAction`	The **@FaultAction** annotation specifies the WS-Addressing action that is added to a fault response. This annotation must be contained within an @Action annotation. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- value** Specifies the action of the wsdl:fault of the operation. (String) **- output** Specifies the name of the exception class. (String) **- className** Specifies the name of the class representing the request wrapper. (String)
`javax.xml.ws.RequestWrapper`	The **@RequestWrapper** annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` as defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the request wrapper. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.ResponseWrapper`	The **@ResponseWrapper** annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- localName** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` + *Response*. `operationName` is defined in javax.jws.WebMethod annotation. (String) **- targetNamespace** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) **- className** Specifies the name of the class representing the response wrapper. (String)
`javax.xml.ws.RespectBinding`	The **@RespectBinding** annotation specifies whether the JAX-WS implementation must use the contents of the wsdl:binding for an endpoint. When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to true are supported. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Method • Properties: **- enabled** Specifies whether the wsdl:binding must be used or not. The default value is `true`. (Boolean)
`javax.xml.ws.ServiceMode`	The **@ServiceMode** annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload. **Important:** • The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation.	• Annotation target: Type • Properties: **- value** Indicates whether the provider class accepts the payload of the message, `PAYLOAD` or the entire message `MESSAGE`. The default value is `PAYLOAD`. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.soap.Addressing`	The **@Addressing** annotation specifies that this service wants to enable WS-Addressing support. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- enabled** Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean) **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)
`javax.xml.ws.soap.MTOM`	The **@MTOM** annotation specifies whether binary content in the body of a SOAP message is sent using MTOM. Apply this annotation to a service endpoint implementation class.	• Annotation target: Class • Properties: **- enabled** Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is `true`. (Boolean) **- threshold** Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)

Annotation class	Annotation	Properties
`javax.xml.ws.WebFault`	The **@WebFault** annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults. This annotation can only be applied to a fault implementation class on the client or server.	• Annotation target: Type • Properties: **- name** Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) **- targetNamespace** Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) **- faultBean** Specifies the name of the fault bean class. (String)
`javax.xml.ws.WebServiceProvider`	The **@WebServiceProvider** annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class. **Important:** • A Java class that implements a Web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. • The @WebServiceProvider annotation is only supported on the service implementation class. Any class with the @WebServiceProvider annotation must implement the javax.xml.ws.Provider interface.	• Annotation target: Type • Properties: **- targetNamespace** Specifies the XML namespace of the WSDL and XML elements generated from the Web service. The default value is the namespace mapped from the package name containing the Web service. (String) **- serviceName** Specifies the service name of the Web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) **- portName** The `wsdl:portName`. The default value is the name of the class + *Port*. (String) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)

Annotation class	Annotation	Properties
`javax.xml.ws.WebServiceRef`	The **@WebServiceRef** annotation defines a reference to a Web service invoked by the client. **Important:** • The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type, Field or Method • Properties: **- name** Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) **- type** Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) **- mappedName** Specified the name to map this resource to. (String) **- value** Indicates the value of the service class and it is a type that extends `javax.xml.ws.Service`. This attribute is required when the type of the reference is a service endpoint interface. (Class) **- wsdlLocation** The Web address of the WSDL document defining the Web service. This attribute is required. (String)
`javax.xml.ws.WebServiceRefs`	The **@WebServiceRefs** annotation associates multiple @WebServiceRef annotations with a specific class. **Important:** • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type • Properties: **- value** Specifies an array for multiple Web service reference declarations. This attribute is required.

JAX-WS Common Annotations (JSR 250)

Annotation class	Annotation	Properties
`javax.annotation.Resource`	The **@Resource** annotation marks a WebServiceContext resource needed by the application. **Important:** Applying this annotation to a WebServiceContext type field on the server endpoint implementation class for a JavaBeans endpoint or a Provider endpoint results in the container injecting an instance of the WebServiceContext into the specified field. When this annotation is used in place of the @WebServiceRef annotation, the rules described for the @WebServiceRef annotation apply.	• Annotation target: Field or Method • Properties: **- type** Indicates the Java type of the resource. You are required to use the default, `java.lang.Object` or `javax.xml.ws.Web ServiceContext` value. If the type is the default, the resource must be injected into a field or a method. In this case, the type of the field or the type of the JavaBeans property defined by the method must be `javax.xml.ws.WebServiceContext`. (Class) If you are using this annotation to inject a Web service, see the description of the @WebServiceRef type attribute.
`javax.annotation.Resources`	The **@Resources** annotation associates multiple @Resource annotations with a specific class and serves as a container for multiple resource declarations.	• Annotation target: Field or Method • Properties: **- value** Specifies an array for multiple @Resource annotations. This attribute is required.
`javax.annotation.PostConstruct`	The **@PostConstruct** annotation marks a method that needs to run after dependency injection is performed on the class. Apply this annotation to a JAX-WS application handler, a server endpoint implementation class.	• Annotation target: Method
`javax.annotation.PreDestroy`	The **@PreDestroy** annotation marks a method that must be run when the instance is in the process of being removed by the container. Apply this annotation to a JAX-WS application handler or a server endpoint implementation class.	• Annotation target: Method

IBM proprietary annotations

Annotation class	Annotation	Properties
`com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing`	The **@SubmissionAddressing** annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification. This annotation is part of the IBM implementation of the JAX-WS 2.1 specification. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)

Rules for methods on classes annotated with @WebService

The following rules apply for methods on classes annotated with the @WebService annotation.

- If the @WebService annotation of an implementation class references an SEI, the implementation class must not have any @WebMethod annotations.
- All public methods for an SEI are considered exposed methods regardless of whether the @WebMethod annotation is specified or not. It is incorrect to have an @WebMethod annotation on an SEI that contains the `exclude` attribute.
- For an implementation class that does not reference an SEI, if the @WebMethod annotation is specified with a value of `exclude=true`, that method is not exposed. If the @WebMethod annotation is not specified, all public methods are exposed including the inherited methods with the exception of methods inherited from java.lang.Object.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) Web service, you must complete the JavaBeans implementation to assemble a Web archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS Web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your Web service application.

.

What to do next

After completing the JavaBeans implementation, assemble your Web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) Web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS Web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your Web service application.

What to do next

After completing the enterprise beans implementation, assemble your Web services application.

Customizing URL patterns in the web.xml file for JAX-WS applications

The web.xml file contains information about the structure and external dependencies of Web components in the module and describes how the components are used at run time. For Java API for XML-Based Web Services (JAX-WS) applications, you can customize the URL pattern in the web.xml file.

Before you begin

Complete the JavaBeans implementation.

About this task

When you package a JavaBeans-based JAX-WS application as a Web service, the Web service is contained within a Web archive (WAR) file or a WAR module within an enterprise archive (EAR) file. A JAX-WS enabled WAR file contains the following items:

- A WEB-INF/web.xml file that describes configuration and deployment information for the Web components that comprise a Web application.
- Annotated classes that implement the Web services contained in the application module including the service endpoint implementation class.
- JAXB classes
- (Optional) Web Services Description Language (WSDL) documents that describe the Web services contained in the application module.
- (Optional) XML schema file
- (Optional) utility classes
- (Optional) Web service clients

The default URL pattern is defined by the @WebService.serviceName attribute that is contained in your Web service implementation class. When the WSDL file that is associated with your service implementation class contains a single port definition, you can choose to use the default URL pattern or you can customize the URL pattern within the web.xml file. When the WSDL file that is associated with your service implementation class contains multiple port definitions within the same service definition, customized URL patterns are required. If you use the default URL pattern when the service implementation class contains multiple port definitions, then multiple service implementation classes are mapped to the same URL pattern which results in an error condition. You must edit the web.xml file and customize the URL patterns for each service definition. Each port maps to a Web service implementation class and to its own custom URL pattern. By customizing the URL pattern in the web.xml file, you correct conflicting URL pattern definitions.

If your JAX-WS application is packaged in an Enterprise JavaBeans (EJB) Java archive (JAR) file within an enterprise archive (EAR) file, you can customize the URL patterns using the endptEnabler command.

1. Determine if custom URL patterns are required or desired. Custom URL patterns are only required when the WSDL file for your JAX-WS Web service contains multiple port definitions within a single service. Otherwise, you can optionally define custom URL patterns.
2. 2. To customize the URL pattern for a service implementation class, edit the web.xml file and provide a <servlet> and corresponding <servlet-mapping> entry for each JAX-WS Web service implementation class for which a custom URL pattern is desired. You must define the <url-pattern> value within the <servlet-mapping> entry.

Results

You now have a Web services-enabled Web archive (WAR) file with customized URL patterns.

Example

Single WSDL port definition within a service implementation class

The following example illustrates the default URL pattern and how to customize the URL pattern when the WSDL file associated with the service implementation class has a single port definition.

This is an excerpt from a sample Web service implementation class.

```
package com.ibm.test;
@WebService(serviceName="EchoService", portName="SOAP11EchoServicePort")
public class EchoServiceSOAP11{
```

This is an excerpt from the WSDL file associated with the EchoServiceSOAP11 Web service implementation class:

```
<wsdl:service name="EchoService">
 <wsdl:port name="SOAP11EchoServicePort" tns:binding="..." >
  ...
 </wsdl:port>
</wsdl:service>
```

As prescribed by JSR-109, the default URL pattern in this example is constructed using the `@WebService.serviceName` attribute and the default URL pattern is `/EchoService`.

To optionally customize the URL pattern for this example, edit the web.xml file and provide a `url-pattern` entry. In this example, the customized URL pattern is now `/EchoServiceSOAP11`.

The following excerpt is from a sample web.xml file that demonstrates setting up a servlet:

```
<servlet id="...">
 <servlet-name>com.ibm.test.EchoServiceSOAP11</servlet-name>
 <servlet-class>com.ibm.test.EchoServiceSOAP11</servlet-class>
 <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
 <servlet-name>com.ibm.test.EchoServiceSOAP11</servlet-name>
 <url-pattern>/EchoServiceSOAP11</url-pattern> ----->  Defining the URL pattern and
pointing it to the service implementation class.
</servlet-mapping>
```

Multiple WSDL port definitions within a service implementation class

The following example illustrates the required URL pattern customizations when the WSDL file associated with the service implementation class has multiple port definitions.

The following excerpt is from a sample Web service implementation class:

```
package com.ibm.test;
@WebService(serviceName="EchoService", portName="SOAP11EchoServicePort")
public class EchoServiceSOAP11{
 ...
}
package com.ibm.test;
@WebService(serviceName="EchoService", portName="SOAP12EchoServicePort")
public class EchoServiceSOAP12{
 ...
}
```

The following excerpt is from the WSDL file associated with the EchoServiceSOAP11 Web service implementation class. Each port in the WSDL file maps to a portName in the Web service implementation class.

```
<wsdl:service name="EchoService">
 <wsdl:port name="SOAP11EchoServicePort" tns:binding="..." >
  ...
 </wsdl:port>
 <wsdl:port name="SOAP12EchoServicePort" tns:binding="..." >
  ...
 </wsdl:port>
</wsdl:service>
```

In this scenario, because there are multiple port definitions within the WSDL file, you must customize the URL pattern by editing the web.xml file. Specify custom URL patterns for each service.

The following excerpt is from a sample web.xml file that demonstrates setting up a servlet:

```
<servlet id="...">
 <servlet-name>com.ibm.test.EchoServiceSOAP11</servlet-name>
 <servlet-class>com.ibm.test.EchoServiceSOAP11</servlet-class>
 <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
 <servlet-name>com.ibm.test.EchoServiceSOAP11</servlet-name>
 <url-pattern>/EchoServiceSOAP11</url-pattern>
</servlet-mapping>

<servlet id="...">
 <servlet-name>com.ibm.test.EchoServiceSOAP12</servlet-name>
 <servlet-class>com.ibm.test.EchoServiceSOAP12</servlet-class>
 <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
 <servlet-name>com.ibm.test.EchoServiceSOAP12</servlet-name>
 <url-pattern>/EchoServiceSOAP12</url-pattern>
</servlet-mapping>
```

What to do next

Assemble a WAR file that is enabled for Web services from Java code.

Developing Web services applications from existing WSDL files with JAX-WS

You can develop a Web service with an existing Web Services Description Language (WSDL) file using the Java API for XML-Based Web Services (JAX-WS) programming model.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

Locate the WSDL file that defines the Web service that you want to implement. You can develop a WSDL file or obtain one from an existing Web service through e-mail, downloading or a Uniform Resource Locator (URL).

About this task

To develop Web services based on the JAX-WS programming model, you can use a bottom-up development approach starting from existing JavaBeans or enterprise beans or you can use a top-down development approach starting with an existing Web Services Description Language (WSDL) file. This task describes the steps when using the top-down development approach.

Considerations when using JavaBeans

JavaBeans exposed as JAX-WS Web services are supported only over an HTTP transport.

Considerations when using enterprise beans

- The enterprise bean must be a stateless session bean.
- Enterprise beans that are exposed as JAX-WS Web services must be packaged in EJB 3.0 or higher modules.
- JAX-WS Web service applications containing enterprise beans must be deployed with the endptEnabler command.
- JAX-WS Web services using enterprise beans are supported over an HTTP or Java Message Service (JMS) transport.

1. Set up a development environment for Web services. You do not have to set up a development environment if you are using Rational Application Developer.
2. Develop Java artifacts for JAX-WS applications using the wsimport command-line tool. The wsimport tool processes a WSDL file and generates portable Java artifacts that are used to create a Web service.
3. (optional) Enable MTOM for JAX-WS Web services. You can use SOAP Message Transmission Optimization Mechanism (MTOM) to optimize the transmission of binary attachments such as images or files along with Web services requests.
4. (optional) Develop and configure a webservices.xml deployment descriptor for JAX-WS applications . You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within your JAX-WS Web services.
5. Complete the implementation of your Web service application.
   - For JavaBeans applications, complete the JavaBeans implementation.
   - For enterprise beans applications, complete the enterprise beans implementation.
6. (Optional) Customize URL patterns in the web.xml file. When JavaBeans are exposed as JAX-WS endpoints, you can optionally customize the URL patterns within the web.xml deployment descriptor contained in the Web archive (WAR) file.
7. Assemble the artifacts for your Web service.
8. Deploy the EAR file into the application server. You can now deploy the EAR file that has been configured and enabled for Web services onto the application server.

Results

You have created a JAX-WS Web service by starting with an existing WSDL file.

What to do next

After you deploy the EAR file, test the Web service to make sure that the service works with the application server.

Generating Java artifacts for JAX-WS applications from a WSDL file

Use JAX-WS tools to generate the Java artifacts that are needed to develop JAX-WS Web services when starting with a Web Services Description Language (WSDL) file.

Before you begin

When using a top-down development approach to developing Java API for XML-Based Web Services (JAX-WS) Web services by starting with a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

You can use the JAX-WS tool, wsimport, to process a WSDL file and generate portable Java artifacts that are used to create a Web service. The portable Java artifacts created using the wsimport tool are:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

Run the wsimport command to generate the portable client artifacts. The wsimport tool is located in the *app_server_root*\bin\ directory.
(Optional) Use the following options with the wsimport command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

Note: A best practice for ensuring that you produce a JAX-WS Web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a Web services client Java archive (JAR) file or a Web archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the-`wsdllocation` annotation attribute. For example, if your *MyService.wsdl* file is located in the META-INF/wsdl/ directory, then run the wsimport tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console.

```
wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

  You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the wsimport command to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS Web service. To learn more about the usage, syntax, and parameters for the wsimport command, see the wsimport command for JAX-WS applications documentation.

Example

The following example illustrates how the wsimport command is used to process the sample Ping WSDL file to generate portable artifacts.

1. Copy the following `ping.wsdl` WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com/ibm/was/wssample/sei/ping/">
 <wsdl:types>
  <xsd:schema
   targetNamespace="http://com/ibm/was/wssample/sei/ping/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema">

   <xsd:element name="pingStringInput">
    <xsd:complexType>
     <xsd:sequence>
      <xsd:element name="pingInput" type="xsd:string" />
     </xsd:sequence>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
```

```
 <wsdl:part element="tns:pingStringInput" name="parameter" />
</wsdl:message>
<wsdl:portType name="PingServicePortType">
 <wsdl:operation name="pingOperation">
  <wsdl:input message="tns:pingOperationRequest" />

 </wsdl:operation>
</wsdl:portType>
<wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
 <soap:binding style="document"
  transport="http://schemas.xmlsoap.org/soap/http" />
 <wsdl:operation name="pingOperation">
  <soap:operation soapAction="pingOperation" style="document" />
  <wsdl:input>
   <soap:body use="literal" />
  </wsdl:input>
 </wsdl:operation>
</wsdl:binding>
<wsdl:service name="PingService">
 <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
  <soap:address
   location="http://localhost:9080/WSSampleSei/PingService" />
 </wsdl:port>
</wsdl:service>
</wsdl:definitions>
```

2. Run the wsimport command from the *app_server_root*\bin\ directory.

After generating the template files using the wsimport command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
com\ibm\was\wssample\sei\ping\PingService.java
```

The *ObjectFactory.java* file contains factory methods for each Java content interface and Java element interface generated in the associated ping package. The *package-info.java* file takes the targetNamespace value and creates the directory structure. The *PingServicePortType.java* file is the generated service endpoint interface (SEI) class that contains the `ping` method definition. The *PinStringInput.java* file contains the JAXB generated type values which are Java classes mapped from XML schema types. The *PingService.java* file is the generated service provider class file that is used by the JAX-WS client.

What to do next

Complete the implementation of your Web service application by completing the JavaBeans or enterprise beans implementation.

wsimport command for JAX-WS applications

The wsimport command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing Java API for XML-Based Web Services (JAX-WS) Web service applications.

The wsimport command-line tool supports the top-down approach to developing JAX-WS Web services. When you start with an existing WSDL file, use the wsimport command-line tool to generate the required JAX-WS artifacts.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

The wsimport tool reads an existing WSDL file and generates the following artifacts:

- Service Endpoint Interface (SEI) - The SEI is the annotated Java representation of the WSDL file for the Web service. This interface is used for implementing JavaBeans endpoints or creating dynamic proxy client instances.
- `javax.xml.ws.Service` extension class - This is a generated class that extends the `javax.xml.ws.Service` class. This class is used to configure and create both dynamic proxy and dispatch instances.
- required data beans, including any Java Architecture for XML Binding (JAXB) beans that are required to model the Web service data.

You can package the generated artifacts in a Web archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation to be deployed.

Note: To correctly use the wsimport tool, you must adhere to the following requirements:

- You must define all your services within the main WSDL file. Services that are defined within an imported WSDL file are not processed by the wsimport tool.
- If you run the wsimport tool on a WSDL file that implements a Document or Literal style pattern, the complexTypes elements that define the input and output types must be composed of unique names to prevent naming conflicts in the parameter list for the operation..
- If you run the wsimport tool and pass a `?wsdl` Uniform Resource Identifier (URI) as a parameter for a WSDL file, ensure that you are using the actual resolved WSDL URI. The wsimport tool correctly resolves the `?wsdl` URI, but other relative URIs that are referenced might not resolve correctly.

Syntax

The command line syntax is:

Parameters

The *WSDL_URI* is the only parameter that is required. The following parameters are optional for the wsimport command:

-b <path>
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option.

-B <jaxbOption>
Specifies to pass this option to the JAXB schema compiler.

-catalog
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats

-d <directory>
Specifies where to place the generated output files.

-extension
Specifies whether to accept custom extensions for functionality that are not specified by the JAX-WS specification. The use of custom extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-httpproxy:<host>:<port>
Specifies an HTTP proxy. The default port value is 8080.

-keep
Specifies whether to keep the generated source files.

-p <package_name>
Specifies a target package with this command-line option and overrides any WSDL file and schema binding customization for the package name and the default package name algorithm defined in the JAX-WS specification.

-quiet
Specifies to suppress the wsimport output.

-s <directory>
Specifies the directory to place the generated source files.

-target <version>>
Specifies to generate code that is compliant with a specific JAX-WS specification level. Specify version 2.0 to generate code that is compliant with the JAX-WS 2.0 specification. The default value is version 2.1 this indicates to generate code that is compliant with JAX-WS 2.1 specification.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information is included in the output and normal command processing does not occur.

-wsdlLocation
Specifies the `@WebServiceClient.wsdlLocation` value.

Note: The wsimport tool does not set the`@WebsService.wsdlLocation` value either by default or when the -wsdlLocation attribute is specified. The wsimport command-line tool updates the @WebServiceClient.wsdlLocation annotation only. You can manually update the @WebService.wsdlLocation annotation with a relative URL that specifies the location of the Web Services Description Language (WSDL) file. If the @WebService.wsdlLocation annotation is present on an endpoint implementation class, then the value must be a relative URL and the WSDL document that it references must be packaged with the application.

Developing and deploying JAX-WS Web services clients

You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-Based Web Services (JAX-WS) programming model.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based

annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

About this task

Developing Web services clients based on the JAX-WS programming model

Web services clients that can both access and invoke JAX-WS Web services are developed based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. The application server supports Enterprise JavaBeans (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-WS programming model. Web services clients based on the JAX-RPC specification can invoke JAX-WS-based Web services if the Web Services Description Language (WSDL) file complies with the Web Services-Interoperability (WS-I) Basic Profile.

The JAX-WS client programming model supports both the Dispatch client API and the dynamic proxy client API. The Dispatch client API is a dynamic client programming model, whereas the static client programming model for JAX-WS is the dynamic proxy client. The Dispatch and dynamic proxy clients enable both synchronous and asynchronous invocation of JAX-WS Web services. The Dispatch client API, `javax.xml.ws.Dispatch`, is an XML messaging-oriented client that is intended for advanced XML developers who prefer using XML constructs. The Dispatch API can send data in either `PAYLOAD` or `MESSAGE` mode. When using the `PAYLOAD` mode, the Dispatch client is only responsible for providing the contents of the `soap:Body` and JAX-WS includes the payload in a `soap:Envelope` element. When using the `MESSAGE` mode, the Dispatch client is responsible for providing the entire SOAP envelope. The dynamic proxy client invokes a Web service based on a service endpoint interface (SEI) that is provided. The JAX-WS dynamic proxy instances leverage the dynamic proxy function in the base Java SE Runtime Environment (JRE) 6.

To develop Web services clients based on the JAX-WS programming model, you must determine the client model that best suits the needs of your Web service application. If you want to work directly with XML rather than a Java abstraction and work with either the message structure or the message payload structure, use the Dispatch API to develop a dynamic Web service client. If you want the Web services client to invoke the service based on service endpoint interfaces with a dynamic proxy, use the Dynamic Proxy API to develop a static Web service client. After the proxies are created, the client application can invoke methods on these proxies just like a standard implementation of the service endpoint interfaces. Complete this task to develop a static Web services client starting with a WSDL file.

To invoke Web services asynchronously using a static or dynamic JAX-WS client, determine if you want to implement the callback or the polling model. Read about invoking JAX-WS Web services asynchronously for more information regarding implementing asynchronous callback or polling for Web service clients. The JAX-WS programming model for the service and client uses annotations to represent the same information that was provided in JAX-RPC client binding in a vendor-neutral manner.

Managed and unmanaged JAX-WS Web services clients

The application server supports both managed and unmanaged Web Services clients when using the JAX-WS programming model:

- Managed clients

  Web services for Java EE clients are defined by Java Specification Requirements (JSR) 109 and are managed clients because they run in a Java EE container. These clients are packaged as enterprise archive (EAR) files and contain components that act as service requesters. These components are comprised of a Java EE client application, a Web component such as a servlet or JavaServer Pages (JSP), or a session Enterprise JavaBeans (EJB). Web services managed clients use JSR 109 APIs and deployment information to look up and invoke a Web service.

  For the managed clients, you can use Java Naming and Directory Interface (JNDI) look up to perform service lookup, or you can use annotations to inject instances of a JAX-WS service or

port. Read about setting up UserName token Web services security, digital signature Web services security and Lightweight Third-Party Authentication (LTPA) token Web services security. The following code is an example of a context lookup that is JSR 109 compliant:

```
InitialContext ctx = new InitialContext();
    FredsBankService service
=(FredsBankService)ctx.lookup("java:comp/env/service/FredsBankService");
    FredsBank fredsBank = service.getFredsBankPort();
    long balance = fredsBank.getBalance();
```

You can use the @WebServiceRef or @Resource annotation to declare managed clients. The usage of these annotations results in the type specified by the annotation being bound into the JNDI namespace. When the annotations are used on a field or method, they also result in injection of a JAX-WS service or port instance. You can use these annotations instead of declaring service-ref entries in the client deployment descriptor. You can still use the client deployment descriptor to declare JAX-WS managed clients, similar to JAX-RPC managed clients. You can also use the deployment descriptor to override and augment the information specified by @WebServiceRef and @Resource annotations. Use the @WebServiceRef annotation to bind and inject a JAX-WS service or port instance. You can only use the @Resource annotation to bind and inject a JAX-WS service instance. The use of either of these annotations to declare JAX-WS managed clients is only supported in certain class types. Some of these class types include JAX-WS endpoint implementation classes, JAX-WS handler classes, enterprise bean classes, and servlet classes.

The following example uses the @WebServiceRef annotation to obtain an instance of FredsBank:

```
@WebServiceRef(name="service/FredsBankPort", value=FredsBankService.class)
FredsBank fredsBank;
```

Now within the class, the fredsBank field does not have to be initialized. You can use this field directly:

```
long balance = fredsBank.getBalance();
```

You can also use the @WebServiceRef annotation to obtain instances of JAX-WS service classes; for example:

```
@WebServiceRef(name="service/FredsBankService")
FredsBankService service;
```

Now within the class, the service field does not have to be initialized. You can use this field directly:

```
 FredsBank fredsBank = service.getFredsBankPort(); long balance = fredsBank.getBalance();
```

In addition to the @WebServiceRef annotation, you can use the @Resource annotation to obtain an instance of JAX-WS service classes; for example:

```
@Resource(name="service/FredsBankService", type=FredsBankService.class)
FredsBankService service;
```

As with the @WebServiceRef annotation, you can now use the service field without instantiation; for example:

```
FredsBank fredsBank = service.getFredsBankPort(); long balance = fredsBank.getBalance();
```

You can use the @Resource or @WebServiceRef annotations on a class. In this case, JNDI must be used to lookup the JAX-WS service or port; for example:

```
@WebServiceRef(name="service/FredsBankService", type=FredsBankService")
public class J2EEClientExample {
  ...
  ...

  public static void main(String[] args) {
   ...
   ...
  InitialContext ctx = new InitialContext();
FredsBankService service =(FredsBankService)ctx.lookup("java:comp/env/service/FredsBankService");
     FredsBank fredsBank = service.getFredsBankPort();
```

```
        long balance = fredsBank.getBalance();

    }
    ...
}
```

For more information on using the @WebServiceRef and @Resource annotations, see the specifications for JSR-109, JSR-224, JSR-250, and Java Platform Enterprise Edition 5 (Java EE 5).

As mentioned previously, when using annotations or JNDI to obtain instances of JAX-WS services and ports, do not instantiate the returned objects. Doing so results in an unmanaged client instance. The following example shows an example of incorrect usage:

```
@WebServiceRef(name="service/FredsBankService")
FredsBankService service;
service = new FredsBankService(); // client becomes unmanaged.
```

For JAX-WS managed clients that are declared by the @WebServiceRef or @Resource annotation and for clients that are declared using service-ref entries in the client deployment descriptor, you can use the administrative console to supply the endpoint URL that the client uses. This specified URL overrides the endpoint URL in the WSDL document that is used by the client. To learn more about specifying this endpoint URL, see the configuring Web services client bindings documentation.

- Unmanaged clients

  Java Platform, Standard Edition (Java SE 6) clients that use the JAX-WS runtime environment to invoke Web services and do not run in any Java EE container are known as unmanaged clients. A Web services unmanaged client is a stand-alone Java client that can directly inspect a WSDL file and formulate the calls to the Web service by using JAX-WS APIs. These clients are packaged as JAR files, which do not contain any deployment information.

Note: In WebSphere Application Server Version 7.0, the default annotation support behavior has changed. In the Version 6.1 Feature Pack for Web services, the default behavior is to scan pre-Java EE 5 Web application modules to identify JAX-WS services and to scan pre-Java EE 5 Web application modules and EJB modules for service clients during application installation. For Version 7.0, the default behavior is to not scan pre-Java EE 5 modules for annotations during application installation or server startup. You can preserve compatibility with feature packs from previous releases by either setting the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a Web archive (WAR) file or EJB module or by defining the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations documentation.

1. Obtain the Web Services Description Language (WSDL) document for the Web service that you want to access.

   You can locate the WSDL from the services provider through e-mail, through a Uniform Resource Locator (URL), or by looking it up in a Universal Description, Discovery and Integration (UDDI) registry.

2. Develop JAX-WS client artifacts from a WSDL file.
   a. For static JAX-WS Web services applications using the dynamic proxy API, develop client artifacts from a WSDL file using the wsimport command.
   b. (optional) Develop JAX-WS client-side deployment descriptors. You can optionally use the application-client.xml, web.xml, or ejb-jar.xml client-side deployment descriptors to augment or override binding information contained in annotations for JAX-WS Web services.

3. Complete the client implementation. Write your client application code that is used to invoke the Web service.

   See Chapter 4 of the JSR 109 specification. For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Note: If an application creates a number of threads in the JSR 109 client, the metadata (including the WebSphere Application Server configuration) is not copied to the thread, and the Global Security Handler is not called.

4. (Optional) Assemble a Web services-enabled client Java archive (JAR) file into an enterprise archive (EAR) file. Complete this step if you are developing a JAX-WS Web services client that runs in the Java EE client container.
5. (Optional) Assemble a Web services-enabled client Web archive (WAR) file into an enterprise archive (EAR) file. Complete this step if you are developing a JAX-WS Web services client that runs in the Java EE web container.
6. (Optional) Deploy the Web services client application. Complete this step to deploy a JAX-WS Web services client that runs in the Java EE client container.
7. Test the Web services-enabled client application. You can test an unmanaged client JAR file or a managed client application.

Results

You have created and tested a Web services client application.

What to do next

After you develop a Web services application client, and the client is statically bound, the service endpoint used by the implementation is the one that is identified in the WSDL file that you used during the development process. During or after installation of the Web services application, you might want to change the service endpoint. For managed clients, you can change the endpoint with the administrative console or the wsadmin scripting tool. For unmanaged JAX-WS Web services clients, you can change the endpoint from within the client application.

You can additionally consider customizing your Web services by implementing extensions to your Web services client. Some examples of these extensions include sending and receiving values in SOAP headers or sending and receiving HTTP or Java Message Service (JMS) transport headers. To learn more about these extensions, read about implementing extensions to Web services clients.

Developing a JAX-WS client from a WSDL file

Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS Web services clients when starting with a Web Services Description Language (WSDL) file.

Before you begin

When you use a top-down development approach to developing JAX-WS Web services by starting with a WSDL file, you must obtain the Uniform Resource Locator (URL) for the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

The static client programming model for JAX-WS is the called the dynamic proxy client. The dynamic proxy client invokes a Web service based on a service endpoint interface that is provided. After you create the proxy, the client application can invoke methods on the proxy just like a standard implementation of those interfaces. For JAX-WS Web service clients using the dynamic proxy programming model, use the JAX-WS tool, wsimport, to process a WSDL file and generate portable Java artifacts that are used to create a Web service client. Create the following portable Java artifacts using the wsimport tool:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the wsdl:fault class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

Run the wsimport command to generate the portable client artifacts. The wsimport tool is located in the *app_server_root*\bin\ directory.
(Optional) Use the following options with the wsimport command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

  Note: A best practice for ensuring that you produce a JAX-WS Web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a Web services client Java archive (JAR) file or a Web archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the`-wsdllocation` annotation attribute. For example, if your *MyService.wsdl* file is located in the META-INF/wsdl/ directory, then run the wsimport tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console.

  ```
  wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
  ```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

  You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the wsimport command to learn more about this command and additional options that you can specify.

Results

You have the generated Java artifacts to create a JAX-WS client that can invoke JAX-WS Web services. To learn more about the usage, syntax, and parameters for the wsimport command, see the wsimport command for JAX-WS applications documentation.

Example

The following example illustrates how the wsimport command is used to process the sample `ping.wsdl` file to generate portable artifacts.

1. Copy the following `ping.wsdl` file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com/ibm/was/wssample/sei/ping/">
 <wsdl:types>
  <xsd:schema
   targetNamespace="http://com/ibm/was/wssample/sei/ping/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema">

   <xsd:element name="pingStringInput">
    <xsd:complexType>
     <xsd:sequence>
      <xsd:element name="pingInput" type="xsd:string" />
     </xsd:sequence>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
  <wsdl:part element="tns:pingStringInput" name="parameter" />
 </wsdl:message>
 <wsdl:portType name="PingServicePortType">
  <wsdl:operation name="pingOperation">
   <wsdl:input message="tns:pingOperationRequest" />

  </wsdl:operation>
 </wsdl:portType>
 <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
  <soap:binding style="document"
   transport="http://schemas.xmlsoap.org/soap/http" />
  <wsdl:operation name="pingOperation">
   <soap:operation soapAction="pingOperation" style="document" />
   <wsdl:input>
    <soap:body use="literal" />
   </wsdl:input>
  </wsdl:operation>
 </wsdl:binding>
 <wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
   <soap:address
    location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
 </wsdl:service>
</wsdl:definitions>
```

2. Run the wsimport command from the *app_server_root*\bin\ directory.

After generating the template files from the wsimport command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingService.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
```

The ObjectFactory.java, PingService.java and PingServicePortType.java files are the generated Java class files to use when you package the Java artifacts with your client implementation inside a Java archive (JAR) or a Web archive (WAR) file.

What to do next

Complete the client implementation.

Developing deployment descriptors for a JAX-WS client

Deployment descriptors are standard text files, formatted using XML and packaged in a Web services application. You can optionally use the Web Services for Java Platform, Enterprise Edition (Java EE) specification (JSR 109) service reference deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) Web services client.

Before you begin

You must first generate the Web services client artifacts from a Web Services Description Language (WSDL) file using the wsimport command.

About this task

You can add `service-ref` entries within the application-client.xml, web.xml, or ejb-jar.xml Java EE deployment descriptors. A `service-ref` entry represents a reference to a Web service that is used by a Java EE component in Web, Enterprise JavaBeans (EJB) or application client containers. A `service-ref` entry has a JNDI name that is used to lookup the service. Specifying the `service-ref` entry enables the client applications to locate the service using a JNDI lookup and you can also use these service references for resource injection.

For each `service-ref` entry found in one of the deployment descriptors, the corresponding service object is bound into the JNDI namespace and the port information is included, if specified. The JAX-WS client can now perform a JNDI lookup to retrieve either a JAX-WS service or port instance.

When binding a JAX-WS service into JNDI, use the javax.xml.ws.Service subclass that is generated by the wsimport tool as the `service-interface` value. This is the class that contains the @WebServiceClient annotation. When binding a JAX-WS port into the namespace, the `service-interface` value is still the javax.xml.ws.Service subclass generated by the wsimport tool, and the `service-ref-type` value specifies the service endpoint interface (SEI) class used by the port. The SEI class is also generated by wsimport, and it is annotated with the @WebService annotation.

1. Define the `service-ref` entry in the your application-client.xml, web.xml, or ejb-jar.xml deployment descriptors.

   For example, suppose a Web archive (WAR) file contains a WEB-INF/web.xml deployment descriptor that includes the following `service-ref` entries:

```
<service-ref>
<service-ref-name>service/ExampleService</service-ref-name>
<service-interface>com.ibm.sample.ExampleService</service-interface>
</service-ref>

<service-ref>
<service-ref-name>service/ExamplePort</service-ref-name>
<service-interface>com.ibm.sample.ExampleService</service-interface>
<service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>

<service-ref>
<service-ref-name>service/ExamplePortInjected</service-ref-name>
<service-interface>com.ibm.sample.ExampleService</service-interface>
```

```
<service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>

<injection-target>
   <injection-target-class>com.ibm.sample.J2EEClient</injection-target-class>
   <injection-target-name>injectedPort</injection-target-name>
    </injection-target>
</service-ref>
```

In this example, `com.ibm.sample.ExampleService` is a generated JAX-WS service class and this class must be a subclass of javax.xml.ws.Service. Additionally, the `ExampleService.getPort()` method returns an instance of `com.ibm.sample.ExamplePort`.

2. Use the deployment descriptors within your Web services client application to customize your application. The following code fragments are examples of how your client application can use the `service-ref` entries within the WAR module:

```
import javax.xml.ws.Service;
import com.ibm.sample.ExampleService;
import com.ibm.sample.ExamplePort;

// Create an InitialContext object for doing JNDI lookups.
InitialContext ic = new InitialContext();

// Client obtains an instance of the generic service class using JNDI.
Service genericService =
(Service) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the generated service class using JNDI.
ExampleService exampleService =
(ExampleService) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the port using JNDI.
ExamplePort ExamplePort =
(ExamplePort) ic.lookup("java:comp/env/service/ExamplePort");

// The container injects an instance of ExamplePort based on the client deployment descriptor
private ExamplePort injectedPort;
```

Results

You can now use the service references that were defined in the deployment descriptor within your client application. Additionally, you can use deployment descriptors to augment or override information specified by @WebServiceRef or @Resource annotations.

What to do next

Complete the client implementation by writing your client application code that is used to invoke the Web service.

Developing a dynamic client using JAX-WS APIs

Java API for XML-Based Web Services (JAX-WS) provides support for the dynamic invocation of service endpoint operations.

About this task

JAX-WS provides a new dynamic Dispatch client API that is more generic and offers more flexibility than the existing Java API for XML-based RPC (JAX-RPC)-based Dynamic Invocation Interface (DII). The Dispatch client interface, javax.xml.ws.Dispatch, is an XML messaging oriented client that is intended for advanced XML developers who prefer to work at the XML level using XML constructs. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file.

The Dispatch API can send data in either PAYLOAD or MESSAGE mode. When using the PAYLOAD mode, the Dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS includes the input payload in a <soap:Envelope> element. When using the MESSAGE mode, the Dispatch client is responsible for providing the entire SOAP envelope.

The Dispatch client API requires application clients to construct messages or payloads as XML and requires a detailed knowledge of the message or message payload. The Dispatch client can use HTTP bindings when using Source objects, Java Architecture for XML Binding (JAXB) objects, or data source objects. The Dispatch client supports the following types of objects:

- javax.xml.transform.Source: Use Source objects to enable clients to use XML APIs directly. You can use Source objects with SOAP and HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP and HTTP bindings.
- javax.xml.soap.SOAPMessage: Use SOAPMessage objects so that clients can work with SOAP messages. You can only use SOAPMessage objects with SOAP version 1.1 or SOAP version 1.2 bindings.
- javax.activation.DataSource: Use DataSource objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use DataSource only with HTTP bindings.

The Dispatch API uses the concept of generics that are introduced in Java SE Runtime Environment (JRE) 6. For each of the invoke() methods on the Dispatch interface, generics are used to determine the return type.

1. Determine if you want your dynamic client to send data in PAYLOAD or MESSAGE mode.
2. Create a service instance and add at least one port to it. The port carries the protocol binding and service endpoint address information.
3. Create a Dispatch<T> object using either the Service.Mode.PAYLOAD method or the Service.Mode.MESSAGE method.
4. Configure the request context properties on the javax.xml.ws.BindingProvider interface. Use the request context to specify additional properties such as enabling HTTP authentication or specifying the endpoint address.
5. Compose the client request message for the dynamic client.
6. Invoke the service endpoint with the Dispatch client either synchronously or asynchronously.
7. Process the response message from the service.

Results

You have developed a dynamic JAX-WS client using the Dispatch API. Refer to Chapter 4, section 3 of the JAX-WS 2.0 specification for more information on using a Dispatch client.

Example

The following example illustrates the steps to create a Dispatch client and invoke a sample EchoService service endpoint.

```
String endpointUrl = ...;

QName serviceName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoService");
QName portName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoServicePort");

/** Create a service and add at least one port to it. **/
Service service = Service.create(serviceName);
service.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);
```

```
/** Create a Dispatch instance from a service.**/
Dispatch<SOAPMessage> dispatch = service.createDispatch(portName,
SOAPMessage.class, Service.Mode.MESSAGE);

/** Create SOAPMessage request. **/
// compose a request message
MessageFactory mf = MessageFactory.newInstance(SOAPConstants.SOAP_1_1_PROTOCOL);

// Create a message.  This example works with the SOAPPART.
SOAPMessage request = mf.createMessage();
SOAPPart part = request.getSOAPPart();

// Obtain the SOAPEnvelope and header and body elements.
SOAPEnvelope env = part.getEnvelope();
SOAPHeader header = env.getHeader();
SOAPBody body = env.getBody();

// Construct the message payload.
SOAPElement operation = body.addChildElement("invoke", "ns1",
 "http://com/ibm/was/wssample/echo/");
SOAPElement value = operation.addChildElement("arg0");
value.addTextNode("ping");
request.saveChanges();

/** Invoke the service endpoint. **/
SOAPMessage response = dispatch.invoke(request);

/** Process the response. **/
```

Invoking JAX-WS Web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking Web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling Web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the wsimport tool and enable asynchronous invocation through the use of the JAX-WS enableAsyncMapping binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The wsimport tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the wsimport tool, see the wsimport command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a Web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous Web service clients consume Web services using either the callback

approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke Web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsynchHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsynchHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsynchHandler` interface contains the `handleResponse(java.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the Web service.
2. (Optional) Configure the client request context. Add the `com.ibm.websphere.webservices.use.async.mep`

property to the request context to enable asynchronous messaging for the Web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
 rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
   a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
   b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.current.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
   c. Implement the `javax.xml.ws.AsynchHandler` interface. The `javax.xml.ws.AsynchHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
   d. Invoke the asynchronous callback method with the parameter data and the callback handler.
   e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,
   a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.
   b. Invoke the asynchronous polling method with the parameter data.
   c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.
5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS Web service client to asynchronously invoke and consume Web services. See the JAX-WS 2.0 specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a Web service interface with methods for asynchronous requests from the client.

```
@WebService

public interface CreditRatingService {
       // Synchronous operation.
       Score getCreditScore(Customer     customer);
       // Asynchronous operation with polling.
       Response<Score> getCreditScoreAsync(Customer customer);
       // Asynchronous operation with callback.
       Future<?> getQuoteAsync(Customer customer,
              AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
       new AsyncHandler<Score>() {
              public void handleResponse (
                     Response<Score> response)
                 {
                    score = response.get();
                    // process the request...
                 }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
       // Do something while we wait.
}

score = response.get();
```

Configuring a Web services client to access resources using a Web proxy

You can configure a Web services client to access resources through a Web proxy server.

About this task

You can configure a Web services client to access resources by connecting to a Web proxy server either with or without requiring authentication, just like other HTTP client applications. You can configure HTTP transport properties for a Web service acting as a client to another Web service. The HTTP transport values you configure are used at runtime. Configure the HTTP transport values in one of the following ways:

- Configure the properties using the Java Virtual Machine (JVM) custom property panel in the administrative console.
- Configure the properties using the **wsadmin** command-line tool.
- Configure the properties with an assembly tool.
- Configure the properties programmatically using the application programming model

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model or the Java API for XML Web Services (JAX-WS) programming model, review the JAX-RPC or JAX-WS specifications.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

For Java API XML-based Remote Procedure Call (JAX-RPC) Web services, the HTTP transport values take the following precedence order with the programmatic method being the most significant:

1. values specified programmatically on the Call object
2. values defined in the deployment descriptors in each `portQNameBinding` attribute using an assembly tool
3. values defined as JVM system properties

For Java API for XML Web Services (JAX-WS) Web services, the HTTP transport values you specify in your policy set definitions take precedence over the values defined programmatically. Subsequently, the HTTP transport values you define programmatically take precedence over the values defined as JVM system properties. For JAX-WS applications, deployment descriptors are not supported. Use annotations to specify deployment information.

1. Configure the HTTP or HTTPS `proxyHost` and `proxyPort` transport properties for the Web services in one of the following ways:
   - using the Java Virtual Machine (JVM) custom property panel in the administrative console
   - using the **wsadmin** command-line tool
   - using assembly tools
   - programmatically using the application programming model

   To access the Web proxy over HTTP:
   - **http.proxyHost**
   - **http.proxyPort**

   To access the Web proxy over HTTPS:
   - **https.proxyHost**
   - **https.proxyPort**
2. If HTTP proxy authentication is required for your Web services client, then additionally configure the HTTP or HTTPS `proxyUser` and `proxyPassword` transport properties using one of the methods specified in the previous step.

   To access the Web proxy over HTTP:
   - **http.proxyUser**
   - **http.proxyPassword**

   To access the Web proxy over HTTPS:
   - **https.proxyUser**
   - **https.proxyPassword**
3. If you are specifying the HTTP or HTTPS properties programmatically, set the properties in the Stub or Call instance to configure the HTTP proxy authentication.
   a. You can set the HTTP or HTTPS properties programmatically using the following Web services constants:

```
com.ibm.wsspi.webservices.Constants.HTTP_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTP_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTP_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTP_PROXYPASSWORD_PROPERTY

com.ibm.wsspi.webservices.Constants.HTTPS_PROXYHOST_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTPS_PROXYPORT_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTPS_PROXYUSER_PROPERTY
com.ibm.wsspi.webservices.Constants.HTTPS_PROXYPASSWORD_PROPERTY
```

Results

You have configured your Web services client to use a Web proxy server to access resources.

You can optionally set the `http.nonProxyHosts` property to specify the host names of machines to which requests will not be sent through the proxy server. Any requests invoked by the client application that are sent to a host whose name is contained in this property will not pass through the proxy server. This property applies for both HTTP and HTTPS connections. To learn more about the `http.nonProxyHosts` property and other HTTP properties that you can configure, read about HTTP transport custom properties for Web services applications.

Example

Configuring the HTTP proxy programmatically

The following code allows you to configure the HTTP proxy programmatically:

```
import com.ibm.wsspi.webservices.Constants
Properties prop = new Properties();
InitialContext ctx = new InitialContext(prop);
Service service = (Service)ctx.lookup("java:comp/env/service/StockQuoteService");
QName portQname = new QName("http://httpchannel.test.wsfvt.ws.ibm.com", "StockQuoteHttp");
StockQuote sq = (StockQuote)service.getPort(portQname, StockQuote.class);
((javax.xml.rpc.Stub) sq)._setProperty(Constants.HTTP_PROXYHOST_PROPERTY, "proxyHost1.ibm.com");
((javax.xml.rpc.Stub) sq)._setProperty(Constants.HTTP_PROXYPORT_PROPERTY, "80");
```

Assembling a Web services-enabled client JAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the Web services application.

Before you begin

For Java API for XML-Based Web Services (JAX-WS) Web service applications, you need the portable artifacts that are generated by the wsimport command-line tool when starting from a WSDL file to complete this task. The wsimport tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types
- An assembled client module that contains the implementation, all of the classes generated by the wsimport command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.

For Java API for XML-based RPC (JAX-RPC) Web service applications, you need the following artifacts that are generated from the WSDL2Java command-line tool to complete this task:

- An assembled client module that contains the implementation, all of the classes generated by the WSDL2Java command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.
- The WSDL file that you used to develop the client.
- The templates for the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` deployment descriptor, if used.

- A generated Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptor.

About this task

You can use assembly tools included with WebSphere Application Server to assemble Web services-enabled client applications.

Assemble the client code and artifacts that enable the application client to access a Web service with steps provided:

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the client implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
5. Assemble the JAR file into an enterprise archive (EAR) file using typical assembly techniques if the client runs in a container.

Results

You have assembled the artifacts required to enable the client application for Web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookClient.jar` JAR file the `AddressBookClient.ear` EAR file:

```
META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/AddressBook_mapping.xml

com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the Web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings so that the client can communicate with a Web service that is deployed on a server.

Assembling a Web services-enabled client WAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the Web services application.

Before you begin

You can assemble Java-based Web services modules with assembly tools provided with WebSphere Application Server.

About this task

Assemble the client code and artifacts that enable the application client to access a Web service with steps provided:

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to an assembly tool. Read about importing Web archive (WAR) files using an assembly tool in the Rational Application Developer documentation.

Results

You have assembled the artifacts required to enable the client application for Web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookWeb.war` WAR file and the `AddressBook.ear` EAR file:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsdl/AddressBook.wsdl
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xmi (optional)
WEB-INF/ibm-webservicesclient-bnd.xmi
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookWeb.war` file into the `AddressBook.ear` file, the `AddressBook.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookWeb.war
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the Web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings so that the client can communicate with a Web service that is deployed on a server.

Deploying a Web services client application

After you have created an enterprise archive (EAR) file for the Web services client application, you can deploy the Web services client application into the Application Server.

Before you begin

To deploy a Java-based Web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for Web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a Web archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) Web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC Web services clients, you must configure the client deployment descriptors.

About this task

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an application containing Web services by using the **wsadmin** command, specify the **-deployws** option for JAX-RPC applications.

Use the **wsdeploy** command only with JAX-RPC applications. The **wsdeploy** command is not applicable for JAX-WS applications.

If you are installing an application containing Web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the **wsadmin** command:

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings"** command at the **wsadmin** prompt.
   - For JAX-RPC Web service applications, enter the **$AdminApp install *EARfile* "-usedefaultbindings -deployws"** command at the **wsadmin** prompt.

Results

You have a deployed a Web service client in the application server runtime environment.

What to do next

Test the Web services client. You can now test a Web services-enabled managed client EAR file or an unmanaged client JAR file.

Implementing extensions to JAX-WS Web services clients

WebSphere Application Server provides extensions to Web services clients using the Java API for XML-based Web Services (JAX-WS) programming model.

About this task

You can customize Web services by using the following extensions to the JAX-WS client programming model.

- Set the **JAXWS_OUTBOUND_SOAP_HEADERS** and **JAXWS_INBOUND_SOAP_HEADERS** properties on the request context of the Dispatch or Proxy object to enable a JAX-WS Web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.

  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  See Sending implicit SOAP headers with JAX-WS or Receiving implicit SOAP headers with JAX-WS to learn how to modify your client code to send or retrieve transport headers.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a Web services client to send or retrieve transport headers.

  Set the properties on the BindingProvider instance.

  By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

  See “Sending transport headers with JAX-WS” on page 554 or “Retrieving transport headers with JAX-WS” on page 555 to learn how to modify your client code to send or retrieve transport headers. See “Transport header properties best practices” on page 551 to learn how to enable a Web services client to send or retrieve transport headers.

Example: Using JAX-WS properties to send and receive SOAP headers

WebSphere Application Server provides extensions to the Java API for XML-Based Web Services (JAX-WS) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS and com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS properties. This example demonstrates how these two properties are used.

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a JAX-WS Web services request and response:

```
1  //Create the hashmaps for the outbound soap headers
2  Map<QName, List<String>> outboundHeaders=new HashMap<QName, List<String>>();
3
4  //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5  List<String> list1 = new ArrayList<String>();
6  list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7  List<String> list2 = new ArrayList<String>();
8  list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>"
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the request context
12 dispatch.getRequestContext().put(Constants.JAXWS_OUTBOUND_HEADERS, outboundHeaders);
13 // Invoke the remote operation
14 dispatch.invoke(parm1);
15 // Get the inbound header map from the response context
16 Map<QName,List<String>> inboundMap = dispatch.getResponseContext().get(Constants.JAXWS_OUTBOUND_HEADERS);
17 List<String> serverUuidList = inboundMap.get(new QName("com.rotbank.security","ServerUuid"));
```

```
18 String text = serverUiidList.get(0);
19 //Note: text now equals a XML object that contains a SOAP header:
21//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
22  </y:uuid></y:ServerUuid.");
```

On line 2, create the outbound SOAP header map.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the request context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message when the operation is invoked.

On line 14, invoke the remote operation.

On line 15, obtain the outbound header map.

On lines 17-18, the ServerUuid header is retrieved from the response Map. The Map accesses the SOAP header from the response message.

Sending implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing Web service request.

Before you begin

To complete this task, you need a Web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

1. Create a java.util.HashMap<QName, List<String>> object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is a List<String> object, and each String is the XML text of the entire SOAP header element. By using List<String> object, you can add multiple SOAP header elements that each have the same QName object.
3. Set the HashMap object as a property on the request context of the Dispatch or Proxy object. The property name is com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Dispatch or Proxy object. The headers within the HashMap object are sent in the outgoing message.

   A WebServiceException error can occur if any of the following are true:

- The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a List<String> object.
- The String representing an SOAP header is not a compliant XML message.
- The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-WS Web services client that is configured to send implicit SOAP headers.

Receiving implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming Web service response.

Before you begin

To complete this task, you need a Web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

1. Issue a remote method call with the Dispatch or Proxy object.
2. Using the property name, com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS, retrieve the Map<QName, List<String>> from the ResponseContext of the Dispatch or Proxy object.
3. From the Map<QName, List<String>> value, retrieve a List<String> using the QName of the SOAP header. If the List<String> value is present, that value contains zero or more String objects that contain the XML text of the SOAP headers for the corresponding QName.

Results

You have a JAX-WS Web services client that can receive values from implicit SOAP headers.

Transport header properties best practices

You can set the REQUEST_TRANSPORT_PROPERTIES property and RESPONSE_TRANSPORT_PROPERTIES property on a Java API for XML-based RPC (JAX-RPC) client Stub, a Call instance, or a Java API for XML-Based Web Services (JAX-WS) BindingProvider instance to enable a Web services client to send or retrieve transport headers.

Note: Use these best practices to enable a Web services client to send or retrieve transport headers.

REQUEST_TRANSPORT_PROPERTIES best practices

Transport headers that require multiple values

Some transport headers such as the HTTP Cookie header and the Cookie2 header contain multiple embedded values. For headers that contain multiple values, the header value must be written in the following way:

- Each name=value pair embedded within the header value must be separated by a semi-colon (;).
- Each *name* and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:

```
name1=value1;name2=value2;name3=value3
```

HashMap values

The HashMap values might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the HashMap. For certain transport headers that contain multiple embedded values, the header values in the HashMap are parsed into individual name=value components. A semi-colon (;) separates the components, for example, name1=value1;name2=value2. Each name=value is appended to the outgoing header unless:

- **The outgoing request header contains a *name* value**.

  In this case, the name=value from the HashMap is silently ignored, preventing a client from overwriting or modifying values for the *name* value that are already set in the outgoing request header by either the server or the Web services engine.
- **The HashMap header value contains multiple *name* values**.

  When the HashMap header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the HashMap header value contains name1=value1;name2=value2;name1=value3, where there are two occurrences of name1, the first value, name1=value1, is used. The other value, name1=value3, is silently ignored.

RESPONSE_TRANSPORT_PROPERTIES best practices

HashMap values

Only the HashMap keys are used; the HashMap values are ignored. The values are filled in this HashMap by retrieving the transport headers, which correspond to the HashMap keys from the incoming response message. An empty HashMap causes all of the transport headers and the associated values to be retrieved from the incoming response message.

HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through REQUEST_TRANSPORT_PROPERTIES overrides the values set any other way.

Header	Send request	Retrieve response

Transfer-encoding	• The transfer-encoding header is ignored for HTTP 1.0. • When using HTTP 1.1, the transfer-encoding header is set to `chunked` if the value is `chunked`.	There is no special processing.
Connection	• The connection header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: – The connection header is set to ″close″ if the value is set to ″close″. – The connection header is set to ″keep-alive″ if the value is set to ″keep-alive″. – All other value settings are ignored.	There is no special processing.
Expect	• The expect header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: – The connection header is set to ″100-continue″ if the value is set to ″100-continue″. – All other value settings are ignored.	There is no special processing.
Host	Ignored	There is no special processing.
Content-type	Ignored	There is no special processing.
SOAPAction	Ignored	There is no special processing.
Content-length	Ignored	There is no special processing.
Cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE	The value is sent on the header if it is structured correctly. See the information in this article for Header value format and HashMap values.	There is no special processing.
Cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE2	See the information in the ″Cookie″ entry.	There is no special processing.
Authorization	Ignored	There is no special processing.
Proxy-authorization	Ignored	There is no special processing.

Set-cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE	There is no special processing.	If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.
Set-cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE2	There is no special processing.	If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.

Example client code

The following is an example of how you can code a Web services client to send and retrieve HTTP transport header values:

```
HashMap sendTransportHeaders=new HashMap();
sendTransportHeaders.put("Cookie","ClientAuthenticationToken=FFEEBCC");
sendTransportHeaders.put("MyRequestHeader","MyRequestHeaderValue");
((Stub) portType)._setProperty(Constants.REQUEST_TRANSPORT_PROPERTIES, sendTransportHeaders);

HashMap receiveTransportHeaders=new HashMap();
receiveTransportHeaders.put("Set-Cookie", null);
receiveTransportHeaders.put("MyResponseHeader", null);
((Stub) portType)._setProperty(Constants.RESPONSE_TRANSPORT_PROPERTIES,
 receiveTransportHeaders);

resultString=portType.echoString("Foo");
```

Sending transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) Web services client to send application-defined information along with your Web services requests by using transport headers.

Before you begin

You need a JAX-WS Web services client that you can enable to send transport headers.

Sending transport headers is supported only by Web services clients, and only supported for the HTTP and JMS transports. The Web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the Web services server is done through non-Web services APIs.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against the BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To send values in the transport headers on outbound requests, modify the client code.

1. Create a java.util.HashMap object that contains the transport header identifiers.
2. Add an entry to the HashMap object for each transport header that you want the client to send.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user defined, such as `MyTransportHeader`. Certain header identifiers

are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.

b. Set the HashMap entry value to a string that contains the value of the transport header.

3. Set the HashMap entry on the BindingProvider instance using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the BindingProvider instance. The headers and the associated values from the HashMap are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

   If the property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:

   - The property value that is set on the BindingProvider instance must be a HashMap object or null.
   - The HashMap must not be empty.
   - Each key in the HashMap must be a String object.
   - Each value in the HashMap must be a String object.

Results

You have a JAX-WS Web services client that is configured to send transport headers.

Retrieving transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a JAX-WS Web services client that you can enable to retrieve transport headers. B

Retrieving transport headers is supported only by Web services clients, and only supported for the HTTP and JMS transports. The Web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the Web services server is done through non-Web services APIs.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider object to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that BindingProvider object until the associated property is set to null or the BindingProvider object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

1. Create a java.util.HashMap object that contains the names of the transport headers to be retrieved from incoming response messages.

2. Add an entry to the HashMap for each header that you want to retrieve a value from every incoming response message.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class. The HashMap entry value is ignored and does not need to be set. An empty HashMap, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the HashMap entry on the BindingProvider instance using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the HashMap is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the BindingProvider instance. The values from the specified transport headers are retrieved from the response message and placed in the HashMap.

   If the property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:
   - The property value that is set on the BindingProvider instance must be either null or an instance of a HashMap.
   - All the HashMap keys must be a string data type, and the keys must not be null.

Results

You have a JAX-WS Web service that can receive transport headers from incoming response messages.

Using JAXB for XML data binding

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified Web services development. JAXB provides a schema compiler, schema generator and a runtime framework to support two-way mapping between Java objects and XML documents.

About this task

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides tooling to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects to use within your JAX-WS applications. You can also use JAXB independently of the JAX-WS programming model as a convenient way to leverage the XML data binding technology to manipulate XML within your Java applications.

Note: WebSphere Application Server Version 7.0 supports the JAXB 2.1 specification. JAX-WS 2.1 requires JAXB 2.1 for data binding.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

JAXB provides the xjc schema compiler tool, the schemagen schema generator tool, and a runtime framework. The xjc schema compiler tool enables you to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the schemagen schema generator tool to create the XML schema. After using either the schema compiler or the schema generator command-line tools, you can convert your XML documents both to and from Java objects and use the resulting Java classes to assemble a Web services application.

In addition to using the tools from the command-line, you can invoke these JAXB tools from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the schemagen schema generator tool.

JAXB annotated classes and artifacts contain all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML files and unmarshaling the XML document back to JAXB class instances. The JAXB binding package, `javax.xml.bind`, defines the abstract classes and interfaces that are used directly with content classes. In addition the package defines the marshal and unmarshal APIs.

JAXB 2.1 provides enhancements such as improved compilation support and support for the @XMLSeeAlso annotation. With JAXB 2.1, you can configure the xjc schema compiler so that it does not automatically generate new classes for a particular schema. Similarly, you can configure the schemagen schema generator to not automatically generate a new schema. This enhancement is useful when you are using a common schema and you do not want a new schema generated. JAXB 2.1 also introduces the @XMLSeeAlso annotation that enables JAXB to bind additional Java classes that it might not otherwise know about when binding a Java class with this annotation. This annotation enables JAXB to know about all classes that are potentially involved in marshalling or unmarshalling as it is not always possible or practical to list all of the subclasses of a given Java class. JAX-WS 2.1 also supports the use of the @XMLSeeAlso annotation on a service endpoint interface (SEI) or on a service implementation bean to ensure all of the classes referenced by the annotation are passed to JAXB for processing.

You can optionally use JAXB binding customizations to customize generated JAXB classes by overriding or extending the default JAXB bindings when the default bindings do not meet your business application needs. In most cases, the default binding rules are sufficient to generate a robust set of schema-derived classes. JAXB supports binding customizations and overrides to the default binding rules that you can make through various ways. For example, you can the overrides inline as annotations in a source schema, as declarations in an external bindings customization file that is used by the JAXB binding compiler, or as Java annotations within Java class files used by the JAXB schema generator. See the JAXB specification for information regarding binding customization options.

Using JAXB, you can manipulate data objects in the following ways:

- Generate an XML schema from a Java class. Use the schema generator schemagen command to generate an XML schema from Java classes.
- Generate Java classes from an XML schema. Use the schema compiler xjc command to create a set of JAXB-annotated Java classes from an XML schema.
- Marshal and unmarshal XML documents. After the mapping between XML schema and Java classes exists, use the JAXB binding runtime to convert XML instance documents to and from Java objects.

Results

You now have JAXB objects that your Java application can use to manipulate XML data.

Using JAXB tools to generate an XML schema file from a Java class

Use Java Architecture for XML Binding (JAXB) tooling to generate an XML schema file from Java classes.

Before you begin

Identify the Java classes or a set of Java objects to map to an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between Java classes and XML schema. XML schema documents describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop Web services using a bottom-up development approach starting from existing JavaBeans or enterprise beans, use the wsgen tool to generate the artifacts for Java API for XML-Based Web Services (JAX-WS) applications. After the Java artifacts for your application are generated, you can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, schemagen command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

You can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, schemagen command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

Note: WebSphere Application Server Version 7.0 supports the JAXB 2.1 specification. JAX-WS 2.1 requires JAXB 2.1 for data binding.

JAXB 2.1 provides improvements in compilation support to enable you to configure the schemagen schema generator so that it does not automatically generate a new schema. This is helpful if you are using a common schema such as the World Wide Web Consortium (W3C), XML Schema, Web Services Description Language (WSDL), or WS-Addressing and you do not want a new schema generated for a

particular package that is referenced. The location attribute on the @XmlSchema annotation causes the schemagen generator to refer to the URI of the existing schema instead of generating a new one.

In addition to using the schemagen tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the schemagen schema generator tool.

1. Locate the Java source files or Java class files to use in generating an XML schema file. Ensure that all classes referenced by your Java class files are contained in the classpath or are provided to the tool using the`-classpath/-cp` options.
2. Use the JAXB schema generator, schemagen command to generate an XML schema. The schema generator is located in the *app_server_root*\bin\ directory.

   The parameters, `myObj1.java` and `myObj2.java`, are the names of the Java files containing the data objects. If `myObj1.java` or `myObj2.java` refer to Java classes that are not passed into the schemagen command, you must use the `-cp` option to provide the classpath location for these Java classes.Read about the schemagen command to learn more about this command and additional options that you can specify.
3. (Optional) Use JAXB program annotations defined in the `javax.xml.bind.annotations` package to customize the JAXB XML schema mappings.
4. (Optional) Configure the `location` property on the @XmlSchema annotation to indicate to the schema compiler to use an existing schema rather than generating a new one. For example,

   ```
   @XmlSchema(namespace="foo")
   package foo;
   @XmlType
   class Foo {
   @XmlElement Bar zot;
   }
   @XmlSchema(namespace="bar",
   location="http://example.org/test.xsd")
   package bar;
   @XmlType
   class Bar {
   ...
   }
   <xs:schema targetNamespace="foo">
   <xs:import namespace="bar"
   schemaLocation="http://example.org/test.xsd"/>
   <xs:complexType name="foo">
   <xs:sequence>
   <xs:element name="zot" type="bar:Bar" xmlns:bar="bar"/>
   </xs:sequence>
   </xs:complex
   ```

   the `location="http://example.org/test.xsd"` indicates the location on the existing schema to the schemagen tool and a new schema is not generated.

Results

Now that you have generated an XML schema file from Java classes, you are ready to marshal and unmarshal the Java objects as XML instance documents.

Note: The **schemagen** command does not differentiate the XML namespace between multiple @XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Example

The following example illustrates how JAXB tooling can generate an XML schema file from an existing Java class, Bookdata.java.

1. Copy the following `Bookdata.java` file to a temporary directory.

```
package generated;

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlType;
import javax.xml.datatype.XMLGregorianCalendar;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "bookdata", propOrder = {
    "author",
    "title",
    "genre",
    "price",
    "publishDate",
    "description"
})
public class Bookdata {

    @XmlElement(required = true)
    protected String author;
    @XmlElement(required = true)
    protected String title;
    @XmlElement(required = true)
    protected String genre;
    protected float price;
    @XmlElement(name = "publish_date", required = true)
    protected XMLGregorianCalendar publishDate;
    @XmlElement(required = true)
    protected String description;
    @XmlAttribute
    protected String id;

     public String getAuthor() {
        return author;
    }
    public void setAuthor(String value) {
        this.author = value;
    }
    public String getTitle() {
        return title;
    }

     public void setTitle(String value) {
        this.title = value;
    }

    public String getGenre() {
        return genre;
    }

    public void setGenre(String value) {
```

```
        this.genre = value;
    }

    public float getPrice() {
        return price;
    }

    public void setPrice(float value) {
        this.price = value;
    }

    public XMLGregorianCalendar getPublishDate() {
        return publishDate;
    }

    public void setPublishDate(XMLGregorianCalendar value) {
        this.publishDate = value;
    }

    public String getDescription() {
        return description;
    }

    public void setDescription(String value) {
        this.description = value;
    }

    public String getId() {
        return id;
    }

    public void setId(String value) {
        this.id = value;
    }

}
```

2. Open a command prompt.
3. Run the **schemagen** schema generator tool from the directory where you copied the `Bookdata.java` file.
4. The XML schema file, `schema1.xsd` is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:complexType name="bookdata">
    <xs:sequence>
      <xs:element name="author" type="xs:string"/>
      <xs:element name="title" type="xs:string"/>
      <xs:element name="genre" type="xs:string"/>
      <xs:element name="price" type="xs:float"/>
      <xs:element name="publish_date" type="xs:anySimpleType"/>
      <xs:element name="description" type="xs:string"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string"/>
  </xs:complexType>
</xs:schema>
```

Refer to the JAXB Reference implementation documentation for additional information about the **schemagen** command.

Using JAXB tools to generate JAXB classes from an XML schema file

Use Java Architecture for XML Binding (JAXB) tooling to compile an XML schema file into fully annotated Java classes.

Before you begin

Develop or obtain an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop Web services using a top-down development approach starting with an existing Web Services Description Language (WSDL) file, use the wsimport tool to generate the artifacts for your Java API for XML-Based Web Services (JAX-WS) applications when starting with a WSDL file. After the Java artifacts for your application are generated, you can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, xjc command-line tool. The resulting annotated Java classes contain all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or other Java applications for processing XML data.

In addition to using the xjc tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the xjc schema compiler tool.

1. Use the JAXB schema compiler, xjc command to generate JAXB-annotated Java classes. The schema compiler is located in the *app_server_root*\bin\ directory. The schema compiler produces a set of packages containing Java source files and JAXB property files depending on the binding options used for compilation.
2. (Optional) Use custom binding declarations to change the default JAXB mappings. Define binding declarations either in the XML schema file or in a separate bindings file. You can pass custom binding files by using the **-b** option with the xjc command.
3. Compile the generated JAXB objects. To compile generated artifacts, add the Thin Client for JAX-WS with WebSphere Application Server to the classpath.

Results

Now that you have generated JAXB objects, you can write Java applications using the generated JAXB objects and manipulate the XML content through the generated JAXB classes.

Example

The following example illustrates how JAXB tooling can generate Java classes when starting with an existing XML schema file.

1. Copy the following `bookSchema.xsd` schema file to a temporary directory.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
   <xsd:element name="CatalogData">
     <xsd:complexType >
       <xsd:sequence>
         <xsd:element name="books" type="bookdata" minOccurs="0"
```

```
 maxOccurs="unbounded"/>
    </xsd:sequence>
   </xsd:complexType>
  </xsd:element>
  <xsd:complexType name="bookdata">
    <xsd:sequence>
      <xsd:element name="author" type="xsd:string"/>
      <xsd:element name="title" type="xsd:string"/>
      <xsd:element name="genre" type="xsd:string"/>
      <xsd:element name="price" type="xsd:float"/>
      <xsd:element name="publish_date" type="xsd:dateTime"/>
      <xsd:element name="description" type="xsd:string"/>
    </xsd:sequence>
    <xsd:attribute name="id" type="xsd:string"/>
  </xsd:complexType>
</xsd:schema>
```

2. Open a command prompt.
3. Run the JAXB schema compiler, xjc command from the directory where the schema file is located. The xjc schema compiler tool is located in the *app_server_root*\bin\ directory.

   Running the xjc command generates the following JAXB Java files:

   ```
   generated\Bookdata.java
   generated\CatalogdData.java
   generated\ObjectFactory.java
   ```
4. Use the generated JAXB objects within a Java application to manipulate XML content through the generated JAXB classes.

Refer to the JAXB 2.0 Reference implementation documentation for additional information about the xjc command.

Using the JAXB runtime to marshal and unmarshal XML documents

Use the Java Architecture for XML Binding (JAXB) run time to manipulate XML instance documents.

Before you begin

Use JAXB to generate Java classes from an XML schema with the schema compiler, xjc command or to generate an XML schema from a Java class with the schema generator, schemagen command.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. After data bindings exist, use the JAXB binding runtime API to convert XML instance documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the data structure. JAXB annotated classes and artifacts contains all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances.

- Marshal JAXB objects to XML instance documents.

  Use the JAXB runtime API to marshal or convert JAXB object instances into an XML instance document.

  1. Instantiate your JAXB classes.
  2. Invoke the JAXB marshaller.

  This example demonstrates how to instantiate the generated JAXB objects within an application and use the JAXBContext class and the JAXB runtime marshaller APIs to marshal the JAXB objects into XML instances.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create marshaller
Marshaller m = jc.createMarshaller();
//Marshal object into file.
m.marshal(myJAXBObject, myOutputStream);
```

The JAXB Reference Implementation introduces additional vendor specific marshaller properties such as namespace prefix mapping, indentation, and character escaping control that are not defined by the JAXB specification. Use these properties to specify additional controls of the marshaling process. These properties operate with the JAXB Reference Implementation only and might not with other JAXB providers. Additional information regarding the vendor specific properties is located in the Java Architecture for XML Binding JAXB RI Vendor Extensions Runtime Properties specification.

- Unmarshal XML files to JAXB objects.

  Use the JAXB runtime API to unmarshal or convert an XML instance document to JAXB object instances.

  1. Obtain an existing XML instance document.
  2. Invoke the JAXB unmarshaller.

  This example demonstrates a program that reads an XML document and unmarshals or converts the XML document into JAXB object instances. Use the JAXBContext class and JAXB runtime Unmarshaller APIs to unmarshal the XML document.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create unmarshaller
Unmarshaller um = jc.createUnmarshaller();
//Unmarshal XML contents of the file myDoc.xml into your Java
  object instance.
MyJAXBObject myJAXBObject = (MyJAXBObject)
um.unmarshal(new java.io.FileInputStream( "myDoc.xml" ));
```

Results

You can now marshal JAXB Java classes, and unmarshal XML data using the JAXB binding framework. Refer to the JAXB 2.0 Reference implementation documentation for additional information about the marshal and unmarshal runtime APIs

Note: If Java 2 Security is enabled, wrap your JAXBContext.newInstance(), Unmarshaller.unmarshal() and, Marshaller.marshal() method calls within a AccessController.doPrivileged method to avoid a security exception.

.

xjc command for JAXB applications

Use the Java Architecture for XML Binding (JAXB) tools to generate Java classes from an XML schema with the xjc schema compiler tool.

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides a runtime environment to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

You can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, xjc command-line tool. Use the xjc schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted

to and from Java objects through the use of the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

Syntax

The command line syntax is:

If a directory is specified, all schema files in the directory are compiled.

Parameters

The schema file/URL JAR file name or location of the directory is the only parameter that is required. The following parameters are optional for the xjc command:

-b <file_name or directory>
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option. If a directory is specified, **/*.xjb is searched.

-catalog <file_name>
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats.

-classpath <path>
Specifies the location of the class files.

-d <directory>
Specifies where to place the generated output files.

-dtd
Specifies to treat the input as XML Document Type Definition (DTD). This option is unsupported and experimental.

-extension
Specifies whether to enable custom extensions for functionality not specified by the JAX-B specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-httpproxy <[user[:password]@]<proxyhost>:<proxyport>>
Specifies an HTTP or HTTPs proxy.

-httpproxyfile <file_name>
Similar to the -httpproxy parameter, but takes the argument in a file to protect the password.

-no-header
Specifies to suppress the generation of a file header with a timestamp.

-npa
Specifies to suppress the generation of the **/package-info.java package level annotation.

-nv
Specifies to not perform a strict validation of the input schemas.

-p <package_name>
Specifies a target package.

-quiet
Specifies to suppress the output from the xjc tool.

-relaxng
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG). This option is unsupported and experimental.

-readOnly
Specifies that the generated files are in read-only mode.

-relaxng-compact
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG) compact syntax. This option is unsupported and experimental.

-target <version>
Specifies to generate output to conform to the specified level of the JAX-WS specification. Specify *2.0* for the tool to generate compliant code for the JAX-B 2.0 specification. The default target version is *2.1* and generates compliant code for JAX-B 2.1.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

-wsdl
Specifies to treat the input as a Web Services Description Language (WSDL) file and compile schemas inside the WSDL. This option is unsupported and experimental.

-xmlschema
Specifies to treat the input as a World Wide Web Consortium (W3C) XML schema. This value is the default.

schemagen command for JAXB applications

Use the schema generator tool, schemagen, to generate an XML schema using Java Architecture for XML Binding (JAXB).

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

You can generate a schema file from Java classes using the schemagen schema generator tool to create the XML schema. After the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse

the XML for marshaling and unmarshaling. You can use the JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The wsimport, wsgen, schemagen and xjc command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. For the most part, artifacts generated by both the tooling provided with WebSphere and the JDK are the same. In general, artifacts generated by the JDK tools are portable across compliant runtime environments. However, it is a best practice to use the WebSphere tools to achieve seamless integration within the WebSphere environment.

Syntax

The command line syntax is:

Parameters

The following parameters are optional for the schemagen command:

-classpath <path>
Specifies the location of the Java source or class files.

-cp <path>
Specifies the location of the Java source or class files.

-d <path>
Specifies where to place the processor and the generated Java class files.

-episode<file_name>
Specifies to generate an episode file for separate compilation.

-help
Displays the help menu.

-version
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

Using handlers in JAX-WS Web services

Java API for XML Web Services (JAX-WS) provides you with a standard way of developing interoperable and portable Web services. Use JAX-WS handlers to customize Web services requests or response handling.

Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. If you are running in a Thin Client for JAX-WS environment, then you are not required to begin with an EAR file. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file must contain the handler classes to configure. The handler classes implement the `javax.xml.ws.handler.LogicalHandler<LogicalMessageContext>` interface or the

javax.xml.ws.handler.soap.SOAPHandler<SOAPMessageContext> interface.

About this task

As in the Java API for XML-based RPC (JAX-RPC) programming model, the JAX-WS programming model provides an application handler facility that enables you to manipulate a message on either an inbound or an outbound flow. You can add handlers into the JAX-WS runtime environment to perform additional processing of request and response messages. You can use handlers for a variety of purposes such as capturing and logging information and adding security or other information to a message. Because of the support for additional protocols beyond SOAP, JAX-WS provides two different classifications for handlers. One type of handler is a logical handler that is protocol independent and can obtain the message in the flow as an extensible markup language (XML) message. The logical handlers operate on message context properties and message payload. These handlers must implement the javax.xml.ws.handler.LogicalHandler interface. A logical handler receives a LogicalMessageContext object from which the handler can get the message information. Logical handlers can exist on both SOAP and XML/HTTP-based configurations.

The second type of handler is a protocol handler. The protocol handlers operate on message context properties and protocol-specific messages. Protocol handlers are limited to SOAP-based configurations and must implement the javax.xml.ws.handler.soap.SOAPHandler interface. Protocol handlers receive the message as a javax.xml.soap.SOAPMessage to read the message data.

The JAX-WS runtime makes no distinction between server-side and client-side handler classes. The runtime does not distinguish between inbound or outbound flow when a handleMessage(MessageContext) method or handleFault(MessageContext) method for a specific handler is invoked. You must configure the handlers for the server or client, and implement sufficient logic within these methods to detect the inbound or outbound direction of the current message.

To use handlers with Web services client applications, you must add the @HandlerChain annotation to the service endpoint interface or the generated service class and provide the handler chain configuration file. The @HandlerChain annotation contains a file attribute that points to a handler chain configuration file that you create. For Web services client applications, you can also configure the handler chain programmatically using the Binding API. To modify the handlerchain class programmatically, use either the default implementation or a custom implementation of the HandlerResolver method.

To use handlers with your server application, you must set the @HandlerChain annotation on either the service endpoint interface or the endpoint implementation class, and provide the associated handler chain configuration file. Handlers for the server are only configured by setting the @HandlerChain annotation on the service endpoint implementation or the implementation class. The handler classes must be included in the server application EAR file.

For both server and client implementations of handlers using the @HandlerChain annotation, you must specify the location of the handler configuration as either a relative path from the annotated file or as an absolute URL. For example:

```
@HandlerChain(file="../../common/handlers/myhandlers.xml")
```

or

```
@HandlerChain(file="http://foo.com/myhandlers.xml")
```

For more information on the schema of the handler configuration file, see the JSR 181 specification.

For more information regarding JAX-WS handlers, see chapter 9 of the JAX-WS specification.

1. Determine if you want to implement JAX-WS handlers on the service or the client.
2. Configure the client handlers by setting the @HandlerChain annotation on the service instance or service endpoint interface, or you can modify the handler chain programmatically to control how the handler chain is built in the runtime. If you choose to modify the handler chain programmatically, then

you must determine if you will use the default handler resolver or use a custom implementation of a handler resolver that is registered on the service instance. A service instance uses a handler resolver when creating binding providers. When the binding providers are created, the handler resolver that is registered with a service is used to create a handler chain and the handler chain is subsequently used to configure the binding provider.

a. Use the default implementation of a handler resolver. The runtime now uses the @HandlerChain annotation and the default implementation of HandlerResolver class to build the handler chain. You can obtain the existing handler chain from the Binding, add or remove handlers, and then return the modified handler chain to the Binding object.
b. To use a custom implementation of a handler resolver, set the custom HandlerResolver class on the Service instance. The runtime uses your custom implementation of the HandlerResolver class to build the handler chain, and the default runtime implementation is not used. In this scenario, the @HandlerChain annotation is not read when retrieving the handler chain from the binding after the custom HandlerResolver instance is registered on the Service instance. You can obtain the existing handler chain from the Binding, add or remove handlers, and then return the modified handler chain to the Binding object.

3. Configure the server handlers by setting the @HandlerChain annotation on the service endpoint interface or implementation class. When the @HandlerChain annotation is configured on both the service endpoint interface and the implementation class, the implementation class takes priority.
4. Create the handler chain configuration XML file. You must create a handler chain configuration XML file for the @HandlerChain to reference.
5. Add the handler chain configuration XML file in the class path for the service endpoint interface when configuring the server or client handlers using the @HandlerChain annotation. You must also include the handler classes contained in the configuration XML file in your class path.
6. Write your handler implementation.

Results

You have the enabled your JAX-WS Web service or Web services client to use handlers to perform additional processing of request and response message exchange.

Example

The following example illustrates the steps necessary to configure JAX-WS handlers on a service endpoint interface using the @HandlerChain annotation.

The @HandlerChain annotation has a file attribute that points to a handler chain configuration XML file that you create. The following file illustrates a typical handler configuration file. The protocol-bindings, port-name-pattern, and service-name-pattern elements are all filters that are used to restrict which services can apply the handlers.

```
<?xml version="1.0" encoding="UTF-8"?>

<jws:handler-chains xmlns:jws="http://java.sun.com/xml/ns/javaee">
<!-- Note:  The '*" denotes a wildcard. -->

 <jws:handler-chain name="MyHandlerChain">
  <jws:protocol-bindings>##SOAP11_HTTP ##ANOTHER_BINDING</jws:protocol-bindings>
  <jws:port-name-pattern
              xmlns:ns1="http://handlersample.samples.ibm.com/">ns1:MySampl*</jws:port-name-pattern>
        <jws:service-name-pattern
              xmlns:ns1="http://handlersample.samples.ibm.com/">ns1:*</jws:service-name-pattern>
  <jws:handler>
   <jws:handler-class>com.ibm.samples.handlersample.SampleLogicalHandler</jws:handler-class>
  </jws:handler>
  <jws:handler>
   <jws:handler-class>com.ibm.samples.handlersample.SampleProtocolHandler2</jws:handler-class>
  </jws:handler>
```

```
  <jws:handler>
   <jws:handler-class>com.ibm.samples.handlersample.SampleLogicalHandler</jws:handler-class>
  </jws:handler>
  <jws:handler>
   <jws:handler-class>com.ibm.samples.handlersample.SampleProtocolHandler2</jws:handler-class>
  </jws:handler>
 </jws:handler-chain>

</jws:handler-chains>

</jws:handler-chains>
```

Make sure that you add the handler.xml file and the handler classes contained in the handler.xml file in your class path.

The following example demonstrates a handler implementation:

```
package com.ibm.samples.handlersample;

import java.util.Set;

import javax.xml.namespace.QName;
import javax.xml.ws.handler.MessageContext;
import javax.xml.ws.handler.soap.SOAPMessageContext;

public class SampleProtocolHandler implements
        javax.xml.ws.handler.soap.SOAPHandler<SOAPMessageContext> {

    public void close(MessageContext messagecontext) {
    }

    public Set<QName> getHeaders() {
        return null;
    }

    public boolean handleFault(SOAPMessageContext messagecontext) {
        return true;
    }

    public boolean handleMessage(SOAPMessageContext messagecontext) {
        Boolean outbound = (Boolean) messagecontext.get(MessageContext.MESSAGE_OUTBOUND_PROPERTY);
        if (outbound) {
            // Include your steps for the outbound flow.
        }
        return true;
    }

}
```

What to do next

Deploy your Web services application.

Running an unmanaged Web services JAX-WS client

WebSphere Application Server provides an unmanaged client implementation that is based on the Java API for XML-based Web Services (JAX-WS) 2.1 specification. The Thin Client for JAX-WS with WebSphere Application Server is an unmanaged and stand-alone Java client environment that enables running JAX-WS Web services client applications to invoke Web services that are hosted by WebSphere Application Server.

Before you begin

Before you set up a JAX-WS unmanaged client execution environment, obtain the Thin Client for JAX-WS Java archive (JAR) file. To obtain the Thin Client for JAX-WS, install WebSphere Application Server Version 7.0 or the Application Client for WebSphere Application Server Version 7.0. The Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_7.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-WS, `com.ibm.jaxws.thinclient_7.0.0.jar` file, to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-WS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-WS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-WS works with IBM Software Development Kits (SDKs) Version 6.0. The Thin Client for JAX-WS is also supported on non-IBM SDKs V6.0 with this limitation:

- Xerces limitation on non-IBM SDKs

  You must download Xerces-J Version 2.6.2, and add the file to the classpath when setting up the Thin Client for JAX-WS environment.

About this task

Set up a Thin Client for JAX-WS environment by completing the following steps.

1. Configure the path. Enter the following command to add the Java `bin` directories to your path:

   ```
   set PATH=<your_JDK_bin_directory>;%PATH%
   ```

2. Configure the classpath.
   - Add the Thin Client for JAX-WS JAR file to the classpath definition.

     ```
     set CLASSPATH=.;<your_jax-ws_thin_client_install_directory>\com.ibm.jaxws.thinclient_7.0.0.jar;
     <your_application_jars>;%CLASSPATH%
     ```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` file and `xercesImpl.jar` file from the Xerces Web site, and configure the classpath definition.

     ```
     set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
     \xercesImpl.jar;%CLASSPATH%
     ```

3. Configure SSL for the client.
   a. Add the following system properties to the Java command:

      ```
      -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
      ```

      You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the com.ibm.ssl.keyStore and com.ibm.ssl.trustStore key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

      ```
      com.ibm.ssl.protocol=SSL
      com.ibm.ssl.trustManager=SunX509
      com.ibm.ssl.keyManager=SunX509
      com.ibm.ssl.contextProvider=SunJSSE

      com.ibm.ssl.keyStoreType=JKS
      com.ibm.ssl.keyStoreProvider=SUN
      com.ibm.ssl.keyStore=/home/user1/etc/key.jks

      com.ibm.ssl.trustStoreType=JKS
      com.ibm.ssl.trustStoreProvider=SUN
      com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
      ```

      The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_7.0.0.jar` file, or add it to the classpath.

4. Enter the following command to run your client application:

```
%JAVA_HOME%/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

Results

You have set up an unmanaged JAX-WS client runtime environment to invoke Web services hosted on a WebSphere Application Server.

Developing Web services applications with JAX-RPC

You can use the Java API for XML-based RPC (JAX-RPC) programming model to develop Web services.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

About this task

To develop Web services based on the JAX-RPC programming model, you can use a bottom-up development approach starting from existing JavaBeans or enterprise beans or you can use a top-down development approach starting with an existing Web Services Description Language (WSDL) file. This task describes the steps when using the bottom-up development approach.

When developing a JAX-RPC Web service starting from existing JavaBeans or enterprise beans, you need develop a WSDL file. You can use existing JavaBeans or enterprise beans and then enable the implementation for Web services. Enabling the bean for Web services includes developing the service endpoint interface, developing a WSDL file that is the description of the Web service, generating and configuring the deployment descriptors, assembling all artifacts required for the Web service, and deploying the application onto the application server.

Considerations when using JavaBeans

JavaBeans exposed as JAX-RPC Web services are supported only over an HTTP transport.

Considerations when using enterprise beans

- The enterprise bean must be a stateless session bean.
- Enterprise beans that are exposed as JAX-RPC Web services must be packaged in EJB 2.1 or in EJB 3.0 or higher modules.
- For JAX-RPC Web services using EJB 2.1 style endpoints, the Web service method parameters must be one of the supported JAX-RPC types. These requirements are documented in the JAX-RPC specification.
- JAX-RPC Web services using enterprise beans are supported over an HTTP or Java Message Service (JMS) transport.

Note: It is a best practice to use EJB 2.1 style enterprise beans with JAX-RPC applications.

1. Set up a development environment for Web services. You do not have to set up a development environment if you are using Rational Application Developer.
2. Determine the existing JavaBeans or enterprise beans that you want to expose as a JAX-RPC Web service.
3. Develop a service endpoint interface. The service endpoint interface defines the JavaBeans or enterprise beans methods for a particular Web service. The JavaBeans must implement methods that have the same signature as the methods on the service endpoint interface.
   - Develop a service endpoint interface for JavaBeans applications.
   - Develop a service endpoint interface for enterprise beans applications.
4. Develop the Java artifacts.
   a. Develop a WSDL file. The WSDL file is the description of a Java Platform, Enterprise Edition (Java EE) Web service. For JAX-RPC applications, a WSDL file is required.
   b. Develop JAX-RPC deployment descriptors. Use the WSDL2Java command-line tool to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans or enterprise beans implementation.
      - Develop Web services deployment descriptor templates for a JavaBeans implementation.
      - Develop Web services deployment descriptor templates for an enterprise beans implementation.
5. Complete the implementation of your Web service application.
   - For JavaBeans applications, complete the JavaBeans implementation.
   - For enterprise beans applications, complete the enterprise beans implementation.
6. Configure the `webservices.xml` deployment descriptor. For JAX-RPC Web services, configure the webservices.xml deployment descriptor so that the application server can process the incoming Web services requests.
7. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that the application server can process the incoming Web services requests.
8. Assemble the artifacts for your Web service.

   Use assembly tools provided with the application server to assemble your Java-based Web services modules.

   If you have assembled an EAR file that contains enterprise beans modules that contain Web services, use the endptEnabler command-line tool or an assembly tool before deployment to produce a Web services endpoint WAR file. This tool is also used to specify whether the Web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
9. Deploy the EAR file into the application server. You can now deploy the EAR file that has been configured and enabled for JAX-RPC Web services onto the application server.

Results

You have developed a JAX-RPC Web service application.

What to do next

After you deploy the EAR file, test the Web service to make sure that the service works with the application server.

Developing a service endpoint interface from JavaBeans for JAX-RPC applications

You must develop a service endpoint interface if you are developing a JAX-RPC Web service from a JavaBeans implementation.

Before you begin

You need to set up a development environment for Web services and access an existing Java bean Web archive (WAR) file.

About this task

This task is a required step in developing a JAX-RPC Web service from a Java bean.

The service endpoint interface defines the methods for particular Java API for XML-based RPC (JAX-RPC) Web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the JAX-RPC specification.

You can also create a service endpoint interface by using assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:

1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

Results

You have developed a service endpoint interface that you can use to develop Web services.

Example

The following example depicts the AddressBook interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the AddressBook interface to create the service endpoint interface:

1. Make a copy of the AddressBook.java interface and name it `AddressBook_SEI.java`. Use this copy as a template for the service endpoint interface.

2. Compile the interface.

What to do next

Continue to gather the artifacts that are required to develop a Web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a Web service. Without a WSDL file, you do not have a Web service.

Developing a service endpoint interface from enterprise beans for JAX-RPC applications

You can develop a service endpoint interface from an Enterprise JavaBeans (EJB) for a JAX-RPC Web service.

Before you begin

Set up a development environment for Web services.

This task is a required step in developing a Java API for XML-based RPC (JAX-RPC) Web service from an enterprise bean.

The service endpoint interface defines the Web services methods. The enterprise beans that implements the Web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification. See the Web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

The easiest method for creating the service endpoint interface for an EJB Web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using assembly tools..

About this task

Develop a service endpoint interface by following the steps provided in this task section.

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

Results

You have a service endpoint interface that you can use to develop a Web service.

Example

This example uses the EJB remote interface, AddressBook_RI, to create a service endpoint interface for an EJB implementation that is used as a Web service. The following code example illustrates the AddressBook_RI remote interface.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
```

```
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
     throws java.rmi.RemoteException;
}
```

Use the following steps to create the service endpoint interface with the AddressBook_RI remote interface:
1. Locate a remote interface that has already been created, like the `AddressBook_RI.java` remote interface.
2. Make a copy of the `AddressBook.java` remote interface and use it as a template for the service endpoint interface.
3. Compile the `AddressBook.java` service endpoint interface.

What to do next

Continue gathering the artifacts that are required to develop a Web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a Web service; without a WSDL file, you have no Web service.

Developing a WSDL file for JAX-RPC applications

You can develop a Web Services Description Language (WSDL) file to describe the characteristics of your Java API for XML-based RPC (JAX-RPC) Web services application including where the service resides and how to invoke the service using an XML format.

Before you begin

Depending on your development path, develop a service endpoint interface from a JavaBeans implementation or develop a service endpoint interface from an enterprise bean implementation.

About this task

You need a WSDL file to use Web services. You can develop your own WSDL file or get one from a Web services provider through e-mail, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:
1. Configure the service endpoint interface class and referenced classes into your CLASSPATH variable.
   - On Windows systems, set `CLASSPATH="%CLASSPATH%;<`*list your application Java archive (JAR) files and classes*`>"`.
   - On UNIX and Linux systems, export `CLASSPATH="$CLASSPATH:<`*list your application JAR files and classes*`>"`.
2. Run the Java2WSDL *seiInterface* command. A WSDL file named *`seiInterface`*`.wsdl` is created.

   Note: The Java2WSDL command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.
   - Move the WSDL file to the `META-INF/wsdl` subdirectory if you are using Enterprise JavaBeans (EJB).
   - Move the WSDL file to the `WEB-INF/wsdl` subdirectory if you are using JavaBeans.
3. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.

4. (Optional) Use the **Java2WSDL** command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the **Java2WSDL** command tool. Generating and setting the part names is done by providing additional information to the **Java2WSDL** command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the **Java2WSDL -implClass *seiImpl seiInterface*** command to generate a WSDL file with the proper part names.

Results

A WSDL file that defines the Web services described by the service endpoint interface.

Example

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the **Java2WSDL -implClass addr.AddressBookBean addr.AddressBook** command to create the file, `AddressBook.wsdl`.

What to do next

Depending on your development path, develop Web services deployment descriptor templates for JavaBeans or develop Web services deployment descriptor templates for an enterprise beans implementation.

Java2WSDL command for JAX-RPC applications

The Java2WSDL command-line tool maps Java classes to a WSDL file for Java API for XML-based RPC (JAX-RPC) applications.

The Java2WSDL command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product.

The Java2WSDL command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification.

The Java2WSDL command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the Java2WSDL command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The Java2WSDL command is protocol independent; when you run the Java2WSDL command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the **Java2WSDL** command has a binding generator to generate the WSDL for that binding.

Command line syntax and arguments

The command line syntax is:

`Java2WSDL [`*`argument...`*`] `*`class`*

The following command-line arguments are supported:

Required arguments

- class

  Represents the fully qualified name of one of the following Java classes:
  - Stateless session Enterprise JavaBeans (EJB) remote interface that extends the javax.ejb.EJBObject class
  - Service endpoint interface that extends the java.rmi.Remote class
  - Java beans

  The **Java2WSDL** command locates the class in the CLASSPATH variable.

Important arguments

- -location *location*

  Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the Web service is deployed.

  The name after the last backslash is the name of the service port, unless the name is overridden by the -servicePortName argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the -location option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the -x flag.

  The following example illustrates how to produce both SOAP over HTTP, and SOAP over Java Message Service (JMS) bindings :

  ```
  java2wsdl -bindingTypes http,jms \
    -x http.location=http://your.server.name:9080/StockQuoteService/services/StockQuote \
    -x jms.location= \
   jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&targetService=StockQuote
  ```

  Use the -location option to determine to which port the -location option value applies by requiring the endpoint URLs to be specified through the binding-specific property values.
- -output *wsdl-uri*

  Indicates the path and file name of the output WSDL file. If not specified, the default *class*.wsdl file is written into the current directory.
- -input *wsdl-uri*

  Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.
- -bindingTypes

  Specifies the list of binding types write to the output WSDL file. Each binding generator in the Java2WSDL command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the my.pkg.MySEI Service Endpoint Interface and the my.pkg.MyEJBClass implementation class :

  ```
  java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
  ```

  The following command is an example of using the -bindingTypes option to generate SOAP over HTTP and SOAP over JMS bindings:

  ```
  java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
  ```
- -style RPC | DOCUMENT

  Specifies the WSDL style to use in the generated WSDL file. For more information about styles, see Mapping between Java, WSDL and XML. This argument is used with the -use argument.

  If RPC is specified with -use ENCODED, a `style=rpc/use=encoded` WSDL file is generated. If RPC is specified with the -use LITERAL option, a `style=rpc/use=literal` WSDL file is generated. If DOCUMENT is specified with the -use LITERAL option, a `style=document/use=literal` WSDL file is generated.
- -use LITERAL | ENCODED

Specifies which style and use combinations are generated into the WSDL file when used with the -style argument. The combinations are rpc and encoded, rpc and literal, or doc and literal. This setting applies to all SOAP bindings. For more information, see the Mapping between Java language, WSDL and XML.

- -transport http | jms

  Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

  This option is deprecated. The -bindingTypes option replaces the -transport option, so that you can generate bindings that are non-SOAP specific.
- -portTypeName *name*

  Specifies the name to use for the portType element. If not specified, the binding name is the port type name.
- -bindingName *name*

  Specifies the name to use for the binding element. If not specified, the binding name is the port type name.
- -serviceElementName *name*

  Specifies the name of the service element.
- -servicePortName *name*

  Specifies the name of the service. If not specified, the service name is derived from the -location argument.
- -namespace *targetNamespace*

  Indicates the target namespace for the WSDL file being generated. See Mapping between Java code, WSDL and XML for the algorithm that is used to obtain the default namespace.
- -PkgtoNS *package namespace*

  Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the Java2WSDL command generates a namespace name. You can repeat the -PkgtoNS argument to specify mappings for multiple packages.
- -extraClasses *classes*

  Specifies other classes that are represented in the WSDL file.
- -implClass *impl-class*

  The Java2WSDL command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the -implClass argument to provide an alternative class from which to obtain method parameter names. The impl-class does not need to implement the class if the class is an interface, but it must implement the same methods as the class.
- -verbose

  Displays verbose messages.
- -help

  Displays the help message.
- -helpX

  Displays the help message for extended options and for various options that are supported by binding generators.

Other arguments

- -wrapped *boolean*

  Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if `use` is literal only. The option defaults to `true`.
- -stopClasses *parent* [, *parent*]

  The Java2WSDL command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the -all argument is specified.

The Java2WSDL command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the -stopClasses argument to define additional classes that cause the search to stop.

- -methods *argument*

  Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.

- -soapAction

  Valid arguments are:
  - DEFAULT

    Sets the soapAction field according to the deployment information.
  - NONE

    Sets the soapAction field to double quotes (`""`).
  - OPERATION

    Sets the soapAction field to the operation name.

- -outputImpl *impl-wsdl*

  Specifies if you want an interface and implementation WSDL file emitted.

- -locationImport *location-uri*

  Specifies the location of the interface WSDL file if you use the -outputImpl argument.

- -namespaceImpl *namespace*

  Specifies the target namespace for the implementation WSDL file, if you use the -outputImpl argument.

- -MIMEStyle <*style*>

  Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (wsi:swaRef) for the binding element.

  <*style*> can be one of the following:
  - WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.
  - AXIS: Map MIME types using AXIS standards, for example image becomes axis:image.
  - swaRef: Map MIME types using WSDL 1.1 standards with two caveats:
    - DataHandler maps to the wsi:swaRef element instead of an application and octet-stream
    - If mapping is illegal through WSDL 1.1, map to the wsi:swaRef element

- -propertiesFile *argument*

  Sets existing options, such as -extraClasses, with a properties file instead of with a command line. The following example illustrates the use of this argument:

  ```
  extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3
  ```

- -voidReturn

  Valid arguments are:
  - ONEWAY

    Methods with void returns are one-way. This argument is the default for a JMS transport.
  - TWOWAY

    Methods with void returns are two-way. This argument is the default for an HTTP transport.

- -debug

  Displays debug messages.

- -property or -x

  You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the **Java2WSDL** command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

```
java2wsdl -x prop1=value1 -x prop2=value2
```

is equivalent to:

```
java2wsdl -x prop1=value1,prop2=value2
```

The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

Mapping between Java language, WSDL and XML for JAX-RPC applications

Data for Java API for XML-based Remote Procedure Call (JAX-RPC) applications flows as extensible Markup Language (XML). JAX-RPC applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For JAX-RPC applications, most of the mappings between the Java language and XML are specified by the JAX-RPC specification. Some mappings that are optional or unspecified in JAX-RPC are also supported. Review the JAX-RPC specification for a complete list of APIs. For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

Notational conventions

The following table specifies the namespace prefixes and corresponding namespace used.

Namespace prefix	Namespace
xsd	`http://www.w3.org/2001/XMLSchema`
xsi	`http://www.w3.org/2001/XMLSchema-instance`
soapenc	`http://schemas.xmlsoap.org/soap/encoding/`
wsdl	`http://schemas.xmlsoap.org/wsdl/`
wsdlsoap	`http://schemas.xmlsoap.org/wsdl/soap/`
ns	user-defined namespace
apache	`http://xml.apache.org/xml-soap`
wasws	`http://websphere.ibm.com/webservices/`

Detailed mapping information

The following sections identify the supported mappings, including:
- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the **Java2WSDL** command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the Web service. The generated WSDL file can require additional manual editing for the following reasons:
- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a java.lang.String class can map to either an xsd:string or soapenc:string construct. The **Java2WSDL** command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.

- Multiple ways exist to generate WSDL constructs. For example, you can generate the wsdl:part in wsdl:message with a type or element attribute. The **Java2WSDL** command makes an informed choice based on the -style and -use option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the **Java2WSDL** command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the wsdl:import construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

General issues

- **Package to namespace mapping**

  The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, com.ibm.webservice, is mapped to the XML namespace `http://webservice.ibm.com`.

  You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.
- **Identifier mapping**

  Java identifiers are mapped directly to WSDL and XML identifiers.

  Java bean property names are mapped to XML identifiers. For example, a Java bean, with getInfo and setInfo methods, maps to an XML construct with the name, `info`.

  The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the WSDL2Java command -implClass option for more details.
- **WSDL construction summary**

  The following table summarizes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Service endpoint interface	wsdl:portType
Method	wsdl:operation
Parameters	wsdl:input, wsdl:message, wsdl:part
Return	wsdl:output, wsdl:message, wsdl:part
Throws	wsdl:fault, wsdl:message, wsdl:part
Primitive types	xsd and soapenc simple types
Java beans	xsd:complexType
Java bean properties	Nested xsd:elements of xsd:complexType
Arrays	JAX-RPC defined xsd:complexType or xsd:element with a maxOccurs=″unbounded″ attribute
User defined exceptions	`xsd:complexType`

- **Binding** and **service** construction

  A wsdl:binding that conforms to the generated wsdl:portType is generated. A wsdl:service containing a port that references the generated wsdl:binding is generated. The names of the binding and service are controlled by the **Java2WSDL** command.

- **Style** and **use**

  Use the -style and -use options to generate different kinds of WSDL files. The four supported combinations are:
  - -style DOCUMENT -use LITERAL
  - -style RPC -use LITERAL
  - -style DOCUMENT -use LITERAL -wrapped false
  - -style RPC -use ENCODED

  The following is a brief description of each combination.
  - **DOCUMENT LITERAL**

    The **Java2WSDL** command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The wsdl:binding is generated with embedded style=″document″ and use=″literal″ attributes. An xsd:element is generated for each service endpoint interface method to describe the request message. A similar xsd:element is generated for each service endpoint interface method to describe the response message.
  - **RPC LITERAL**

    The **Java2WSDL** command generates a WS-I compliant rpc-literal WSDL file. The wsdl:binding is generated with embedded style=″rpc″ and use=″literal″ attributes. The wsdl:message constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the wsdl:message constructs.
  - **DOCUMENT LITERAL not wrapped**

    The **Java2WSDL** command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of wsdl:message constructs to define the request and response messages.
  - **RPC ENCODED**

    The **Java2WSDL** command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The wsdl:binding is generated with embedded style=″rpc″ and use=″encoded″ attributes. Certain soapenc mappings are used to represent types and arrays.

Mapping of standard XML types from Java types

Many Java types map directly to standard XML types. For example, a java.lang.String maps to an xsd:string. These mappings are described in the JAX-RPC specification.

Generation of wsdl:types

Java types that cannot be mapped directly to standard XML types are generated in the `wsdl:types` section. A Java class that matches the Java bean pattern is mapped to an `xsd:complexType`. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

Java:

```
public abstract class Base {
     public Base() {}
     public int a;                          // mapped
     private int b;                         // mapped via setter/getter
     private int c;                         // not mapped
     private int[] d;                       // mapped via indexed setter/getter

     public int getB() { return b;}         // map property b
     public void setB(int b) {this.b = b;}

     public int[] getD() { return d;}       // map indexed property d
     public void setD(int[] d) {this.d = d;}
     public int getD(int index) { return d[index];}
     public void setB(int index, int value) {this.d[index] = value;}

     public void someMethod() {...}         // not mapped
```

```
  }

  public class Derived extends Base {
     public int x;                          // mapped
     private int y;                         // not mapped
  }
```

Mapped to:

```
<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
  <xsd:element name="a" type="xsd:int"/>
  <xsd:element name="b" type="xsd:int"/>
  <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
  <xsd:extension base="ns:Base">
   <xsd:sequence>
    <xsd:element name="x" type="xsd:int"/>
   </xsd:sequence>
  </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>
```

- **Unsupported classes**

  If a class cannot be mapped to an XML type, the **Java2WSDL** command issues a message and an xsd:anyType reference is generated in the WSDL file. In these situations, modify the Web service implementation to use the JAX-RPC compliant classes.

WSDL-to-Java mapping

The **WSDL2Java** command generates Java classes using information described in the WSDL file.

General issues

- **Mapping of a namespace to a package**

  JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name com.ibm.websphere.

  The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the com.ibm.websphere Java package. You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.

  Identifier mapping

  XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- **Java construction summary**

  The following table summarizes the Java-to-XML construction. See the JAX-RPC specification for a description of these mappings.

WSDL and XML construction	Java construction

xsd:complexType	Java bean class, Java exception class, or Java array
nested xsd:element/xsd:attribute	Java bean property
xsd:simpleType (enumeration)	JAX-RPC enumeration class
wsdl:message The method parameter signature typically is determined by the wsdl:message.	Service endpoint interface method signature
wsdl:portType	Service endpoint interface
wsdl:operation	Service endpoint interface method
wsdl:binding	Stub
wsdl:service	Service interface
wsdl:port	Port accessor method in Service interface

- **Mapping standard XML types**
  - **JAX-RPC simple XML types mapping**

    Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

    Mapping the XML types defined in the wsdl:types section

    The **WSDL2Java** command generates Java types for the XML schema constructs that are defined in the wsdl:types section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The **WSDL2Java** command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The **WSDL2Java** command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an xsd:element is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, javax.xml.soap.SOAPElement.

    The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The xsd:complexType defines the type. The nested xsd:elements within the xsd:sequence or xsd:all groups are mapped to Java bean properties. For example:

    XML:

```
<xsd:complexType name="Sample">
  <xsd:sequence>
  <xsd:element name="a" type="xsd:string"/>
  <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
 </xsd:sequence>
</xsd:complexType>
```

    Java:

```
public class Sample {
     // ..
     public Sample() {}

     // Bean Property a
     public String getA()             {...}
     public void   setA(String value) {...}

     // Indexed Bean Property b
     public String[] getB()           {...}
     public String   getB(int index)  {...}
     public void     setB(String[] values) {...}
     public void     setB(int index, String value) {...}

  }
```

– **Mapping of the wsdl:portType construct**

  The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.

– **Mapping of the wsdl:operation construct**

  A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

  - **Effect of document literal wrapped format**

    If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The document literal wrapped and literal format is automatically detected by the **WSDL2Java** command. The following criteria must be met:
    - The WSDL file must have style=″document″ in its wsdl:binding construct.
    - The input and output constructs of the operations within the wsdl:binding must contain soap:body elements that contain use=″literal″.
    - The wsdl:message referenced by the wsdl:operation input construct must have a single part.
    - The part must use the element attribute to reference an xsd:element.
    - The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
    - The wrapper element must not contain any xsd:attributes.

    In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

    WSDL:

```
<xsd:element name="myMethod">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="param1" type="xsd:string"/>
   <xsd:element name="param2" type="xsd:int"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
 <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
```

    Java:

```
void myMethod(String param1, int param2) ...
```

  - **Parameter mapping**

    If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

    Each parameter is defined by a wsdl:message part referenced from the input and output elements.
    - A wsdl:part in the request wsdl:message is mapped to an input parameter.
    - A wsdl:part in the response wsdl:message is mapped to the return value. If multiple wsdl:parts exist in the response message, they are mapped to output parameters.

  - A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
- A wsdl:part that is both the request and response wsdl:message is mapped to an inout parameter.
  - A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
  - The wsdl:operation parameterOrder attribute defines the order of the parameters.

XML:

```
<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
 <part name="param2" type="xsd:int"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>

Java:

void myMethod(String param1, int param2) ...
```

– **Mapping of wsdl:binding**

The **WSDL2Java** command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the Web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

- **MIME attachments**

  For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

  XML:

```
<wsdl:types>
 <schema ...>
  <complexType name="ArrayOfBinary">
   <restriction base="soapenc:Array">
     <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]"/>
   </restriction>
  </complexType>
 </schema>
</wsdl:types>

<wsdl:message name="request">
 <part name="param1" type="ns:ArrayOfBinary"/>
<wsdl:message name="response"/>

<wsdl:message name="response"/>
 ...

 <wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
 </wsdl:operation>
  ...

<binding ...
 <wsdl:operation name="myMethod">
```

```
  <input>
   <mime:multipartRelated>
    <mime:part>
     <mime:content part="param1" type="image/jpeg"/>
    </mime:part>
   </mime:multipartRelated>
  </input>
   ...
 </wsdl:operation>
```

Java:

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

MIME type	Java type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
multipart/*	javax.mail.internet.MimeMultipart
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source

– **Mapping of wsdl:service**

  The wsdl:service element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the wsdl:service element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

  In addition, the wsdl:service element is mapped to the implementation-specific ServiceLocator class, which is an implementation of the generated service interface.

Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The **WSDL2Java** command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

DOCUMENT versus RPC, LITERAL versus ENCODED

If a wsdl:binding element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a wsdl:binding element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the wsdl:part element is defined using the type attribute, the name and type of the part are used in the message. If the wsdl:part element is defined using the element attribute, the name and type of the element are used in the message. The element attribute is not supported by the JAX-RPC specification when use=″encoded″.

If a wsdl:binding element indicates that a message is encoded, the values in the message are sent with xsi:type information. If a wsdl:binding element indicates that a message is literal, the values in the message are typically not sent with xsi:type information. For example:

DOCUMENT/LITERAL
WSDL:

```
<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="a" type="xsd:string"/>
   <xsd:element ref="ns:c"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
  <wsdl:message name="request">
    <part name="parameters" element="ns:method"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
  <input message="request"/>
 ...
```

Message:

```
<soap:body>
  <ns:method>
   <a>ABC</a>
   <c>123</a>
  <ns:method>
</soap:body>
```

RPC/ENCODED
WSDL:

```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>
 ...
```

Message:

```
<soap:body>
  <ns:method>
   <a xsi:type="xsd:string">ABC</a>
   <element attribute is not permitted in rpc/encoded mode>
  </ns:method>
 </soap:body>
```

DOCUMENT/LITERAL not wrapped
WSDL:

```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>

...
```

Message:

```
<soap:body>
  <a>ABC</a>
  <c>123</a>
</soap:body>
```

Developing JAX-RPC Web services deployment descriptor templates for a JavaBeans implementation

Deployment descriptors are standard text files, formatted using XML and packaged in a Web services application. Deployment descriptors are required to deploy Java API for XML-based RPC (JAX-RPC) Web services that are developed using Web Services for Java Platform, Enterprise Edition (Java EE) technology.

Before you begin

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use Web services. You can develop your own WSDL file or get one from a Web services provider through e-mail, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

About this task

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component for Java API for XML-based RPC (JAX-RPC) applications.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the Web address looks like this example: file:drive:\path\file_name.wsdl. If you are using the Linux or Unix platform, the Web address looks like this example: file:/path/file_name.wsdl. You can also specify local files using the absolute or relative file system path.

When the Web service is a JavaBeans implementation in a Web module, the webservices.xml,ibm-webservices-bnd.xmi and ibm-webservices.ext.xmi deployment descriptors and the JAX-RPC mapping file are generated in the WEB-INF subdirectory.

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the WEB-INF subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

Note: The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Results

You have deployment descriptor templates that are required to implement or use JAX-RPC Web services.

Example

The following example uses a WSDL file named `AddressBookJ2WB.wsdl`:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the WEB-INF subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

What to do next

Now, you need to configure the webservices.xml deployment descriptor and configure the ibm-webservices-bnd.xmi deployment descriptor so that application server can process the incoming Web services. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

WSDL2Java command for JAX-RPC applications

Run the WSDL2Java command-line tool against the WSDL file to create Java APIs and deployment descriptor templates.

The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform.

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the Web service. The Web Services for Java Platform, Enterprise Edition (Java EE) specification defines deployment descriptors that deploy a Web service in a Java EE environment. The **WSDL2Java** command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. However, if you have an established WSDL or schema that relies on relative namespaces, under specific conditions you can use the allowRelativeNamespace property to disable the relative namespace restrictions in the WSDL2Java tool. For additional information, see the property description.

You can convert any relative namespaces to absolute namespaces. The following is an example of a relative namespace:

```
targetNamespace="MyRelNamespace"
```

. You can change the relative namespace in this example to an absolute namespace by adding the protocol and base URI information:

```
targetNamespace="http://www.sample.com/MyRelNamespace"
```

.

Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

Required arguments

- WSDL-URI

  Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

Important arguments

- -role *Java EE role*

  Specifies the Java EE development role that identifies which files to generate. Valid arguments include:
  - client

    A combination of the develop-client and deploy-client arguments.
  - deploy-client

    Generates binding files for client deployment.
  - deploy-server

    Generates binding files for server deployment.
  - develop-client (default)

    Generates files for client development.
  - develop-server

    Generates files for server development.
  - server

    A combination of the develop-server and deploy-server arguments.
- -container *Java EE-container*

  Indicates the Java EE container to use. Valid arguments include:
  - client

    Indicates client container.
  - ejb

    Indicates an Enterprise JavaBeans (EJB) container.
  - none

    Indicates no container.
  - web

    Indicates a Web container.

  For client roles (see the -role option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.
- -output *directory*

  Sets the root directory for emitted files.
- -inputMappingFile mapping file

  Specifies the file name of the Web Services for Java EE mapping file.
- -introspect

  Uses existing Java beans with a new Web service API.

  In some scenarios, it is good to use existing Java classes instead of generating new classes. The -introspect option directs the **WSDL2Java** command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

  Suppose you have an existing Java bean

```
public class Bean {
 public Date x;
}
```

  The WSDL file defines *x* as xsd:dateTime. Without the -introspect option, the **WSDL2Java** command generates a Java bean that is similar to the following example:

```
public class Bean {
 private Calendar x;
 public void setx(Calendar value) (x=value;)
 public Calendar getX() { return x;)
}
```

  The **WSDL2Java** command uses the -introspect option to examine the original Java bean and to generate classes that are compatible with existing Java beans.
- -classpath *paths*

Defines an alternative class path to search for Java classes.

- -noDataBinding

  Disables the binding of XML types to Java types. Instead, each XML type is mapped to a javax.xml.soap.SOAPElement interface defined by the SOAP with Attachments API for Java (SAAJ) specification.

  The Java API for XML Web Services (JAX-WS) programming model supports SAAJ 1.2 and 1.3.

  The JAX-RPC programming model supports SAAJ 1.2.

  The Java programming models define Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the **WSDL2Java** command maps the type to an SAAJ SOAPElement. A SAAJ SOAPElement is a generic representation of the element in the message. The methods on the SOAPElement can be used to examine the element and its children.

  In some scenarios, it might be more appropriate to use the generic SOAPElement mapping exclusively. To read more about the use of SOAPElement see SOAP with Attachments API for Java and Custom data binders.

  For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.
- -help

  Displays a help message and exits.
- -helpX

  Displays a help message for extended options. The options include:
- -verbose

  Displays processing information, including the names of the generated files.
- -NStoPkg *namespace=package*

  By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form *http://x.y.com* or *urn:x.y.com*, the corresponding package is *com.y.x*.

  You can provide your own mapping by using the -NStoPkg argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the samples.addr package, provide the -NStoPkg ″http://urn:AddressFetcher2/″=samples.addr argument to the **WSDL2Java** command.
- -timeout *seconds*

  Specifies how long the **WSDL2Java** command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; -1 disables the timeout.
- -genResolver

  Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future **WSDL2Java** command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named _AbsoluteImportResolver.java. Compile and package this class with the other Java classes that are generated by the **WSDL2Java** command.
- -useResolver *resolver-class*

  Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the **WSDL2Java** command that uses the -genResolver option. The class must be available in the CLASSPATH variable.
- -deployScope *argument*

  Indicates how to deploy the server implementation. Valid arguments include:
  - Application

    Uses one instance of the implementation class for all requests.
  - Request

    Creates a new instance of the implementation class for each request.

– Session

  Creates a new instance of the implementation class for each session.

Other arguments

- -user *id*

  Specifies the login user name to access the WSDL URI.
- -password *password*

  Specifies the login user password to access the WSDL URI.
- -all

  Generates Java files for all types, even those that are not referenced.
- -allowRelativeNamespace *true or false*

  Specifies whether to disable the relative namespace restrictions. If you specify `-allowRelativeNamespace=true`, the relative namespace restrictions are disabled.

  Note: Only use this property if you have an established WSDL file or schema that relies on a relative namespaces and you are seeking to interoperate with a defined set of vendors that permit the use of relative namespaces.
- -debug

  Prints debugging information.
- -genJava *argument*

  Generates Java files. Valid arguments include:
  – IfNotExists, default
  – Overwrite
  – No
- -javaSearch *argument*

  The -javaSearch option is used with the -genJava option. If the -genJava IfNotExists, use the -javaSearch option to determine how file existence is detected.
  – File (default): Looks for a file in the output directory
  – Classpath: Looks for a class in the CLASSPATH variable
  – Both: Looks for a file in the output directory or in a class in the CLASSPATH variable
- -genXML *argument*

  Generates the `.xml` and `.xmi` files. Valid arguments are:
  – IfNotExists, default
  – Overwrite
  – No
- -genImplSer *true or false*

  Indicates that each generated Java bean implements the java.io.Serializable. The default is `false`.
- -genEquals *true or false*

  Indicates that each generated Java bean have `equals` and `hashCode` methods. The default is false.
- -noWrappedOperations

  Disables wrapped operations detection. Java beans for the request and response messages are generated.
- -noWrappedArrays

  Disables wrapped array detection.
- -fileNStoPkg *file name*

  Specifies the file of the namespace to package mappings. The default is NStoPKG.properties.
- service *wsdl service name*

  Generates files for the installed WSDL service only.

- -testCase

  Generates the template for a JUnit test case for testing Web services. JUnit is a simple framework to write repeatable tests.

Developing JAX-RPC Web services deployment descriptor templates for an enterprise bean implementation

You can develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Java API for XML-based RPC (JAX-RPC) Web services.

Before you begin

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

About this task

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a Web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

When the Web service implementation contains an enterprise bean in an EJB module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `META-INF` subdirectory.

Run the **WSDL2Java -verbose -role develop-server -container ejb -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the `META-INF` subdirectory. If the -verbose option is specified, a list of all generated files displays when the command runs.

Note: The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Results

You have deployment descriptor templates that are required to implement a Web service.

Example

The following example uses the `AddressBookJ2WE.wsdl` WSDL file:

1. Generate the template files with the following command syntax:

   ```
   WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
   ```

   The deployment descriptor templates are generated into the `META-INF` subdirectory as follows:

```
Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml
```

What to do next

Continue to complete the steps that are necessary to develop a JAX-RPC Web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) Web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a Web archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop Web services deployment descriptor templates for a JavaBeans implementation using the wsdl2java command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

1. Edit the JavaBeans implementation template, *binding*Impl.java. The *binding* is the name of the <wsdl:binding> element in the WSDL file. The JavaBeans implementation is generated by the wsdl2java command-line tool.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using Web module assembly tools. Include all of the classes generated from running the wsdl2java command tool for JAX-RPC Web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC Web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

.

What to do next

If you are developing a JAX-RPC Web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming Web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) Web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a Web archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC Web services using the **wsdl2java** command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the Web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

1. Inspect the EJB remote interface template, *portType*_RI.java. If necessary, modify the template. The value *portType* is the name of the <wsdl:portType> element in the WSDL file.
2. Edit the *binding*Impl.java EJB implementation template. Where *binding* is the name of the <wsdl:binding> element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the WSDL2Java command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC Web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from Web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC Web service with an enterprise bean, you need to, configure the webservices.xml deployment descriptor.

Configuring the webservices.xml deployment descriptor for JAX-RPC Web services

You can configure the webservices.xml deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Before you can configure the ibm-webservices-bnd.xml deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC Web services, this task is one of the required steps in developing a Web service. You need to configure the deployment descriptors so that the application server can process the incoming Web services requests.

If you are developing a Web service from JavaBeans, you can develop Web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a Web service from an enterprise bean, you can develop Web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing Web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the Web module Web archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the webservices.xml deployment descriptor. The archive files must be assembled before you can configure the webservices.xml deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the webservices.xml deployment descriptor by following the steps provided in this task section.

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Results

You have a webservices.xml deployment descriptor that is configured.

What to do next

For JAX-RPC Web services, you must configure the `ibm-webservices-bnd.xmi` deployment descriptor.

Configuring the webservices.xml deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a Web service or a Web service client.

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) Web services. For JAX-WS Web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the `webservices.xml` deployment descriptor. See the Web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

About this task

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC Web services

Use assembly tools to configure the ibm-webservices-bnd.xml deployment descriptor. This file stores binding information that is associated with the endpoints defined with the webservices.xml deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xmi` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based Web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a Web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming Web services requests.

Depending on if you are developing a Web service from JavaBeans or an enterprise bean:
- Develop Web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop Web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the Web module Web archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Results

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the Web service implementation module.

What to do next

If you are developing a Web service from JavaBeans, assemble a WAR file that is enabled for Web services from Java code.

If you are developing a Web service from an enterprise bean, assemble a JAR file that is enabled for Web services from an enterprise bean. In this task you assemble the artifacts that are required to enable the EJB module for Web services into the JAR file.

JAX-RPC Web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

This article is an introduction to the `ibm-webservices-bnd.xmi` deployment descriptor file for Java API for XML-based RPC (JAX-RPC) Web services.

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Web services-enabled Web module or an Enterprise JavaBeans (EJB) module. This file contains information for the Web services run time that is required by WebSphere Application Server.

You can edit these properties using an assembly tool. See Configuring the `ibm-webservices-bnd.xmi` deployment descriptor for instructions.

The following user-defined assembly properties are supported:

- **wsDescNameLink**

  Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the `webservices.xml` file.
- **pc-name-link**

  Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the `webservices.xml` file.
- **scope**

  Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed Web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

Using WSDL EJB bindings to invoke an EJB from a Web services client

WebSphere Application Server supports directly accessing an Enterprise JavaBeans (EJB) as a Web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client.

Before you begin

You need an EJB that you can directly access as a Web service.

About this task

You can achieve this task because of a multiprotocol technology that uses Java API for XML-based remote procedure call (JAX-RPC) and Remote Method Invocation over Internet Inter-ORB Protocol (RMI/-IIOP) together.

RMI-IIOP with JAX-RPC supports WebSphere Java clients to invoke enterprise beans with a WSDL file and the JAX-RPC programming model instead of the standard Java EE programming model. When a Web service is implemented by an enterprise bean, multiprotocol JAX-RPC permits the Web service invocation path to be optimized for WebSphere Java clients.

This method yields better performance and enables you to get support for client transactions, which are not standard for Web services.

To use EJB bindings of Web Services Description Language (WSDL) files to transport Web services requests:

1. (Optional) Create a WSDL file that contains non-SOAP protocol bindings.

   You can use the -bindingTypes option of the **Java2WSDL** command to create a WSDL file that contains non-SOAP protocol bindings. The -bindingTypes option specifies the binding types to write to the output of the WSDL document. Review the Java2WSDL article for more information on using the -bindingTypes option. The following command is an example that you can use to generate SOAP over HTTP, and EJB bindings for a service endpoint interface, my.pkg.MySEI and an EJB implementation, my.pkg.MyEJBClass:

   ```
   java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
   ```

2. (Optional) Obtain an existing WSDL file to add the EJB binding to.
3. Add an EJB binding to the WSDL file.
4. Add a port address that contains an endpoint using the wsejb prefix.
5. Deploy the Web services application.
6. Configure the endpoint URL information for EJB bindings.

   The WSDL publisher uses this partial Web address string to produce the actual enterprise bean Web address for each port component that is defined in the enterprise bean JAR file. The published WSDL file can be used by clients that need to invoke the Web service.

Results

You have an EJB that can be accessed by a Web services client that uses the JAX-RPC programming model. The RMI-IIOP protocol is used instead of SOAP over HTTP

What to do next

Publish the WSDL file.

EJB endpoint URL syntax

An Enterprise JavaBean (EJB) endpoint URL is used to access a Web service with the EJB Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) transport. The URL specifies the EJB endpoint, including the EJB home class, the EJB Java Naming and Directory Interface (JNDI) name, and optional properties.

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

An EJB endpoint URL has the following format:

```
wsejb:/[classname]?<property>=<value>&amp;<property>=<value>&amp;...
```

Where:

- wsejb is the transport type
- *classname* is the name of the home interface class associated with the EJB to be invoked
- *property* and *value* pairs represent the set of required and optional properties. These properties are used to set certain values in the EJB endpoint URL. The various properties and definitions are described in the table.

JNDI-related properties

Property name	Description
jndiName	Specifies the JNDI name of the EJB. This property is required.
initialContextFactory	Specifies the name of the JNDI initial context factory. This property is optional
jndiProviderURL	Specifies the JNDI provider URL. This property is optional.

Example: Developing and deploying a JAX-RPC Web service from an existing application

You can develop a JAX-RPC Web service from an Enterprise JavaBeans (EJB) or JavaBeans implementation. The development process is based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

1. **Select the enterprise bean or JavaBeans implementation that you want to enable as a JAX-RPC Web service.**

   The implementation must meet the following Web Services for Java EE specification requirements:

   - It must have methods that can be mapped to a service endpoint interface. See step 2 for more information.
   - It must be a stateless session EJB implementation or a JavaBeans implementation without client-specific state, because the implementation bean might be selected to process a request from any client. If a client-specific state is required, a client identifier must be passed as a parameter of the Web services operation.

     The selected methods of an enterprise bean must not have a transaction attribute of mandatory, because no standard currently exists, for these Web services transactions.

     A JavaBeans implementation in a Web container requires the following contents:

     – A public default constructor
     – Exposed public methods
     – It must not save a client-specific state between method calls
     – It must be a public, non-final, and non-abstract class
     – It must not define a finalize method

2. **Develop a service endpoint interface**.

   Developing a Web service requires a service endpoint interface.

   If you are using an EJB implementation, develop a service endpoint interface from an EJB remote interface.

   If you are using a JavaBeans implementation, develop a service endpoint interface for a JavaBeans implementation.

3. Develop a Web Services Description Language (WSDL) file.

4. **Develop deployment descriptor templates**.

   If you are using an EJB implementation, develop Web services deployment descriptor templates from an EJB implementation.

   If you are using a JavaBeans implementation, develop Web services deployment descriptor templates for a JavaBeans implementation.

5. **Configure the deployment descriptors.**

   By setting the `ejb-link` or `servlet-link` values of the service-impl-bean elements you can link to the enterprise bean or JavaBeans implementation that implement the service.

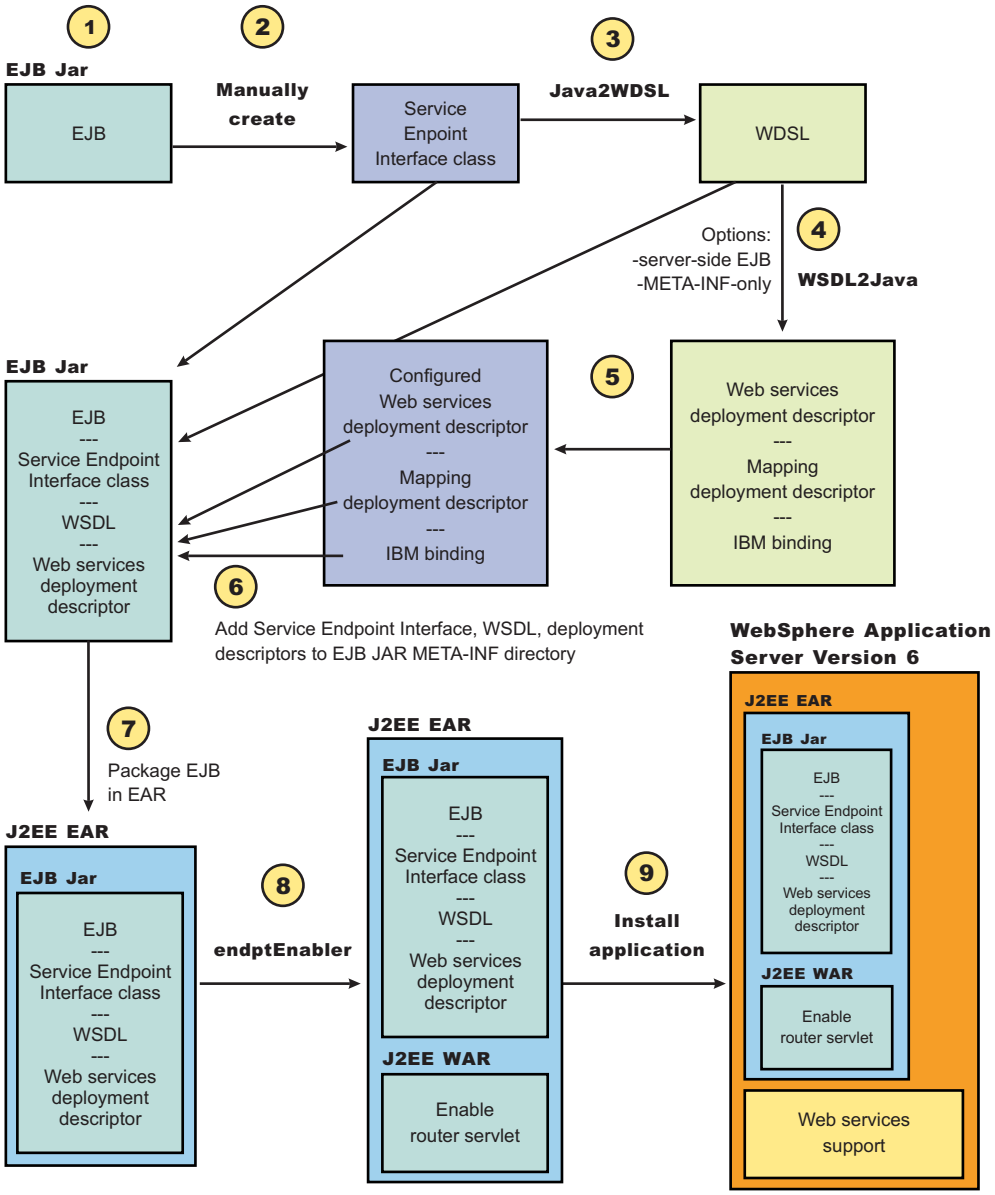
   Configure the `webservices.xml` deployment descriptor.

Configure the `ibm-webservices-bnd.xmi` deployment descriptor.

6. Assemble an enterprise archive (EAR) file from a JAR file or assemble an EAR file from a WAR file.
7. Enable the Web service-enabled EAR file.

   This step only applies if you are using an EJB implementation.
8. Deploy the Web service application.
9. Publish the WSDL file.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.



Developing Web services applications from existing WSDL files with JAX-RPC

You can develop a Web service with an existing Web Services Description Language (WSDL) file using the Java API for XML-based RPC (JAX-RPC) programming model.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

Locate the WSDL file that defines the Web service that you want to implement. You can develop a WSDL or obtain one from an existing Web service through e-mail, downloading or a Uniform Resource Locator (URL).

About this task

To develop Web services based on the JAX-RPC programming model, you can use a bottom-up development approach starting from existing JavaBeans or enterprise beans or you can use a top-down development approach starting with an existing Web Services Description Language (WSDL) file. This task describes the steps when using the top-down development approach.

When developing a JAX-RPC Web service starting from an existing WSDL file, create the JavaBeans or enterprise bean and artifacts that enable the bean as Web services and assemble all artifacts that are required for the Web service, and deploy the application onto the application server.

Considerations when using JavaBeans

JavaBeans exposed as JAX-RPC Web services are supported only over an HTTP transport.

Considerations when using enterprise beans

- The enterprise bean must be a stateless session bean.
- Enterprise beans that are exposed as JAX-RPC Web services must be packaged in EJB 2.1 or in EJB 3.0 or higher modules.
- For JAX-RPC Web services using EJB 2.1 style endpoints, the Web service method parameters must be one of the supported JAX-RPC types. These requirements are documented in the JAX-RPC specification.
- JAX-RPC Web services using enterprise beans are supported over an HTTP or Java Message Service (JMS) transport.

Note: It is a best practice to use EJB 2.1 style enterprise beans with JAX-RPC applications.

1. Set up a development environment for Web services. You do not have to set up a development environment if you are using Rational Application Developer.
2. Develop the Java artifacts from a WSDL file. You need to create the deployment descriptor templates and bindings that are configured to map the service implementation to the JavaBeans or enterprise beans implementation.
   - Develop JavaBeans artifacts from a WSDL file.
   - Develop enterprise beans artifacts from a WSDL file.
3. Complete the implementation of your Web service application.
   - For JavaBeans applications, complete the JavaBeans implementation.
   - For enterprise beans applications, complete the enterprise beans implementation.
4. Configure the `webservices.xml` deployment descriptor. For JAX-RPC Web services, configure the webservices.xml deployment descriptor so that the application server can process the incoming Web services requests.

5. Configure the `ibm-webservices-bnd.xmi` deployment descriptor. Configure the `ibm-webservices-bnd.xml` deployment descriptor so that the application server can process the incoming Web services requests.
6. Assemble the artifacts for your Web service.

   Use assembly tools provided with the application server to assemble your Java-based Web services modules.

   If you have assembled an Enterprise Archive (EAR) file that contains enterprise beans modules that contain Web services, use the endptEnabler command-line tool or an assembly tool before deployment to produce a Web services endpoint WAR file. This tool is also used to specify whether the Web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
7. Deploy the EAR file into the application server. You can now deploy the EAR file that has been configured and enabled for JAX-RPC Web services onto the application server.

Results

You have developed a JAX-RPC Web service application by starting with an existing WSDL file.

What to do next

After you deploy the EAR file, test the Web service to make sure that it works with the application server.

Developing Java artifacts for JAX-RPC applications from a WSDL file

You can develop Java artifacts from a Web Services Description (WSDL) file for JAX-RPC applications from a WSDL file by using the WSDL2Java command-line tool to create Java implementation templates and bindings.

Before you begin

To develop the JavaBeans implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the -role develop-server option of the WSDL2Java command. The WSDL2Java command also generates bindings and deployment descriptors.

The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

About this task

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can

convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

Run the **WSDL2Java -verbose -role develop-server -container web *wsdlURL*** command. Since the -verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement a Web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

Example

The following example uses the AddressBook JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the **WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

What to do next

Complete the Java bean implementation.

Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC Web services

You can develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and bindings from a Web Services Description Language (WSDL) file for a JAX-RPC application.

Before you begin

To develop EJB implementation templates and bindings from a WSDL file for a Java API for XML-based RPC (JAX-RPC) Web service, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

This task is one a required step in developing a Web service from an enterprise bean.

Implementation templates are generated using the -role develop-server option of the WSDL2Java command.

Templates are generated for an EJB implementation for the following components:
- enterprise bean
- EJB remote interface
- EJB Home

The WSDL2Java command also generates bindings and deployment descriptors.

The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

Run the **WSDL2Java -verbose -role develop-server -container ejb *wsdlURL*** command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement Web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

Example

The following example uses the enterprise bean AddressBook enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the **WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.

```

What to do next

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

Developing and deploying JAX-RPC Web services clients

You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-based RPC (JAX-RPC) programming model.

Before you begin

Note: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation Web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of Web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new Web services applications and clients.

About this task

Developing Web services clients based on the JAX-RPC programming model

The Web services client programming model provides the guidelines for accessing Web services in a Java EE environment. You can develop Web services clients based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification and the Java API for XML-based remote procedure call (JAX-RPC) specification. The application server supports Enterprise JavaBeans (EJB) clients, Java EE application clients, JavaServer Pages (JSP) files and servlets that are based on the JAX-RPC programming model.

Managed and unmanaged JAX-RPC Web services clients

The application server supports both managed and unmanaged Web Services clients when using the JAX-RPC programming model:

- Managed clients

  Web services for Java EE clients are defined by Java Specification Requirements (JSR) 109 and are managed clients because they run in a Java EE container. These clients are packaged as enterprise archive (EAR) files and contain components that act as service requesters. These components are comprised of a Java EE client application, a Web component such as a servlet or JavaServer Pages (JSP), or a session Enterprise JavaBeans (EJB). Web services managed clients use JSR 109 APIs and deployment information to look up and invoke a Web service.

  For the managed clients, the service look up is through Java Naming and Directory Interface (JNDI) lookup. Read about setting up UserName token Web services security, digital signature Web services security and Lightweight Third-Party Authentication (LTPA) token Web services security. The following code is an example of a context lookup that is JSR 109 compliant:

  ```
  InitialContext ctx = new InitialContext();
      FredsBankServiceLocator locator
  =(FredsBankService)ctx.lookup("java:comp/env/service/FredsBankService");
      FredsBank fb = locator.getFredsBank(url);
      long balance = fb.getBalance();
  ```

  When you are instantiating a context lookup for a managed client, do not use new() for the service locator. Here is an example that is not JSR 109 compliant (new ServiceLocator):

  ```
  Properties prop = new Properties();
      InitialContext ctx = new InitialContext(prop);
      FredsBankServiceLocator locator = new FredsBankServiceLocator();
      FredsBank fb = locator.getFredsBank(url);
      long balance = fb.getBalance();
  ```

  Without the lookup() call, the client has no access to the deployment descriptor. For JAX-RPC Web services, the Web services security configuration is in the Web services deployment descriptor.

- Unmanaged clients

  Java Platform, Standard Edition (Java SE 6) clients that use the JAX-RPC runtime environment to invoke Web services and do not run in any Java EE container are known as unmanaged clients. A Web services unmanaged client is a stand-alone Java client that can directly inspect a

WSDL file and formulate the calls to the Web service by using the JAX-RPC APIs directly. These clients are packaged as JAR files which do not contain any deployment information.

For a Java application to act as a Web service client, a mapping between the WSDL file and the Java application must exist. For JAX-RPC Web services, the mapping is defined by the JAX-RPC specification. You can use a Java component to implement a Web service by specifying the component interface and binding information in the WSDL file and designing the application server infrastructure to accept the service request. This entire process is based on the Web Services for Java EE specification. The JAX-RPC specification defines the mapping between a WSDL file, Java code, and XML Schema types.

1. Obtain the Web Services Description Language (WSDL) document for the Web service that you want to access.

   You can locate the WSDL from the services provider through e-mail, through a Uniform Resource Locator (URL) or by looking it up in a Universal Description, Discovery and Integration (UDDI) registry.
2. Develop client bindings from a WSDL file using the WSDL2Java command-line tool. The information needed to invoke the Web service is generated, including the service endpoint interface and implementations, the generated service interface and the `ibm-webservicesclient-bnd.xmi` and `ibm-webservicesclient-ext.xmi` deployment descriptors.
3. Complete the client implementation. Write your client application code that is used to invoke the Web service.

   See Chapter 4 of the JSR 109 specification. For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

   Note: If an application creates a number of threads in the JSR 109 client, the metadata (including the WebSphere Application Server configuration) is not copied to the thread, and the Global Security Handler is not called.

   You can review the JAX-RPC-based Web services sample, GetQuote client, in the WebServicesSamples application that is available in the Samples Gallery.
4. (Optional) Assemble a Web services-enabled client Java archive (JAR) file into an enterprise archive (EAR) file. Complete this step if you are developing a managed JAX-RPC Web services client that runs in the Java EE client container.
5. (Optional) Assemble a Web services-enabled client Web archive (WAR) file into an enterprise archive (EAR) file. Complete this step if you are developing a managed JAX-RPC Web services client that runs in the Java EE client container.
6. (Optional) Configure the client deployment descriptor. Complete this step if you are developing a managed JAX-RPC client.
7. (Optional) Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Complete this step if you are deploying a managed JAX-RPC client that runs in the Java EE client container, and you want to override the default client settings. See ibm-webservicesclient-bnd.xmi assembly properties for more information about the `ibm-webservicesclient-bnd.xmi` deployment descriptor.
8. (Optional) Deploy the Web services client application. Complete this step to deploy a managed JAX-RPC Web services client that runs in the Java EE client container.
9. Test the Web services-enabled client application. You can test an unmanaged client JAR file or a managed client application.

Results

You have created and tested a Web services client application.

What to do next

After you develop a Web services application client, and the client is statically bound, the service endpoint used by the implementation is the one that is identified in the WSDL file that you used during the

development process. During or after installation of the Web services application, you might want to change the service endpoint. For managed clients, you can change the endpoint with the administrative console or the wsadmin scripting tool.

You can additionally consider customizing your Web service by implementing extensions to your Web services client. Some examples of these extensions include sending and receiving values in SOAP headers, sending and receiving HTTP or JMS transport headers, or using custom bindings. To learn more about these extensions, read about implementing extensions to Web services clients.

Developing client bindings from a WSDL file for a JAX-RPC client

You can develop client bindings from a Web Services Description (WSDL) file for a JAX-RPC client.

Before you begin

To develop the client bindings from a WSDL file for JAX-RPC Web service applications, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a Web service.

If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the -role develop-client option in combination with the -container option of the **WSDL2Java** command. The -container option takes the following parameters:

- **-container client**

  Generates bindings and deployment descriptors for a client residing in the application client container.
- **-container ejb**

  Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.
- **-container web**

  Generates bindings and deployment descriptors for a client residing in the Web container.

The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

About this task

Develop client bindings from a WSDL file by running the appropriate command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the WSDL2Java tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the WSDL2Java tool, see the WSDL2Java command for JAX-RPC applications documentation.

Run the **WSDL2Java -verbose -role develop-client -container *type wsdlURL*** command,
where *type* is **ejb** for an enterprise EJB client, **web** for a JavaBeans client, or **client** for an application client.
You can use the following combinations in the command-line:

- -container web

- -container `ejb`
- -container `client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

Results

You have the bindings and deployment descriptors needed by a client to use a Web service.

Example

The following example uses the AddressBook enterprise bean the `AddressBook.wsdl` WSDL file. After generating the bindings from the **WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl** command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

What to do next

Complete the client implementation by writing your client application and then assembling the client artifacts.

.

Changing SOAP message encoding to support WSI-Basic Profile

Support for Universal Transformation Format (UTF)-16 encoding is required by the WS-I Basic Profile 1.0. WebSphere Application Server conforms to the WS-I Basic Profile 1.1. UTF-16 is a kind of unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet and UTF-16 encoding is typically used for Java and Windows product applications. You can change the encoding in a SOAP message from UTF-8 to UTF-16.

Before you begin

To learn more about the requirements of the Web Services-Interoperability Basic Profile (WS-I), including UTF-16, see Web Services-Interoperability Basic Profile.

About this task

Support for UTF-16 encoding is required by WS-I Basic Profile. The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

You can change the character encoding in one of two ways:

- Use a property on the Stub for users to set.

  This choice applies to the client only.

  For a client, the encoding is specified in the SOAP request. The SOAP engine serializes the request and sends it to the Web service engine. The Web service engine receives the request and deserializes the message to Java objects, which are returned to you in a response.

When the Web service engine on the server receives the serialized request, a raw message in the form of an input stream, is passed to the parser, which understands Byte Order Mark (BOM). BOM is mandatory for UTF-16 encoding and it can be used in UTF-8. The message is deserialized to a Java objects and a service invocation is made. For two-way invocation, the engine needs to serialize the message using a specific encoding and send it back to the caller. The following example shows you how to use a property on the Stub to change the character set:

```
javax.xml.rpc.Stub stub=service.getPort("MyPortType");
((javax.xml.rpc.Stub)stub).setProperty(com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING,"UTF-16");
stub.invokeMethod();
```

In this code example, **com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING** = *"com.ibm.wsspi.webservices.xmlcharset";*

- Use a handler to change the character set through SOAP with Attachments API for Java (SAAJ).

  If you are using a handler, the SOAP message is transformed to a SAAJ format from other possible forms, such as an input stream. In such cases as a handleRequest method on the client side and a handleResponse method on the server side, the Web services engine transforms from a SAAJ format back to the stream with appropriate character encoding. This transformation or change is called a *roundtrip transformation*. The following is an example of how you can use a handler to specify the character encoding through SAAJ:

```
handleResponse(MessageContext mc) {
 SOAPMessageContext smc = (SOAPMessageContext) context;
 javax.xml.soap.SOAPMessage msg = smc.getMessage();
 msg.setProperty (javax.xml.soap.SOAPMessage.CHARACTER_SET_ENCODING, "UTF-16");
 }
}
```

Results

You have modified the character encoding from UTF-8 to UTF-16 in the Web service SOAP message.

Configuring the JAX-RPC Web services client deployment descriptor with an assembly tool

You can configure JAX-RPC Web services client deployment descriptor with an assembly tool.

Before you begin

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, Web archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file.

About this task

Complete this task if you are developing a managed client that runs in the Java EE client container. This task is done after you assemble the EJB or Web module.

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.

3. Migrate the Web archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to assembly tools. To migrate files, import your WAR or JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer documentation.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the Web services client. This task explains how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Configuring the JAX-RPC client deployment descriptor for handler classes

You can configure the JAX-RPC client deployment descriptor for user-provided handler classes.

Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java Platform, Enterprise Edition (Java EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification. The application modules must contain the `webservices.xml`(for server) and the client deployment descriptors.

For a complete list of the supported standards and specifications, see the Web services specifications and API documentation.

About this task

Configure a handler in the client deployment descriptor by following the steps provided:

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the Web archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. Read about importing WAR or JAR files using an assembly tool in the Rational Application Developer documentation.
4. Configure the client deployment descriptor. Read about creating Web services handlers in the Rational Application Developer documentation.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the Web services client. This task explains how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Handler class properties with JAX-RPC

This article describes handler class properties using Java API for XML-based RPC (JAX-RPC).

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See Configuring the `webservices.xml` deployment descriptor for Handler classes or Configuring the client deployment descriptors for Handler classes for instructions on how to configure the properties.

Description:

Standard Java Platform, Enterprise Edition (Java EE) technology descriptor field.

Display name:

Standard Java EE technology descriptor field.

Small icon:

Standard Java EE technology descriptor field.

Large icon:

Standard Java EE technology descriptor field.

Handler name:

The name of the handler. This name must be unique within the module.

Handler class:

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

Initial parameters:

Property names and values available to the handler.

SOAP headers:

Qualified names (Qnames) of the SOAP headers that are processed by this handler.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through Web services specifications and APIs , for more information about setting this property.

SOAP roles:

URIs containing the SOAP actor names for which the handler acts in the role.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through Web services specifications and APIs , for more information about setting this property.

Example: Configuring handler classes for Web services deployment descriptors

This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
 package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
     public ClientHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleRequest");
   return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleResponse");
   return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ClientHandler: In handleFault");
   return true;  }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() {
  }

public javax.xml.namespace.QName[] getHeaders() {
   return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
 package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
  public ServerHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ServerHandler: In handleRequest");
   return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ServerHandler: In handleResponse");
   return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext
 context) {
   System.out.println("ServerHandler: In handleFault");
   return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) { }

public void destroy() {  }

public javax.xml.namespace.QName[] getHeaders() {
   return null;  }
}
```

1. Compile these classes using:
2. Open an assembly tool and import the two sample enterprise archive (EAR) files:

-
-

3. Import the compiled handler classes into the projects for the sample modules:
   - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
   - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the client deployment descriptor for handler classes.

   This topic explains how to configure the client deployment descriptor for user-provided handler classes.
5. Configure the webservices.xml deployment descriptor for handler classes.

   This topic explains how to configure the `webservices.xml` deployment descriptor for user-provided handler classes.
6. Save your changes and export the EAR files.
7. Uninstall the `WebServicesSamples.ear` application from your server if it is already installed.
8. Install the new `WebServicesSamples.ear` application.
9. Start the server.
10. Run the client:

    launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar

    When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```

       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       2 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       3 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
```

```
>> Response is:
       4 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
```

For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```
[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleResponse
```

Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming Web services requests.

What to do next

Deploy the EAR file that has been configured and enabled for Web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

Configuring the JAX-RPC Web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor

You can configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with assembly tools.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

You must configure the assembly tool before you can use it. Read about configuring the assembly tool in the Rational Application Developer documentation.

About this task

Now that you have assembled the client module, complete this step to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming Web services requests.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with the following steps provided:

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Switch to the Java EE Perspective.
   a. Click **Window** > **Open Perspective** > **Other** > **Java EE**.
3. Open the Project Explorer.
   a. Click **Window** > **Show View** > **Other** > **Project Explorer**.
4. Locate the deployment descriptor file for the module. Hint: Deployment Descriptor: <*module*>
5. Double-click the deployment descriptor file to open the Deployment Descriptor editor.
   a. Select the **WS Binding** tab at the bottom of the editor window to open the Web Services Client Bindings editor.
6. Verify the serviceRefLink element settings.

a. Open the **Web Services Client Bindings** editor.
b. Click the **Services References** tab.
c. Click **Add**.
d. Select the service references defined in the client deployment descriptor file from the list.

7. Verify the deployedWSDLFile element settings.
   a. Open the **Web Services Client Bindings** editor.
   b. Select the service reference.
   c. Expand the **Service Reference Details** section.
   d. Click **Browse** that is located to the right of the Deployed WSDL file field.
   e. Select the new Web Services Description Language (WSDL) file.
   f. Click **OK**.

   You can also change the deployedWSDLFile element of a deployed Web service using the administrative console. Click **Enterprise Applications** > *application* > **Web module** or **EJB module** > *module* >**Web services client bindings**.
8. Verify the `defaultMappings` element settings.
   a. Open the **Web services client bindings** editor.
   b. Click **Default mappings**.
   c. Click **Add**.
   d. Edit the entries in the newly added row to establish a mapping between a *portType* and a *port* in the WSDL file. Only one entry is supported for each *portType*.
   e. Click **OK**.

   You can also change the defaultMappings element of a deployed Web service using the administrative console. Click **Enterprise Applications** > *application* > **Web module** or **EJB module** > *module* >**Web services client bindings**.
9. Access the Web services client Port bindings editor through the **Port qualified name binding details** section at the bottom of the editor pane.
10. Verify the syncTimeout element settings.
    a. Create a Port qualified name bindings for the port.
    b. Open the **Web services client bindings** editor.
    c. Confirm that a service reference is selected in either the **Component-scoped references** or the **Service references** section.
    d. Expand the **Port qualified name binding** section.
    e. Click **Add**. The **Add port qualified name binding** dialog opens.
    f. Type the *namespace* of the WSDL file port you want to configure, in the **Port namespace link** field.
    g. Type the *local_name* of the WSDL file port you want to configure in the **Port local name link** field. The name displayed in the **Port qualified name binding** list is the local name of the WSDL file port.
    h. Click **OK**.
    a. Configure the syncTimeout property by locating the Synchronization timeout field and enter the desired value. The default is 300 seconds.
11. Verify the basicAuth element settings.
    a. Locate the **HTTP basic authentication** field in the **Port qualified name binding details** section.
    b. Type the desired value in the User ID and Password fields.
    c. Click **OK**.
12. Verify the sslConfig element settings.
    a. Locate the **SSL configuration** field in the **Port qualified name binding details** section.

b. Type the desired value in the **Name** field.
c. Click **OK**.

13. After editing the properties, type **ctrl-s** on your keyboard to save the changes.

Results

You have configured the `ibm-webservicesclient-bnd.xmi` deployment descriptor. If you have configured all of the client deployment descriptors, test the Web services client. If you have not configured all of the client deployment descriptors, complete the configurations and then test the Web services client.

Related concepts

Assembly tools
WebSphere Application Server supports *assembly tools* that you can use to develop, assemble, and deploy Java Platform, Enterprise Edition (Java EE) modules.

ibm-webservicesclient-bnd.xmi assembly properties for JAX-RPC applications

The `ibm-webservicesclient-bnd.xmi` deployment descriptor file contains information for the Web services run time that is WebSphere product-specific. This deployment descriptor file is used with Java API for XML-based RPC (JAX-RPC) Web services. This binding file is not applicable for Java API for XML-Based Web Services (JAX-WS) Web services.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server. Read about configuring the JAX-RPC Web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor to learn more about configuring this deployment descriptor.

Assembly properties

The following user-definable assembly properties are supported:

- **componentNameLink**

  An attribute of the componentScopedRefs element. When a Web service is implemented by an Enterprise JavaBeans (EJB) implementation, each <componentScopedRefs> element contains assembly properties for an individual enterprise bean. The componentNameLink attribute of the <componentScopedRefs> element identifies the enterprise bean that the assembly properties apply to by specifying the <ejb-name>. This property is used only when the Web service client is an enterprise bean.
- **serviceRefLink**

  An attribute of the serviceRefs element. Specifies the link to the <service-ref-name> in the <service-ref> element in the client deployment descriptor. The client deployment descriptor is either `ejb-jar.xml`, `web.xml` or `application-client.xml`.
- **deployedWSDLFile**

  An attribute of the serviceRefs element is optional. Permits an alternate Web Services Description Language (WSDL) file to use other than that specified in the <wsdl-file> element of the <service-ref> element in the client deployment descriptor. If an attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The deployedWSDLFile property supplies a new WSDL file containing a different endpoint Web address than the original WSDL file.
- **defaultMappings** element

  Identifies which port to use for a given portType when one is not selected by the client. This element has the following attributes: portTypeNamespace, portTypeLocalName, portNamespace, portLocalName. These attributes identify which wsdl:port is used for a wsdl:portType.
- **syncTimeout**

  An attribute of the portQnameBindings element. Specifies how long, in seconds, to wait for a response from a synchronous call. The default is 300 seconds.
- **basicAuth**

An element of the portQnameBindings element. Authenticates a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and Java Message Service (JMS). Set the user ID and password attributes as needed.

- **sslConfig**

  An element of the portQnameBindings element. Specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of an SSL configuration entry or alias that is defined in the SSL configuration repertoire. This attribute is used only when the client is running in the WebSphere Application Server.

  For WebSphere Application Server for z/OS, some digital certificate and keyring management is required. Refer to Creating Secure Sockets Layer digital certificates and System Authorization Facility keyrings applications to initiate HTTPS requests for more information.

A bindings file example

The following example demonstrates the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template `xmi` files generated by the **WSDL2Java** command for examples of ID strings. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

 <componentScopedRefs componentNameLink="myComponent ref"/>

 <serviceRefs serviceRefLink="myService ref" deployedWSDLFile="META-INF/wsdl/alternate.wsdl">
  <defaultMappings portTypeLocalName="AddressBook" portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
   <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
    <basicAuth userid="myId" password="myPassword"/>
    <sslConfig name="mynode/DefaultSSLSettings"/>
   </portQnameBindings>
  </serviceRefs>
 </com.ibm.etools.webservice.wscbnd:ClientBinding>
```

Implementing extensions to JAX-RPC Web services clients

WebSphere Application Server provides extensions to Web services clients using the Java API for XML-based RPC (JAX-RPC) programming model.

About this task

You can customize Web services by using the following extensions to the JAX-RPC client programming model.

- Set the **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties in a JAX-RPC client Stub to enable a Web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.

  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  See “Sending implicit SOAP headers with JAX-RPC” on page 632 or “Receiving implicit SOAP headers with JAX-RPC” on page 633 to learn how to modify your client code to send or retrieve transport headers.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a Web services client to send or retrieve transport headers.

  Set the properties on the Stub or Call object.

  By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

  See “Sending transport headers with JAX-RPC” on page 634 or “Retrieving transport headers with JAX-RPC” on page 635 to learn how to modify your client code to send or retrieve transport headers. See “Transport header properties best practices” on page 551 to learn how to enable a Web services client to send or retrieve transport headers.

- Implement support for **javax.xml.rpc.ServiceFactory.loadService()** methods.

  The loadService methods create an instance of the generated service implementation class in an implementation-specific manner. The loadService methods are new for JAX-RPC 1.1 and include three signatures:

  – **public.javax.xml.rpc.Service loadService (Class serviceInterface)**

    As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. See the Web services specifications and API documentation to review the JAX-RPC specification.

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

    This method behaves like the loadService (Class serviceInterface) because the following parameters are ignored:

    - wsdlDocumentLocation
    - properties

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

    This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

    - wsdlDocumentLocation - ignored
    - serviceName - QName (namespace, localpart) of the service

- properties - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

  If the properties argument contains an entry with a key (namespace) that matches the namespace portion of the QName serviceName argument, the entry value (`javaPackage`) is used as the package name when trying to locate the service implementation.

For more information on these methods, see the JAX-RPC specification.

- Implement the **CustomBinder interface** to provide concrete custom data binders for a specific XML schema type **(JAX-RPC applications only)**.

  Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The CustomBinder interface has three properties, in addition to deserialize and serialize methods:

  – QName for the XML schema type
  – QName scope
  – Java type

  The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the Web services runtime using a SOAPElement. They are added to the runtime by using custom binding providers. Read about the custom data binders and the custom binding provider to learn more. See the CustomBinder interface documentation to learn more about how you can implement this interface to provide concrete custom data binders for a specific XML schema type.

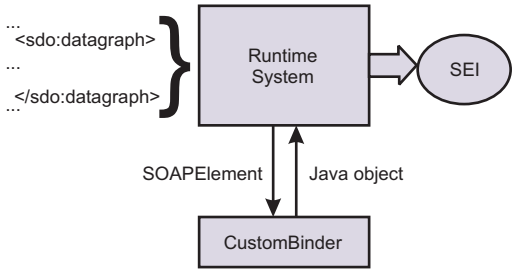
Custom data binders for JAX-RPC applications

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the run time system and interacts with the Web services runtime using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the run time system processes as follows:

1. The run time system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example SDOCustomBinder.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the SDOCustomBinder.

Within the deserialized method, the SDOCustomBinder extracts the content from the SOAPElement and builds a concrete DataGraph object with a `commonj.sdo.DataGraph` type. The figure displays the Web services runtime flow and a custom data binder.



When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```
<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
  <xsd:complexContent>
    <xsd:extension base="sdo:BaseDataGraphType">
      <xsd:sequence>
        <xsd:any minOccurs="0" maxOccurs="1"
                 namespace="##other" processContents="lax"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
  <xsd:sequence>
    <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
    <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
    <xsd:element name="changeSummary"
                 type="sdo:ChangeSummaryType" minOccurs="0"/>
   </xsd:sequence>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>

  <xsd:complexType name="ModelsType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##other" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="XSDType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="http://www.w3.org/2001/XMLSchema" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="ChangeSummaryType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##any" processContents="lax"/>
  </xsd:sequence>
  <xsd:attribute name="create" type="xsd:string"/>
```

```
  <xsd:attribute name="delete" type="xsd:string"/>
  </xsd:complexType>

</xsd:schema>
```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, read about custom binding providers. You can also read about usage patterns for deploying custom data binders to learn more about how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Custom binding providers for JAX-RPC applications

A *custom binding provider* is the packaging of custom data binder classes for with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

You can review information in Custom data binders to learn more about custom data binders and CustomBinder interface, which is the API included in WebSphere Application Server to define the custom data binders. After you have reviewed these articles you are ready to deploy the custom binder package. To learn how to deploy this package, see Usage patterns for deploying custom data binders.

The declarative metadata file, `CustomBindingProvider.xml`, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the `/META-INF/services/directory`. After a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the WSDL2Java command-line tool and the run time system.

The following example is the XML schema for the `CustomBindingProvider.xml` file. The top level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in CustomBinder interface. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
    targetNamespace=
       "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:customdatabinding=
        "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified" attributeFormDefault="qualified">

   <xsd:element name="provider" type="customdatabinding:providerType"/>

   <xsd:complexType name="providerType">
   <xsd:sequence>
     <xsd:element name="description" type="xsd:string" minOccurs="0"/>
     <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
```

```
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="description" type="xsd:string" minOccurs="0"/>
          <xsd:element name="xmlQName" type="xsd:QName"/>
          <xsd:element name="javaName" type="xsd:string"/>
          <xsd:element name="qnameScope"
                       type="customdatabinding:qnameScopeType"/>
          <xsd:element name="binder" type="xsd:string"/>
        </xsd:sequence>
       /xsd:complexType>
      </xsd:element>
       <xsd:attribute name="scope"
             type="customdatabinding:ProviderScopeType" default="module"/>
       </xsd:sequence>
   </xsd:complexType

  <xsd:simpleType name="qnameScopeType">
      <xsd:restriction base="xsd:string">
         <xsd:enumeration value="simpleType"/>
         <xsd:enumeration value="complexType"/>
         <xsd:enumeration value="element"/>
      </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="ProviderScopeType">
     <xsd:restriction base="xsd:string">
         <xsd:enumeration value="server"/>
         <xsd:enumeration value="application"/>
         <xsd:enumeration value="module"/>
     </xsd:restriction>
  </xsd:simpleType>
</xsd:schema>
```

The following is an example of the `CustomBindingProvider.xml` file for the SDO DataGraph schema that was introduced in CustomBinder interface. The example displays the mapping between a schema type, DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is called `test.sdo.SDODataGraphBinder`.

```
<cdb:provider
 xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
   xmlns:sdo="commonj.sdo">
   <cdb:mapping>
     <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
     <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
     <cdb:qnameScope>complexType</cdb:qnameScope>
     <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
   </cdb:mapping>
</cdb:provider>
```

You need to import your custom data binders into the WSDL2Java command-line tool for development purposes. The custom data binders affect how the development artifacts, including the Service Endpoint Interface and the JSR 109 mapping data, are generated from the Web Services Description Language (WSDL) file. The WSDL2Java command-line tool ships with WebSphere Application Server and uses the custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in the CustomBinder interface topic.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
   xmlns:impl="http://sdo.test"
   xmlns:intf="http://sdo.test"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema"
   xmlns:sdo="commonj.sdo">
```

```
<wsdl:types>
 <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
      xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
  <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
 </schema>
</wsdl:types>

<wsdl:message name="echoResponse">
 <wsdl:part element="sdo:datagraph" name="return"/>
</wsdl:message>

<wsdl:message name="echoRequest">
  <wsdl:part element="sdo:datagraph" name="parameter"/>
</wsdl:message>

<wsdl:portType name="EchoService">
  <wsdl:operation name="echo">
    <wsdl:input message="impl:echoRequest" name="echoRequest"/>
    <wsdl:output message="impl:echoResponse" name="echoResponse"/>
   </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
  <wsdlsoap:binding style="document"
                   transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="echo">
       <wsdlsoap:operation soapAction=""/>
       <wsdl:input name="echoRequest">
        <wsdlsoap:body use="literal"/>
       </wsdl:input>

      <wsdl:output name="echoResponse">
         <wsdlsoap:body use="literal"/>
      </wsdl:output>
   </wsdl:operation>
 </wsdl:binding>

 <wsdl:service name="EchoServiceService">
    <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
      <wsdlsoap:address location="http://<uri>"/>
   </wsdl:port>
 </wsdl:service>

</wsdl:definitions>
```

If you run the WSDL2Java command without the custom data binding package, the following Service Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```
public interface EchoService extends java.rmi.Remote {
  public javax.xml.soap.SOAPElement
   echo(javax.xml.soap.SOAPElement parameter)
    throws java.rmi.RemoteException;
}
```

When you run the WSDL2Java command with the custom data binding package, the custom data binders are used to generate the parameter types. To apply the custom data binders, use the -classpath option on the WSDL2Java tool. The tool searches its classpath to locate all the files with the same file path of `/META-INF/services/CustomBindingProvider.xml`. The following is an example how you can use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.Datagraph`:

```
WSDL2Java -role develop-server -container web classpath sdobinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```
public interface EchoService extends java.rmi.Remote {
  public commonj.sdo.DataGraph
   echo(commonj.sdo.DataGraph parameter)
    throws java.rmi.RemoteException;
}
```

The custom binder packaged JAR file has to be made available at runtime to make sure the Web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

CustomBinder interface for JAX-RPC applications

WebSphere Application Server defines a CustomBinder interface that you can implement for Java API for XML-based Remote Call Procedure (JAX-RPC) applications to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods. These properties are QName for the XML schema type, the QName scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

getQName

The getQName method returns the QName of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the getQName method returns the QName of the containing element.

For named types, the getQName method returns the QName of the complexType or the simpleType.

getQNameScope

The getQNameScope method returns the binder qnameScope property that indicates whether the schema type is a named type or an anonymous type. The qnameScope property value can be *complexType* for an <xsd:complexType>, *simpleType* for an <xsd:simpleType> or *element* for an <xsd:element> that is defined with an anonymous type.

In the following schema, data1 is an element that is defined with an anonymous type. The element, data2, is defined using the named type, data2Type.

```
<xsd:element name="data1">
 <xsd:complexType>
  ...
 </xsd:complexType>
</xsd:element>

<xsd:element name= "data2" type="data2Type"/>
<xsd:complexType name="data2Type">
 ...
</xsd:complexType>
```

The anonymous type, data1, has a qNameScope of element and a qName of data1. The type, data2Type, has a qNameScope of complexType and a qName of data2Type.

The element, data2, is not represented in the custom data binder. The custom data binder only processes types and not elements.

getJavaName

The getJavaName method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from

the deserialize method has a type that is compatible with the Java type that is returned by the getJavaName method.

serialize

The serialize method returns the SOAPElement that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the getJavaName method. The SOAPElement parameter does not have child elements, but it does have a valid QName. This parameter is a reference for the binder to create the final SOAPElement.

In most cases, the binder implementation appends the child elements to the root SOAPElement. The run time system guarantees that the SOAPElement QName is correct. Therefore, the custom data binder for named types keeps the QName of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the QName in the returned SOAPElement that matches the defined schema type. WebSphere Application Server does not have concrete methods in the CustomBindingContext parameter.

deserialize

The deserialize method returns a Java object that the custom data binder builds from the passed root SOAPElement. The object type of the returned Java object must match what is returned from the getJavaName method. Unlike the parameter serialize method, the passed SOAPElement contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO DataGraph binder, where the convertToSDO and convertToSAAJ utility methods convert between SOAPElement and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
 public QName getQName() {
  return new QName("commonj.sdo", "DataGraphyType");
}
public String getJavaName() {
 return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
}
public String getJavaName() {
 return commonj.sdo.DataGraph.class.getName();
}
public javax.xml.soap.SOAPElement serialize(
  Object bean,
  SOAPElement rootNode,
  CustomBindingContext context)
  throws javax,xml.soap.SOAPException {
 // convertToSAAJ is a utility method to convert
 // the SDO DataGraph to the SOAPElement
 return convertToSAAJ(bean, rootNode);

public Object deserialize(
  SOAPElement source,
  CustomBindingContext context)
  throws javax.xml.soap.SOAPException {
  // convertToSDO is a utility method to convert
  // the SOAPElement to the SDO DataGraph
  return convertToSDO(source);
 }
}
```

To learn more about custom data binders, see “Custom data binders for JAX-RPC applications” on page 623. To learn how to plug your custom data binders into the WSDL2Java command-line tool for development, see Custom binder providers.

Usage patterns for deploying custom data binders for JAX-RPC applications

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

You can learn about the CustomBinder API in the topic CustomBinder interface. The topic Custom data binders includes general information about custom binders and the topic Custom binding providers reviews how they are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the Web Services for Java Platform, Enterprise Edition (Java EE) specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a `CustomBindingProvider.xml` file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.
- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the Web services deployment tools after the application is installed.

Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

- **Deploy the custom data binders at the server level**

  This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

  This type of situation occurs frequently for new Web services specifications that define new schema types. For example, the WS-Addressing specification defines an EndpointReferenceType schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.
- **Deploy the custom binders for one or more application**

  Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.
- **Deploy the custom binders for a specific Web module within an application**

Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

- **Server level deployment**

  If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as *server*. Setting the value to *server* guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath see Java virtual machine settings.

- **Deploying custom data binders for one or more applications**

  To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as *application*. Setting the value to application guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path see Managing shared libraries.

- **Deploy the custom data binders for a specific Web module within an application**

  To deploy custom data binders for a specific Web module within an application, set the scope attribute of the declared custom binding provider to the value *module*. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the Web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

Example: Using JAX-RPC properties to send and receive SOAP headers

WebSphere Application Server provides extensions to the Java API for XML-based RPC (JAX-RPC) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the REQUEST_SOAP_HEADERS and RESPONSE_SOAP_HEADERS Stub properties. This is an example of how these two properties are used.

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a Web services request and response:

```
1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUuid1" and "AtmUuid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid1"),
7   "<AtmUuid1 xmlns=\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid2"),
9  ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10   "x:AtmUuid2 xmlns:x=\"com.rotbank.security\"><x:uuid>ROTB-0A01254385FCA09
     </x:uuid><x:AtmUuid2>"));
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS.requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS.responseHeaders);
20
21 //Call the operationon the Stub.
22 stub.foo(parm2, parm2);
23
```

```
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26   (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
   </y:uuid></y:ServerUuid.");
```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the Web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the Web services engine.

Sending implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing Web service request.

Before you begin

To complete this task, you need a Web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

1. Create a java.util.HashMap object.

2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is either an SAAJ SOAPElement object or a String that contains the XML text of the entire SOAP header element.
3. Set the HashMap object as a property on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Stub or Call object. The headers within the HashMap object are sent in the outgoing message.

   A `JAXRPCException` error can occur if any of the following are true:

   - The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a String or a SOAPElement object.
   - The HashMap object contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC Web services client that is configured to send implicit SOAP headers.

Receiving implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming Web service response.

Before you begin

To complete this task, you need a Web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

1. Create a java.util.HashMap object
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to receive. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is null.
3. Set the HashMap entry on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS. The value of the property is the HashMap.

4. Issue remote method calls against the Stub or Call object. The Web services engine extracts the specified response headers from the Web services response message and inserts them into the HashMap. After the remote method returns, the response headers are accessible from the HashMap object.

   A JAXRPCException error can occur if any of the following are true:

   - The HashMap contains a key that is not a QName.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC Web services client that can receive values from implicit SOAP headers.

Sending transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send application-defined information along with your Web services requests by using transport headers.

Before you begin

You need a JAX-RPC Web services client that you can enable to send transport headers.

Sending transport headers is supported only by Web services clients, and only supported for the HTTP and JMS transports. The Web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the Web services server is done through non-Web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against that Stub or Call object until the associated property is set to null or the Stub or Call object is discarded.

To send values in the transport headers on outbound requests, modify the client code as follows:

1. Create a java.util.HashMap object that contains the transport header identifiers.
2. Add an entry to the HashMap object for each transport header that you want the client to send.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
   b. Set the HashMap entry value to a string that contains the value of the transport header.
3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to null, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The headers and the associated values from the HashMap are added to the outgoing request for each method invocation. If the invocation

uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:

- The property value that is set on the Stub or Call object must be a HashMap object or null.
- The HashMap must not be empty.
- Each key in the HashMap must be a String object.
- Each value in the HashMap must be a String object.

Results

You have a JAX-RPC Web services client that is configured to send transport headers.

Retrieving transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a Web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by Web services clients, and only supported for the HTTP and JMS transports. The Web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the Web services server is done through non-Web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object in order to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that Stub or Call instance until the associated property is set to null or the Stub or Call object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

1. Create a java.util.HashMap object that contains the names of the transport headers to be retrieved from incoming response messages.
2. Add an entry to the HashMap for each header that you want to retrieve a value from every incoming response message.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class. The HashMap entry value is ignored and does not need to be set. An empty HashMap, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the HashMap is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent

invocations to retrieve the headers from the responses. If you set the property to null, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.

4. Issue remote method calls against the Stub or Call object. The values from the specified transport headers are retrieved from the response message and placed in the HashMap.

   If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:

   - The property value that is set on the Stub or Call object must be either null or an instance of a HashMap.
   - All the HashMap keys must be a string data type, and the keys must not be null.

Results

You have a JAX-RPC Web service that can receive transport headers from incoming response messages.

Running an unmanaged Web services JAX-RPC client

WebSphere Application Server Version 7.0 and the Application Client for WebSphere Application Server Version 7.0 provides an unmanaged client implementation that is based on the Java API for XML-based RPC (JAX-RPC) 1.1 specification. The Thin Client for JAX-RPC with WebSphere Application Server is an unmanaged and stand-alone Java client environment that enables you to run JAX-RPC Web services client applications to invoke Web services that are hosted by the application server.

Before you begin

Before you can set up a JAX-RPC unmanaged client environment you will need to obtain the Thin Client for JAX-RPC Java archive (JAR) file. To obtain the Thin Client for JAX-RPC, you must either install the application server or the application client.

The Thin Client for JAX-RPC JAR file, `com.ibm.ws.webservices.thinclient_7.0.0.jar`, is located in the *app_server_root*`\runtimes` directory. Refer to the license agreements to ensure correct usage and for limitations on copies of the Thin Client for JAX-RPC outside of the WebSphere environment.

The Thin Client for JAX-RPC runs on distributed operating systems with IBM Software Development Kits (SDKs) Version 6.0 and Sun Java Development Kit (JDK) Version 6.0 that are provided by IBM. The Thin Client for JAX-RPC is supported on non-IBM SDKs Version 6.0 with this limitation:

- Xerces limitation on non-IBM SDKs

  If you are using a non-IBM SDK, because of dependencies with the Xerces implementation, you will need to download Xerces-J version 2.6.2 and set it in the classpath before attempting to run the Thin Client for JAX-RPC.

About this task

Set up a Thin Client for JAX-RPC environment by completing the following steps.

1. Configure the path. You can add the Java `bin` directories to your path by typing:

   ```
   set PATH=<your_JDK_bin_directory>;%PATH%
   ```

2. Configure the classpath.

   ```
   set CLASSPATH=.;<your_web_services_thin_client_install_directory>\com.ibm.ws.webservices.thinclient_7.0.0.jar;
   <your_application_jars>;%CLASSPATH%
   ```

   - If you are using a non-IBM SDK, obtain a Xerces xml-apis.jar and xercesImpl.jar from the Xerces Web site and configure the classpath definition.

     ```
     set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
     \xercesImpl.jar;%CLASSPATH%
     ```

3. Configure SSL for the client.
   a. Add the following system properties to the Java command:

      ```
      -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
      ```

      You can obtain the ssl.client.props file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the com.ibm.ssl.keyStore and com.ibm.ssl.trustStore key files in the ssl.client.props file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

      ```
      com.ibm.ssl.protocol=SSL
      com.ibm.ssl.trustManager=SunX509
      com.ibm.ssl.keyManager=SunX509
      com.ibm.ssl.contextProvider=SunJSSE

      com.ibm.ssl.keyStoreType=JKS
      com.ibm.ssl.keyStoreProvider=SUN
      com.ibm.ssl.keyStore=/home/user1/etc/key.jks

      com.ibm.ssl.trustStoreType=JKS
      com.ibm.ssl.trustStoreProvider=SUN
      com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
      ```

      The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

      You must override the default ORB implementation of the non-IBM product JRE with the com.ibm.ws.orb_7.0.0.jar file, or add it to the classpath.
4. Enter the following command to run your client application:

   ```
   %JAVA_HOME%/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
   ```

Results

You have set up an unmanaged JAX-RPC client runtime environment that can be used to invoke Web services hosted on a WebSphere Application Server.

Using HTTP to transport Web services

You can develop an HTTP accessible Web service when you have an existing JavaBeans object to enable as a Web service.

Before you begin

Develop a Web Services Description Language (WSDL) file. You need a WSDL file to use Web services. You can develop your own WSDL file or get one from a Web services provider through e-mail, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

About this task

The application server supports the use of HTTP to transport Web services client requests. With HTTP, your Web services clients and servers can communicate through SOAP messages. SOAP is the underlying communication protocol that is used in Web services that support the Web Services for Java Platform, Enterprise Edition (Java EE), the Java API for XML-Based Web Services (JAX-WS), and the Java API for XML-based remote procedure call (JAX-RPC) specifications.

HTTP is the most commonly used transport for Web services.

1. Depending on your application programming model,
   - Use HTTP to transport Web Services requests for JAX-WS applications.
   - Use HTTP to transport Web Services requests for JAX-RPC applications.
2. Deploy the Web services application.
3. Configure security for the HTTP connection.

Results

You have a JavaBeans object that uses HTTP to transport Web services client requests.

What to do next

Publish the WSDL file.

Using HTTP to transport Web services requests for JAX-WS applications

You can develop an HTTP accessible Java API for XML-Based Web Services (JAX-WS) Web service when you have an existing JavaBeans object to enable as a Web service.

Before you begin

You must have an annotated JAX-WS JavaBeans object to enable as a Web service. Optionally, you can run the **wsgen** command to create a Web Service Description Language (WSDL) file from your annotated JAX-WS JavaBeans component. You must specify the `-wsdl` option with the **wsgen** command to create the WSDL file.

For example:

Note: The wsimport, wsgen, schemagen and xjc command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

To learn about developing a JAX-WS Web service using annotations, read about developing Java artifacts for JAX-WS applications using JavaBeans.

About this task

The application server supports the use of HTTP to transport Web services client requests. With HTTP, your Web services clients and servers can communicate through SOAP messages. SOAP is the underlying communication protocol that is used in Web services that support the Web Services for Java Platform, Enterprise Edition (Java EE) and the Java API for XML-Based Web Services (JAX-WS) specifications.

HTTP is the most commonly used transport for Web services.

1. Add an HTTP binding and a SOAP address to the WSDL file.

   The WSDL file of a Web service must include an HTTP binding and a SOAP address, which specifies an HTTP endpoint URL string, that is accessible on the HTTP transport. An HTTP binding is a wsdl:binding element that contains a soap:binding element with a transport attribute that ends in `soap/http`.

   In addition to the HTTP binding, a wsdl:port element that references the HTTP binding must be included in the wsdl:service element within the WSDL file. The wsdl:port element contains a soap:address element with a location attribute that specifies an HTTP endpoint URL string.

   When you develop the Web service, you can use a placeholder such as `file:unspecified_location` for the endpoint URL string.

   Note: If you deploy a JAX-WS JavaBeans component as a Web service without a WSDL file, a WSDL file is automatically generated for the component.
2. For JAX-WS Web services applications, no HTTP transport configuration is needed. The HTTP transport settings are generated dynamically by the application server. The Web archive {WAR) file only needs the JavaBeans object along with the optional WSDL file properly installed.
3. Deploy the Web services application.
4. Configure security for the HTTP transport.

   To configure a secure HTTP transport, attach the SSLTransport policy to the application. To specify the basic authentication transport token, use the administration console to set the user ID and the password attributes in the HTTPTransport binding.
5. (Optional) Configure HTTP session management.

   HTTP session management enables JAX-WS Web Services applications to appear dynamic to application users.
6. (Optional) Configure the asynchronous response listener for JAX-WS clients.

   You can use the asynchronous response listener within the Thin Client for JAX-WS and application client environments to receive responses for requests that are invoked asynchronously.
7. Configure the endpoint URL information for HTTP bindings.

   The WSDL publisher uses this partial URL string to produce the actual HTTP URL for each port component defined in the enterprise archive (EAR) file. The published WSDL file can be used by clients, that need to invoke the Web service.

Results

You have a JavaBeans object that uses HTTP to transport JAX-WS Web services client requests.

What to do next

Publish the WSDL file.

Using the asynchronous response servlet

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response servlet, which is used within the application server environment to receive responses for JAX-WS requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking Web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When a JAX-WS client that is running within the application server environment uses an asynchronous client invocation, the responses are received by the asynchronous response servlet. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS Web services asynchronously.

About this task

The asynchronous response servlet is used within an application server to handle incoming asynchronous responses. The servlet uses the same secure and unsecure HTTP ports assigned to the application server. The servlet starts automatically when the application server starts. Because the asynchronous response servlet does not perform role-based authorization checks, only user authentication checks are performed.

The asynchronous response servlet supports both the HTTP and HTTPS protocols. Since the servlet inherits the SSL configuration of the application server, configuring the application server also configures the servlet. The asynchronous response servlet is not affected by the custom HTTP and SSL port properties used by the asynchronous response listener and only runs on the application ports for the application server.

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the Web container transport chains to modify the SSL configuration of the application server. The servlet inherits these settings. Read about configuring transport chains to learn how to configure the Web container transport chains.

Results

The asynchronous response servlet is configured to enable your JAX-WS clients to receive asynchronous responses on the HTTP or HTTPS transport protocol.

Using the asynchronous response listener

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response listener, which is used within the Thin Client for JAX-WS and application client environments to receive responses for requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking Web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When the JAX-WS client uses an asynchronous client invocation, the responses are received by the asynchronous response listener. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS Web services asynchronously.

About this task

The asynchronous response listener is used within a Web services client to handle incoming asynchronous responses. You can use the listener in Thin Client for JAX-WS environments and application

client environments. By default, the listener opens a random port to listen for asynchronous responses or you can optionally configure a specific port for the listener to use. The listener starts automatically in the JAX-WS run time when the JAX-WS client is configured to expect an asynchronous response.

There are two versions of the asynchronous response listener. The unsecure version of the asynchronous response listener supports the HTTP protocol, and the secure version of the asynchronous response listener supports the HTTPS protocol. The correct asynchronous response listener is automatically started based on the particular transport used by the JAX-WS client. To ensure that the correct Secure Sockets Layer (SSL) handshaking occurs between the asynchronous response listener and the application server, configure the SSL properties using the SSL transport policy or the Java system properties.

For Web services clients running in the application server environment, use the asynchronous response servlet for receiving asynchronous responses.

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the asynchronous response listener for unsecure communication using HTTP.

   You can configure the HTTP port for the asynchronous response listener as a Java system property or as a custom property within the transport policy. Properties that are defined in the policy set binding files override any Java system property that might have been defined.

   a. Define the `com.ibm.websphere.webservices.http.listenerPort` property as a Java system property. If this property is set as a Java system property, then all asynchronous response listeners within that Java Virtual Machine (JVM) are affected.
   b. Define the `com.ibm.websphere.webservices.http.listenerPort` property within the `HTTPTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.
3. Configure the asynchronous response listener for secure communication using HTTPS.

   You can configure the HTTPS port for the asynchronous response listener as a Java system property or as a custom property within the transport policy.

   a. Define the `com.ibm.websphere.webservices.https.listenerPort` property as a Java system property. If this property is set as a Java system property, thenall asynchronous response listeners within that JVM are affected.
   b. Define the `com.ibm.websphere.webservices.https.listenerPort` property within the `SSLTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.

Results

Your JAX-WS Web services client is configured to use the asynchronous response listener to receive incoming asynchronous responses.

Example

The following examples demonstrate how to enable the asynchronous response listener when defining the custom port of 9999:

Use the following Java command to configure the custom HTTP port for the asynchronous response listener in a thin client environment:

```
- java.exe -Dcom.ibm.websphere.webservices.http.listenerPort=9999 com.ibm.websphere.my_program
```

Use the following launchClient command to configure the custom HTTP port for the asynchronous response listener in an application client container:

```
- launchClient.bat MyClient.ear -CCDcom.ibm.websphere.webservices.http.listenerPort=9999
```

The following is an excerpt from an HTTPTransport policy binding.xml file that includes the asynchronous response listener properties:

```
</wsp:Policy>
   </wsp:ExactlyOne>
 </wsp:All>
    <wshttp:outAsyncResponseProxy>
     <wshttp:connectInfo host="" port=""></wshttp:connectInfo>
                  <wshttp:basicAuth userid="" password=""></wshttp:basicAuth>
    </wshttp:outAsyncResponseProxy>
    <wshttp:properties>
  <wshttp:customProperty name="com.ibm.websphere.webservices.http.listenerPort" value="9999" />
   </wshttp:properties>
 </wsp:All>
   </wsp:ExactlyOne>
</wsp:Policy>
```

What to do next

Run the JAX-WS client with the specified asynchronous response listener options.

Using HTTP session management support for JAX-WS applications

HTTP session management is performed in the HTTP transport layer by using either cookies or URL rewriting. By providing multiple options for tracking a series of requests, HTTP session management enables Java API for XML-Based Web Services (JAX-WS) applications to appear dynamic to application users.

Before you begin

Develop a JAX-WS dynamic proxy or Dispatch client. To learn more about developing JAX-WS clients, read about developing a JAX-WS client from a Web Services Description Language (WSDL) file or developing a dynamic client using JAX-WS APIs.

About this task

You can use HTTP session management to maintain user state information on the server, while passing minimal information back to the user to track the session. You can implement HTTP session management on the application server using either session cookies or URL rewriting.

The interaction between the browser, application server, and application is transparent to the user and the application program. The application and the user are typically not aware of the session identifier provided by the server.

Session cookies

The HTTP maintain session feature uses a single cookie, JSESSIONID, and this cookie contains the session identifier. This cookie is used to associate the request with information stored on the server for that session. On subsequent requests from the JAX-WS application, the session ID is transmitted as part of the request header, which enables the application to associate each request for a given session ID with prior requests from that user. The JAX-WS client applications retrieve the session ID from the HTTP response headers and then use those IDs in subsequent requests by setting the session ID in the HTTP request headers.

URL rewriting

URL rewriting works like a redirected URL as it stores the session identifier in the URL. The session identifier is encoded as a parameter on any link or form that is submitted from a Web page. This encoded URL is used for subsequent requests to the same server.

1. Configure the server to enable session tracking. Specify either session cookies or URL rewriting for your session tracking mechanism using the administration console. Read about configuring session tracking to learn how to track sessions with cookies or with URL rewriting.
2. Enable HTTP session management for the JAX-WS client. You can manually set the maintainSession property to **true** in the policy set binding.
   - Enable session management on the client using a HTTP transport policy set file. You can configure the HTTP transport policy using the administration console. On the HTTP transport setting page, select the **Session enable** checkbox to enable an HTTP session. Read about configuring the HTTP transport property to learn how to set this property. You can also manually set the `maintainSession` property to `yes` to enable HTTP session management.
   - Enable session management on the client by setting the JAX-WS property, `javax.xml.ws.session.maintain`, to `true`.

Results

You have enabled HTTP session management for your JAX-WS application.

Example

The following example is an excerpt from a HTTP Transport policy set that demonstrates how to configure the `maintainSession` property:

```
<!-- This is the PolicyType for HTTP transport -->
        <wsp:ExactlyOne>
                <wsp:All>
                        <wshttp:readTimeout>300</wshttp:readTimeout>
                        <wshttp:writeTimeout>300</wshttp:writeTimeout>
                        <wshttp:connectTimeout>180</wshttp:connectTimeout>
                        <wshttp:persistConnection>yes</wshttp:persistConnection>
                        <wshttp:messageResendOnce>no</wshttp:messageResendOnce>
                        <wshttp:chunkTransferEnc>no</wshttp:chunkTransferEnc>
                        <wshttp:acceptRedirectedURL>no</wshttp:acceptRedirectedURL>
                        <wshttp:sendExpectHeader>no</wshttp:sendExpectHeader>
                        <wshttp:maintainSession>yes</wshttp:maintainSession>
                        <wshttp:compressRequest>
                                <wshttp:compressType name="none"></wshttp:compressType>
                        </wshttp:compressRequest>
                        <wshttp:compressResponse>
                                <wshttp:compressType name="none"></wshttp:compressType>
                        </wshttp:compressResponse>
                        <wshttp:protocolVersion>HTTP/1.1</wshttp:protocolVersion>
                </wsp:All>
        </wsp:ExactlyOne>
```

The following code example is demonstrates how to programmatically enable session management on the client by setting the javax.xml.ws.session.maintain property on the correct JAX-WS object.

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
...
...
rc.put(BindingProvider.SESSION_MAINTAIN_PROPERTY, Boolean.TRUE);
...
...
```

Using HTTP to transport Web services requests for JAX-RPC applications

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) Web service when you already have a JavaBeans object to enable as a Web service.

Before you begin

Run the **Java2WSDL** command to create a Web Services Description Language (WSDL) file. When you run the **Java2WSDL** command, use the -bindingsTypes option, along with `http`, to set the HTTP transport bindings. For example:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

To learn more about using the **Java2WSDL** command, see the Java2WSDL command for JAX-RPC applications documentation.

The Java2WSDL command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

About this task

The application server supports the use of HTTP to transport Web services client requests. With HTTP, your Web services clients and servers can communicate through SOAP messages. SOAP is the underlying communication protocol that is used in Web services that support the Web Services for Java Platform, Enterprise Edition (Java EE) and the Java API for XML-based remote procedure call (JAX-RPC) specifications.

HTTP is the most commonly used transport for Web services.

To develop an HTTP-accessible Web service from an existing an existing JavaBean object:

1. Add an HTTP binding and a SOAP address to the WSDL file.

   The WSDL file of a Web service must include an HTTP binding and a SOAP address, which specifies an HTTP endpoint URL string, to be accessible on the HTTP transport. An HTTP binding is a wsdl:binding element that contains a wsdlsoap:binding element with a transport attribute that ends in `soap/http`.

   In addition to the HTTP binding, a wsdl:port element that references the HTTP binding must be included in the wsdl:service element within the WSDL file. The wsdl:port element contains a wsdlsoap:address element with a location attribute that specifies an HTTP endpoint URL string.

   When you develop the Web service, a placeholder such as `file:unspecified_location` can be used for the endpoint URL string.
2. Add the HTTP endpoints to your enterprise archive (EAR) file using the **endptEnabler** command, if your application includes enterprise beans.

   By default, the **endptEnabler** command adds only HTTP endpoints.
3. Deploy the Web services application.
4. Configure security for the HTTP connection.

   For a secure HTTP connection, add the basicAuth assembly property to the `ibm-webservicesclient-bnd.xmi` deployment descriptor file. Set the user ID and the password attributes.
5. Configure the endpoint URL information for HTTP bindings.

   The WSDL publisher uses this partial URL string to produce the actual HTTP URL for each port component defined in the EAR file. The published WSDL file can be used by clients, that need to invoke the Web service.

Results

You have a JavaBean object that uses HTTP to transport Web services client requests.

What to do next

Publish the WSDL file.

Using SOAP over Java Message Service to transport Web services

You can use the SOAP over Java Message Service (JMS) transport protocol as an alternative to SOAP over HTTP for communicating SOAP messages between clients and servers.

Before you begin

A Web service must be implemented as an enterprise bean for accessibility through the JMS transport.

About this task

Note: WebSphere Application Server Version 7.0 introduces support for an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services. By using the JMS transport, your enterprise beans based Web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

Note:

The benefits of using JMS include:
- Reliable messaging transport for communicating request and response messages.
- Flexible one-way requests for clients and servers. For example, the server does not have to be active when the client sends the one-way request. Simultaneous one-way requests can be sent to multiple servers through the use of a topic.
- Synchronous two-way requests are supported for both JAX-WS and JAX-RPC clients.
- Asynchronous requests are supported for JAX-WS clients.

The SOAP over JMS specification defines a JMS endpoint URI syntax for specifying JMS destinations. A JMS endpoint URL is used to access JAX-WS or JAX-RPC Web services with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

1. Develop the enterprise bean that you intend to use as your service implementation bean.
   - For JAX-WS applications, develop an enterprise beans- based JAX-WS service implementation bean.
   - For JAX-RPC applications, develop an enterprise beans-based JAX-RPC service implementation bean.

2. Develop Java artifacts for JAX-WS applications. Although a Web Services Description Language (WSDL) file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. Therefore, if you are developing a JAX-WS web service using the bottom-up approach, use the wsgen tool to generate a WSDL file from your JAX-WS implementation bean, and then package the WSDL file along with any associated schema files with your application.
3. Modify your WSDL file so that the ports that are accessible using the SOAP over JMS transport have an endpoint location URL that starts with the `jms:` prefix. For example:

```
<service name="MyService">
    <port name="MyJMSPort" binding="tns:MyJMSPortBinding">
      <soap:address location="jms:my_actual_endpoint_URL"/>
    </port>
</service>
```

   Using the `jms:` prefix enables the WSDL publisher to identify the `MyJMSPort` port as a JMS port, and a JMS-style endpoint location URL is used when publishing the WSDL.
4. Assemble the enterprise beans.
   a. Assemble a JAR file that is enabled for Web services from an enterprise bean. You can assemble the artifacts that are required to enable the enterprise beans module for Web services into a Java archive (JAR) file.
   b. Assemble a Web services-enabled enterprise bean JAR file into an enterprise archive (EAR) file. You can assemble the artifacts that are required to enable the Web services-enabled JAR file into an EAR file.
5. Enable the enterprise beans-based endpoints by using the endptEnabler command. Use the `-transport jms` option to request that the endptEnabler command create a message-driven bean (MDB) listener for each Enterprise JavaBeans (EJB) JAR file that contains Web services implementation beans. This message-driven bean serves as a listener for requests that are associated with the Web service endpoints contained in the EJB JAR file.
6. Decide on the names and the types of the JMS objects that your application uses.

   Before you install your application, you need to:

   - Decide whether your Web service receives requests from a queue or a topic.
     - Decide whether to use a secure destination or a nonsecure destination.
     - Decide the names for your queues and topics, connection factory and activation specification.

   Use the following guidelines for deciding JMS object names and types. In typical situations, you can use a queue for receiving Web services requests.

   - Queue
     - A queue receive all types of requests. Valid requests include one-way, two-way, and synchronous. Asynchronous requests are only valid with JAX-WS Web services.
     - A queue is used only by a single EJB JAR file for receiving the requests for Web services endpoints contained within that EJB JAR file.
   - Topic
     - A topic is used to receive only one-way requests.
     - You can share a topic among multiple EJB JAR files. Each request message that is sent to a topic is processed by each of the MDB listeners that are configured to listen on that topic. This means that each request message is processed by each EJB JAR file associated with that specific topic.

   The following example describes a typical configuration for a single EJB JAR file containing Web services endpoints:

   - Suppose the EJB JAR file is StockQuoteEJB.jar and contains one or more Web services endpoints related to the StockQuote service.

- You have a single queue, StockQuote_Q, with the JNDI name, `jms/StockQuote_Q`, that is used to receive requests.
- You have a connection factory, StockQuote_CF, with JNDI name, `jms/StockQuote_CF`, that can be used by clients to connect to the JMS provider.
- You also have a connection factory, StockQuote_ReplyCF, with JNDI name, `jms/StockQuote_ReplyCF`, that is used by the MDB listener for the EJB JAR file to connect to the JMS provider when sending reply messages.
- You have an activation specification, StockQuote_AS, with JNDI name, `jms/StockQuote_AS`, that is used to associate the StockQuoteEJB.jar's MDB listener with the queue named StockQuote_Q.

7. Define the JMS administered objects.

   After you decide on the names and types of the JMS objects, use the administrative console or the wsadmin scripting tool to define the JMS objects. There are multiple ways to administer JMS resources depending on what type of JMS provider is being used. Read about choosing a messaging provider to learn more about administering JMS resources.

8. Deploy the Web services application.

   During the installation process you are prompted for two types of information for each enterprise bean JAR file that is enabled for Web services and is contained in your EAR file:
   - The JNDI name of the connection factory that is used by the MDB listener to use for sending reply messages.

     If your Web service contains two-way operations, the MDB listener that is defined by the endptEnabler command needs to access a queue connection factory to add a reply message to the reply queue. The MDB listener uses a resource environment reference of `java:comp/env/jms/WebServicesReplyQCF`. Therefore, during the application installation process, you must provide the actual JNDI name of the connection factory for the MDB listener to use for that Web service. Using the previous example, the JNDI name is `jms/StockQuote_ReplyCF`.
   - The name of the activation specification for the MDB listener to use.

     An activation specification is an object that is used to associate a JMS connection factory with a JMS destination (queue or topic). When deployed, an MDB is configured with the correct activation specification so that messages from the queue or topic are properly delivered to the MDB. During deployment, you can modify the name of the activation specification that is associated with each MDB listener. The activation specification name contained in the input EAR file is displayed as a default value. If you specify the correct activation specification name to the endptEnabler command, you can accept the default value. Otherwise, enter the correct activation specification name.

9. Decide whether to use the new industry standard SOAP over JMS protocol or the IBM proprietary SOAP/JMS protocol.

   Note: It is a best practice to use the industry standard SOAP/JMS protocol. The IBM proprietary SOAP/JMS protocol has been deprecated with this release. However, if your application needs to interoperate with previous versions of the product, then use the proprietary protocol.
   - If you use the industry standard SOAP over JMS protocol, use the Configure endpoint URL information for JMS bindings task to specify a JMS endpoint URL prefix that adheres to the JMS endpoint URI syntax that is associated with the standard; for example:

     ```
     jms:jndi:jms/StockQuote_Q&jndiConnectionFactoryName=jms/StockQuote_CF
     ```
   - If you use the IBM proprietary SOAP over JMS protocol, use the Configure endpoint URL information for JMS bindings task to specify a JMS endpoint URL prefix that adheres to the IBM proprietary SOAP over JMS protocol; for example:

     ```
     jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
     ```

10. (Optional) Configure endpoint URL information for JMS bindings.

    Use the administrative console to configure a JMS endpoint URL prefix that you can associate with each EJB JAR module in your application. The WSDL publisher uses this partial URL string to

produce the actual JMS URL for each port component that is defined in the enterprise bean JAR file. The clients that need to invoke the Web service can use the published WSDL file.

Perform this step only if you are publishing the WSDL file for your application.

11. (Optional) Publish the WSDL file for your application.

    Publishing the WSDL file, this produces WSDL documents that you can use to develop your client applications. The publishing process produces fully-resolved endpoint location URLs within the WSDL files.

    Perform this step only if the published WSDL files are needed to develop your client applications.

Results

You have a Web service that is configured to use SOAP over JMS to transport the requests.

What to do next

Develop a Web services client.

SOAP over Java Message Service (JMS) protocol

The Web services engine supports the use of an emerging industry standard SOAP over Java Message Service (JMS)-compliant messaging transport as an alternative to HTTP for communicating SOAP messages between clients and servers.

Note: WebSphere Application Server Version 7.0 introduces support for an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services. By using the JMS transport, your enterprise beans based Web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the proposed SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this draft specification was jointly published in October, 2007. Refer to the SOAP over JMS specification for details of this industry standard.

This topic provides a summary of the emerging industry-standard SOAP over JMS protocol. Use this SOAP over JMS transport protocol if you need to provide implementations for the client or server components. Also, you need to make sure that the implementations are interoperable with the client and server components provided by the Web services engine in WebSphere Application Server.

Client responsibilities

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use a BytesMessage, for example, javax.jms.BytesMessage, to transmit the SOAP request message to the server.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **SOAPJMS_contentType**: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, has the following value set for this JMS message property:

```
text/xml; charset="UTF-8"
```

For a SOAP message containing attachments, use the following code to set the SOAPJMS_contentType property on the JMS message:

```
multipart/related; type="text/xml"; start="<...content-id_of_first_ part...>"
```

This example represents a multipart message, where the first part is of type `text/xml` and contains the SOAP envelope. The other parts of the multipart message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.

- **enableTransaction**: Set this optional property to true on an outbound JMS request message if you want the server component to process the Web service request under the same transaction that was used to receive the message from the destination queue or topic.

  Note: For client components, only set this property to true for one-way or two-way asynchronous requests to avoid synchronization problems that can occur with two-way synchronous Web service requests. If this property is not set or is set to the default value of false, the server suspends the transaction that was used to receive the request message from the destination queue or topic prior to invoking the Web services engine to process the request.
- **SOAPJMS_requestIRI**: You must set this property to the JMS endpoint URL associated with the request.
- **SOAPJMS_soapAction**: This optional property is set on an outbound JMS request message to indicate the soapAction value associated with the Web services request. This property is similar to the SOAPAction HTTP header used when transporting Web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the SOAPJMS_soapAction property is specified, it is used by the server component to determine the target of the request. The SOAP specification places no restrictions on the format or specificity of the URI nor does the specification require that the URI is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
- **SOAPJMS_targetService**: You must set this property on an outbound JMS request message, and the value must match the targetService property value that is found in the JMS endpoint URL for the request. This value is used by the server component to determine the port component to which the request is dispatched.
- **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1.0.

- If the request message represents a two-way request, meaning that a reply is expected, the client component must set the JMS message JMSReplyTo property to specify the queue that is used for the reply message. The JMS message setJMSReplyTo method is used to specify the queue. You can benefit from configuring a permanent reply queue on the client to prevent the client from having to create a temporary queue each time a Web service request is made. Read about configuring a permanent reply queue for Web services using SOAP over JMS to learn more about creating this special queue.
- If the SOAP request message represents a one-way request, meaning that a reply message is not expected, the client component must not set the JMS message JMSReplyTo property.
- The client component can assume that a reply message is a JMS BytesMessage object.
- The client component can assume that the reply message correlation ID matches the message ID of the original request message.

Server responsibilities

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages, while adhering to the following protocol constraints:

- The server component can expect to receive a JMS BytesMessage. If something other than a BytesMessage is received by the server component, then a fault with the subcode, unsupportedJMSMessageFormat, is returned to the client if a reply is expected.

- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's JMSReplyTo property is set. The JMS message getJMSReplyTo method is used to retrieve the JMSReplyTo property value from the JMS message.
- The server component must set the following properties in the JMS reply message before sending the message to the reply queue:
  - **SOAPJMS_contentType**: This property is used to describe the content type of the message. See the description for this property in the client responsibilities section in this topic.
  - **correlation ID**: Set the correlation ID property of the JMS reply message to the message ID of the original JMS request message. This correlation is done by calling the JMS message setJMSCorrelationID method.
  - **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1.0.

Example: SOAP request without attachments

The following example displays the results from calling the JMS message toString method for a request message without attachments:

```
  JMSMessage class: jms_bytes
  JMSType:          null
  JMSDeliveryMode:  2
  JMSExpiration:    0
  JMSPriority:      4
  JMSMessageID:     null
  JMSTimestamp:     -1
  JMSCorrelationID: null
  JMSDestination:   null
  JMSReplyTo:       queue://_Q_7D6C2035383215AB00000000000F4241?busName=WsFvtBus
  JMSRedelivered:   false
    JMS_IBM_MsgType: 1
    SOAPJMS_contentType: text/xml; charset=UTF-8
    SOAPJMS_targetService: MaelstromWsEndpoint
    SOAPJMS_requestIRI: jms:jndi:jms/MyRequestQueue?jndiConnectionFactoryName=jms/MyConnFactory&targetService=MyPort1
    SOAPJMS_soapAction: "getQuote"
    SOAPJMS_bindingVersion: 1.0

...
```

JMS endpoint URL syntax

As part of an emerging industry-standard SOAP over JMS protocol, a Java Message Service (JMS) endpoint URL syntax has been defined. A JMS endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

Note: WebSphere Application Server Version 7.0 introduces support for an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) Web services. By using the JMS transport, your enterprise beans based Web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the W3C SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this document was jointly published in October, 2007. The application server supports the current draft specification from W3C.

Note: A JMS endpoint URL has the following general form:

```
jms:jndi:<destination-jndi-name>?<property>=<value>&<property>=<value>&...
```

The URL consists of the jms: transport type, followed by the jndi: variant type, followed by the JNDI name of the destination queue or topic, followed by the query string containing a list of property and value pairs that are used to specify various JMS endpoint information. The jndi: variant means that JNDI is used to locate object names in the endpoint URL string.

The properties supported in the URL string are described in the following tables:

Destination-related properties (required)

Property name	Description
jndiConnectionFactoryName	Specifies the JNDI name of the connection factory that is used by the client runtime to establish a connection to the JMS messaging engine.
targetService	Specifies the name of the port component to which the request is dispatched.

JNDI-related properties (optional)

Property name	Description
jndiInitialContextFactory	Specifies the name of the initial context factory class to use. This value maps to the java.naming.factory.initial property.
jndiURL	Specifies the JNDI provider URL. This value maps to the java.naming.provider.url property.

JMS-related properties (optional)

Property name	Description
deliveryMode	Indicates whether the request message is persistent or not. The valid values are PERSISTENT and NON_PERSISTENT. The default value is NON_PERSISTENT.
timeToLive	Specifies the lifetime, in milliseconds, of the request message. A value of 0 indicates an infinite lifetime. If this parameter is not specified, then the JMS-defined default value is used.
priority	Specifies the JMS priority associated with the request message. Specify this value as a positive integer from 0, the lowest priority, to 9, the highest priority. If this parameter is not specified, then the JMS-defined default value is used.
replyToName	Specifies the JNDI name of the JMS destination to which the response message is sent. Using this optional property enables the client to use a previously defined, permanent queue rather than a temporary queue, for receiving replies.

The required properties jndiConnectionFactoryName and targetService must be in the JMS endpoint URL string. The remaining properties are optional.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

See the SOAP over Java Message Service specification in the Web services specifications and APIs documentation to learn more about this industry standard.

IBM proprietary SOAP over JMS protocol (deprecated)

You can use a SOAP over Java Message Service (JMS) transport as an alternative to HTTP for communicating SOAP messages between clients and servers. The Web services engine supports the use of an IBM proprietary implementation as well as the industry standard implementation.

Note: In earlier versions of the application server, an IBM proprietary SOAP over JMS protocol was supported for Java API for XML-based RPC (JAX-RPC) applications. In WebSphere Application Server 7.0, this proprietary SOAP over JMS protocol is now deprecated in favor of an emerging industry standard SOAP over JMS protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC Web services; however, take advantage of the emerging standard SOAP over JMS protocol. If your client application invokes enterprise beans-based Web services that are supported by an earlier version of the WebSphere Application Server, you must continue to use the IBM proprietary SOAP over JMS protocol to access those Web services.

You can use a SOAP over JMS transport if you need to provide implementations for the client or server components, and you need to make sure that the implementations are interoperable with the client and server components provided by the Web services engine in the application server. The IBM proprietary SOAP over JMS protocol describes specific message exchange requirements for client and server components so they can exchange SOAP request and response messages through the use of the JMS APIs supported by the application server.

Client responsibilities

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use either a JMS TextMessage object, for example, javax.jms.TextMessage, or a BytesMessage object, for example, javax.jms.BytesMessage, to transmit the SOAP request message to the server. If the request message contains attachments, a BytesMessage object must be used. If the request message does not contain attachments, the client can use a TextMessage or a BytesMessage object. The application server client implementation uses only a BytesMessage object for the request message due to the potential need to transmit attachments.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **contentType**: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, is written as follows:

    ```
    text/xml; charset="UTF-8"
    ```

    The **contentType** property in a SOAP request message that contains attachments must be set as follows:

    ```
    multipart/related; type="text/xml"; start="<...content-id of first part...>"
    ```

    This example represents a multi-part message, where the first part is of type `text/xml` that contains the SOAP message. The other parts of the multi-part message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.
  - **enableTransaction**: Set this optional property to `true` on the outgoing SOAP over JMS request message if the server component should process the Web service request under the same transaction that was used to receive the message from the destination queue or topic. The client component should only set this property to `true` for a one-way request to avoid synchronization problems that can occur with a two-way Web service request. If this property is not set or is set to the default value of `false`, then the server will suspend the transaction that was used to receive the request message from the destination queue or topic prior to invoking the Web services engine to process the request.

  - **endpointURL**: This property must be set to the JMS endpoint URL associated with the request.
  - **soapAction**: This optional property is set on an outgoing SOAP over JMS request message to indicate the soapAction value associated with the Web services request. This property is similar to the SOAPAction HTTP header used when transporting Web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the soapAction property is specified, it is used by the server component to determine the target of the request. The SOAP specification places no restrictions on the format or specificity of the URI or that it is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
  - **targetService**: This property must be set to the targetService property value that is found in the JMS-style endpoint location URL for the request. This value is used by the server component to determine the port component in the target when dispatching the request.
  - **transportVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).
- If the SOAP request message represents a two-way request, the client component must set the JMS message's replyTo property to specify the queue that is used for the reply message. The JMS message `setJMSReplyTo` method is used for this. It can be beneficial to configure a permanent **replyTo** queue on the client to prevent the client from having to set the JMS message's replyTo property each time a Web service request is made.
- If the SOAP request message represents a one-way request, the client component must not set the JMS message's replyTo property.
- The client component must be prepared to handle a reply message that is a BytesMessage or a TextMessage object, regardless of the type of JMS message used to transmit the SOAP request. The application server component responds with the same type of JMS message that is received from the client, unless the response contains attachments and a BytesMessage object must be used.
- The client component can assume that the reply message correlation ID matches the original request message ID.

Server responsibilities

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages while adhering to the following protocol constraints:

- The server must be prepared to receive a TextMessage or a BytesMessage. If the request contains attachments, a ByteMessage must be used. The WebSphere product implementation of the server component responds in kind when sending the reply message back to the client, unless the response contains attachments and a BytesMessage is used.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's replyTo property is set.
- The server component must set the following properties in the JMS reply message before sending the message to the replyTo queue:
  - **contentType**: See the description for this property in the client responsibilities section in this article.
  - Set the **correlation ID** of the JMS reply message to the message ID of the original JMS request message. This is done by calling the JMS message `setJMSCorrelationID` method.
  - **transportVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).

Example: SOAP request without attachments

The following example displays the results from calling the JMS message `toString` method for a request message without attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  2
JMSExpiration:    0
JMSPriority:      4
JMSMessageID:     ID:d438eebf04cb124aa25c5821110a134f0000000000000001
JMSTimestamp:     1092110476167
JMSCorrelationID: null
JMSDestination:   topic://NewsGroupTopic?topicSpace=FvtTopicSpace
JMSReplyTo:       null
JMSRedelivered:   false
JMS_IBM_System_MessageID: 6B6765B36943A18C_11000001
transportVersion: 1
JMSXUserID:
targetService: NGConsumerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/topic?destination=jms/NewsGroupTopic&connectionFactory;
  =jms/NewsGroupTCF&targetService;=NGConsumerJMS

contentType: text/xml; charset=utf-8
3c736f6170656e763a456e76656c6f706520786d6c6e733a736f6170656e763d22687474703a2f2f
736368656d61732e786d6c736f61702e6f72672f736f61702f656e76656c6f70652f2220786d6c6e
...
```

The following SOAP Version 1.1 example displays the payload from the previous message example:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

For SOAP Version 1.2, the `encodingStyle` parameter is not supported, so the example looks similar to the following:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

Example: SOAP request with attachments

The following example displays the results from calling the JMS message `toString` method for a request message with attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  1
JMSExpiration:    1092086312310
JMSPriority:      4
JMSMessageID:     ID:4bb64ed64e7d813d59ba5fec110a134f0000000000000001
JMSTimestamp:     1092086012310
JMSCorrelationID: null
JMSDestination:   queue://Logger_Q
JMSReplyTo:       queue://_Q_6B6765B36943A18C_00000385
JMSRedelivered:   false
```

```
JMS_IBM_System_MessageID: 6B6765B36943A18C_10000001
transportVersion: 1
JMSXUserID:
targetService: WSLoggerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/queue?
destination=jms/Logger_Q&connectionFactory=jms/Logger_CF&targetService=WSLoggerJMS
contentType: multipart/related; type="text/xml";
start="<945414389.1092086011970.IBM.WEBSERVICES@myhost1>";
boundary="----=_Part_0_247953397.1092086011970"

...
```

IBM proprietary JMS endpoint URL syntax (deprecated)

A Java Message Service (JMS) endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services with the JMS transport. This proprietary URL specifies the Java Message Service (JMS) destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

Note: In earlier versions of the application server, an IBM proprietary SOAP over JMS protocol was supported for Java API for XML-based RPC (JAX-RPC) applications. In WebSphere Application Server 7.0, this proprietary SOAP over JMS protocol is now deprecated in favor of an emerging industry standard SOAP over JMS protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC Web services; however, take advantage of the emerging standard SOAP over JMS protocol. If your client application invokes enterprise beans-based Web services that are supported by an earlier version of the WebSphere Application Server, you must continue to use the IBM proprietary SOAP over JMS protocol to access those Web services.

Note: A JMS endpoint URL has the following general form:

`jms:/[`*queue*`|`*topic*`]?<`*property*`>=<`*value*`>&<`*property*`>=<`*value*`>&...`

The URL consists of the `jms:` transport type, followed by either `/queue` or `/topic` to indicate the JMS destination type, followed by the query string containing a list of property and value pairs that are used to specify the JMS endpoint information.

The properties supported in the URL string are described in the following tables:

Destination-related properties (required)

Property name	Description
destination	Specifies the Java Naming and Directory Interface (JNDI) name of the destination queue or topic.
connectionFactory	Specifies the JNDI name of the connection factory.
targetService	Specifies the name of the port component to which the request is dispatched.

JNDI-related properties (optional)

Property name	Description
initialContextFactory	Specifies the name of the initial context factory to use which is mapped to the java.naming.factory.initial property.
jndiProviderURL	Specifies the JNDI provider URL, which is mapped to the java.naming.provider.url property.

JMS-related properties (optional)

Property name	Description
deliveryMode	Indicates whether the request message is persistent or not. The valid values are `1` for nonpersistent and `2` for persistent. The default value is `1`.
timeToLive	Specifies the lifetime, in milliseconds, of the request message. A value of `0` indicates an infinite lifetime.
priority	Specifies the JMS priority associated with the request message. Valid values are between `0` to `9`. The default value is `4`. A value of `0` is the lowest priority and a value of `9` is the highest priority.
replyToDestination	Specifies the JNDI name of a queue to be used to receive reply messages. Using this optional property enables the client to use a permanent queue, rather than a temporary queue, for receiving replies.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

The required properties, destination, connectionFactory, and targetService must be contained in the JMS endpoint URL string. The rest of the properties are optional.

You can set any of the properties on the client Stub object. The various properties can be specified by including them as part of the endpoint URL or you can set these properties programmatically by the client on the Stub object. Properties specified on the client Stub object take precedence over properties that are specified as part of a JMS endpoint URL string.

Using the JMS asynchronous response message listener

Java API for XML-Based Web Services (JAX-WS) includes a Java Message Service (JMS) asynchronous response message listener, which is used to receive responses to asynchronous JAX-WS requests that use the JMS transport. The JMS asynchronous response message listener is used in the application server and application client environments.

Before you begin

JAX-WS provides support for invoking Web service operations asynchronously by using either a callback or a polling model. When the JAX-WS client uses the JMS transport to invoke asynchronous operations, the responses are received by the asynchronous response message listener. To learn how to use the JAX-WS asynchronous client invocation model, read about invoking JAX-WS Web services asynchronously.

About this task

The JMS asynchronous response message listener is used within the Web services client environment to receive incoming asynchronous responses when the client application is using the JMS Transport. The listener requires a connection factory and a queue to function correctly. Begin by configuring the connection factory and queue, and then specify the JNDI names of the connection factory and queue to the listener by setting Java system properties. The environment in which the client is running determines how the system properties are set.

The JMS asynchronous response message listener is started automatically by the Web services client runtime environment when the client invokes the first asynchronous JAX-WS operation using the JMS transport.

The connection factory and the queue configured with the asynchronous response message listener is used for all requests that are invoked within a particular Java process such as for the application server or an application client container. You can share the connection factory among different Java processes. However, you cannot share a queue among Java processes.

1. Determine if you want the JAX-WS client to use the JMS transport mechanism.
2. For each Java process that will use JMS as a transport for asynchronous JAX-WS requests, configure the connection factory and queue that are used by the JMS asynchronous response listener for that process. You can share a connection factory among multiple Java processes, but you cannot share a queue among Java processes.
3. For each Java process, set the com.ibm.websphere.webservices.AsyncReplyQueueName and com.ibm.websphere.webservices.AsyncReplyCFName Java system properties to specify the JNDI names of the queue and connection factory that are used by the JMS asynchronous response message listener for that process.

   If the JNDI name of the queue is the default value, jms/DefaultAsyncReplyQueue, then you do not need to set the AsyncReplyQueueName property. Likewise, if the JNDI name of the connection factory is the default value, jms/DefaultAsyncReplyCF, then you do not need to set the AsyncReplyCFName property as well.

   If your client runs within the application server environment, then set the properties as application server system properties by using the administrative console or the wsadmin command.

   If your client runs within the application client container environment, then you should set the properties by using the –CCD option on the launchClient command line.

Results

Your JAX-WS Web services client is configured to use the JMS asynchronous response message listener to receive asynchronous response messages when using the JMS transport.

Example

Suppose that you have a JAX-WS Web services client that runs in the application client container environment and uses the JMS transport to communicate with the server. Suppose also that the client invokes asynchronous JAX-WS operations. You can create a connection factory with the JNDI name, jms/MyAppCF, and a queue with the JNDI name, jms/MyAppAsyncReplyQueue. When you invoke the client with the launchClient command, specify the JNDI names of the queue and connection factory as illustrated in the following command:

```
launchClient MyAppClient.ear \
   -CCDcom.ibm.websphere.webservices.AsyncReplyQueueName=jms/MyAppReplyQueue \
   -CCDcom.ibm.websphere.webservices.AsyncReplyCFName=jms/MyAppCF \
   <application arguments>
```

Configuring a permanent reply queue for Web services using SOAP over JMS

When using two-way Web service communications using the industry standard SOAP over JMS protocol, you can benefit from configuring a permanent reply queue on a Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web services client. The use of a permanent reply queue can improve performance because this reply queue prevents the client from having to create a temporary reply queue each time a Web services request is invoked.

About this task

A permanent reply queue is configured on the Web services client in one of the following ways:

- Specify the optional `replyToName` property in the JMS endpoint URL.
- Set the reply queue programmatically.
  - For a JAX-WS Web services client, set the JNDI name of the reply queue programmatically on the client RequestContext object. Setting the reply queue JNDI name on the RequestContext object affects all subsequent requests that are invoked using that RequestContext object.
  - For a JAX-RPC Web services client, set the JNDI name of the reply queue programmatically on the client Stub or Call object. Setting the reply queue JNDI name as a Stub or a Call property affects all subsequent requests that are invoked using that Stub or Call object.
- Set the reply queue as a Java virtual machine (JVM) system property. Setting the reply queue as a JVM system property affects all of your Web services clients running in the particular JVM. If there are multiple clients running in the same JVM that need to use a different reply queue, then this option does not work. Instead, use one of the other two options.

To set the permanent reply queue using any of these options, only client-side configuration is necessary. There is no configuration necessary for the Web service provider.

Use the typical administrative functions of the JMS messaging provider to create the permanent reply queue prior to configuring the reply queue with the Web services client.

Configure the JNDI name of the permanent reply queue using one of the following ways:

- Specify the optional `replyToName` property in the JMS endpoint URL; for example:

  ```
  jms:jndi:jms/MyRequestQueue&jndiConnectionFactoryName=jms/MyCF&replyToName=jms/MyReplyQueue
  ```

- Set the reply queue programmatically on the client.

  The value of the property is a String and represents the JNDI name of the reply queue.

  - For JAX-WS Web services clients, set the com.ibm.wsspi.webservices.Constants.JMS_REPLY_QUEUE_JNDI_NAME property on the client JAX-WS RequestContext object; for example:

    ```
    ((BindingProvider) port).getRequestContext().put
    (com.ibm.wsspi.webservices.Constants.JMS_REPLY_QUEUE_JNDI_NAME, "jms/MyReplyQueue");
    ```

  - For JAX-RPC Web services clients, set the com.ibm.wsspi.webservices.Constants.JMS_REPLY_QUEUE_JNDI_NAME property on the client JAX-RPC Stub or Call object; for example:

    ```
    ((javax.xml.rpc.Stub) stub)._setProperty(com.ibm.wsspi.webservices.Constants.JMS_REPLY_QUEUE_JNDI_NAME,
    "jms/MyReplyQueue");
    ```

- Set the JNDI name of the reply queue as a JVM system property.
  - For a Java client invocation, enter the following code at a command prompt:

    ```
    java -Dcom.ibm.websphere.webservices.JMSReplyQueueJndiName=jms/MyReplyQueue
    ```

  - For a JVM running on the application server, perform the following actions:
    - Set a JVM system property using the administrative console for the application server that runs the Web service client application.

      To set custom properties, log on to the administrative console, and navigate to the Java virtual machine custom properties panel.

      1. Click **Servers > Server Types > WebSphere application servers > *server_name*> Java and Process Management > Process Definition > Java Virtual Machine > Custom Properties> New**
      2. Set the **Name** property to: com.ibm.websphere.webservices.JMSReplyQueueJndiName
      3. Set the **Value** property to: jms/Permanent_Q
      4. Click OK to save your changes.

5. Click **Synchronize changes with Nodes** and click **Save**.
6. Restart the application server.

Results

Your Web services client can now receive SOAP overJMS messages from a permanent reply queue.

Configuring a permanent replyTo queue for JAX-RPC Web services using SOAP over JMS (deprecated)

When using two-way Web service communications using the IBM proprietary SOAP over JMS transport, you can benefit from configuring a permanent replyTo queue on Java API for XML-based RPC (JAX-RPC) Web services client to prevent the client from having to create a temporary reply queue each time a Web service request is made.

About this task

Note: In WebSphere Application Server 7.0, the IBM proprietary SOAP over JMS protocol is now deprecated in favor of the emerging industry standard protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC Web services, however, you are encouraged to take advantage of the SOAP over JMS protocol standard. This task describes configuring a permanent replyTo queue when using the IBM proprietary SOAP over JMS transport. To learn more about the SOAP over JMS standard, see the using SOAP over JMS to transport Web services documentation.

A permanent replyTo queue is configured on the Web services client in one of the following ways:

- Specify the optional `replyToDestination` property in the JMS endpoint URL.
- Set the replyTo queue programmatically on the client JAX-RPC Stub or Call object. Setting the replyTo queue as a Stub or a Call property affects all requests that are invoked using that Stub or Call object.
- Set the replyTo queue as a Java virtual machine (JVM) system property. Setting the replyTo queue as a JVM system property affects all of your SOAP over JMS clients running in the particular JVM. If there are multiple clients in the same application that need to use a different replyTO queue, then the best option is to set the property programmatically.

Note: To set the permanent replyTo queue using any of these options, only client-side configuration is necessary. There is no configuration necessary on the Web service provider side.

- Specify the optional `replyToDestination` property in the JMS endpoint URL.

  ```
  jms:/queue?destination=jms/MyRequestQueue&connectionFactory=
  jms/MyCF&replyToDestination=jms/MyReplyQueue&targetService=MyService
  ```

- Set the replyTo queue programmatically on the client JAX-RPC Stub or Call object.

  The client uses the JAX-RPC Stub or Call object to invoke the Web service.

  ```
  ((javax.xml.rpc.Stub)stub)._setProperty(com.ibm.wsspi.webservices.Consta
  nts.JMS_REPLY_QUEUE_JNDI_NAME,
  "jms/Permanent_Q");
  ```

  The value of the property is a String.

- Set the replyTo queue as a JVM system property.
  - For a Java client invocation, enter at a command prompt:

    ```
    java -Dcom.ibm.websphere.webservices.JMSReplyQueueJndiName=jms/Permanent_Q
    ```

  - For a JVM running on the application server:
    - Set a JVM system property using the administrative console for the application server which runs the Web service client application.

      To set custom properties, connect to the administrative console and navigate to the Java virtual machine custom properties panel.

1. Click **Servers > Server Types > WebSphere application servers > *server_name*> Java and Process Management > Process Definition > Java Virtual Machine > Custom Properties> New**
2. Set the **Name** property to: `com.ibm.websphere.webservices.JMSReplyQueueJndiName`
3. Set the **Value** property to: `jms/Permanent_Q`
4. Click OK to save your changes.
5. Click **Synchronize changes with Nodes** and click **Save**.
6. Restart the application server.

Results

Your Web services client can now receive IBM proprietary SOAP over JMS messages from a permanent replyTo queue.

Invoking Web service requests transactionally using SOAP over JMS transport

Use the enableTransactionalOneWay property to ensure that one-way and two-way asynchronous Web service requests using the industry standard SOAP over JMS transport will be sent to the destination queue or topic transactionally.

About this task

When using JMS to transport Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) Web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way synchronous Web service requests. However, you can choose to enable one-way and two-way asynchronous requests to be processed as part of a transaction. You can use the enableTransactionalOneWay property to ensure that one-way and two-way asynchronous Web service requests that use the JMS transport are sent to the destination queue or topic transactionally. When the client application invokes the Web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the enableTransactionalOneWay property.

- Set the enableTransactionalOneWay property programmatically. The value of the property is a Boolean.
  - For JAX-WS clients, set the property on the client JAX-WS RequestContext object. For example:

    ```
    ((BindingProvider) port).getRequestContext().put
    (com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
    new Boolean(true));
    ```

  - For JAX-RPC clients, set the property on the client JAX-RPC Stub or Call object. For example:

    ```
    stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
    new Boolean(true));
    ```

- For JAX-RPC clients, set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the wsadmin command.

  For more information about the wsadmin tool options, review Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands.

  Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay` , is either `true` or `false`.
  - Using Jacl:

    ```
    $AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
    service/MyServiceRef MyPort enableTransactionalOneWay true}}}
    ```

  - Using Jython:

```
AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
```

Results

You have a Web services client application that is configured to invoke one-way and two-way asynchronous requests transactionally when using the JMS transport.

What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

Invoking one-way JAX-RPC Web service requests transactionally using the JMS transport (deprecated)

Use the enableTransactionalOneWay property to ensure that one-way JAX-RPC Web service requests using the IBM proprietary JMS transport will be sent to the destination queue or topic transactionally.

About this task

Note: In WebSphere Application Server 7.0, the IBM proprietary SOAP over JMS protocol is now deprecated in favor of the emerging industry standard protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC Web services, however, you are encouraged to take advantage of the SOAP over JMS protocol standard. This task describes configuring a permanent replyTo queue when using the IBM proprietary SOAP over JMS transport. To learn more about the SOAP over JMS standard, see the using SOAP over JMS to transport Web services documentation.

When using JMS to transport Web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way Web service requests. However, you can choose to enable one-way requests to be processed as part of the transaction. The `enableTransactionalOneWay` property can be used to ensure that one-way Web service requests that use the JMS transport will be sent to the destination queue or topic transactionally. When the client application invokes the one-way Web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the `enableTransactionalOneWay` property.

- Set the `enableTransactionalOneWay` property programmatically on the client JAX-RPC Stub or Call object.

  When using a static Stub to invoke the Web service operation, set the `enableTransactionalOneWay` property on the Stub object before invoking the Web service method. When using a Call object to invoke the Web service operation, set the `enableTransactionalOneWay` property on the Call object before invoking the `invokeOneWay()` method.

  ```
  Service service = /* Obtain the desired service */
  MyStub stub = service.getPort();

  /* Set enableTransactionalOneWay property on Stub */
  stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY, new Boolean(true));

  /* Invoke the one-way operation */
  stub.myOneWayOperation("Parm1");
  ```

  The value of the property is Boolean.
- Set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the wsadmin command.

For more information about the wsadmin tool options, review Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands.

Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay` , is either `true` or `false`.

– Using Jacl:

```
$AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
service/MyServiceRef MyPort enableTransactionalOneWay true}}}
```

– Using Jython:

```
 AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
```

Results

You have a Web service client application that is configured to invoke one-way requests transactionally while using the JMS transport.

What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

Developing applications that use Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between Web services by defining a standard way to address Web services and to provide addressing information in messages. This task describes the steps that are required to create a Web service that is accessed using a WS-Addressing endpoint reference.

About this task

Perform these tasks if you are using endpoint references in your Web service application logic to address Web service endpoints, or if you are creating a Web service that complies with the WS-Addressing interoperability protocol.

- To perform the basic WS-Addressing development activities that are required by Web services developers, such as creating a Web service that is referenced by an endpoint reference, refer to “Using the Web Services Addressing APIs: Creating an application that uses endpoint references” on page 682.
- To perform more advanced WS-Addressing functions, such as setting or retrieving message-addressing properties, refer to “Using the IBM proprietary Web Services Addressing SPIs: Performing more advanced Web Service Addressing tasks” on page 699.
- To configure a service or a client to use the WS-Addressing support, refer to “Enabling Web Services Addressing support for JAX-RPC applications” on page 712.

Web Services Addressing support

The Web Services Addressing (WS-Addressing) support in this product provides the environment for Web services that use the Worldwide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing.

Note: This release provides support for the Java API for XML-Based Web Services (JAX-WS) 2.1 API, which you can use to create portable applications that use WS-Addressing. Existing JAX-WS applications will work as before.

You do not normally need to be aware of the underlying WS-Addressing support because WebSphere Application Server ensures that your Web service applications are WS-Addressing compliant when required. Read this topic only if you need to use the WS-Addressing support directly. For example, if you have one of the following roles:

- A Web service developer who needs to use the WS-Addressing application programming interfaces (APIs) to create endpoint references within an application, and then use these references to target Web service resource instances.
- A system programmer who needs to use the IBM proprietary WS-Addressing system programming interfaces (SPIs) to perform more advanced WS-Addressing operations, such as specifying message-addressing properties on Web services messages.
- An administrator who is configuring policy sets for JAX-WS applications.

The WS-Addressing support for developers consists of two sets of programming interfaces: the JAX-WS 2.1 standard interfaces, and the IBM proprietary implementation of the WS-Addressing specification.

Features of the JAX-WS 2.1 WS-Addressing support

This product provides support for the JAX-WS 2.1 WS-Addressing APIs, which you can use to perform basic addressing functions such as creating an endpoint reference, enabling WS-Addressing support, and specifying the action URIs that are associated with the WSDL operations of the Web service. Use these APIs if you want to perform simple WS-Addressing functions and create JAX-WS applications that are portable.

The JAX-WS 2.1 WS-Addressing APIs provide the following features for core WS-Addressing application development:

- Java representations of WS-Addressing endpoint references.
  - You can create Java endpoint reference instances for the application endpoint, or other endpoints in the same application, at run time. You do not have to specify the URI of the endpoint reference.
  - You can create Java endpoint reference instances for endpoints in other applications by specifying the URI of the endpoint reference.
  - On services, you can use annotations to specify whether WS-Addressing support is enabled and whether it is required.
  - On clients, you can use features to specify whether WS-Addressing support is enabled and whether it is required.
  - You can configure client proxy or Dispatch objects using endpoint references.
- Java support for endpoint references that represent Web Services Resource (WS-Resource) instances.
  - You can associate reference parameters with an endpoint reference at the time of its creation, to correlate it with a particular resource instance.
  - In targeted Web services, you can extract the reference parameters of an incoming message, so that the Web service can route the message to the appropriate WS-Resource instance.

Features of the IBM proprietary WS-Addressing support

This product provides an IBM proprietary implementation of the WS-Addressing specification, which you can use with JAX-RPC applications as well as JAX-WS applications, to perform more advanced functions such as creating endpoint references that represent highly available objects, or directly setting message addressing properties in the SOAP header. Use these APIs and SPIs if you want to create JAX-RPC applications that use addressing, or you want to perform more advanced functions that are not possible with the JAX-WS 2.1 APIs.

The IBM proprietary API provides the following basic features:

- You can easily create Java endpoint reference instances to represent any endpoint in the server, based on the deployment environment of the application. You do not have to specify the URI of the endpoint reference. Additionally, endpoint references can represent highly available or workload-managed objects.
- You can configure client JAX-WS BindingProvider request context objects, or JAX-RPC Stub or Call objects, with a WS-Addressing endpoint reference. Future invocations on these objects are targeted at the endpoint that is represented by the endpoint reference. The invocations also automatically conform to the WS-Addressing specification (namespace) that is associated with that endpoint reference.

The IBM proprietary WS-Addressing SPIs provide support for extended WS-Addressing system development using the following features:

- Reasoning and manipulation of endpoint references beyond what is available at the application programming level.
  - You can manipulate the contents of the endpoint reference, as specified by the WS-Addressing specification.
  - You can associate a WS-Addressing namespace, and therefore specification behavior, with an endpoint reference.
- Java representations of the WS-Addressing message-addressing properties.
  - You can specify WS-Addressing message-addressing properties for outbound Web service messages. In the targeted Web service, you can extract message addressing properties from inbound Web service messages.
  - You can specify the WS-Addressing namespace of an outbound WS-Addressing message, although in most cases the namespace is automatically derived based on the target endpoint reference. In a targeted Web service, you can acquire the WS-Addressing namespace of an incoming message.

Support for WS-Addressing specifications and interoperability

By default, this product supports the W3C WS-Addressing 1.0 Core and SOAP Binding specifications that are identified by the http://www.w3.org/2005/08/addressing namespace. Unless otherwise stated, WS-Addressing semantics that are described in this documentation refer to these specifications.

For interoperability, other levels of the WS-Addressing specification are supported in this version of the product; in particular, the WS-Addressing W3C submission with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing.

For JAX-WS applications, this product supports the WS-Addressing metadata specification identified by the http://www.w3.org/2007/05/addressing/metadata namespace. This specification supersedes the WS-Addressing Web Services Description Language (WSDL) binding specification identified by the http://www.w3.org/2006/05/addressing/wsdl namespace.

In addition, this product supports the following features from the WS-Addressing WSDL binding specification:

- The wsaw:UsingAddressing extensibility element, on the WSDL Binding element only. The supported namespaces for this element are the http://www.w3.org/2006/05/addressing/wsdl namespace and the http://www.w3.org/2006/02/addressing/wsdl namespace (deprecated).
- The wsaw:Action extensibility element. The supported namespaces for this element are the http://www.w3.org/2006/05/addressing/wsdl namespace, the http://www.w3.org/2006/02/addressing/wsdl namespace (deprecated), and the http://schemas.xmlsoap.org/ws/2004/08/addressing namespace.

Web Services Addressing overview

Web Services Addressing (WS-Addressing) is a Worldwide Web Consortium (W3C) specification that aids interoperability between Web services by defining a standard way to address Web services and provide addressing information in messages. The WS-Addressing specification introduces two primary concepts:

endpoint references, and message-addressing properties. This topic contains an overview of each concept; for further details, refer to the WS-Addressing specifications.

Endpoint references

Endpoint references provide a standard mechanism to encapsulate information about specific endpoints. Endpoint references can be propagated to other parties and then used to target the Web service endpoint that they represent. The following table summarizes the information model for endpoint references.

Table 11. Information model for endpoint references

Abstract Property name	Property type	Multiplicity	Description
[address]	xs:anyURI	1..1	The absolute URI that specifies the address of the endpoint.
[reference parameters]*	xs:any	0..unbounded	Namespace qualified element information items that are required to interact with the endpoint.
[metadata]	xs:any	0..unbounded	Description of the behavior, policies and capabilities of the endpoint.

The following prefix and corresponding namespace is used in the previous table.

Table 12. Prefix and corresponding namespace

Prefix	Namespace
xs	http://www.w3.org/2001/XMLSchema

The following XML fragment illustrates an endpoint reference. This element references the endpoint at the URI http://example.com/fabrikam/acct, has metadata specifying the interface to which the endpoint reference refers, and has application-defined reference parameters of the http://example.com/fabrikam namespace.

```
<wsa:EndpointReference xmlns:wsa="http://www.w3.org/2005/08/addressing"
                       xmlns:wsaw="http://www.w3.org/2006/05/addressing/wsdl"
                       xmlns:fabrikam="http://example.com/fabrikam"
                       xmlns:wsdli="http://www.w3.org/2005/08/wsdl-instance"
                       wsdli:wsdlLocation="http://example.com/fabrikam
                       http://example.com/fabrikam/fabrikam.wsdl">
    <wsa:Address>http://example.com/fabrikam/acct</wsa:Address>
    <wsa:Metadata>
        <wsaw:InterfaceName>fabrikam:Inventory</wsaw:InterfaceName>
    </wsa:Metadata>
    <wsa:ReferenceParameters>
        <fabrikam:CustomerKey>123456789</fabrikam:CustomerKey>
        <fabrikam:ShoppingCart>ABCDEFG</fabrikam:ShoppingCart>
    </wsa:ReferenceParameters>
</wsa:EndpointReference>
```

Message-addressing properties

Message addressing properties (MAPs) are a set of well defined WS-Addressing properties that can be represented as elements in SOAP headers and provide a standard way of conveying information, such as the endpoint to which message replies should be directed, or information about the relationship that the message has with other messages. The MAPs that are defined by the WS-Addressing specification are summarized in the following table.

Table 13. Message-addressing properties defined by the WS-Addressing specification

Abstract WS-Addressing MAP name	MAP content type	Multiplicity	Description
[action]	xs:anyURI	1..1	An absolute URI that uniquely identifies the semantics of the message. This proprety corresponds to the [address] property of the endpoint reference to which the message is addressed. This value is required.
[destination]	xs:anyURI	1..1	The absolute URI that specifies the address of the intended receiver of this message. This value is optional because, if not present, it defaults to the anonymous URI that is defined in the specification, indicating that the address is defined by the underpinning protocol.
[reference parameters]*	xs:any	0..unbounded	Correspond to the [reference parameters] property of the endpoint reference to which the message is addressed. This value is optional.
[source endpoint]	EndpointReference	0..1	A reference to the endpoint from which the message originated. This value is optional.
[reply endpoint]	EndpointReference	0..1	An endpoint reference for the intended receiver of replies to this message. This value is optional.
[fault endpoint]	EndpointReference	0..1	An endpoint reference for the intended receiver of faults relating to this message. This value is optional.
[relationship]*	xs:anyURI plus optional attribute of type xs:anyURI	0..unbounded	A pair of values that indicate how this message relates to another message. The content of this element conveys the [message id] of the related message. An optional attribute conveys the relationship type. This value is optional.
[message id]	xs:anyURI		An absolute URI that uniquely identifies the message. This value is optional.

The abstract names in the previous tables are used to refer to the MAPs throughout this documentation.

The following example of a SOAP message contains WS-Addressing MAPs:

```
<S:Envelope xmlns:S="http://www.w3.org/2003/05/soap-envelope"
            xmlns:wsa="http://www.w3.org/2005/08/addressing"
            xmlns:fabrikam="http://example.com/fabrikam">
    <S:Header>
        ...
        <wsa:To>http://example.com/fabrikam/acct</wsa:To>
                  <wsa:ReplyTo>
             <wsa:Address> http://example.com/fabrikam/acct</wsa:address>
        </wsa:ReplyTo>
        <wsa:Action>...</wsa:Action>
        <fabrikam:CustomerKey wsa:IsReferenceParameter='true'>123456789</fabrikam:CustomerKey>
        <fabrikam:ShoppingCart wsa:IsReferenceParameter='true'>ABCDEFG</fabrikam:ShoppingCart>
        ...
    </S:Header>
    <S:Body>
    ...
    </S:Body>
</S:Envelope>
```

Web Services Addressing message exchange patterns:

The Worldwide Web Consortium (W3C) Web Services Addressing (WS-Addressing) specification explicitly defines the WS-Addressing core properties for the message exchange patterns (MEPs) that are defined by WSDL 1.0. These MEPs are summarized in this topic, illustrating the mandatory WS-Addressing properties for each pattern.

One-way MEP

This straightforward one-way message is defined in WSDL 1.0 as an input-only operation. The WSDL fragment for this operation has the following form:

```
<operation name="myOperation">
    <input message="tns:myInputMessage"/>
</operation>
```

The following WS-Addressing message addressing properties (MAPs) are automatically added to the message header of a one-way WS-Addressing input message by the client application server run time, to ensure compliance with the WS-Addressing specification.

Note: You can override these values using the IBM proprietary WS-Addressing system programming interfaces (SPIs).

Table 14.

Abstract WS-Addressing MAP name	Default value for a one-way input message
[action]	The WS-Addressing action that is generated in accordance with the version of the WS-Addressing specification that is in use.
[reply endpoint]	The WS-Addressing reply endpoint indicating that no replies are expected to this input message. The value of this MAP depends on the version of the WS-Addressing specification that is in use.
[message id]	A uniquely generated message identifier. Although not mandated by the specification, the WebSphere Application Server run time automatically sets this value.

Although the WSDL operation for this message exchange does not specify any responses, related messages can be sent as part of other message exchanges. In particular, applications can use the WS-Addressing reply endpoint or fault endpoint MAPs to indicate to the target of a one-way message where to send related messages. To propagate a reply endpoint or fault endpoint, associate the appropriate property with the JAX-WS BindingProvider object's request context, or with the JAX-RPC Stub or Call object, as described in "Specifying and acquiring message-addressing properties using the IBM proprietary Web Services Addressing SPIs" on page 700, to override the defaults.

Two-way request-response

This is a request-response MEP as defined in WSDL 1.1. The response part of the operation might be defined as an output message, or a fault message, or both. The following WSDL code extracts show the various forms of definition for such an operation:

```
<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <output message="tns:myOutputMessage"/>
   <fault="tns:myFaultMessage"/>
</operation>
```

```
<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <output message="tns:myOutputMessage"/>
</operation>
```

```
<operation name="myOperation">
   <input message="tns:myInputMessage"/>
   <fault="tns:myFaultMessage"/>
</operation>
```

The application server client run time ensures that the SOAP header of the outgoing request message contains the relevant WS-Addressing message information headers. The calling application does not have to set the WS-Addressing headers. A response is expected, therefore you must specify a reply endpoint or fault endpoint in the request message.

Note: In the 2005/08 specification, an unspecified reply endpoint is valid because it defaults to an endpoint reference that contains the anonymous URI.

The following table summarizes the MAPs that the product sets by default on a Web service request that uses WS-Addressing. You can override or specify other MAPs using the IBM proprietary WS-Addressing SPIs.

Table 15.

Abstract WS-Addressing MAP name	**Default value for the input message of a request-response operation**
[action]	The WS-Addressing action that is generated in accordance with the version of the WS-Addressing specification that is in use.
[message id]	A uniquely generated message identifier.

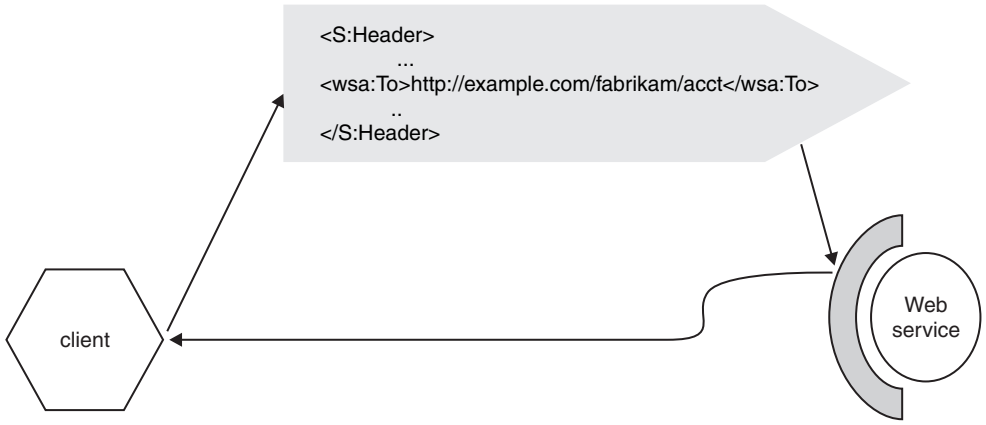
The following table summarizes the MAPs that are set by default by the product on a WS-Addressing response or fault message.

Table 16.

Abstract WS-Addressing MAP name	**Default value for the input message of a request-response operation**
[action]	The WS-Addressing action that is generated in accordance with the version of the WS-Addressing specification that is in use.
[relationship]*	A relationship set containing a reply relationship to the message id that is passed in the request message.
[message id]	A uniquely generated message identifier; although not mandated by the specification, the application server run time automatically sets this property.

Synchronous request-response

By default, if you do not use the IBM proprietary WS-Addressing SPI to set the reply endpoint or fault endpoint, the response part of a two-way message is returned according to the underlying protocol in use. In particular, in the case of an HTTP request, the response is returned synchronously in the HTTP response.



For JAX-WS synchronous invocations, if you set the reply endpoint or the fault endpoint, the endpoint reference that you set must use the anonymous URI. If the endpoint reference does not use the anonymous URI, a javax.xml.ws.WebServiceException exception is thrown. Although the endpoint reference uses the anonymous URI, you can use reference parameters within the endpoint reference to target the reply or fault endpoint.

For JAX-WS applications, you can specify a synchronous message exchange pattern by applying and configuring a WS-Addressing policy type. This exchange pattern is particularly useful in the following scenarios:

- You do not have WS-Security enabled, or have not used an assembly tool to specify that the ReplyTo and FaultTo elements of the SOAP message should be signed. In this situation, it is possible for a JAX-WS endpoint to be used to send messages to a third party, potentially taking part in a Denial of Service attack. To prevent such attacks, specify the synchronous message exchange pattern, and enable WS-Policy so that clients are aware of this requirement.
- A JAX-WS client is communicating through a NAT device. URIs in the ReplyTo or FaultTo elements of the SOAP message cannot be routed through such a device. In this situation, the client must use the anonymous URI defined by the WS-Addressing specification, and a synchronous message exchange pattern. To ensure that the client conforms to these requirements even if the server uses WS-Policy to request a non-anonymous URI in the ReplyTo element, specify the synchronous message exchange pattern on the client.

You can ensure that servers or clients are aware of the requirement for synchronous messaging by enabling WS-Policy.

Asynchronous request-response

The JAX-RPC 1.0 programming model does not allow for asynchronous replies or faults to a two-way request-response operation.

Responses to, or faults generated from, requests that are directed at endpoints hosted on WebSphere Application Server are targeted at the reply endpoint or fault endpoint, in accordance with the WS-Addressing specification. The connection with the requesting client will be closed with an HTTP 202 response.

For JAX-WS asynchronous invocations, the reply endpoint is generated automatically for use by the JAX-WS implementation. If you attempt to set either a reply endpoint or a fault endpoint , a javax.xml.ws.WebServiceException exception is thrown.

For JAX-WS applications, you can specify an asynchronous message exchange pattern by applying and configuring a WS-Addressing policy type. This exchange pattern is particularly useful if a JAX-WS endpoint has a long-running invocation time. Client and server resources are used to keep the connection open, but this use of resource might be impractical if the service takes a long time to respond. You can ensure that clients are aware of the requirement for asynchronous messaging by enabling WS-Policy.

Web Services Addressing version interoperability

The Web Services Addressing (WS-Addressing) support in this product can interoperate with various versions of the WS-Addressing specification.

Table 17. Supported set of WS-Addressing versions

Associated namespace	Specification download location	Details
http://www.w3.org/2005/08/addressing	http://www.w3.org/2002/ws/addr/	W3C Candidate Recommendation (CR) versions of the WS-Addressing core and SOAP specifications. These specifications are sometimes referred to collectively as the 2005/08 version of WS-Addressing.

Table 17. Supported set of WS-Addressing versions (continued)

Associated namespace	Specification download location	Details
http://www.w3.org/2007/05/addressing/metadata	http://www.w3.org/2002/ws/addr/	W3C final version of the WS-Addressing metadata specification. This specification defines WS-Addressing WSDL extensions and WS-Policy assertions. For JAX-WS applications, this specification supersedes the http://www.w3.org/2006/05/addressing/wsdl specification.
http://www.w3.org/2006/05/addressing/wsdl	http://www.w3.org/2002/ws/addr/	W3C Candidate Recommendation (CR) version of the WS-Addressing WSDL specification. This is the default namespace used by this product for the WSDL parts of the WS-Addressing specification, for JAX-RPC applications. For JAX-WS applications, this specification is superseded by the http://www.w3.org/2007/05/addressing/metadata specification.
http://www.w3.org/2006/02/addressing/wsdl	http://www.w3.org/2002/ws/addr/	W3C Last Call (LC) version of the WS-Addressing WSDL specification. Support for this namespace is deprecated.
http://schemas.xmlsoap.org/ws/2004/08/addressing	http://www.w3.org/Submission/ws-addressing/	W3C WS-Addressing Submission specification This specification is sometimes referred to as the 2004/08 specification. It combines the core, SOAP and WSDL aspects of WS-Addressing in a single specification.

This version of the product interoperates with each of the WS-Addressing specifications that are defined in the previous table. This interoperability results in the following behavior:

- Incoming Web service messages that contain WS-Addressing message addressing properties (MAPs) are appropriately bound to SOAP, and WS-Addressing SOAP elements are appropriately deserialized to their WS-Addressing programming model representations according to the namespace in use.
- WS-Addressing programming model artifacts are appropriately serialized into SOAP elements, and the MAPs are bound to SOAP according to the namespace in use.
- Differing WS-Addressing semantics are adhered to, according to the WS-Addressing version currently in use.

Determining the WS-Addressing namespace of inbound messages

The WS-Addressing namespace of incoming Web service messages is the namespace of the first WS-Addressing [action] MAP that is found. The runtime looks for an [action] MAP of the default namespace prior to searching for other namespaces on the inbound message, in an undefined order. The

namespace of the WS-Addressing core specification in use is available to the target endpoint through the message context.

Determining the WS-Addressing namespace of outbound messages

WS-Addressing messages that are issued from this version of the product adopt the namespace that is associated with the destination endpoint reference. If this namespace is unknown, the message adopts the default WS-Addressing namespace.

This product provides a proprietary system programming interface (SPI) to change the namespace that is associated with an endpoint reference to any namespace in the supported set.

The WS-Addressing specification to use

Note: In most cases, use the default WS-Addressing specification that is supported by the product. You do not need to perform any additional actions to use this specification. The following list gives examples of occasions where you must override the default namespace:

- When interoperating with an endpoint that does not support the default namespace, for example, an earlier version of the product.
- When a namespace other than the default is required. For example, when implementing a specification that uses a level of WS-Addressing other than the default.

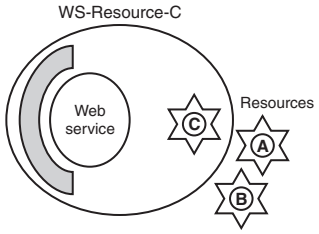
The W3C Last Call (LC) version of the WS-Addressing WSDL specification is deprecated. Use this specification only when you are interoperating with WebSphere Application Server 6.1 nodes that do not have fix pack V6.1.0.2 or later. Otherwise, use the W3C Candidate Recommendation version of the specification, or for JAX-WS applications, the WS-Addressing metadata specification.

Web Services Addressing application programming model

The Web Services Addressing (WS-Addressing) specification defines an endpoint reference that is represented in Extensible Markup Language (XML) by an EndpointReferenceType object that encapsulates information about the endpoint address as well as additional contextual information associated with the endpoint. Some services might be addressable using a simple URI address, as is most typical in Web services. Other services might require the use of an endpoint reference to address them, so that the additional contextual information associated with the endpoint is present in messages sent to the endpoint.

Examples of services that use WS-Addressing endpoint references include Web Services Resources and Web Services Notification message producers and message consumers, all of which have the notion of stateful resources associated with their endpoints. In these cases the endpoint reference not only contains the service address but also some data that is used to select the specific stateful resource instance for use in the processing of a Web services message.

A WS-Resource is defined as the combination of a resource and a Web service through which the resource is accessed. The following figure illustrates a Web service, at http://www.example.com/service, and three resources, A, B, and C, which are accessed through the Web service. Three WS-Resources are therefore illustrated in the figure:



A WS-Resource is referenced by a WS-Addressing endpoint reference that uniquely identifies the WS-Resource, typically by containing an identifier of the resource component of the WS-Resource inside the EndpointReference ReferenceParameter element. In the previous example, WS-Resource-C is the combination of the Web service and the resource that is identified by C, and a reference to WS-Resource-C might be as follows:

```
<wsa:EndpointReference>
    <wsa:Address>
        http://www.example.com/service
    </wsa:Address>
    <wsa:ReferenceParameters>
        <tns:SomeDisambiguatorElement>C</tns:SomeDisambiguatorElement>
    </wsa:ReferenceParameters>
    ...
</wsa:EndpointReference>
```

The WS-Addressing APIs provide the appropriate interfaces for implementing the previous pattern.

Web Services Addressing annotations

The WS-Addressing specification provides transport-neutral mechanisms to address Web services and to facilitate end-to-end addressing. If you have a JAX-WS 2.1 application you can use Java annotations in your code to specify WS-Addressing behavior at run time. Use WS-Addressing annotations to specify the actions that are associated with Web service operations, and also to enable or disable WS-Addressing support.

Note: This release provides support for the WS-Addressing annotations specified by the JAX-WS 2.1 standard. Use these annotations in the Java code for a Web service, to enable WS-Addressing support, to specify whether WS-Addressing information is required in incoming messages, and to specify actions to be associated with a Web service operation or fault response.

The following WS-Addressing annotations are supported in this product. These annotations are defined in the JAX-WS 2.1 specification unless otherwise stated.

javax.xml.ws.Action
: Specifies the action that is associated with a Web service operation. When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method. For this attribute to be added to the WSDL operation you must also specify the Addressing annotation on the implementation class. If you do not want to use the Addressing annotation you can supply your own WSDL document with the Action attribute already defined.

javax.xml.ws.FaultAction
: Specifies the action that is added to a fault response. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. For this attribute to be added to the WSDL operation you must also specify the Addressing annotation on the implementation class. If you do not want to use the Addressing annotation you can supply your own WSDL document with the Action attribute already defined. This annotation must be contained within an Action annotation.

javax.xml.ws.soap.Addressing
: Specifies that this service wants to enable WS-Addressing support. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing
: This annotation is part of the IBM implementation of the JAX-WS 2.1 specification. This annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

The following example code uses the Action annotation to define the invoke operation to be invoked (input), and the action that is added to the response message (output). The example also uses the FaultAction annotation to specify the action that is added to a response message if a fault occurs:

```
@WebService(name = "Calculator")
public interface Calculator {
   ...
    @Action(
      input="http://calculator.com/inputAction",
      output="http://calculator.com/outputAction",
      fault = { @FaultAction(className=AddNumbersException.class,
                value="http://calculator.com/faultAction")
      }
   )
   public int add(int value1, int value2) throws AddNumbersException {
      return value1 + value2;
   }
}
```

If you use a tool to generate service artefacts from code, the WSDL tags that are generated from the preceding example are as follows:

```
<definitions targetNamespace="http://example.com/numbers" ...>
   ...
   <portType name="AddPortType">
      <operation name="Add">
         <input message="tns:AddInput" name="Parameters"
                        wsaw:Action="http://calculator.com/inputAction"/>
         <output message="tns:AddOutput" name="Result"
                          wsaw:Action="http://calculator.com/outputAction"/>
         <fault message="tns:AddNumbersException" name="AddNumbersException"
                         wsaw:Action="http://calculator.com/faultAction"/>
      </operation>
    <portType>
    ...
<definitions>
```

Web Services Addressing security considerations

It is essential that communications using Web Services Addressing (WS-Addressing) are adequately secured and that a sufficient level of trust is established between the communicating parties. You can achieve secure communications through the signing of WS-Addressing message-addressing properties and the encryption of endpoint references.

Perform these actions for both the supported addressing namespaces, http://www.w3.org/2005/08/addressing and http://schemas.xmlsoap.org/ws/2004/08/addressing, even if you intend to use only one of those namespaces.

Signing of WS-Addressing message-addressing properties

You can use an assembly tool to specify the message-addressing properties, and therefore the WS-Addressing message elements, that require signing, or that require signature verification on inbound requests. The receiver of the message might rely on the presence of this verifiable signature to determine that the outbound message originated from a trusted source. Similarly, the lack of a verifiable signature that is associated with the specified inbound message addressing properties causes the rejection of the message with a SOAP fault.

Encryption of endpoint references

You can encrypt endpoint references as part of the SOAP header or SOAP body. Alternatively, you can remove the need for encryption by not including sensitive information in the [address] or [reference parameters] properties of the endpoint reference.

Use of the synchronous message exchange pattern

This method applies to JAX-WS applications only.

If you do not secure the WS-Addressing information in the SOAP message using one or more of the previous methods, and you do not have WS-Security enabled, the ReplyTo and FaultTo elements of the SOAP message could be used to send messages to a third party, potentially taking part in a Denial of Service attack. To prevent such attacks, apply a WS-Addressing policy type and configure it to specify synchronous messaging only. You should also enable WS-Policy so that this requirement is communicated to clients.

Web Services Addressing: firewalls and intermediary nodes

Using the Web Services Addressing (WS-Addressing) support in this product, you can create endpoint references that can be distributed across firewalls and intermediary nodes.

Using the WS-Addressing support, you can automatically generate endpoint references that represent endpoints on the node on which the references are generated. These endpoint references contain appropriate address information, based on the URL configured for the endpoint and any valid proxy configuration for the server on which the endpoint resides. Messages targeted at the endpoint reference from the client are routed to the endpoint through the appropriate intermediary node or nodes, as described in the following topology scenarios.

If you use the IBM proprietary API to create the endpoint reference, the topology of your system can also affect the type of endpoint reference that the WS-Addressing programming model generates. For example, if you use the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method to create an endpoint reference in a cluster environment, the endpoint reference, by default, represents an endpoint that is workload-managed in the cluster in which the endpoint was created, in accordance with the appropriate topologies in the following sections. This behavior therefore provides a performance enhancement for the application.

Note: If the requesting application component runs under a transaction or in an HTTP session, affinity constraints might apply to the workload-management of endpoints.

- Use the “Direct connection” topology for non-clustered configurations.
- Use the “HTTP server, such as IBM HTTP Server” on page 679, topology when endpoint references refer to services that:
  - are deployed in a workload-managed cluster
  - do not access any stateful information that is localized to a specific server
- Use the “Proxy Server for IBM WebSphere Application Server” on page 679 topology, or the “HTTP server with a Proxy Server for IBM WebSphere Application Server” on page 680 topology, when endpoint references refer to services that:
  - are deployed in a workload-managed cluster
  - optionally, access stateful information that is localized to a specific server
  - optionally, can be failed over in a highly-available configuration

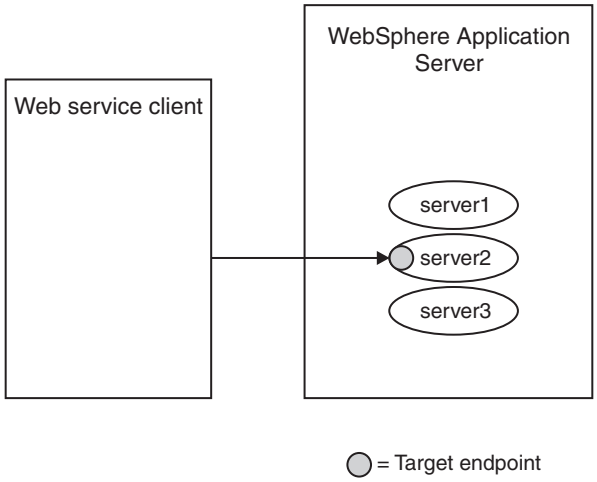
  The HTTP server with a Proxy Server for IBM WebSphere Application Server topology is useful when the HTTP server itself has no integrated capability for affinity-based routing to WS-Addressing endpoints.

For endpoint references that refer to services that do not access stateful information that is localized to a specific server, all the following topology scenarios are suitable.

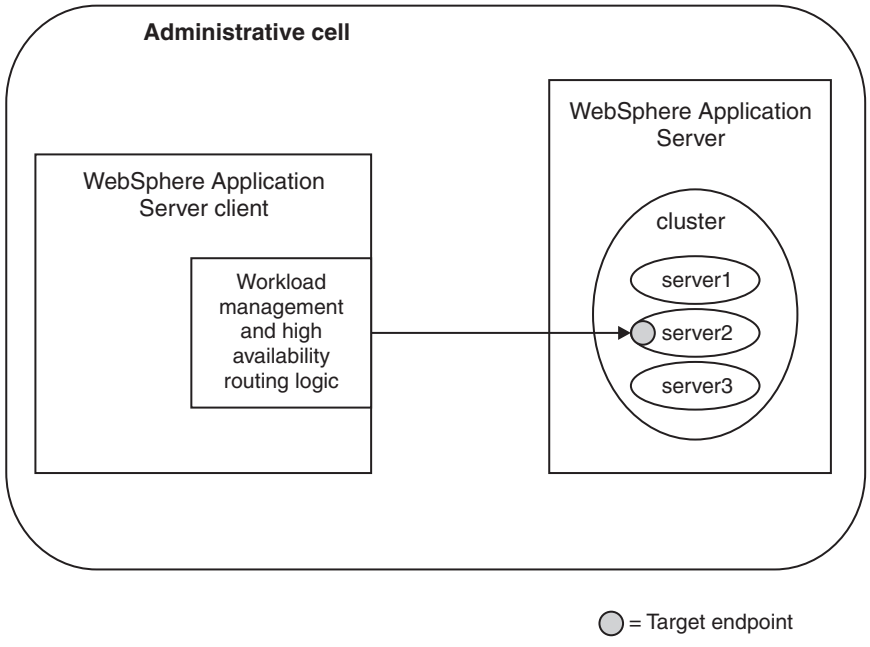
Direct connection

Use this topology for non-clustered configurations.

In this topology, there is no intermediary node. The client communicates directly with the server on which the target endpoint resides. In this topology, the WS-Addressing APIs automatically generate the appropriate endpoint reference address, based on the URL configured for the Web service module. This scenario is illustrated in the following diagram.



You can also use this topology when endpoint references created using the IBM proprietary API refer to services that are deployed in a workload-managed cluster. However, messages targeted at the endpoint reference are workload-managed only if the client targeting the endpoint reference is a WebSphere Application Server client, at Version 6.1 or later, that exists in the same administrative cell as the endpoint, as illustrated in the following diagram.

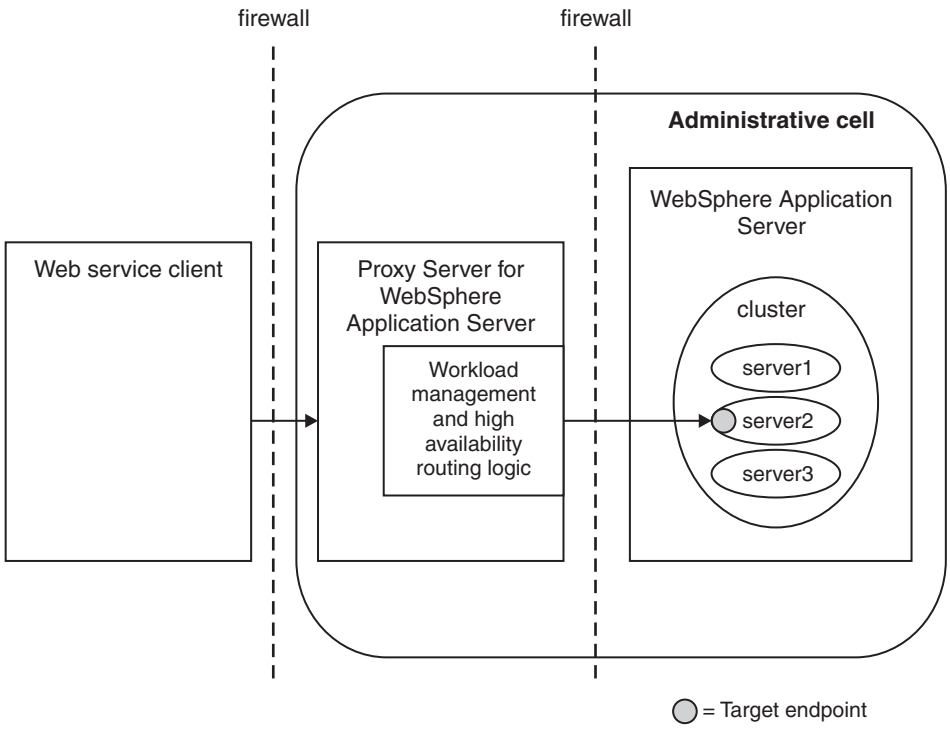


Endpoint references created using the standard JAX-WS API are not workload managed.

Proxy Server for IBM WebSphere Application Server

Use this topology when endpoint references refer to services that are deployed in a workload-managed cluster, optionally access stateful information that is localized to a specific server, and optionally can be failed over in a highly-available configuration.

In this topology, the WS-Addressing APIs automatically generate the appropriate endpoint reference address, based on the URL prefix of the Proxy Server for IBM WebSphere Application Server that is configured for the target Web service module. You must provide HTTP endpoint URL information, that is, configure the HTTP URL prefix for each deployment of each application. The client can exist outside the administrative cell that contains the proxy server and target server. The client communicates with the proxy server, which dynamically routes the client requests to the appropriate server in the cluster.

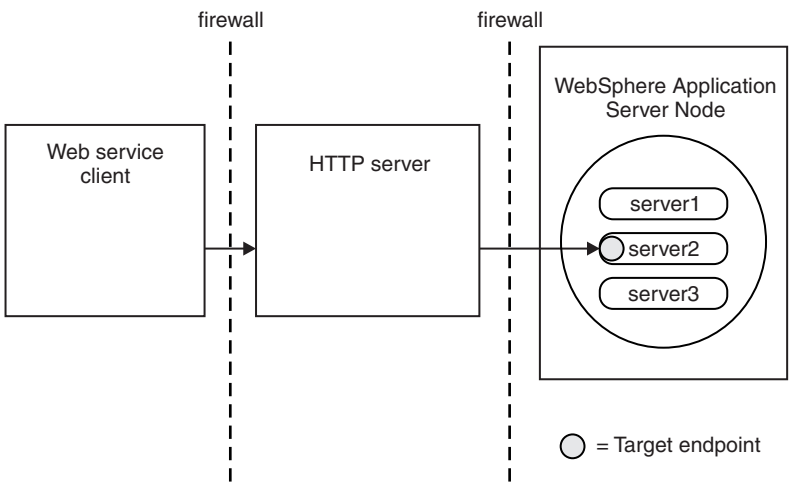


If the proxy that is addressed by the endpoint reference is a Proxy Server for IBM WebSphere Application Server, at Version 6.1 or later, that exists in the same administrative cell as the endpoint, messages targeted at a workload-managed endpoint reference are workload-managed, based on the cluster.

HTTP server, such as IBM HTTP Server

Use this topology when endpoint references refer to services that are deployed in a workload-managed cluster, and that do not access any stateful information that is localized to a specific server.

In this topology, the IBM WS-Addressing API automatically generates the appropriate endpoint reference address based on the URL prefix of the HTTP server that is configured for the target Web service module. You must provide HTTP endpoint URL information, that is, configure the HTTP URL prefix for each deployment of each application. The client communicates with the HTTP server, which then routes the client requests to a specific server based on the HTTP server configuration.

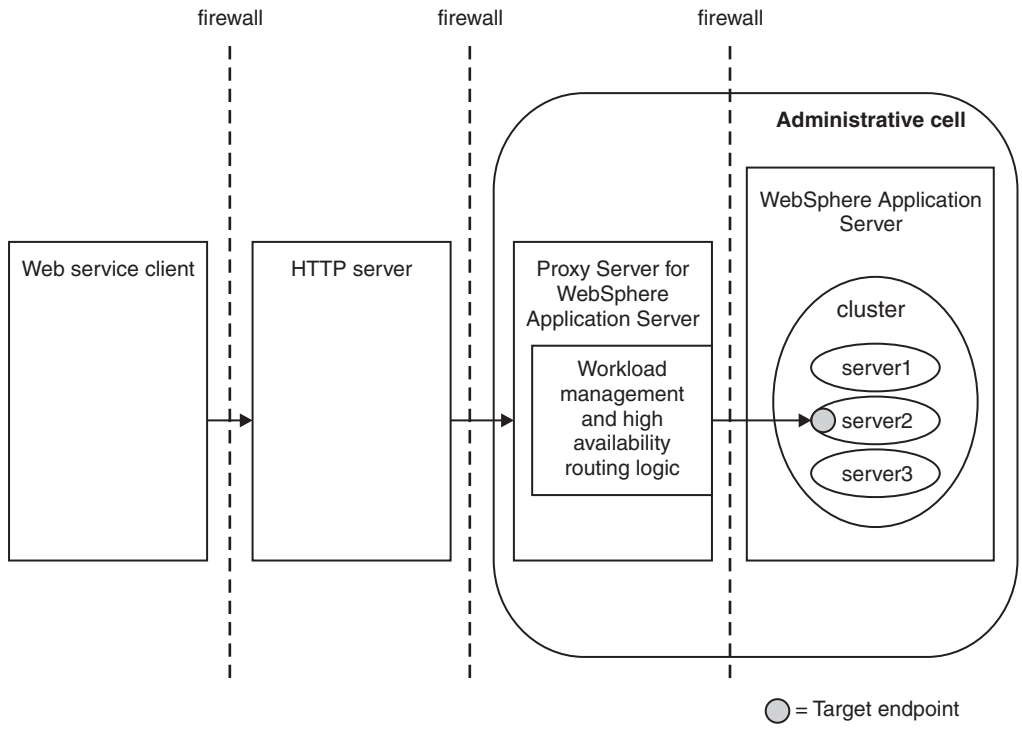


HTTP server with a Proxy Server for IBM WebSphere Application Server

Use this topology when endpoint references refer to services that are deployed in a workload-managed cluster, optionally access stateful information that is localized to a specific server, and optionally, can be failed over in a highly-available configuration. The topology is similar to the Proxy Server for IBM WebSphere Application Server topology, but supports the use of any HTTP server as the external reverse proxy.

In this topology, the WS-Addressing API automatically generates the appropriate endpoint reference address based on the URL prefix of the HTTP server that is configured for the target Web service module. You must provide HTTP endpoint URL information, that is, configure the HTTP URL prefix for each deployment of each application.

The client communicates with the HTTP server, which you configure, by routing requests from a plug-in to a proxy server, to forward the client requests to a Proxy Server for IBM WebSphere Application Server. The proxy then dynamically routes the requests to the appropriate server.



If the proxy that is addressed by the endpoint reference is Proxy Server for IBM WebSphere Application Server, at Version 6.1 or later, and exists in the same administrative cell as the endpoint, messages targeted at a workload-managed endpoint reference are workload-managed, based on the cluster.

Web Services Addressing and the service integration bus

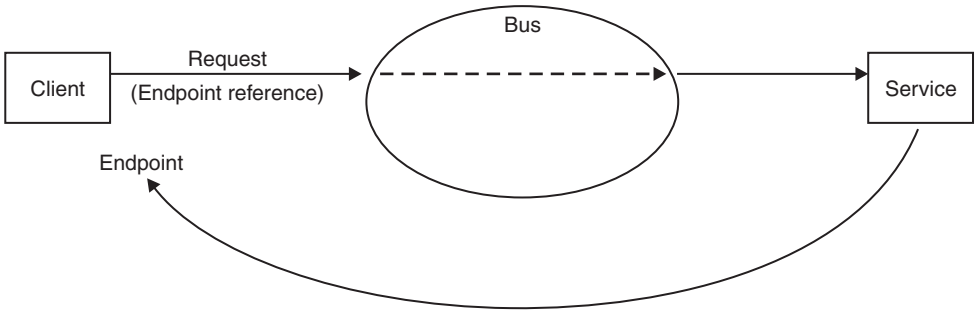
If you are using the Web Services Addressing (WS-Addressing) support, the presence of a service integration bus can affect the routing of messages. If you are also using a firewall, you might have to perform some additional configuration.

In the following scenarios, the client must conform to the WS-Addressing specification.

One-way messaging scenario

The path taken by one-way messages is as follows:

1. The client sends a request, containing an endpoint reference specifying the endpoint to which replies are sent, to the service integration bus. This request is a one way request, so the client does not wait for a response.
2. The bus passes the message intact to the Web service.
3. The Web service sends a response directly to the endpoint that is specified in the request.

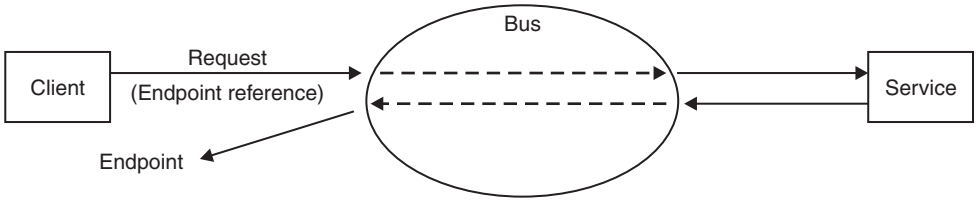


This scenario works if messages can flow directly from the Web service to the endpoint. If you have a configuration that does not support direct message flow, for example if you have a firewall, you must create handlers that can redirect the message as required.

Request-response messaging scenario

For request-response scenarios, the messages take the following path:

1. The client sends a request, containing an endpoint reference specifying the endpoint to which replies are sent, to the service integration bus.
2. The bus passes the message intact to the Web service, as a synchronous request. As the message leaves the bus, the endpoint reference is replaced with the anonymous URI listed in the WS-Addressing specification. This step ensures that the Web service does not send a response directly to the endpoint.
3. The Web service sends a response back to the bus, as part of the synchronous interaction.
4. As the message leaves the bus, the anonymous URI is replaced with the original endpoint reference, enabling the bus to pass the message to the endpoint.



Using the Web Services Addressing APIs: Creating an application that uses endpoint references

This product provides application programming interfaces for applications that need to create endpoint references and use those endpoint references to target Web service endpoints.

Before you begin

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Perform this task if you are a Web service developer who needs to create endpoint references within an application, and then use these references to target Web service resource instances. For example, a WSRF application developer.

1. Create a Web service that is referenced by an endpoint reference, and a client that accesses the Web service. For JAX-WS 2.1 applications, use the instructions in "Creating a JAX-WS Web service application that uses Web Services Addressing." For JAX-WS 2.0 or JAX-RPC applications, use the instructions in "Creating a JAX-RPC Web service application that uses Web Services Addressing" on page 688
2. Optional: You can extend the application that you created in the previous step so that it conforms to the Web Services Resource Framework (WSRF) specifications, by following the instructions in "Creating stateful Web services using the Web Services Resource Framework" on page 715.

Creating a JAX-WS Web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between Web services by defining a standard way to address Web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-WS Web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the Web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Perform this task if you are creating a JAX-WS Web service that uses the WS-Addressing specification. This task uses the JAX-WS 2.1 WS-Addressing APIs to create the required endpoint reference. Alternatively, you can create endpoint references using the IBM proprietary WS-Addressing API, and convert them into JAX-WS 2.1 API objects for use with the rest of the application.

1. Provide a Web service interface that returns an endpoint reference to the target service.

   The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the Web service created in the previous step. For the WS-Addressing portion of the implementation, perform the following steps:
   a. Include annotations to specify WS-Addressing behavior. See "Web Services Addressing annotations" on page 675 for more details.
   b. Optional: If your interface involves a Web service that fronts a resource instance, create or look up the resource instance.
   c. Optional: If you are using a resource instance, obtain the identifier of the resource. The resource identifier is application dependent and might be generated during the creation of the resource instance.

      Note: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
   d. Create an endpoint reference that references the Web service by following the instructions in "Creating endpoint references using the JAX-WS 2.1 Web Services Addressing API" on page 686. If you are using a resource instance, pass in the resource identifier as a parameter.
   e. Return the endpoint reference.
3. If your Web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not need to expose it on the Web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to perform the following actions:

a. Obtain the resource instance identifier from the message context.
   - If you are using the 2005/08 WS-Addressing namespace, use the REFERENCE_PARAMETERS property of the MessageContext class.
   - If you are using the 2004/08 WS-Addressing namespace, you must use the IBM WS-Addressing API, specifically the EndpointReferenceManager.getReferenceParameterFrom MessageContext(QName resource_id) method.

   Use the following method for the 2005/08 namespace:

```
...
List resourceIDList = (List)getContext().getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
...
```

   Use the following method for the 2004/08 namespace:

```
...

String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
...
```

b. Forward the message to the appropriate resource instance.

4. Optional: Configure a proxy client to communicate with the service.
   a. Use the wsimport or xjc tool to generate the artifacts required by the client.

      Note: If you want to use the 2004/08 WS-Addressing specification, specify the provided binding file, *app_server_root*/util/SubmissionEndpointReference.xjb, as the -b parameter of the tool. This parameter tells the tool to generate endpoint reference objects using the SubmissionEndpointReference class which is part of the IBM implementation of the standard JAX-WS 2.1 API. If you do not specify this bindings file, the resulting endpoint reference objects will not work with the standard JAX-WS 2.1 API.

   b. In the client code, create an instance of the service class.
   c. Obtain a proxy object from the service class. There are several ways to use the JAX-WS 2.1 API to obtain proxy objects. For example, there are several getPort methods on the Service class and one on the EndpointReference class. For more information, refer to the API documentation.
   d. Optional: Use the Addressing or SubmissionAddressing feature to enable WS-Addressing support. For example, create a proxy using a getPort method that accepts Web service features as a parameter. If you prefer, you can enable WS-Addressing support using another method, such as policy sets. For more information see “Enabling Web Services Addressing support for JAX-WS applications” on page 708.
   e. Use the proxy object to invoke the service method that returns the endpoint reference.

   The following sample code shows a client invoking a Web service to add two numbers together. The Web service issues a ticket (the resource identifier) to the client, and requires the client to use this ticket when invoking the Web service.

   The client creates two proxies. The first proxy obtains the ticket as an endpoint reference from the service. The second proxy uses the AddressingFeature class to enable WS-Addressing for the 2005/08 specification, and invokes the service to add the two numbers together.

```
...
CalculatorService service = new CalculatorService();
// Create the first proxy
Calculator port1 = service.getCalculatorServicePort();
// Obtain the ticket as an endpoint reference from the service
W3CEndpointReference epr = port1.getTicket();

// Create the second proxy, using an addressing feature to enable WS-Addressing
Calculator port2 = epr.getPort(Calculator.class, new AddressingFeature());
```

```
// Invoke the service to add the numbers
int answer = port2.add(value0, value1);
System.out.println("The answer is: " + answer);
...
```

Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the proxy object is configured to represent a different interface, a javax.xml.ws.WebServiceException exception is thrown on attempts to invoke the endpoint.

If you want to set message-addressing properties, such as a reply to endpoint, you must use the IBM proprietary WS-Addressing SPI and the BindingProvider class, as described in “Specifying and acquiring message-addressing properties using the IBM proprietary Web Services Addressing SPIs” on page 700.

5. Optional: Configure a Dispatch client to communicate with the service. You can configure a client in different ways; the following steps describe one example.
   a. Create an instance of the service.
   b. Add a port to the service object.
   c. Create an instance of the Dispatch class, passing in the endpoint reference.
   d. Create a Dispatch<T> object. Use the Service.createDispatch method with the following parameters:
      - The endpoint reference returned by the service, which represents the resource to forward messages to.
      - An array of Web service features. Include one or more WS-Addressing features to enable WS-Addressing. See “Enabling Web Services Addressing support for JAX-WS applications” on page 708 for more details.

      There are several variations of the Service.createDispatch method; see the API documentation for more details.
   e. Compose the client request message.
   f. Invoke the service endpoint with the Dispatch client.

   The following code shows an example fragment of a Dispatch client that enables 2004/08 WS-Addressing.

```
...
CalculatorService service = new CalculatorService();
Dispatch(<SOAPMessage> dispatch = service.createDispatch(
    endpointReference,
    SOAPMessage.class,
    Service.Mode.MESSAGE,
    new SubmissionAddressingFeature(true));
...
```

Results

The Web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see “Example: Creating a Web service that uses the JAX-WS 2.1 Web Services Addressing API to access a generic Web service resource instance” on page 694.

What to do next

- Refer to “Web Services Addressing security considerations” on page 676 for information about security with WS-Addressing.
- Deploy the application. If you used WS-Addressing annotations or features in the code, you do not have to take any additional steps to enable WS-Addressing support. For more information and for other scenarios that might require additional steps, for example enabling WS-Addressing support using policy sets, see “Enabling Web Services Addressing support for JAX-WS applications” on page 708.

Creating endpoint references using the JAX-WS 2.1 Web Services Addressing API:

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. This product provides interfaces for you to create endpoint references using the standard JAX-WS 2.1 API.

About this task

This task is a subtask of “Creating a JAX-WS Web service application that uses Web Services Addressing” on page 683.

Perform this task if you are writing an application that uses the standard JAX-WS 2.1 WS-Addressing API. Such applications require endpoint references to target Web service endpoints. The standard JAX-WS API is designed to create only simple endpoint references, and therefore has the following restrictions:

- You cannot create highly available or workload managed endpoint references.
- You cannot create endpoint references that represent stateful session beans.
- You cannot use classes created using the JAX-WS 2.1 API with the IBM proprietary WS-Addressing SPI.

You can overcome these restrictions by using the IBM proprietary WS-Addressing API to create the endpoint references and then converting them into standard JAX-WS 2.1 endpoint references that can be used by the rest of the application. Refer to “Creating endpoint references using the JAX-WS 2.1 Web Services Addressing API” for instructions.

Note: Endpoint references that are created using this API contain metadata that complies with the WS-Addressing 1.0 Metadata specification. This behavior is not a requirement of the JAX-WS 2.1 specification, so endpoint references created using vendor software might contain metadata that complies with a different specification. This difference could cause problems if you are interoperating with an application created using vendor software.

- If an endpoint needs to create an endpoint reference that represents itself, use the getEndpointReference method of the Web service context object, passing in an Element object representing the reference parameters to be associated with the endpoint reference (or a null object if you do not want to specify any reference parameters).

  By default, this method creates a W3CEndpointReference object. If you want to create a SubmissionEndpointReference object, representing an endpoint that conforms to the 2004/08 WS-Addressing specification, pass the endpoint reference type as a parameter. For example, the following code fragment uses the getEndpointReference method to return a W3CEndpointRerence object that has a ticket ID associated with it:

```
...
@WebService(name="Calculator",
            targetNamespace="http://calculator.org")

public class Calculator {
    @Resource
    WebServiceContext wsc;

    ...
    // Create the ticket id
    element = document.createElementNS(
                      "http://calculator.jaxws.axis2.apache.org", "TicketId");
    element.appendChild( document.createTextNode("123456789") );
    ...

    public W3CEndpointReference getEPR() {
        // Get the endpoint reference and associate the ticket id
        // with it as a reference parameter
        W3CEndpointReference epr = (W3CEndpointReference)wsc.getEndpointReference(element);
```

```
        return epr;
    }
...
```

The following line of code shows how to create a 2004/08 endpoint reference for the preceding sample:

```
SubmissionEndpointReference epr = (SubmissionEndpointReference)
        wsc.getEndpointReference(SubmissionEndpointReference.class, element);
```

- If an endpoint needs to create an endpoint reference that represents a different endpoint, use either the W3CEndpointReferenceBuilder class or the SubmissionEndpointReferenceBuilder class, depending on the namespace that you want to use.
  1. Create an instance of the appropriate builder class. Use the W3CEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2005/08 WS-Addressing specification. Use the SubmissionEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2004/08 WS-Addressing specification.
  2. Set the following property or properties of the builder instance according to the location of the endpoint.
     - If the endpoint is in another module in this application, set the serviceName and endpointName properties to appropriate values. You must set the serviceName property before you set the endpointName property, otherwise the application throws an error. The endpoint reference that is returned contains a suitable address for the endpoint, as determined by the implementation.

       Note: This behavior differs from the IBM WS-Addressing API, in that creating an endpoint reference using the com.ibm.websphere.wsaddressing.EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method is not restricted to endpoints in the same application.
     - If the endpoint is in another Java EE application, set the address property to point to the endpoint.
  3. Optional: Set other properties of the builder instance as required. For example, if the Web service is used to access a resource instance, use the referenceParameter property to associate the identifier of the resource with the endpoint reference. For more information on the properties that you can set, see the API documentation.
  4. Invoke the build method on the builder instance to obtain the endpoint reference.

  For example, the following code fragment uses the W3CEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2005/08 specification, and points to an endpoint that is in another module in this application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        W3CEndpointReferenceBuilder builder = new
                                W3CEndpointReferenceBuilder();

        // Modify builder properties
        builder.address(calculatorServiceURI);

        // Create the endpoint reference from the builder object
        W3CEndpointReference epr = builder.build();
        return epr;
    }
...
```

The following code fragment uses the SubmissionEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2004/08 specification, and points to an endpoint that is in another application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        SubmissionEndpointReferenceBuilder builder = new
                          SubmissionEndpointReferenceBuilder();

        // Modify builder properties
        builder.serviceName(calculatorService);
        builder.endpointName(calculatorPort);

        // Create the endpoint reference from the builder object
        SubmissionEndpointReference epr = builder.build();
        return epr;
    }
...
```

Results

You created an endpoint reference for use by your application.

What to do next

1. If required, convert the endpoint reference to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, using the createIBMEndpointReference method. For example, on a client you might want to set the FaultTo message addressing property for outbound messages. You cannot set this property using the JAX-WS 2.1 API, so you must convert the endpoint reference representing the FaultTo endpoint to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, before setting it as a property on the BindingProvider object.
2. Continue with “Creating a JAX-WS Web service application that uses Web Services Addressing” on page 683.

Creating a JAX-RPC Web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between Web services by defining a standard way to address Web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-RPC Web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the Web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Perform this task if you are creating a Web service that uses the WS-Addressing specification.

1. Provide a Web service interface, by creating or generating a Web Services Description Language (WSDL) document for the Web service, that returns an endpoint reference to the target service. The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.

2. Implement the Web service created in the previous step. For the WS-Addressing portion of the implementation, perform the following steps:
   a. Create an endpoint reference that references the Web service, by following the instructions in “Creating endpoint references using the IBM proprietary Web Services Addressing API” on page 690.
   b. Optional: If your interface involves a Web service that fronts a resource instance, create or look up the resource instance.
   c. Optional: If you are using a resource instance, obtain the identifier of the resource and associate it with the endpoint reference as a reference parameter, using the EndpointReference.setReferenceParameter(QName resource_id_name, String value) method. The resource identifier is application-dependent and might be generated during the creation of the resource instance.

      Note: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.

      The endpoint reference now targets the resource.
   d. Return the endpoint reference.
3. If your Web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not need to expose it on the Web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to perform the following actions:
   a. Obtain the resource instance identifier from the message context, using the EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id_name) method.
   b. Forward the message to the appropriate resource instance.
4. To configure a client to communicate with the service, use the endpoint reference that is produced by the service in the first step to send messages to the endpoint.
   a. Obtain a Stub object (by looking up the service in the Java Naming and Directory Interface (JNDI)), or create an empty Call object.
   b. Associate the endpoint reference with the proxy object. Use the setProperty(String property_name, Object value) method of the Stub or Call object, using the WS-Addressing constant WSADDRESSING_DESTINATION_EPR as the property name, and the endpoint reference as the value.

      This procedure automatically configures the Stub or Call object, to represent the Web service (or resource instance if your interface uses a Web service that fronts a resource instance) of the endpoint reference. For Call objects, this process includes the configuration of the interface and endpoint metadata (portType and port elements) that are associated with the endpoint reference.

      Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the Stub object is configured to represent a different interface, a javax.xml.rpc.JAXRPCException exception is thrown on attempts to invoke the endpoint.

   Invocations on the Stub or Call object are now targeted at the Web service or resource instance that is defined by the endpoint reference. When an invocation occurs, the product adds appropriate message addressing properties, such as a reference parameter contained within the endpoint reference that identifies a target resource, to the message header.

Results

The Web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see “Example: Creating a Web service that uses the IBM proprietary Web Services Addressing API to access a generic Web service resource instance” on page 692.

What to do next

- Refer to “Web Services Addressing security considerations” on page 676 for information about security with WS-Addressing.
- Deploy the application. For this scenario, you do not have to take any additional steps to enable the WS-Addressing support in WebSphere Application Server because you specified a WS-Addressing property on the client. For more information, and for other scenarios which might require additional steps, see “Enabling Web Services Addressing support for JAX-RPC applications” on page 712.

Creating endpoint references using the IBM proprietary Web Services Addressing API:

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. This product provides interfaces for you to create endpoint references using the IBM proprietary implementation of the WS-Addressing standard.

About this task

This task is a subtask of “Creating a JAX-RPC Web service application that uses Web Services Addressing” on page 688.

Perform this task if you are writing an application that uses the IBM proprietary WS-Addressing API. Such applications require endpoint references to target Web service endpoints. When you are writing the application, you might not know the address of the endpoint, because the address can change when the application is deployed. Using the IBM proprietary API, you can either specify the endpoint address, or allow the product to generate it for you at run time.

You can also specify the behavior of endpoint references in a cluster environment.

If you want to use endpoint reference objects from the standard JAX-WS 2.1 API instead of the IBM proprietary equivalents, but want the extra functionality provided by the IBM proprietary API, create the endpoint references using the methods described in this task and then convert them using the supplied converter classes. For example, you might want to perform such a conversion if you have a JAX-WS service application and you are creating endpoint references that represent stateful session beans, or that have an affinity to a particular server, or are workload managed. You cannot create such endpoint references using the JAX-WS 2.1 API.

- To create an endpoint reference with an address that you specify directly, use the WS-Addressing EndpointReferenceManager.createEndpointReference(URI address) method of the system programming interface (SPI) provided. This method is useful in test scenarios, where the address of the service does not change.
- To create an endpoint reference with an address that is automatically generated by the product, perform the following steps.
  1. If you created the Web service deployment descriptor file, webservices.xml, manually, ensure that the webservice-description-name in the file is the same as the local part of the Web Services Description Language (WSDL) service name. If you generated the webservices.xml file using the tools provided, the names match by default. This match is required for the generation of the correct URI for the endpoint reference.
  2. Create the endpoint reference using the method that is appropriate for the object that the reference will represent.

– If you are creating an endpoint reference to represent a stateful session bean that maintains in-memory state, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName, Remote statefulSessionBean) method of the application programming interface (API) provided. This method ensures that requests are targeted at the specific server that hosts the stateful session bean instance, and are not workload-managed.

  Also, if high availability for stateful session beans is specified, the endpoint reference remains valid even if the stateful session bean is failed over.

  Note: Affinity to stateful session beans using this method is not supported on the z/OS operating system. If a highly available stateful session bean fails over to another control region, or is passivated from one servant region and reactivated on another servant region in the same control region, the endpoint reference is no longer valid. To achieve affinity with a stateful session bean, run the application in a transaction to use transactional context affinity, or use HTTP session affinity.

– If you are creating an endpoint reference to represent any other object, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method of the API. The combination of service name and endpoint name must be unique in the server. If there is more than one Web service application with the same service name and endpoint name, the application server cannot generate a unique URI object for the endpoint. If you cannot ensure that the combination of service name and endpoint name is unique, use an SPI method to create the endpoint reference.

  Because the endpoint reference might be workload-managed at a later date, ensure that the endpoint does not contain any in-memory state. For JAX-WS applications, you can prevent the endpoint reference from being workload-managed by attaching a WS-Addressing policy set to the application and configuring the policy set binding to prevent the workload management of referenced endpoints in clusters.

  Note: You can use the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method to create an endpoint reference for any endpoint reference in the application server. This behavior differs from that of the JAX-WS 2.1 API, where creating an endpoint reference using the service name and endpoint name is restricted to endpoints within the same Java EE application.

When the application invokes either of the previous two methods, the product generates the address URI for the endpoint reference, and puts the service name and endpoint name into the metadata of the newly created endpoint reference.

Note: If you configured a virtual host for the server on which the endpoint is created, the URI of the endpoint reference refers to the virtual host of the HTTP server's configuration. You can override the HTTP endpoint URL information using the administrative console, see Provide HTTP endpoint URL information. The methods described previously will use the overridden value to generate the address URI for the endpoint reference.

Results

You created an endpoint reference for use by your application.

What to do next

1. If you want to convert the endpoint references from IBM proprietary WS-Addressing objects to standard JAX-WS 2.1 WS-Addressing objects, use one of the following methods of the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class, depending on the namespace of the endpoint reference:
   - createW3CEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2005/08 specification. This method creates a W3CEndpointReference object.

- createSubmissionEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2004/08 specification. This method creates a SubmissionEndpointReference object.

2. Continue with “Creating a JAX-RPC Web service application that uses Web Services Addressing” on page 688, or if you converted the endpoint reference to the standard JAX-WS 2.1 API, continue with “Creating a JAX-WS Web service application that uses Web Services Addressing” on page 683.

Example: Creating a Web service that uses the IBM proprietary Web Services Addressing API to access a generic Web service resource instance

Consider an IT organization that has a network of printers that it wants to manage using Web services. The organization might represent each printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service using the IBM proprietary Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server, and JAX-WS.

Providing a Web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                    type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
                  message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

Implementing the Web service interface

The createPrinter method shown in the following example creates an endpoint reference to the Printer service. The operation then obtains the identifier for the individual printer resource instance, and

associates it with the endpoint reference. Finally, the createPrinter method converts the EndpointReference object, which now represents the new printer, into a W3CEndpointReference object, and returns the converted endpoint reference.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
import com.ibm.websphere.wsaddressing.EndpointReference;
import com.ibm.websphere.wsaddressing.jaxws.EndpointReferenceConverter;
import com.ibm.websphere.wsaddressing.jaxws.W3CEndpointReference;

import javax.xml.namespace.QName;

public class MyClass {

    // Create the printer
    ...

    // Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_ID_PARAM_QNAME = new QName("example.printersample",
                                                          "IBM_WSRF_PRINTERID", "ws-rf-pr" );
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final String PRINTER_ENDPOINT_NAME = new String("PrinterService");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    throws Exception {
     // Create an EndpointReference that targets the appropriate WebService URI and port name.
     EndpointReference epr =  EndpointReferenceManager.createEndpointReference(PRINTER_SERVICE_QNAME,
                                                                    PRINTER_ENDPOINT_NAME);

     // Create or lookup the stateful resource and derive a resource
     // identifier string.
     String resource_identifier = "...";

     // Associate this resource identifier with the EndpointReference as
     // a reference parameter.
     // The choice of name is arbitrary, but should be unique
     // to the service.
     epr.setReferenceParameter(PRINTER_ID_PARAM_QNAME,resource_identifier);
     // The endpoint reference now targets the resource rather than the service.
     ...

     return EndpointReferenceConverter.createW3CEndpointReference(epr);
    }
}
```

Extending the target service to match incoming messages to Web service resource instances

Because of the Web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the Web service, and can be used by the Web service to match incoming messages to the appropriate printer.

When a Web service receives a message containing WS-Addressing message-addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer Web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The Web service implementation can forward messages based on the printer identity acquired from the getReferenceParameterFromMessageContext method to the appropriate printer instances.

Using endpoint references to send messages to an endpoint

The client creates a JAX-WS proxy for the printer, and converts the proxy into a BindingProvider object. The client then associates the EndpointReference object obtained previously with the request context of the BindingProvider object, as illustrated in the following example.

```
import javax.xml.ws.BindingProvider;
...

 javax.xml.ws.Service service= ...;
 Printer myPrinterProxy = service.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider bp = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference that represents the new printer to the request context
 // so that the BindingProvider object now represents a specific printer instance.
 myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

...
```

The BindingProvider object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the BindingProvider object, WebSphere Application Server adds appropriate message-addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

Alternatively, the client can use a JAX-RPC Stub or Call object, which the client configures to represent the new printer. The use of the Call object is illustrated in the following example.

```
import javax.xml.rpc.Call;
...
 :
 // Associate the endpoint reference that represents the new printer with the call.
 call.setProperty(
        "com.ibm.websphere.wsaddressing.WSAConstants.
                            WSADDRESSING_DESTINATION_EPR ", epr);
```

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct Web service operations to the endpoint that is represented by the endpoint reference, as shown.

Example: Creating a Web service that uses the JAX-WS 2.1 Web Services Addressing API to access a generic Web service resource instance

Consider an IT organization that has a network of printers that it wants to manage using Web services. The organization might represent each printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service using the JAX-WS 2.1 Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server.

Providing a Web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
                  message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

Implementing the Web service interface

The createPrinter method shown in the following example obtains the identifier for the individual printer resource instance. The operation then creates an endpoint reference to the Printer service, and associates the printer ID with the endpoint reference. Finally, the createPrinter method returns the endpoint reference.

```
import javax.xml.ws.wsaddressing.W3CEndpointReference;
import javax.xml.ws.wsaddressing.W3CEndpointReferenceBuilder;

import javax.xml.namespace.QName;

import org.w3c.dom.Document;
import org.w3c.dom.Element;

public class MyClass {

  // Create the printer
  ...

  //Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final QName PRINTER_ENDPOINT_NAME = new QName("example.printer.com", "PrinterService", "...");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    {
```

```
    Document document = ...;

    // Create or lookup the stateful resource and derive a resource
    // identifier string.
    String resource_identifier = "...";

    // Associate this resource identifier with the EndpointReference as
    // a reference parameter.
    // The choice of name is arbitrary, but should be unique
    // to the service.
    Element element = document.createElementNS("example.printersample",
            "IBM_WSRF_PRINTERID");
    element.appendChild( document.createTextNode(resource_identifier) );
    ...

    // Create an EndpointReference that targets the appropriate WebService URI and port name.
    // Alternatively, the getEndpointReference() method of the MessageContext could be used.
    W3CEndpointReferenceBuilder builder = new W3CEndpointReferenceBuilder();
    builder.serviceName(PRINTER_SERVICE_QNAME);
    builder.endpointName(PRINTER_ENDPOINT_NAME);
    builder.referenceParameter(element);

    // The endpoint reference now targets the resource rather than the service.
    return builder.build();
   }
}
```

Extending the target service to match incoming messages to Web service resource instances

Because of the Web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the Web service, and can be used by the Web service to match incoming messages to the appropriate printer.

When a Web service receives a message containing WS-Addressing message addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer Web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
@Resource
private WebServiceContext context;
...
List list = (List) context.getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
```

If your application uses the 2004/08 version of the WS-Addressing specification, use the IBM proprietary API to retrieve the message parameters, as illustrated in the following example.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The Web service implementation can forward messages based on the printer ID to the appropriate printer instances.

Using endpoint references to send messages to an endpoint

The client uses the endpoint reference returned from the service to create a JAX-WS proxy for the printer, as illustrated in the following example.

```
javax.xml.ws.Service jaxwsServiceObject= ...;
W3CEndpointReference epr = ...;
...
Printer myPrinterProxy = jaxwsServiceObject.getPort(epr, Printer.class, new AddressingFeature());
```

The proxy object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the service, WebSphere Application Server adds appropriate message addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct Web service operations to the endpoint that is represented by the endpoint reference, as shown.

Web Services Addressing APIs

This product provides interfaces at the application programming level to enable application developers, including developers of Web Services Resource Framework applications, to create references to, and to target, Web service resource instances. If you are a system programmer, you can use some these interfaces with the Web Services Addressing (WS-Addressing) system programming interfaces.

This product provides two separate sets of application programming interfaces (APIs):

- Standard Java API for XML-Based Web Services (JAX-WS) 2.1 APIs. Use these APIs with JAX-WS applications.
- IBM proprietary WS-Addressing APIs. Use these APIs with applications that use either JAX-WS or JAX-RPC. For JAX-WS applications, this API provides more functionality than the standard JAX-WS 2.1 API.

These APIs are described in more detail in the WS-Addressing API documentation.

JAX-WS 2.1 APIs

The standard JAX-WS 2.1 APIs in this product are contained in the javax.xml.ws.wsaddressing package. Refer to the JAX-WS 2.1 API documentation for more information about these APIs.

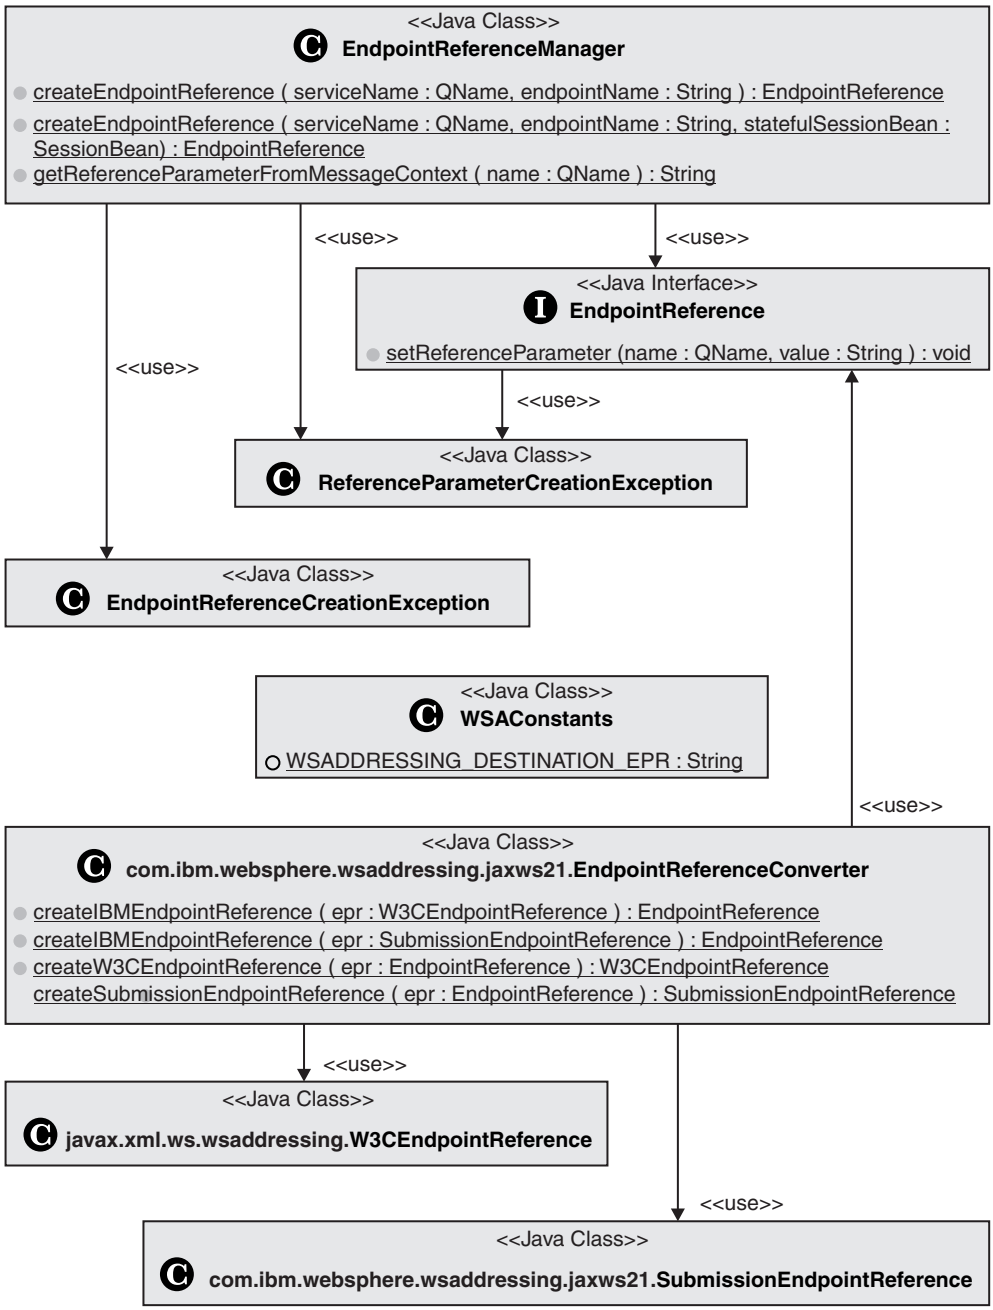
The implementation of the standard JAX-WS 2.1 APIs in this product also contains application programming interfaces, in the com.ibm.websphere.wsaddressing.jaxws21 package. These APIs are described in more detail in the generated API documentation in this information center. These APIs provide the following features:

- A class, com.ibm.websphere.wsaddressing.jaxws21.SubmissionEndpointReference, for representing endpoints that conform to the 2004/08 WS-Addressing specification.
- A class, com.ibm.websphere.wsaddressing.jaxws21.SubmissionEndpointReferenceBuilder, for creating a SubmissionEndpointReference instance to represent 2004/08 endpoints in Web services other than the one generating the endpoint reference.
- A class, com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceCoverter, for converting EndpointReference instances created using the IBM proprietary WS-Addressing API into either W3CEndpointReference or SubmissionEndpointReference instances, or back again.

- A class, com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressingFeature, for enabling WS-Addressing on clients, and an annotation, @SubmissionAddressing, for enabling WS-Addressing on servers.

IBM proprietary WS-Addressing APIs

These application programming interfaces are contained in the com.ibm.websphere.wsaddressing package and are summarized in the following diagram. The diagram also shows the following classes from the JAX-WS 2.1 API: com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter, javax.xml.ws.wsaddressing.W3CEndpointReference and com.ibm.websphere.wsaddressing.jaxws21.SubmissionEndpointReference.



These interfaces provide the following features:

- A mechanism for creating a com.ibm.websphere.wsaddressing.EndpointReference instance to represent a WS-Addressing endpoint reference using the com.ibm.websphere.wsaddressing.EndpointReferenceManager.createEndpointReference interface.
- A deprecated class, com.ibm.websphere.wsaddressing.EndpointReferenceCoverter, for converting EndpointReference instances into deprecated classes com.ibm.websphere.wsaddressing.W3CEndpointReference or com.ibm.websphere.wsaddressing.SubmissionEndpointReferences, for use in JAX-WS applications.

  Note: These classes are deprecated in favour of the JAX-WS 2.1 classes of the same name (EndpointReferenceConverter, SubmissionEndpointReference, and W3CEndpointReference) contained in the com.ibm.websphere.wsaddressing.jaxws21 and javax.xml.ws.wsaddressing.jaxws21 packages, as shown on the diagram.
- A method, com.ibm.websphere.wsaddressing.EndpointReference.setReferenceParameter, to enable you to associate reference parameters with an EndpointReference instance.
- An interface to enable a client to configure its BindingProvider request context, or Stub or Call object, based on an EndpointReference instance. All invocations on the BindingProvider, Stub or Call object are subsequently targeted at the endpoint that is represented by the EndpointReference instance. To achieve this behavior, set the com.ibm.websphere.wsaddressing.WSAConstants.WSADDRESSING_DESTINATION_EPR property on the BindingProvider request context, or Stub or Call object, to the appropriate EndpointReference instance.
- A mechanism for acquiring individual reference parameters that are associated with the incoming message context, to correlate the message to a specific resource instance through the com.ibm.websphere.EndpointReferenceManager.getReferenceParameterFromMessageContext interface.

Using the IBM proprietary Web Services Addressing SPIs: Performing more advanced Web Service Addressing tasks

This product provides proprietary system programming interfaces for more advanced Web Services Addressing (WS-Addressing) tasks, which involve the WS-Addressing message-addressing properties that are passed in the SOAP header of a Web service message. You can also use the SPIs to choose a WS-Addressing specification level other than the default used by the product.

Before you begin

You cannot use the standard JAX-WS 2.1 API classes with these proprietary SPIs. However, you can convert endpoint references created using the standard JAX-WS 2.1 API classes to instances of the com.ibm.websphere.wsaddressing.EndpointReference class, using the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class. You can then use these converted endpoint references with the SPIs.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Perform this task to specify or acquire WS-Addressing message-addressing properties, or if you have an application that needs to interoperate with a client or endpoint that is not using the default WS-Addressing specification supported by this product.

- To manipulate message-addressing properties, follow the instructions in “Specifying and acquiring message-addressing properties using the IBM proprietary Web Services Addressing SPIs” on page 700
- To interoperate with the pre-W3C specification of WS-Addressing, with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing, refer to “Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server” on page 701.

Specifying and acquiring message-addressing properties using the IBM proprietary Web Services Addressing SPIs

Using the proprietary Web Services Addressing (WS-Addressing) system programming interfaces (SPIs), you can add WS-Addressing message addressing properties (MAPs) to the SOAP headers of an outbound client message, through properties on the JAX-WS BindingProvider request context, or the JAX-RPC Stub or Call object. When the target endpoint receives the message, the SPI enables the endpoint to acquire the MAPs through properties on the message context.

About this task

There are no equivalent SPIs in the JAX-WS 2.1 standard. If you want to set message-addressing properties in a client that uses JAX-WS 2.1 endpoint references, you must convert the endpoint references to the IBM proprietary classes, before using them with these SPIs.

Perform this task if you are a Web service developer using the WS-Addressing support, or a system programmer using the IBM proprietary WS-Addressing SPIs to specify message addressing properties, such as fault or reply endpoint references, on Web services messages.

The properties that you can set or retrieve are described, with the Java type of property instances, in “IBM proprietary Web Services Addressing SPIs” on page 702. Most properties are of type com.ibm.websphere.wsaddressing.EndpointReference, for example destination, reply, or fault endpoint references. The relationship property is a java.util.Set object that contains instances of the com.ibm.wsspi.wsaddressing.Relationship class. Use relationships when you want to specify an association between messages; for example, in a response message you might want to specify the ID of the message to which you are replying. The action property is an AttributedURI object that identifies a specific method or operation within the target endpoint.

Note: The destination endpoint reference and action properties are required for the message to be WS-Addressing compliant.

1. On the client, obtain the endpoint reference from the service and associate it with your BindingProvider object’s request context, or your Stub or Call object, as described in “Creating a JAX-RPC Web service application that uses Web Services Addressing” on page 688.
2. Create instances of the required properties. For example, if you want to specify an endpoint reference for the target service to send replies to, create an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, to use as the WSADDRESSING_REPLYTO_EPR property.
3. Set the required properties by associating them with the BindingProvider object’s request context, or the Stub or Call object. If you are using a Stub or Call object, use the setProperty(String property_name, Object value) method. Note that unlike the endpoint reference required for the first step, these endpoint references do not need to be converted to another type, because they are passed in the header of the SOAP message rather than the body. The following example sets a destination endpoint reference and a reply endpoint reference on a BindingProvider object’s request context:

```
import javax.xml.ws.BindingProvider;
...
 javax.xml.ws.Service jaxwsServiceObject=...;
 Printer myPrinterProxy = jaxwsServiceObject.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider myBindingProvider = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference for the Web service. This property is required for the message
 // to be WS-Addressing compliant.
```

```
myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

// Associate the endpoint reference that represents the reply to the request context
myMap.put(WSADDRESSING_REPLYTO_EPR, replyToEpr);
```

When an invocation occurs on the BindingProvider, Stub, or Call object, the product adds the appropriate MAPs to the message header.

4. On the server, retrieve the MAPs from the inbound message through the javax.xml.ws.WebServiceContext or javax.xml.rpc.handler.MessageContext object that is currently on the thread. When WebSphere Application Server receives the message, it puts the MAP information into the message context on the thread, making it available to the service. You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 standard. The following example retrieves the reply endpoint reference using the Web service context:

```
import javax.xml.ws.handler.MessageContext;
import javax.xml.ws.WebServiceContext;
...

  // Obtain the message context from the WebService context
  private WebServiceContext wsContext;
  MessageContext context = wsContext.getMessageContext();

  // Retrieve the reply endpoint reference
  replyToEpr = context.getProperty(WSADDRESSING_INBOUND_REPLYTO_EPR);
```

Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server

A target Web service endpoint might not support the same Web Services Addressing (WS-Addressing) namespace as this product. In most cases, you do not need to perform any extra actions to interoperate with such endpoints, however some scenarios require additional steps in the implementation of your Web service.

About this task

WebSphere Application Server supports the default WS-Addressing 2005/08 namespace http://www.w3.org/2005/08/addressing. Perform this task when you want to interoperate with endpoints that support other namespaces. This task specifically describes interoperation with endpoints that are hosted on a node that supports only the 2004/08 namespace: http://schemas.xmlsoap.org/ws/2004/08/addressing.

If you are using the standard JAX-WS 2.1 API, ensure that you use the appropriate feature, annotation or endpoint reference class for the 2004/08 namespace.

If you are sending to or receiving messages from an endpoint that supports only the 2004/08 namespace, you do not have to perform any additional steps for interoperability. This product recognizes and understands incoming WS-Addressing messages that conform to the 2004/08 specification, and outbound messages automatically adhere to the namespace of their destination endpoint reference. If you are sending a request, all WS-Addressing elements, such as [reply endpoint] or [fault endpoint] elements, must use the same namespace as the message. Any discrepancy results in a JAX-WS or JAX-RPC configuration error.

If you are interacting in a different way with an endpoint that supports only the 2004/08 namespace, such as exporting endpoint references in the message header or body, and you are not using the JAX-WS 2.1 standard API, you must perform additional steps as detailed below.

- If you are generating a Web service for use by a client that supports only the 2004/08 specification, update the WS-Addressing namespace in the Web Services Description Language (WSDL) document for your Web service, by changing `http://www.w3.org/2006/05/addressing/wsdl` to `http://schemas.xmlsoap.org/ws/2004/08/addressing`.

Note: Only the WS-Addressing WSDL Action extensibility element is recognized by pre-W3C WS-Addressing clients.

- If you are creating endpoint references at run time for export to an endpoint that supports the 2004/08 namespace only, perform the following steps:
  1. Create the endpoint reference to export.
  2. Associate the appropriate namespace with the endpoint reference, using the setNamespace method. The following example illustrates the association of the 2004/08 namespace with an endpoint reference:

```
import com.ibm.wsspi.wsaddressing.EndpointReference;
import com.ibm.wsspi.wsaddressing.NamespaceNotSupportedException;
import com.ibm.wsspi.wsaddressing.WSAConstants;

:

EndpointReference epr = ...

try
{
    epr.setNamespace(WSAConstants.WSADDRESSING_NAMESPACE_2004_08);
} catch (NamespaceNotSupportedException e)
{
    // Error handling code here
}
```

  When you pass the endpoint reference to the target endpoint, in either the SOAP body or the SOAP header of a message, the endpoint reference is appropriately serialized into SOAP elements according to its namespace.
- To establish the namespace of an inbound request, use the IBM proprietary WS-Addressing system programming interface (SPI) to retrieve the WSADDRESSING_INBOUND_NAMESPACE property from the inbound message context. This property specifies the Core WS-Addressing specification namespace of the incoming message.

  Note: This procedure uses the IBM proprietary WS-Addressing API. There is no equivalent procedure in the JAX-WS 2.1 API.

  You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 specification. The following code example shows how you can establish the namespace of an incoming message on the receiving endpoint:

```
import com.ibm.wsspi.wsaddressing.WSAConstants;
import javax.xml.rpc.handler.MessageContext;

:
  // If the endpoint is implemented as an enterprise bean, you can use its session context
  // to obtain the message context
  private SessionContext sessionContext;
  MessageContext context = sessionContext.getMessageContext();

  try
  {
    String namespace = (String)msgContext.getProperty(WSAConstants.WSADDRESSING_INBOUND_NAMESPACE);
  } catch (IllegalArgumentException e)
  {
    // Error handling code here
  }
```

IBM proprietary Web Services Addressing SPIs

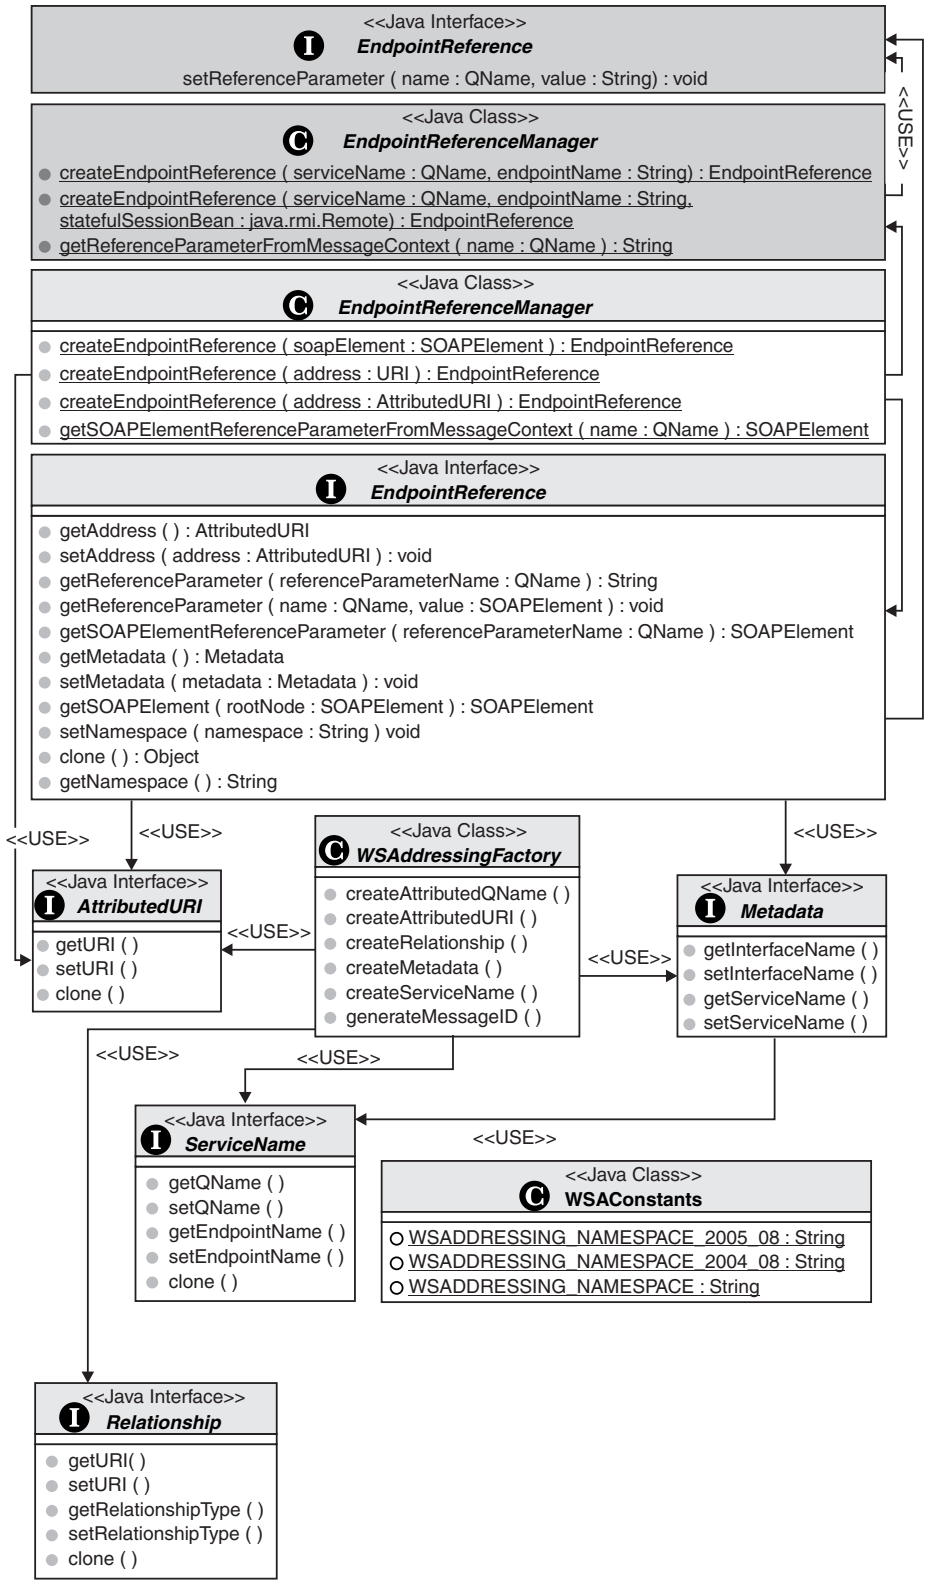
The IBM proprietary Web Services Addressing (WS-Addressing) system programming interfaces (SPIs) extend the IBM proprietary WS-Addressing application programming interfaces (APIs) to enable you to create and reason about the contents of endpoint references and other WS-Addressing artifacts, and to set or retrieve WS-Addressing message-addressing properties (MAPs) on or from Web service messages.

You cannot use the standard JAX-WS 2.1 API classes with these proprietary SPIs. However, you can convert endpoint references created using the standard JAX-WS 2.1 API classes to instances of the proprietary com.ibm.websphere.wsaddressing.EndpointReference class, using the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class. You can then use these converted endpoint references with the proprietary SPIs.

The programming interfaces in this topic are described in more detail in the IBM WS-Addressing SPI documentation.

Creating, refining, and reasoning about the contents of endpoint references

The proprietary SPIs for creating, refining, and reasoning about the contents of endpoint references are contained in the com.ibm.wsspi.wsaddressing package and are summarized in the following illustration (the first two interfaces are proprietary API interfaces that are extended by the SPIs):



The SPI extends the proprietary WS-Addressing com.ibm.websphere.wsaddressing.EndpointReference API to provide a number of additional methods through the com.ibm.wsspi.wsaddressing.EndpointReference interface. You can cast instances of com.ibm.websphere.wsaddressing.EndpointReference to com.ibm.wsspi.wsaddressing.EndpointReference to access this additional functionality.

Similarly, the SPI com.ibm.wsspi.wsaddressing.EndpointReferenceManager extends the functionality that is provided in the com.ibm.websphere.wsaddressing.EndpointReferenceManager API.

You can perform the following actions using the additional methods that are provided by the EndpointReference and EndpointReferenceManager SPIs:

Create endpoint references

Create EndpointReference objects by specifying the URI of the endpoint that the EndpointReference object is to represent, using the createEndpointReference(URI) operation, or the EndpointReferenceManager.createEndpointReference(AttributedURI) operation. These methods differ from the createEndpointReference method that is provided at the API level, in that they do not automatically generate the URI for the EndpointReference instance. You might use these methods when you know that the URI of the endpoint is stable, for example in a test environment with no deployment considerations.

Map between XML and Java representations of an endpoint reference

You can serialize instances of the EndpointReference interface to their corresponding SOAP element instances using the EndpointReference.getSOAPElement operation. Conversely, you can deserialize SOAP elements of type EndpointReferenceType into their corresponding EndpointReference Java representation, by using the EndpointReference.createEndpointReference(SOAPElement) operation. You might find these serialization and deserialization interfaces useful if you are creating custom binders for types that contain EndpointReference instances.

Use more complex reference parameter types

The proprietary interfaces that are provided at the API level are restricted to reference parameters of type xsd:string to allow for a simpler programming model. The SPIs extend this support to allow reference parameters of type <xsd:any>. The EndpointReference interface provides mechanisms for getting and setting reference parameters as SOAP elements. Additionally, the EndpointReferenceManager class provides the getSOAPElementReferenceParameterFromMessageContext operation, which enables receiving endpoints to acquire reference parameters that are not of type String from the incoming message.

Note: When invoking a service with an EndpointReference object that contains a reference parameter, you must create the reference parameter using a complete QName object, with all parts present: namespace, localpart, and prefix. If the QName object is not complete, service invocations fail.

Set and reason about endpoint reference contents

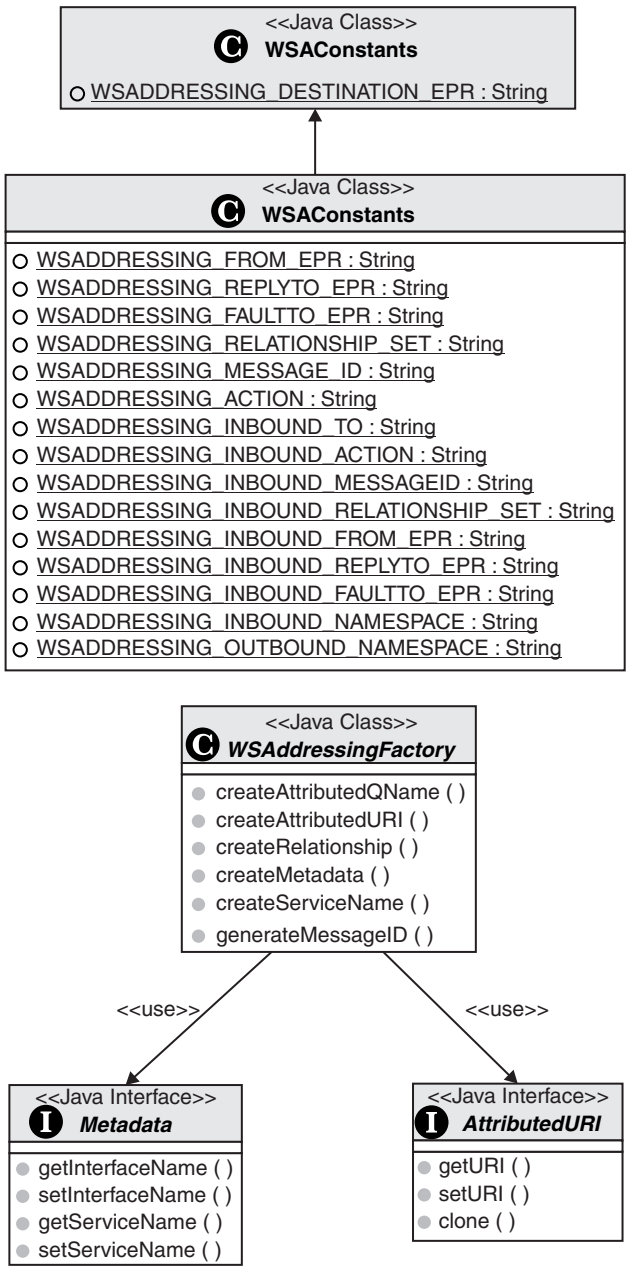
The EndpointReference interface provides operations for you to set and reason about the contents of an EndpointReference instance, such as its WS-Addressing address and metadata properties. Additional interfaces are provided to represent the artifacts making up an endpoint reference: Metadata, AttributedURI, and ServiceName. You create instances of these interfaces using operations that are provided by the proprietary WSAddressingFactory class.

Acquire and change the supported namespace

The WS-Addressing support in this product supports multiple namespaces. The setNamespace and getNamespace operations that are provided on the proprietary EndpointReference interface enable you to change and acquire the namespace that is associated with a particular EndpointReference object. Serialization to SOAP elements is in accordance with the namespace of the EndpointReference object. By default, the namespace of the destination endpoint reference (the endpoint reference set as the com.ibm.websphere.wsaddressing.WSAConstants.WSADDRESSING_DESTINATION_EPR property on the JAX-WS BindingProvider object's request context or the JAX-RPC Stub or Call object), defines the namespace of the message-addressing properties of the message.

Setting and Retrieving WS-Addressing message-addressing properties

The IBM proprietary WS-Addressing SPI provides a number of constants that identify JAX-WS or JAX-RPC properties that you can use to set WS-Addressing MAPs on outbound messages, and message context properties that you can use to retrieve MAPs on inbound messages. These constants are shown in the following diagram in the com.wsspi.wsaddresssing.WSAConstants class. The diagram also shows the interfaces that are required for generating instances of the appropriate property value types AttributedURI and Relationship. The first WSAConstants interface is a proprietary API interface.



Setting WS-Addressing message-addressing properties on outbound messages

You can add WS-Addressing message information headers to outgoing messages by setting the appropriate properties on the JAX-WS BindingProvider object's request context, or the JAX-RPC Stub or

Call object, prior to invoking a message with the BindingProvider, Stub, or Call object. The following table summarizes the relevant properties and their types.

Table 18. Outbound properties that you can set on the BindingProvider object's request context (or the Stub or Call object), their Java types and equivalent abstract WS-Addressing MAP name or names.

Property name (of type String)	**Java type of property value**	**Abstract WS-Addressing MAP name or names**	**Default value**
WSADDRESSING_ DESTINATION_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[destination] URI [reference parameters]* (any)	Not set Note that this property comes from the API.
WSADDRESSING_ FROM_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[source endpoint]	Not set
WSADDRESSING_ REPLYTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[reply endpoint]	Either 'none', if the message is a one-way message with no reply, or not set. For two-way asynchronous messages in JAX-WS applications, this property is generated automatically. If, in this situation, you attempt to set this property, a javax.xml.ws.WebServiceException exception is thrown. This exception is also thrown for two-way synchronous messages that do not use the anonymous URI.
WSADDRESSING_ FAULTTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[fault endpoint]	Not set If you attempt to set this property for two-way asynchronous messages in JAX-WS applications, a javax.xml.ws.WebServiceException exception is thrown. This exception is also thrown for two-way synchronous messages that do not use the anonymous URI.
WSADDRESSING_ RELATIONSHIP_SET	java.util.Set containing instances of com.ibm.wsspi.wsaddressing. Relationship	[relationship]	Not set
WSADDRESSING_ MESSAGE_ID	com.ibm.wsspi.wsaddressing. AttributedURI	[message id]	Generated and set to a unique value
WSADDRESSING_ ACTION	com.ibm.wsspi.wsaddressing. AttributedURI	[action]	Generated and set, according to the WS-Addressing specification

Table 18. Outbound properties that you can set on the BindingProvider object's request context (or the Stub or Call object), their Java types and equivalent abstract WS-Addressing MAP name or names. (continued)

Property name (of type String)	Java type of property value	Abstract WS-Addressing MAP name or names	Default value
WSADDRESSING_ OUTBOUND_ NAMESPACE	String	none	The WS-Addressing namespace of the WSADDRESSING_ DESTINATION_EPR property, if specified, otherwise the default namespace

Retrieving WS-Addressing message-addressing properties from inbound messages

WS-Addressing message information headers that correspond to the last inbound message are available from the inbound properties that are defined in the WSAConstants class. The following table summarizes the available inbound properties. You acquire reference parameters from the message context using the proprietary EndpointReferenceManager.getReferenceParameter interface.

Table 19. Inbound properties that you can acquire from the message context, their Java types and equivalent abstract WS-Addressing MAP name.

Message context property name (of type String)	Java type of property value	Abstract WS-Addressing MAP name
WSADDRESSING_INBOUND_TO	com.ibm.wsspi.wsaddressing. AttributedURI	[destination]
No specific property. Use the EndpointReferenceManager. getReferenceParameter(QName name) method to obtain the associated MAP.	Any	[reference parameters]*
WSADDRESSING_INBOUND_FROM_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[source endpoint]
WSADDRESSING_INBOUND_REPLYTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[reply endpoint]
WSADDRESSING_INBOUND_FAULTTO_EPR	com.ibm.websphere.wsaddressing. EndpointReference	[fault endpoint]
WSADDRESSING_INBOUND_RELATIONSHIP	java.util.Set containing instances of com.ibm.wsspi.wsaddressing. Relationship	[relationship]
WSADDRESSING_INBOUND_MESSAGE_ID	com.ibm.wsspi.wsaddressing. AttributedURI	[message id]
WSADDRESSING_INBOUND_ACTION	com.ibm.wsspi.wsaddressing. AttributedURI	[action]
WSADDRESSING_INBOUND_NAMESPACE	String	The WS-Addressing namespace of the incoming message

Enabling Web Services Addressing support for JAX-WS applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address Web services and provide addressing information in messages. For JAX-WS applications, you can enable WS-Addressing support in several different ways, such as configuring policy sets or using annotations in code.

About this task

Note: This release introduces a new way to enable WS-Addressing. You can now use JAX-WS 2.1 annotations and feature classes to enable WS-Addressing from either the server or the client. You also have more control over the behavior of WS-Addressing when using policy sets; you can specify whether WS-Addressing is enabled and whether to use synchronous, asynchronous, or both messaging patterns.

Perform this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party. This task also describes how to disable the WS-Addressing support, which can improve performance for those applications that do not use WS-Addressing or any protocol that depends on the WS-Addressing support.

For service providers, WS-Addressing support is enabled by default, so you do not have to perform any actions to enable support. However, you can use the enabling mechanisms to modify other WS-Addressing behavior for the service, such as whether WS-Addressing information is required, and what is included in the generated WSDL document.

- Modify the behavior of the WS-Addressing support after the application is deployed by attaching a policy set to the application. Within the policy set, you can configure the WS-Addressing policy type to specify whether WS-Addressing information is required in incoming messages, and whether to use synchronous or asynchronous messaging. You can communicate the WS-Addressing policy configuration to other servers and clients that support WS-Policy, by enabling policy sharing on the server, and by applying the provider policy on the client. Settings set using this method override those set using other methods.
- Modify the behavior of the WS-Addressing support during development of the service by using the Addressing or SubmissionAddressing annotations in the service code. Within each annotation you can specify whether the server requires WS-Addressing information in incoming messages. The presence of the Addressing annotation in the code also adds a UsingAddressing element to any WSDL document that is generated for the service. If you provide your own WSDL document instead of relying on the JAX-WS runtime environment to generate one, you must include the UsingAddressing element yourself, if required.

For service clients, WS-Addressing support is disabled by default. Use one of the following methods to enable WS-Addressing support:

- Specify the UsingAddressing element in the WSDL document for the service. If the service uses the Addressing annotation and the WSDL document is generated from the code, the UsingAddressing element will already exist.
- Use addressing features in the client code. Settings set using this method override those set in the WSDL document for the service.
- Set the com.ibm.websphere.webservices.use.async.mep property on the client request context.
- You can also use any option available to JAX-RPC applications, such as manually adding the UsingAddressing element to the WSDL document, or using the IBM proprietary WS-Addressing SPI to add message-addressing properties to the message request context.

The behavior of the WS-Addressing support is summarized in the following paragraphs.

WebSphere Application Server clients add WS-Addressing headers to messages in the following situations:

- A policy set containing a WS-Addressing policy is attached to a client artifact, and one or both of the following statements are true:
  - The WS-Addressing policy for the client specifies that WS-Addressing is mandatory.
  - The client artifact has provider and client policies applied, policy sharing is enabled on the server, and the policy configuration for the server requires WS-Addressing.

- The client application code uses a WS-Addressing feature class to specify that WS-Addressing is enabled.
- The WSDL document for the service contains the UsingAddressing element, for example if the document was generated from service application code that contains the Addressing annotation. The value of the `required` parameter is irrelevant.

  Note: This statement does not apply to Dispatch clients, because these clients do not use the WSDL document.
- Message-addressing properties are set on the client.
- The com.ibm.websphere.webservices.use.async.mep property is set on the client request context.

If a client does not include WS-Addressing headers in messages, the server generates a fault message in the following situations:

- A policy set containing a WS-Addressing policy is attached to a server artifact, and the WS-Addressing policy specifies that WS-Addressing is mandatory.
- The server application code uses the Addressing or SubmissionAddressing annotation to specify that WS-Addressing is required.
- To modify the behavior of the WS-Addressing support using policy sets, perform the following steps:
  1. Ensure that you have a policy set that contains the WS-Adressing policy type. If you need to create a new policy set, or add the WS-Addressing policy to an existing policy set, refer to Managing policy sets using the administrative console for instructions.
  2. Configure the WS-Addressing policy type according to the instructions in Configuring the WS-Addressing policy. You can specify whether WS-Addressing is mandatory, and whether to use a synchronous or asynchronous message exchange pattern. The default settings are that WS-Addressing is not mandatory, and both synchronous and asynchronous messaging patterns are used.
  3. Attach the policy set to a Web service provider or client artifact, according to the instructions in Attaching a policy set to a service artifact.
  4. Optional: If you want to communicate the WS-Addressing policy settings to other servers and clients, configure policy sharing as described in Configuring a service provider to share its policy configuration or Configuring the client policy using a service provider policy. If policy sharing is enabled and the server and client cannot agree a policy, normal WS-Policy behavior applies (a policy error is produced).
- To modify the behavior of the WS-Addressing support programmatically in the service application, use one of the following addressing annotations with up to two optional parameters, which specify whether WS-Addressing is enabled and whether WS-Addressing is required. The default settings are that WS-Addressing is enabled but not required.
  - @Addressing: use this annotation if you want to use the 2005/08 WS-Addressing specification
  - @SubmissionAddressing: - use this annotation if you want to use the 2004/08 WS-Addressing specification.

  In the following example, the Addressing annotation is used with no parameters, so the default settings apply.

```
import javax.xml.ws.soap.Addressing;

@Addressing
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

  In the following example, the SubmissionAddressing annotation is used with parameters that specify that WS-Addressing is enabled and required.

```
import javax.xml.ws.soap.Addressing;

@SubmissionAddressing(enabled="true", required="true")
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

The server processes any WS-Addressing headers that conform to this relevant specification in inbound SOAP messages. If you specify that WS-Addressing is required, and an inbound SOAP message does not include any WS-Addressing headers, or includes WS-Addressing headers that do not conform to the specification indicated by the annotation, the server returns a fault message. For example, if a client sends a message that includes 2004/08 WS-Addressing headers, and the server requires 2005/08 headers, the server returns a fault message.

If you use the Addressing annotation and generate a WSDL document from the code, a UsingAddressing element, with parameters that match those of the annotation, is created in the WSDL document. Clients using this WSDL document will include WS-Addressing information in their messages. The SubmissionAddressing annotation is not understood by current WSDL generation tools. However, the WSDL document does not distinguish between the 2005/08 specification and the 2004/08 specification, so if you want to generate a WSDL document from code that contains a SubmissionAddressing annotation, you can do so by using both the Addressing and SubmissionAddressing annotations together.

Note:

- You can use the Addressing annotation only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the Web service fails to deploy.
- Annotation settings override settings in the WSDL document. Annotation settings might differ from WSDL settings if you create the WSDL document manually rather than generating it from the code.
- If you generate a WSDL document from this code, the UsingAddressing element generated currently has a namespace prefix of wsaw, rather than wsam as specified by the WS-Addressing Metadata specification. This result is because the existing WSDL generation tools are not aware of this new specification. The product supports both prefixes, but if you require the wsam prefix, edit the WSDL document manually.

- To enable WS-Addressing support programmatically on the client by using features, create an instance of one of the following addressing feature classes, with up to two optional parameters, which specify whether WS-Addressing is enabled and whether WS-Addressing is required. The default settings are that WS-Addressing is enabled but not required, however the required property is not used by the client.
  - AddressingFeature: use this class if you want to send messages that include WS-Addressing headers that conform to the 2005/08 WS-Addressing specification
  - SubmissionAddressingFeature: use this class if you want to send messages that include WS-Addressing headers that conform to the 2004/08 WS-Addressing specification

  For example, to specify that WS-Addressing is enabled and required, and that the 2005/08 specification should be used, use the following code:

  ```
  AddressingFeature feat = new AddressingFeature(true, required);
  ```

  To specify that WS-Addressing is disabled for the 2004/08 specification, use the following code:

  ```
  SubmissionAddressingFeature feat = new SubmissionAddressingFeature(false);
  ```

  If you specify that WS-Addressing is enabled, the client includes WS-Addressing headers in SOAP messages. The required property is ignored, but could be used by the application to check that the client has created the correct headers. The headers conform to the WS-Addressing specification indicated by the type of feature class used. If the server does not use annotations, or uses policy sets to enable WS-Addressing, the server accepts both the 2005/08 and 2004/08 specifications.

Note:

- You can use the addressing feature classes only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the Web service fails to deploy.
- If you use both feature classes, the specification that is used depends on the type of endpoint reference that you also specify. For example, if you specify a W3CEndpointReference object, the specification that is used is the 2005/08 specification. If you do not specify an endpoint reference, the default specification is the 2005/08 specification. If you specify an endpoint reference whose type conflicts with that indicated by the feature class, for example a W3CEndpointReference object with a SubmissionAddressingFeature instance, an error is thrown.

- On WebSphere Application Server clients, you can also enable WS-Addressing support by setting the com.ibm.websphere.webservices.use.async.mep property on the client request context. For more information, see “Invoking JAX-WS Web services asynchronously” on page 540.

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Enabling Web Services Addressing support for JAX-RPC applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address Web services and provide addressing information in messages. To enable the WS-Addressing support for JAX-RPC applications, either configure the Web Services Description Language (WSDL) file for a service that runs on WebSphere Application Server, or use the WS-Addressing application programming interface (API) or system programming interface (SPI) to add WS-Addressing properties in a WebSphere Application Server client.

About this task

Perform this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party. This task also describes how to disable the WS-Addressing support, which can improve performance for those applications that do not use WS-Addressing or any protocol that depends on the WS-Addressing support.

If you are creating a Web service, you can enable the WS-Addressing support during development of the service, by including the UsingAddressing extensibility element in the WSDL binding element for the service. This element contains a `required` attribute that has a value of either `false`, which specifies that WS-Addressing information is accepted but not required in incoming messages, or `true`, which specifies that WS-Addressing information is required in incoming messages. The default value is `false`. Messages from WebSphere Application Server Version 7.0 clients always include WS-Addressing information if your service WSDL file includes the UsingAddressing element, regardless of the value of the `required` attribute.

If you are creating a client application to use a service from another provider, you might not have access to the WSDL file for the service, or the service might use a version of WSDL that does not support the UsingAddressing element (if the service is not running on a current version of this product). However, you can still enable WS-Addressing support, during run time, by setting WS-Addressing properties on the JAX-RPC Stub or Call object that you use to communicate with the service.

The following table summarizes the behavior of the WS-Addressing support in each of the scenarios mentioned previously.

Table 20. The behavior of the WS-Addressing support in the product

	The WSDL for the service specifies UsingAddressing required = ″false″	**The WSDL for the service specifies UsingAddressing required = ″true″**	**The WSDL for the service does not specify UsingAddressing**
A client sends a message that contains WS-Addressing information	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.
A non-WebSphere Application Server client sends a message that does not contain WS-Addressing information	The message is accepted.	The service returns a fault.	The message is accepted.
A WebSphere Application Server client sends a message, without specifying addressing properties	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	WS-Addressing information is not added. The message is accepted.

- To enable WS-Addressing support from the server by configuring the WSDL file, perform the following steps:
  1. Ensure that the WSDL file for the service contains the UsingAddressing extensibility element on the binding element. If you generated the WSDL file using the Java2WSDL tool, this element is automatically added for you. If you created the WSDL file yourself, for use with the WSDL2Java tool, you must add the extensibility element. The UsingAddressing element has a `required` attribute with a default value of `false`. For example:

     ```
     <wsdl:binding name="TestServiceSoapBinding" type="intf:TestService">
          <wsaw:UsingAddressing wsdl:required="false"
                                xmlns:wsaw="http://www.w3.org/2006/05/addressing/wsdl"/>

          <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

          <wsdl:operation name="invokeInstance">
            ...
          </wsdl:operation>

       </wsdl:binding>
     ```

     This code indicates that the endpoint will process WS-Addressing information, but that this information is not required.
  2. Optional: To specify that WS-Addressing information is required, change the value of the `required` attribute to `true`. If the endpoint receives a message that does not contain the mandatory WS-Addressing elements within the message header, the endpoint returns a fault message, as defined in the WS-Addressing specification.

     WebSphere Application Server clients and Proxy Server for IBM WebSphere Application Server always send WS-Addressing conformant messages to endpoints with bindings that specify the UsingAddressing element.
- To enable WS-Addressing support from a WebSphere Application Server client, use the IBM proprietary WS-Addressing API or SPI to associate one or more WS-Addressing properties with the JAX-RPC Stub or Call object that is used to send messages to the endpoint.

These properties become message-addressing properties (MAPs) in the SOAP message header. If the node that receives the message is a WebSphere Application Server node, it processes the incoming MAPs in accordance with the WS-Addressing specification, even if the service does not have a UsingAddressing element in its WSDL file.
